**6.1. Clinical site selection:** Our consortium partners have been conducting lab and human surveillance research, including during outbreaks, for >20 years and have developed strong relationships with local clinical facilities and processes in SE Asia and in LMIC globally. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1 with high zoonotic viral diversity. Clinical sites will additionally serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. We have already developed successful working relationships with the major healthcare facilities in Thailand and Malaysia and will use these established partners to rapidly gain appropriate permits and begin data collection quickly. Focusing on these EID hotspots in select biogeographic areas (see **Fig 13**) also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites are fairly minimal, and include ability to enroll patients that meet the clinical case definitions of interest, collect and temporarily store biological samples, and follow standards for data management and subject protection with locked filing cabinets to store all paper records and an encrypted computer. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently hired staff at each site. We will recruit and train hospital staff in project-specific procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data management plans. During the development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data.

**6.2. Standardized approach, oversight, and implementation:** Management and oversight for all study sites will be undertaken by the local country coordinator with support from our Core Administrative team at EHA. Our research team has over 10 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research and SOPs for screening, enrollment, and retention of participants. The country coordinator will conduct regular site visits to the clinical sites and annual visits to observe, monitor and evaluate the research process, and conduct follow-up training if required. Through our work with clinical sites under the USAID-PREDICT project we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll avoiding potential enrollees from being overlooked if staff are too busy or not on duty. Patients will be enrolled following established clinical criteria (**see Section 6.3**), samples collected and brief surveys conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; and 3) the environment. With permission

from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between CoV, henipavirus, or FV in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. The country coordinator will be continually monitoring the project database to ensure we hit target sample sizes. While patient's enrollment is limited by the number of individuals presenting at hospitals, in previous research we enrolled an average of 105 patients per year, ranging from 77-244.

**6.3. Clinical cohort setup, recruitment, enrollment:** We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever, of unknown etiology or severe diarrhea with unusual presentation for symptoms to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500  $\mu$ L whole blood; two 500  $\mu$ L serum samples and two nasal or oropharyngeal swabs will be collected. Controls who test positive for CoVs, FVs, or Henipaviruses will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500  $\mu$ L serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

**6.4. Utilization of collected data:** Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses that are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire data will allow us to assess relative measures of human-wildlife contact that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either CoV, henipavirus, or FV via PCR tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations, and are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

**6.5. Development of reagents of value to the community.** Members of the EID-SEARCH consortium have substantial experience producing reagents, assays, and other products that are used widely by the clinical and research community, and some of which are on a pathway to commercialization. These include: PIs Daszak and Co-I Olival have produced software for analyzing the spread of novel viral agents through air travel networks; Co-I Baric has collaborated with a Norovirus surveillance collaboration with surveillance cohort at CDC and has developed therapeutics that have reached phase 2 and 3 clinical trials, He is currently working with Takeda Sanofi Pasteur on a Dengue therapeutic and with NIH on a tetravalent vaccine; Co-I Broder

developed a Hendra virus subunit vaccine that was commercially produced by Zoetis for horses and is labeled for human use under compassionate circumstances during outbreak situations.

**6.6. Potential expansion:** Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research, the EID-SEARCH information network, or an outbreak being identified in the region by other organizations. If expansion is required we would rapidly shift research activities towards the clinical or community sites where the outbreak is active, using the same process we used to set up initial research locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transpiration, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provide necessary information for granular understanding of disease spread.

## **7. Statistical Analysis Plan:**

**7.1. Framework:** Statistical analyses across the project will be conducted under a common Bayesian framework. These models provide a unified, probabilistic approach best-suited for estimating effect sizes in heterogeneous populations of human clinical and wildlife subjects in observational studies. Within this Bayesian framework, we will use generalized linear mixed models to estimate population prevalences and seroprevalences, and estimate the effects of demographic, occupational and environmental factors affecting these. We will use occupancy models (223) to estimate total viral species and strain diversity and completeness of sampling within the human and wildlife sub-populations, and discrete phylogeographic models to identify taxonomic and geographic centers of viral diversification. All statistical analyses will be performed reproducibly using scripted, programmatic workflows (e.g., the R and Stan languages) and maintained under source code version control (git). As with data management, the DMA team will act as trainers and consultants for exploratory data analysis, power analysis, and study design with project partners, and the EHA computing cluster will be available for partners undertaking additional or expansion studies. Power analyses, current and expansion, are performed via simulation approaches allowing planning for complex, hierarchical variation in study populations. Power analyses and specific analytical components of this study are detailed under each Specific Aim.

**7.2. Data Quality Control and Data Harmonization:** All data will be examined at entry by field and lab teams upon data entry, followed by examination by DMA team members at upload and integration, for complete de-identification, completeness, accuracy, and logical consistency. The DMA will provide field and lab teams with reports, produced automatically, of data summaries, including aggregates, distribution, detected outliers and possible mis-entries. On a regular basis (quarterly or as-needed during data collection), DMA team members will review reports with field and lab teams to identify errors and update collection and entry procedures as necessary.

**7.3. Statistical Considerations for Behavioral Questionnaires and Clinical Metadata:** The data collected from the questionnaire will be analyzed to assess the reported measures of contact for each risk group under study, related to 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, rodents, and primates in/around house and other livestock animals (e.g. farming, butchering, slaughtering); 3) proximity of residence or workplace to environments of increased risks (e.g. nearby bat roosts); 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12 months and lifetime. Specific measures we are interested in are the proportion of respondents indicating they consume wildlife, where wildlife is obtained for consumption, have hunted wildlife, butchered or slaughtered live animals, seen wildlife in their homes, been bitten or scratched by animals, etc. Comparisons of measures of exposure contacts and types between men and women, children and adults, different study regions will be conducted in order to explore the occupational, environmental, and demographic factors (gender, age, socioeconomic status (SES)) that influence contact with animals and to determine who is

most at-risk. Statistical analysis will be employed to identify differences between groups with a 95% probability of detecting a difference. Measures of contact related to different activities within specific groups will be compared to determine the activities that put groups at most risk. As appropriate multivariate analysis (e.g. ordinary linear regression, logistic regression, non-normal distributions of outcome, least absolute shrinkage and selection operator (LASSO) regression, etc.) will be utilized to evaluate the relationship between the outcome variables, positive biological results (PCR or serology) key measures of contact and the factors that influence frequency and types of human-animal contact.

