

**Dicamba Volatility Measurements –  
Results and Relations Between Vapor  
Concentration and Plant Injury**

Alison MacInnes, TCM 2010

TCM 2010

Monsanto Confidential

TCM 2010

## Dicamba review

---

- ▶ Concern about off-site movement of Dicamba
  - ▶ Spray drift
  - ▶ Tank contamination
  - ▶ Active ingredient volatility
- ▶ Drift and contamination are issues for all herbicide formulations
- ▶ How real of an issue is volatility?

# Dicamba Volatility Tests

---

- ▶ Laboratory tests
  - ▶ Centrifuge tube tests
  - ▶ Humidome tests
    - ▶ See Julie Webb and Alison MacInnes poster for methods
- ▶ Field tests
  - ▶ Stollte Farm tests
  - ▶ University of Tennessee tests
    - ▶ See Hannah Smith poster

## Data Generated in the Humidome Test

---

- ▶ Direct measurement of Dicamba in the air
  - ▶ Monsanto is the only company directly measuring Dicamba
- ▶ Comparison of volatility from different surfaces
- ▶ Comparison of volatility at different temperatures
- ▶ Injury data on sensitive plants

# Factors that affect volatility

---

- ▶ Surface
  - ▶ Soil vs canopy
  - ▶ Type of soil
  - ▶ Moisture content of soil
- ▶ Temperature
  - ▶ Range of temperatures 27°C and 35°C
  - ▶ Length of exposure
  - ▶ Injury related to length of exposure

# Volatility from soybean canopy vs soil

# At 27°C more volatility is detected from a soybean canopy vs soil

# At 35°C more volatility is detected from soil surface vs canopy

# The effect of temperature on volatility

• 7x more volatility from soil vs 2x more volatility from canopy with the increase in temperature

# Dicamba detected on PUF is small percentage of Dicamba applied

## Closed System Test

---

- ▶ 20ml of Dicamba acid solutions placed in a Petri dish
- ▶ Soybeans placed in the humidome
- ▶ Placed in growth chamber at 35°C for 24 hours
- ▶ 1 volume of air removed through the PUF
- ▶ PUF extracted and analyzed by LC-MS
- ▶ 11 DAT injury data on soybeans

# Soybean injury observed when levels of Dicamba were too low to detect by LC-MS

% wt Dicamba acid	Dicamba in air (ng/L)	% DAT injury
0.5000%	161.9	68%
0.2500%	34.4	42%
0.1250%	12.3	33%
0.0625%	2.2	32%
0.0313%	1.8*	27%
0.0156%	*	25%
0.0078%	*	21%
0.0039%	*	16%

\* At or below the level of detection on LC-MS

11 DAT injury to soybeans after a 24 hour exposure at 35°C in a closed system

## Comparison of Volatility of Dicamba Formulations

---

- ▶ Dicamba formulation tank mixed with Roundup® PowerMAX™
- ▶ Tank mix sprayed onto 50/50 soil at 10 GPA
- ▶ Indicator plants placed onto soil, foil protecting the roots
- ▶ Humidome placed in growth chamber
- ▶ Air pulled through PUF at 2 LPM for 24 hours

# Injury in soybeans is independent of the level of Dicamba detected in the air

---

30% injury is observed in soybeans after 24 hour exposure to Dicamba formulations.

The level of Dicamba in the air is much higher at 35°C vs 27°C but the injury remains constant at 30%.

# Velvetleaf plants show a dose response

## Future plans in the humidomes

---

- ▶ Soil
  - ▶ Type
  - ▶ Moisture content
- ▶ Temperature
  - ▶ Range of temperatures
- ▶ DOE study
- ▶ Dicamba sensitive species
  - ▶ Tomatoes
  - ▶ Grapes
  - ▶ Peppers
  - ▶ Melons
- ▶ Sensitivity at different temperatures, Dicamba concentrations, length of exposure