## 8. Project Milestones and Timelines

**8.1 Milestones: End of Year 1: Aim 1:** Sample targeting locations, species (for wildlife), sample size justifications completed for whole project and reported to in-country teams; Sample testing, viral isolation, NGS, glycoprotein sequencing begun for all archival and some newly-collected samples; *in vitro* work begun; host-pathogen dynamic analyses; animal model work begun. **Aim 2:** Target human community populations identified and sample sizes calculated for some sites in each country; Community data collection, serological testing and RT-PCR testing begun; first epidemiological analyses of data begin in last quarter. **Aim 3:** Clinical cohort selection underway; clinical enrollment, data collection and sample analysis begun. First Annual meeting in last quarter. First publications submitted by end of year, summary overview papers or reviews.

**End of Year 2: Aim 1:** No sample targeting or sample size justification analyses needed. All other aspects underway **Aim 2:** All aspects underway **Aim 3:** All sub-aims underway. Second Annual meeting in last quarter. Further 2 publications submitted by end of year, including first data papers.

**End of Year 3: Aim 1:** No sample targeting or sample size justification analyses needed. All other aspects underway **Aim 2:** All aspects underway **Aim 3:** All sub-aims underway. Third Annual meeting in last quarter. Further 3 publications submitted by end of year, largely data papers.

**End of Year 4: Aim 1:** No sample targeting or sample size justification analyses needed. All other aspects underway **Aim 2:** All aspects underway. Receptor binding work completed. **Aim 3:** No further cohort selection required; all other sub-aims underway. Fourth Annual meeting in last quarter. 3 further publications submitted, including first papers analyzing risk factors, pathogenic potential of novel viruses submitted.

**End of Year 5: Aim 1:** No sample targeting or sample size justification analyses needed. No receptor binding assays continuing. Serological and PCR testing completed end of 2<sup>nd</sup> quarter. Glycoprotein, *in vitro* and *in vivo* analyses, analysis of viral risk continue to end of project. **Aim 2:** No further community targeting or sample size work. Community data collection completed at end of 2<sup>nd</sup> quarter. All other aspects continue to end of project **Aim 3:** All sub-aims underway. Final Annual meeting in last quarter. Further 3 publications submitted.

### 8.2. Timeline:

ACTIVITIES	YEAR 1				YEAR 2				YEAR 3				YEAR 4				YEAR 5			
	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4
AIM 1	1.4.a. sampling targets																			
	1.4.b. sample size justifications																			
	1.4.c. sample collection & testing																			
	1.4.d. NGS																			
	1.4.e. sequencing Spike GP																			
	1.5.a. human cell infection																			
	1.5.b. receptor binding																			
	1.5.c. host-pathogen dynamics																			
	1.5.d. viral strain prioritization																			
	1.5.e. animal models																			
AIM 2	2.4 target population & sample sizes																			
	2.5 community data collection																			
	2.6.a serological testing																			
	2.6.b RT-PCR testing																			
	2.6.c virus characterization																			
	2.7 epidemiological analysis																			
AIM 3	3.4.a cohort selection																			
	3.4.b clinic enrollment & follow-up																			
	3.4.c clinical data collection																			
	3.5 sample testing																			
	3.6 risk characterization																			
	annual meeting

---

Dear All,

Just to let you all know that the grant was successfully submitted today with time to spare, and no errors. It's in the system, and it's all down to the reviewers now! Thanks to all of you for your help and support in getting this finalized and completed. Please pass on my personal thanks to the Co-Investigators, Key Personnel and Consultants who you also brought into the team.

I've attached a pdf of the final proposal text and will send the Word version in a few minutes. It's actually a good read, and I'm especially grateful to Hongying who generated all the cool graphics, based largely on Ralph's previous NIH grant proposals.

As you read the text, please remember that the wording is very carefully targeted to a typical US-based NIH reviewer, and to the Program Officers, with the sole purpose of trying to win the grant. If I've exaggerated or made mistakes, or used language that isn't quite right, I apologize, but I did it for the key goal of getting funded.

In the meantime, please don't share this proposal beyond our group on this email chain, so we don't give our competitors an edge!

Good luck, and I'll be keeping my fingers crossed all summer in the hope that we win this...

Cheers,

Peter

**Subject:** EID-SEARCH Comments

Thanks everyone for sending the comments back. Working on v5 now, while others in the office are cranking out sample size calculations, new figures, human and vert. subjects and all the additional information needed after the research plan.

As I go through all your comments, I'll send the occasional email with questions to clarify specific points, so please be on standby for a quick turnaround.

Cheers,

Peter

Dear All,

Here's version 4. Apologies for the delay. It's in better shape now, but there are still lots of areas that need your attention. Please put in time today, and tomorrow to edit and firm up the text. I've put your names in some of the comment boxes where I need specific help but I also need you to read this critically now and edit and tighten it up. We have 30 pages of space, and our research plan is now 21 pages, so we need to lose maybe 3 or 4 pages. There are also some weak points, specifically on Filoviruses, on the details of where we'll do our clinical work, and on what we'll do with the animal models for henipias and filoviruses.

Please get comments back with me before Wednesday 26<sup>th</sup> 4pm New York time, so that I have Wednesday evening and all day Thursday to incorporate them. In the meantime, I'll be working with folks here on better figures, and all the extra sections that come after the research plan. I'll need you all to help with those on Thursday while I'm finishing off the draft.

Thanks to all of you in advance and look forward to the next round.

Cheers,

Peter

**Subject:** EIDRC-SEA v.3

**Importance:** High

Dear all,

Thanks to everyone for comments and text for the earlier draft at the beginning of the week. Kevin's spent the last couple of days pulling all the comments together into one draft and inserting his changes, and I've now attached a v3 of the draft. It's still rough, and now too long, but it's getting there. I wanted you to look at this rough version because I'm stuck in Liberia in meetings Friday, then flying back home Saturday. I'll continue editing this draft on the plane and will be working solely on this grant from home on Sunday, Monday, Tues, Wed, Thurs.

Please work on this rapidly if possible. If you can all push your comments through, using track changes, and get them back to me **by Sunday evening New York Time**, I will turn round a polished draft by Tuesday, giving us time for significant last go-over on Wed, Thurs. It's tight, but unfortunately, it is what it is, so please commit the time if you can!! As well as general edits (using track changes, with references in comment boxes), please do the following...

Linfa/Danielle – We especially need your input in section 1.1, 1.3, 1.4 and 2.5

Ralph/Amy - Please work your magic on this draft, inserting text, editing and reducing text, and

making sure the technical details of the characterization are correct and fit the proposed work on CoVs, PMVs and Henipaviruses

Chris/Eric – Eric – congratulations on your (b) (6) and thanks for working on it at this time!  
Chris – please help and edit/finesse the language in the relevant sections for you

Tom – Your edits crossed over with Kevin’s changes, so please insert all the bits that were new in the last version you sent to me, into this version. I think these are mainly the sections and comments from the other Malaysian colleagues, but please check and re-insert all key text. We especially need to be specific about which partner in Malaysia is doing what cohorts, and where, and about who’s doing the testing

Thanks again all, and I’m looking forward to non-stop work on this as soon as I get on my flight in 24 hours...

Cheers,

Peter

<EIDRC Southeast Asia v4.docx>

## II. Research Strategy:

### 1. Significance:

Southeast Asia is a critical hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of key ecological and socioeconomic drivers of emergence (Fig. 1) (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is also undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread.

**Fig. 1:** Southeast Asia, and in particular, parts of Thailand and Malaysia are hotspots of risk for disease emergence (left), and predicted high diversity of 'missing' or as-yet undiscovered viruses, yellow = highest diversity (left). From (1, 2).

Not surprisingly a number of novel viruses, including near-neighbors of known agents, have emerged in the region leading to sometimes

unusual clinical presentations (Table 1). These factors are also behind a significant background burden of repeated Dengue virus outbreaks in the region (16), and over 30 known *Flavivirus* species circulating throughout S. and SE Asia (17). The events in Table 1 are dominated by three viral families: coronaviruses, henipaviruses and filoviruses, which serve as initial examples of team research focus and capabilities. These viral groups have led to globally important emerging zoonoses (18-29). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (30-32). Furthermore, relatives and near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium: henipaviruses in bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (33-39); a novel henipavirus, *MòjiāngMòjiāng* virus, in wild rats in Yunnan (10); serological evidence of filoviruses in bats in Bangladesh (40) and Singapore (41); Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (Hughes *et al.*, in prep.); evidence of novel filoviruses in bats in China (42-44), including Mènglà virus that appears capable of infecting human cells (45); novel paramyxoviruses in bats and rodents consumed as bushmeat in Vietnam (46); a lineage C  $\beta$ -

Commented [EL1]: Did you want preliminary data?

presentations for known or close relatives of known viruses.

172 novel  $\beta$ -CoVs (52 novel SARSr-CoVs) and a new  $\beta$ -CoV clade ("lineage E") in bat species in S. China that are also found throughout the region (20, 47, 49, 50); and 9 and 27 novel wildlife-origin CoVs and

paramyxoviruses in Thailand (respectively) and 9 novel CoVs in Malaysia identified as part our work under USAID-PREDICT funding (49, 51). These discoveries underscore the clear and present danger of future zoonotic events in the region. Furthermore, the wide diversity of potentially pathogenic viral strains has significant potential to help in the development of broadly active vaccines, immunotherapeutics and drugs (47).

Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 2). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (29, 52). However, these regions tend to be in the developing world, where nations often lack the resources to investigate novel zoonotic events, or wildlife reservoirs of zoonoses, and prioritize more immediate public health concerns such as Dengue virus or NTDs (16). Zoonotic disease surveillance and control is also hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (53). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in x/xx (x%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (12, 54). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (3) as well as 12/856 (1.4%) people screened in Singapore (4). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (7), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (55). Preliminary

Commented [PD2]: Peter will correct

screening in Malaysia with funding from DTRA for serological surveillance of Henipaviruses and Filoviruses spillover found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in non-human primates (NHPs) and people (Hughes, in prep.). Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70% (56). Nipah virus has been reported in people in West Bengal, India, which borders Bangladesh (26), in bats in Central North India (57), and now in people in Kerala, South India in 2018 and 2019, raising the specter of future spillover at other sites in the region (14, 58).

**Fig. 2: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC

proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (52).

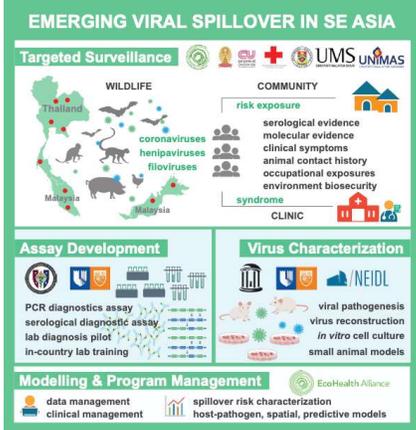

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (59), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (20, 47, 49, 50, 60-62). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-concept for an early warning approach that we will expand in this EIDRC to target key viral groups in**

Commented [PD3]: Peter to do

**one of the world's most high-risk EID hotspots.**

The overall premise for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. To scale-up this approach, we propose to launch **EID-SEARCH** (the **E**merging **I**nfectious **D**iseases - **S**outh **E**ast **A**sia **R**esearch **C**ollaboration **H**ub), to better understand the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and novel CoVs, henipaviruses, and filoviruses in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development, and cross-training in surveillance and novel diagnostic platforms. We will develop and transfer technology to test these viruses' capacity to infect human cells and mouse models, develop new specific and sensitive serological and molecular diagnostic tools, conduct surveillance of human communities with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover of viruses causing previously 'cryptic' clinical syndromes in people. We will test the capacity of novel viruses we isolate, or genetically characterize, to infect human cells and/or mouse models, and thus assess potential for spillover and spread which will feed into our risk models. Our group also has extensive experience in other viruses, including vector-borne flaviviruses, and alphaviruses, and will use this experience to provide robust long-term surveillance, diagnostics, human and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EID-SEARCH is poised to rapidly respond to any new emerging outbreak. Thus, filoviruses, henipaviruses and coronaviruses are examples of sentinel surveillance systems in place that can capture, identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.

**2. Innovation:** Previous work by our consortium has developed strategies to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses. In the EID-SEARCH we scale up this approach in a central research "hub" made up of leading laboratories, clinics and surveillance sites in three critically high-risk EID hotspot countries in SE Asia. EID-SEARCH's reach is expanded through its regional network of collaborators that covers nearly all of the greater SE Asia region. The innovation of the EID-SEARCH is in: 1) its multidisciplinary approach that combines modeling to target geographic and taxonomic sampling targets with on-the-ground zoonotic disease surveillance in human and wildlife populations; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). **In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. We will use *in silico* methods (inovel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into

to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). **In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. **Fig. 2:** EID-SEARCH approach, core members, and roles.

**Commented [BRS4]:** Statement should be in the aims. ...Our center covers the worlds most high risk EID hostspot?

**Commented [PD5]:** Hongying – Figure needs edits to text: top panel, 'wildlife' should read "Aim 1: WILDLIFE", "AIM 2: COMMUNITY", "AIM 3: CLINIC". Right hand side: "Clinical symptoms" should be "Clinical history", "Occupational exposures" should be "Occupational exposure", "environment biosecurity" should be "environmental risk factors"

Middle panel: "Assay Development" and "Virus Characterization" should have "(Aim 1)" after them. Left hand side: should read "PCR diagnostics", "serology", "piloting diagnostics" and the last one is ok. Right hand side bullets should be "receptor binding characterization" "in vitro characterization" and "mouse models"

Bottom panel: all good

high-risk human populations. **In Aim 2, we will conduct focused, targeted surveys and sampling of human communities with high exposure to wildlife and other animals.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. Serological findings will be analyzed together with clinical metadata (including a simple animal-contact survey, location data, viral sequence/isolates etc.) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise 'cryptic' outbreaks.** We will enroll and collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs. Our US partner BSL-4 laboratory, **NEIDL**, will attempt isolation and characterize any viruses requiring high levels of containment (e.g. any novel filoviruses discovered).

### 3. Approach

**Research team:** The EID-SEARCH builds on long-term collaboration among world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (**Fig. 2**). Over the past two decades, our consortium partners have conducted high profile research on EIDs within the region and globally, including identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (20, 25, 59, 63-66), discovering SADS-CoV (13), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (60-62, 67-80). Our team has substantial experience conducting human surveillance in the community and during outbreaks (See sections 2.x.x, 3.x.x), including: USAID-PREDICT, and DTRA-funded viral surveillance of indigenous communities in Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah (Co-I Hughes); collection of >2,000 serum samples from healthy blood donors and sanitation workers, febrile and influenza like illness (ILI), and diarrheal stool samples from children under 5 years of age (Co-I Kamruddin); collaboration on the MONKEYBAR project with the London School of Hygiene and Tropical Medicine to analyze risk and prevalence of the zoonotic malaria *Plasmodium knowlesi* (Co-Is William, Tock Hing); case control and cross-sectional studies in Sabah villages (~800, 10,000 participants resp.) (Co-Is GR, TYW). As a proof-of-concept of how our team can rapidly scale up resources for diagnostics and surveillance in the face of a new EID, in 2016, we discovered a novel bat-origin HKU-2 CoV (81, 82) killing >20,000 pigs in S. China, designed PCR and LIPS serology tests, then surveyed pig farmers for evidence of exposure, and conducted experimental infections, pathogenesis and molecular studies, **all in the span of 3 months** (13, 83).

The administration of this center (**See section X**) will be led by PI Daszak, who has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5- 20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival and Zambrana are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesadee, Hughes and collaborators have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from NIH, DoD, USAID, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to our EIDRC.

**Geographical focus:** The three core (hub) countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses diverse cultural and

**Commented [PD6]:** PD will get stronger letter from Jerry Keusch: opportunity for visiting scholars to be certified for BSL-4 research, strong Ebola person at NEIDL to conduct characterization if we find filoviruses.

socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH, DTRA, and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our core member's extensive network of collaborators in clinics, research institutes and public health laboratories in almost every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in XX countries that are currently

collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Fig.3 :** Map of Southeast Asia indicating three hub countries for this proposed EIDRC (Red: Thailand, Singapore, Malaysia) and countries in which Key Personnel have collaborating partners (Green), indicating that EID-SEARCH provides access to key collaborators throughout the region.

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and non-human primates (84). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (Fig. 1) (2). In Aim 1, we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and apply novel predictive models to estimate viral diversity and host range to identify wildlife species that have been ignored or under-sampled by previous zoonotic disease surveillance efforts. We will strategically collect specimens from these species and screen them, together with some of the tens of thousands of recently collected samples we have archived in freezers in our labs, for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel virus in high risk RNA viral families, *Coronaviridae*, *Paramyxoviridae*, and *Filoviridae*. We will expand to other groups of pathogens, pending available resources and priorities established with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation. On this subset of viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, gene edited humanized transgenic mice and the collaborative cross genetic reference mouse population) previously developed and widely used by our team to predict capacity of novel viruses to infect people and spillover (61, 85-88). These high-risk viruses and their close relatives will be targets for human community and clinical sampling in Aim 2 and 3, respectively.

**1.2 Preliminary data: 1.2.a. Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a major high risk location for pathogen emergence (1, 2). For Southeast Asia, these EID hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (Fig 1). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (2). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 1). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate)

**Commented [PD7]:** Hongying – “EIDRC Program Countries” should be “EID-SEARCH core countries” and “External Partner Countries” should be “Collaborating Partners”

**Commented [PD8]:** PD to Remember to correct specific aims with same titles

**Commented [KJO9]:** Will we? If so, make sure we mention primates more and include in vert animal sections.

**Commented [PD10]:** PD will discuss both of these comments with Kevin

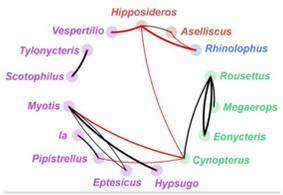

**Commented [KJO11]:** Do you think we need to add in or mention vectors (arthropods)? We don't have big banks of these as far as I know, so maybe best not too?

**Commented [CB12]:** I would not mention arthropods. The scope here so far is well laid out, and expansive enough as it is, and most of our focus are viruses known to originate in mammalian hosts.

**Commented [PD13]:** From Kevin - we need to specify in the methods below how many viruses (number of) we will have resources to do this on

differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (89). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data and flight model software we have produced with Dept Homeland Security funds (90). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

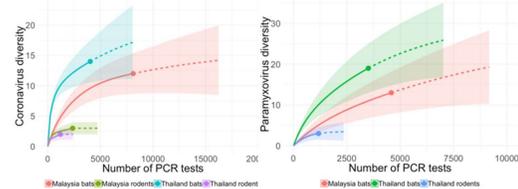

**1.2.b. Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primates represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential(91). Thus, the bulk of our proposed wildlife sampling and testing will consist of these three taxa with a focus on bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses (48, 92-94). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (2), and are exceedingly diverse in Southeast Asia (~500 species). To further prioritize taxonomic sampling targets within these diverse geographic hotspots, we have used a novel, Bayesian phylogeographic analysis to identify host taxa that are the most important centers of evolutionary diversity for a given viral group, e.g. bat genera for  $\beta$ -CoVs using an extensive CoV sequence dataset from our NIH-funded research (Fig. 5) (49). This approach will be extended to other mammal taxa and viral families of interest, allowing us to identify the ancestral wildlife hosts of specific zoonotic viral groups, where their diversity is likely highest.

**Fig 5:** Preliminary analysis to identify the most important bat genera in Southeast Asia as hosts for beta-CoVs using our previously-collected CoV sequence data. Line thickness is proportional to the probability of virus sharing between two genera. Inter-family switches are highlighted in red. We will apply this Bayesian discrete phylogeographic model to identify taxonomic and geographic centers of viral

diversification and sharing for relevant paramyxovirus, coronavirus, and other virus clades.

Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (95, 96) (Fig. 6). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. **In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively identify new strains to support experimental infection studies and risk assessment.**

**Fig. 6:** Estimated coronavirus (left) and paramyxovirus (right) putative viral 'species' diversity in bats and rodents for Thailand and Malaysia, using RdRp gene sequence preliminary data from >13,000 PCR tests in bats and 4,500 in rodents. Bats in Thailand and Malaysia have 4X the number of viruses than rodent species, controlling for sampling effort. CoV and paramyxovirus diversity estimates are comparable, but discovery has not yet

saturated in any taxonomic group or location. We estimate that additional sampling of ~5,000 bats and testing of our archived rodents specimens alone will identify >80% of remaining CoV and paramyxovirus viral species in these key reservoirs. We will use this approach to define sampling targets for other wildlife taxa, and for viral strain diversity.

**1.2.c. Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. Under the 10-year PREDICT program globally, we identified 912 novel and 210 known viruses, more than the total number of viruses previously recognized in mammals by the International Committee on Taxonomy of Viruses. This work included collecting nearly 300,000 individual mammal samples from 14 EHA-led PREDICT countries and PCR-screening more than 60,000 individual specimens(51). In southern China alone, this sampling lead to the identification of 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARS-CoVs). Included were members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus, SADS-CoV, responsible for killing >20,000 pigs in Guangdong Province (13). Many of the identified bat species are

**Commented [BRS14]:** I would say we focus on these three species (plus vectors?). To demonstrate the capability of the team, this proposal will focus on bat surveillance (for a variety of reasons), noting that this approach will also be applied to other zoonotic vectors during the 5 year program throughout the region.

**Commented [PD15]:** Ralph – have we done this well enough now? If not, please add text/edit

**Commented [PD16]:** Kevin - Can you get rid of the shading on the background to this figure and change the colors so the circles and genus names are more visible (esp. the green). Colors should be darker and more contrasty

**Commented [KJO17]:** We can show just a single curve per country (aggregating all wildlife species) for simplicity, and could fit CoVs and PMVs on one graph.

**Commented [PD18]:** Evan/Hongying/Kevin, please send that also and I'll choose one

**Commented [PD19]:** Kevin – please get someone to check EIDITH – I think I just guesstimated these numbers...

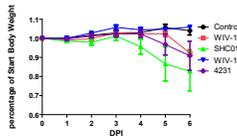

found across the region. We have collected 28,957 samples from bats, rodents and primates in Thailand and 51,373 in Malaysia, conducting 146,527 PCR tests on a large proportion of these specimens. We have **archived duplicate samples which are now available for use in this project**, including fecal, oral, urogenital and serum samples from bats, rodents, and non-human primates, and primate biopsies. In Thailand this screening has identified 100 novel viruses and 37 known viruses in wildlife reservoirs. In Malaysia this screening has identified 77 novel viruses and 23 known viruses in wildlife reservoirs (66 novel and 19 known in Sabah and 11 novel and 9 known from Peninsular Malaysia). We used family level primers for henipaviruses, filoviruses and CoVs and have already discovered 9 novel and 7 known CoVs and 26 novel and 2 known paramyxoviruses in Thailand. This is in addition to 13 novel and 5 known CoVs and 15 novel and 1 known paramyxovirus in Malaysia from wildlife. In the current proposed work, we will attempt to sequence, isolate and characterize those viruses that our analyses below suggest are most likely to be able to infect humans.

Our collaborative group has worked together on these projects, as well as other DTRA funded projects in Singapore/Thailand (Co-Is Broder, Wacharapleusadee, Wang) to design, cross-train, and use novel serological and molecular platforms to investigate virus infection dynamics in bats and examine potential spillover events with or without human disease. For serology, Co-Is Wang and Anderson (Duke-NUS) will develop a phage-display method to screen antibodies for all known and related bat-borne viruses, focusing on henipaviruses, filoviruses and coronaviruses. Once various “trends” are discovered, additional platforms (including Luminex and LIPS) will be used for verification and expanded surveillance. For molecular investigation, we will combine targeted PCR approach with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified. In Malaysia (Co-Is Hughes, Broder, Laing) **we** have transferred the Luminex-based serology platform to partner laboratories for screening of wildlife, livestock and human samples to investigate the spillover of henipaviruses and filoviruses at high risk interfaces. These interfaces include farms near the forest and indigenous communities with lots of subsistence hunting in Peninsular Malaysia, and preliminary screening has found serological evidence of past exposure to viruses antigenically-related to Nipah and Ebola in humans, bats and non-human primates (NHPs). In Thailand, Co-Is Broder, Laing and Wacharapleusadee have transferred a Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses and known henipaviruses in wildlife and human samples, with testing underway and currently being validated in our Chulalongkorn University laboratory (**See also section 2.2.d**).

**1.2.d. In vitro & in vivo characterization of viral potential for human infection:** Using Coronaviridae as an example, we have conducted *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3-7% (20, 59, 97). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (59). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of two different variants. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in those without ACE2 (20, 59, 97). We used the SARS-CoV reverse genetics system (71) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (60). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry**. The Baric lab has a well-established hACE2 and DPP4 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect (85, 98). We used this chimera approach to demonstrate that pathogenicity of bat SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the value of this model in assessing novel SARSr-CoV pathogenicity**. Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity, nor after challenge following vaccination against SARS-CoV** (60). We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they**

are unable to use the ACE2 receptor. Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines.

A similar approach to the above pipeline for CoVs will be applied to novel henipaviruses and filoviruses we discover during our research. Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G), where all known species within the paramyxovirus genus, *Henipavirus*, encode a receptor-binding (G) glycoprotein. The broad mammalian tropism of Hendra virus and Nipah virus (67) is likely mediated by their G glycoprotein's usage of highly conserved ephrin ligands for cell entry (15, 99). A third isolated henipavirus, Cedar virus (*CedV*) does not cause pathogenesis in animal models. Recently, **Co-Is Broder and Laing** have developed a reverse genetics system and rescued a recombinant *CedV* to test ephrin receptor usage/tropism and pathogenicity during henipavirus infections (76). *CedV* is unable to use the eEphrin-B3 receptor (76, 100) which is found in spinal cord and may underlie NiV encephalitis (101) and that pathogenesis also involves virulence factors V and W proteins. *CedV* is also capable of utilizing ephrin-B1 and two additional A-class ephrins (Broder and Laing, submitted). The putative henipaviruses, Ghana virus (*GhV*) and *Mojiang/Mojiang* virus (*MoJV*), predict V and W protein expression, with *GhV* able to bind to ephrin-B2, but not -B2 (102), and but the receptor for *MoJV* remaining-remains unknown (103) but is likely ephrin-B2 (104). Novel henipaviruses can be rapidly characterized by an analysis of their encoded G glycoprotein and structural modeling and comparison to several known x-ray structures, to predict ephrin ligand binding competence, while at the same time, either infectious virus isolates (if available) can be assayed for host cell tropism using a panel of B and A class ephrin ligand expressing cells. If other novel henipaviruses are discovered that also encode the known interferon

antagonist gene products (V or W) which would preclude work in low level containment or reverse genetics experiments, the receptor tropism and characteristics of these henipaviruses can be analyzed by through the reverse genetics and generation of chimeric viruses using the recombinant *CedV* platform and glycoprotein genes of other henipaviruses, which the Broder lab is currently doing with Nipah and Hendra to create a BSL-2 based neutralization system.

The host cell binding step of known filoviruses is less well understood, but filovirus tropism is determined by the glycoprotein spike (GP) that facilitates binding with target cells. Ebolavirus is the best well-characterized filovirus, and it productively infects a broad range of cell types such as monocytes, macrophages, dendritic cells, endothelial cells, fibroblasts, hepatocytes, and adrenal cortical cells (Feldmann H, Geisbert TW Lancet. 2011 Mar 5; 377(9768):849-62). Indeed, primary human lung endothelial cells are highly susceptible to Ebolavirus infection (105). Huh7 cells are good candidates for ebolavirus in the liver, oftentimes used to isolate virus from clinical samples (106) Huh7 cells also offer advantages for reverse genetic recovery of novel filoviruses (107). Following host cell attachment, the virus is internalized by macropinocytosis, a non-selective process of engulfment (Davey RA, Shtanko O, Anantpadma M, Sakurai Y, Chandran K, Maury W. Curr Top Microbiol Immunol. 2017;411:323-352). Binding to target cells is mediated by a variety of different attaching factors, and no single class of molecules serves as a classical entry receptor. However, the surface GP is a class I fusion protein with a well-defined mechanism of mediating membrane fusion and virion entry following the endocytosis of the virus particle. In its native state, GP is a triplet of heterodimers, each composed of a receptor binding subunit (GP1) and a fusion subunit (GP2). The GP1 and GP2 subunits are derived by the cleavage within the Golgi complex of a single precursor protein, and remain associated as a trimer. After initial internalization, virus particles traffic into the endo-lysosomal pathway, where the low-pH-dependent cysteine proteases cathepsins B and L process GP1 into a 19 kDa fusogenic form, leading to a putative receptor binding domain exposure and allowing for the interaction between the processed GP1 and the late endosomal/lysosomal protein Neimann-Pick C1 (NPC-1) triggering GP2-dependent fusion of the viral envelope with the endosomal membrane (Carette J.E., et al. Nature. 2011;477:340-343; Côté M., et al. Nature. 2011;477:344-348). Here, novel filoviruses however can readily be characterized following the identification of their encoded GP sequences which can be easily pseudotyped into recombinant GP-bearing vesicular stomatitis virus (VSV) pseudovirions (Brouillette RB, Maury W. Methods Mol Biol. 2017;1628:53-63). These pseudovirions can be safely used to characterize the tropism and entry filoviruses mediated by GP without a

Formatted: Font: Italic

need for BSL4 containment. Primary human lung endothelial cells are highly susceptible to Ebola virus infection (105). Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (106). Huh7 cells also offer advantages for reverse genetic recovery of novel filoviruses (107). Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G).

**Commented [PD20]:** Ralph/Danielle/Eric/Chris – need something substantial here on filovirus binding that shows we have a valid approach for novel filoviruses

**Fig. 7:** Body weight change in hACE2 transgenic mice after SARSr-CoV infection, demonstrating that bat-origin SARSr-CoVs cause similar clinical presentation to outbreak strain (4231). From (60, 61).

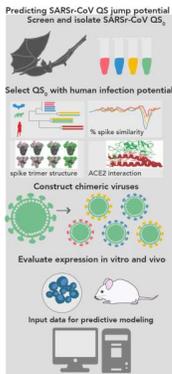

**Commented [PD21]:** Ralph – I think I mis-spoke in this fig. description – please correct.

**Models of Outbred Populations.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments (108). We have used this model for CoV, filo (Ebola), Flaviviruses, and alphaviruses infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection (86-88, 109-112). **Bat Models.** Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (113).

**Commented [PD22]:** Ralph – please add data from the CC mouse re. filoviruses, to beef up the image of us as a filovirus group

**Commented [PD23]:** Linfa/Danielle – please draft a brief para explaining how we'll use these two models

**1.3. General Approach:** We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new sampling of wildlife in high risk locales. We will use viral family level PCR screening to identify and partially characterize viruses, then follow up sequencing of relevant receptor binding proteins to assess homology and predict binding affinity, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will follow this with *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease (Fig. 8). EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses, as well as cross-training and tech transfer to the hub labs in Thailand and Malaysia. This will include via support of one Malaysian Ph.D student, Mei-Ho Lee (CM Ltd.) who has worked with the EID-SEARCH collaborators for 9 years. The focus of her study will be infection potential of novel CoVs and paramyxoviruses already found in bats in Malaysia under preliminary data for this proposal.

**Fig. 8:** Schematic showing EID-SEARCH approach to selection of sampling, viral testing, prioritization and characterization to identify novel, high zoonotic-risk viruses in wildlife.

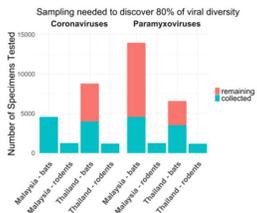

**Commented [PD24]:** Hongying – this is a placeholder from DARPA proposal. We need a new one with Stages: 1) Geographic and taxonomic modeling to maximize discovery of potential zoonotic viruses; 2) PCR screening and partial RNA sequencing; 3) Full genome or RBD and Glycoprotein sequencing to model receptor binding based on sequence similarity; 4) Cell line infections (for prioritized viruses); 5) animal model infections (for prioritized); 6) High priority viruses ranked based on data (red, yellow, green) schematic.

**1.4 Wildlife samples: 1.4.a. Geographic and taxonomic targeting for newly collected wildlife samples:** We will prioritize sites within each country that rank highest for both the risk of zoonotic disease emergence (114) and the predicted number of 'missing' zoonotic viruses (91). Our preliminary analysis (Fig. 1) suggests priority areas include: the Isthmus of Kra (S. Thailand and N. Peninsular Malaysia), NW Thailand (near the Myanmar-Laos border), and the lowland rainforests of Sarawak and Sabah. In each of these 'hottest of the hotspots' regions, we will identify 2-4 distinct sampling sites based on the geographic distribution of key hosts we prioritize for intensive wildlife sampling. We will priority rank bat, rodent, and primate species using analysis of host trait data for the highest predicted number of viruses based (91). We will also identify species predicted to be centers of evolutionary diversity for Corona-, Paramyxo-, and Filoviridae using ancestral host reconstruction of available sequence data and Bayesian discrete phylogeographic models (115-117). We will ensure wildlife sampling is complimentary to specimens archived in our extensive freezer banks. We will collect only the additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes given predicted levels of viral richness and rates of discovery (see 1.4.b). We will leverage our strong collaborations with wildlife experts in Malaysia and Thailand to ground-truth geographic and taxonomic model

outputs with local expert knowledge to ensure the sampling plan is realistic based on current species distributions, population size estimates, seasonality, and accessibility to sites.

Recognizing that most zoonotic viruses are multi-host, i.e. naturally harbored by multiple wildlife species, and that the phylogenetic relatedness of those hosts is predictable and varies across viral families (91) – we will also apply a generalizable phylogenetic and spatial modeling approach to rapidly predict new (unsampled) hosts for novel viruses we discover during our research. We will use a combined network analysis and a phylogeographic model to estimate a viruses' host range and to prioritize additional wildlife species for sampling and testing for viruses we discover. Our recently developed model of viral sharing uses just two phylogeographic traits (wildlife species range overlap and phylogenetic similarity between host species) to successfully predict host species in the top 2% of all 4,200 possible mammal species (118).

**1.4.b. Sample size justifications for testing new and archived wildlife specimens:** We will use our preliminary data on average PCR prevalence from screening tens of thousands of bat, rodent and primate specimens for CoV and Paramyxoviruses under the USAID-PREDICT project in Malaysia and Thailand. We will refine these sample size targets, in real-time, over the course of our project using viral discovery curve analyses (Fig. 6) to either scale-up or scale-back sampling and testing of archived specimens for each species depending on their viral diversity. For example, given 5-12% prevalence of CoVs in the most common bat species we previously-sampled in Thailand and Malaysia, a target of XXX individuals per species would yield XX (± x) PCR positive individual bats, and an estimated ~xx novel strains. Similarly, for paramyxoviruses with an average PCR detection rate of X%, we would need XX individuals per species to detect 80% of predicted viral strain diversity with 80% power. Preliminary analysis indicates we will require XX,000 samples to identify 80% of remaining viral diversity (Fig. 9). All wildlife sampling will be nondestructive. In the event that an animal is found dead or needs to be euthanized due to injury we will collect biopsy samples for screening.

**Fig. 9.** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMVs from high-risk bat and rodent taxa in Malaysia and Thailand

We estimate the following sampling effort, broken down for each region: **Peninsular Malaysia:** Wildlife sampling will be led by CM Ltd / EHA in collaboration with PERHILITAN. Archive bat, rodent and NHP samples will be screened serologically using the BioPlex and other serology techniques identified through this project. New wildlife sampling will focus on bats but it is expected that rodents and NHPs will be sample as well. Wildlife sampling will be conducted around Orang Asli communities sampled as part of aim 2. Three new communities will be identified in the districts we have already sampled in. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at PERHILITAN's NWFL. **Sarawak, Malaysia:** Wildlife sampling will be led by CM Ltd / EHA in collaboration with UniMAS. Wildlife sampling will be conducted around Dyak communities sampled as part of aim 2. One community will be identified. Concurrent sampling trip will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at UniMAS or BMHRC. **Sabah, Malaysia:** Bat sampling will be led by CM Ltd / EHA in collaboration with SWD and WHU. Bat sampling will initially focus on 3 caves. Batu Supu Sabah low disturbance cave and surrounding area, Madai medium disturbance cave and surrounding area, Gomantong cave high disturbance cave and surrounding area. Each cave will be sampled twice once in wet season and once in dry season targeting 500 bats at each cave on each trip for a total of 3000 bats. Wildlife samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored at WHGFL, molecular testing will be conducted at WHGFL and serology screening at BMHRC. In addition at Madi cave the community that lives in the mouth of the cave will also be sampled targeting 150 people, while at

**1.4.c. Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C. PCR will be performed with pan-coronavirus, filovirus and paramyxovirus primers. PCR products will be gel purified and sequenced. We will attempt isolation on samples that contain viruses of interest (determined in **1.4, below**), using Vero cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). **This includes the over 30 bat cell lines maintained at Duke-NUS** from four different bat species.

**1.4.d. Moving beyond RNA viruses:** To detect pathogens from other families, such as non-RNA viruses we will combine conserved PCR assays with NGS. We will perform either unbiased NGS, or use a pan-viral enrichment library to sequence full-length genomes. We will conduct this work via EID-CC research projects or as part of outbreak detection/investigation in the region from DNA viruses or other agents.

**1.4.e. Sequencing Spike Glycoproteins:** Based on earlier studies, our working hypothesis is that zoonotic coronaviruses, filoviruses and henipaviruses encode receptor binding glycoproteins that elicit efficient infection of primary human cells (e.g., lung, liver, etc.) (12, 59, 60). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (**Fig. 4**) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are undersampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (20, 60, 119), suggesting that existing vaccines and immunotherapeutics could easily fail against future emerging SARS-like CoV. Moreover, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic receptor binding protein genes of MERS-related, Ebola-related and Nipah/Hendra-related viruses will also program efficient entry via human ortholog receptors. For all novel virus strains, we will sequence the complete entry spike genes by amplifying overlapping fragments using degenerate primers as shown previously (20, 59). Full-length genomes of selected CoV strains (representative across subclades) will be sequenced using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR or Minlon sequencing will be performed to fill gaps in the genome. The full length spike gene sequences, including the amount of variation in the receptor binding residues that bind the appropriate human receptor will be used to select strains for Aim 3 experiments.

**1.5. Assessing risk for spillover. 1.5.a. Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, filoviruses and henipaviruses, we will use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (60, 61, 120). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs or other test filoviruses or henipaviruses to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other viruses (62, 70). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (61, 121) or monoclonal antibodies targeting the Ebola or Marburg E glycoprotein (Available through BEI), or Nipah or Hendra viruses (122). As controls or

**Commented [PD33]:** Kevin – who can write this bits?

**Commented [PD34]:** Linfa – can you give a v. brief description of these please, e.g.: “This includes 13 primary lung, 5 primary gut epithelial, and 1 primary liver cell line. In addition we have 12 immortalized cell lines, 7 of which are intestinal, and therefore suitable for CoVs. Cell lines are derived from insectivorous and frugivorous bats (genera.....)”

**Commented [BRS35]:** Any antibodies available? If not we can synthesize them from published co-crystals.

**Commented [EL36R35]:** Yes, Broder has NiV and HeV G binding, characterized mAbs. Have been used in crystal structural/ephrin analyses

**Commented [PD37]:** Can someone answer Ralph’s question please?

if antisera is not available, the S genes of novel SARSr-CoV or spike entry genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (123). Polyclonal sera against SARS-related viruses will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (61, 124, 125). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (126) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (127-129). Similar approaches will be applied to novel MERS-related viruses, other CoV, filoviruses or henipaviruses. While most wildlife-origin viruses with unknown transmission potential or pathogenicity in people are BSL-2 or -3, cell culture for potentially BSL-4 pathogens will be undertaken at collaborating institute NEIDL. To facilitate this, duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (**See letter of support**) for culture, characterization and sharing with other approved agencies including NIH RML. When appropriate or feasible, training opportunities at NEIDL for in-country staff will be given.

**1.5.b. Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the *intraspecific* scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (69). A lot of variation in the NPC1 receptor alters EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains (130). Signatures of positive selection in bat NPC1 were concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in *Eidolon helvum* cells. Thus NPC1 is a genetic determinant of filovirus susceptibility in bats, and some NPC1 variations likely reflect host adaptations to reduce filovirus replication and virulence (131). Nipah and Hendra use ephrin B2 or ephrin B3 as a receptor, and variation affects its ability to use human vs bat receptor molecules (102, 132).

**1.5.c. Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RdRp (or L genes), receptor binding glycoproteins, and full genome sequence (when available) data to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, filoviruses and henipaviruses that we identify. We will rerun MCC analyses (**Fig. 3**) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR-positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (**Fig. 4**) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) or other virus families within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (96, 133).

**1.5.d. Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (121, 134-136). For novel henipaviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize strains that are predicted to interact with ephrin-B2 and expression V/W proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models. We will assess ability to infect human cells using a

**Commented [PD38]:** Kevin/Alice – please edit this section to include relevance for filoviruses and henipaviruses as well (and other hosts)

continuous lung epithelial cell line, Calu3, that our group has previously used to generate data on NiV and HeV growth curves and a variety of host expression changes after infection (137). We will also use primary human airway cultures to assess human infection for Henipavirus and MERS- and SARS-related CoV (138) (139). There is some evidence for Nipah and Hendra virus replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (140, 141). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted Ebola infections (86-88).

**1.5.e. Animal models:** We will use transgenic mouse models and the UNC Collaborative Cross model to assess spillover potential of viruses. For work on CoVs, we will follow the protocols in the transgenic mouse model used by the Baric lab previously. Briefly, in the BSL3 lab, n=8 10- to 20-week old hACE2 or hDPP4 transgenic mice will be intranasally inoculated with  $5 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins or MERS-CoV and MERS-related CoV, respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV or MERS-CoV mAbs (142, 143) will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (120, 144). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (61, 120). For the Collaborative Cross model, we will....

Finally, for more detailed pathogenesis studies in the natural reservoir, we will use the bat models (natural and transgenic mouse model) at Duke-NUS. Both animal systems can be used to test susceptibility, pathogenesis and immune responses of any newly discovered viruses.

**1.6. Potential problems/alternative approaches:** **to sample bats in sites or provinces we select.** We have a >20-year track record of successful field work in Malaysia, Thailand and >10 years in Singapore, and have worked with local authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based on a range of PCR data and are fairly conservative in our approach. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses. The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (145), do not suggest a strong pattern of seasonality in CoV shedding, although there are studies that suggest this occurs in henipavirus and filovirus (MARV?) shedding (REFS?). Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province.

**Aim 2: Test evidence of viral spillover in high-risk communities using novel serological assays.**

**Commented [PD39]:** Ralph – please insert a couple of sentences on how we'll use the cc mouse and what we'd expect

**Commented [PD40]:** Linfa/Danielle – could you put a couple of sentences in on what we might do with the models. Remember – this could be an additional short project from the EIDCC extra funding.

**Commented [PD41]:** Kevin – please edit/check

**Commented [PD42]:** Kevin – please check the veracity of these comments

**2.1 Rationale/Innovation:** Rapid response requires early detection. Thus, assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that interface frequently with wildlife that harbor high risk emerging viral strains. To enhance the low statistical probability of identifying these rare events, we will target rural human communities inhabiting regions of high wildlife biodiversity, that also engage in practices that increase the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will build and expand on our preliminary biological sampling and enroll large cross-sectional samples in human populations with high behavioral risk of exposure to wildlife-origin viruses and that live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will initially identify 2 sites in each of Thailand, Peninsular Malaysia, Sarawak, and Sabah for repeated biological sampling. We will design and deploy behavioral risk factor questionnaires, and specific and sensitive serological assays to identify the baseline frequency, and causes of, spillover of known and related novel viral pathogens in these populations. In participants where symptoms are reported in the last 10 days, paired serum specimens (acute and 21 days after fever) will be collected to determine titer of positive antibody. Samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, and for isolation and biological characterization of potential pathogens, using the approach laid out in Aim 1.

Country, site	Lead	# enrolled, focus	Findings
Peninsular Malaysia	Hughes	1,390 Orang Asli indigenous population, PCR/serol.	25+ novel CoVs, influenza, Nipah ab+ve, filovirus ab+ve
Malaysia Sabah	Kamruddin	1,283 serology	40% JE, 5% ZIKV ab+ve
Malaysia Sabah	William	10,800 zoonotic malaria	High burden of macaque-origin malaria
Malaysia Sabah	Hughes	150 bat cave workers	Ongoing
Malaysia Sarawak	Tan	500 Bidayuh and Iban people	8% PCR prevalence HPV in women
Malaysia PREDICT	Hughes	9,933 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Thailand	Wacharapluesadee	1,000 bat guano harvesters/villagers	Novel HKU1-CoV assoc. clinical findings
Thailand PREDICT	Wacharapluesadee	9,269 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Singapore	Wang	856, Melaka virus	7-11% ab+ve

serological testing by EID-SEARCH. Our core group has collected and tested many thousand additional specimens from other important community cohorts (**Table 2**), and some of these will continue under EID-SEARCH (**See section 2.4**). Of particular interest is the access to indigenous communities in Peninsular Malaysia (Orang Asli) and Sarawak (Bidayuh, Iban people), and the bat guano harvesters in Thailand. These communities hunt, butcher and eat wildlife daily, and work in supremely high-risk zoonotic interfaces (e.g. bat caves). One of our indigenous community sites is experiencing an ongoing outbreak of unknown etiology that we are investigating currently (**See section 3.2.a**).

**Table 2:** Current or recent biological sample collection from healthy populations conducted by members of our consortium in EID-SEARCH hub countries

**2.2.b Human Contact Risk Factors:** EHA is the lead organization across all 27 USAID-PREDICT project countries for collecting data on, and analyzing the human aspects of, zoonotic spillover risk (146, 147). We conducted exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities, using these data to assess local social and cultural norms underlying wildlife contact (147). We then developed a risk factor survey to accompany human biological sampling to evaluate the type and frequency of animal contact, wildlife

**2.2 Preliminary data on high-zoonotic risk human community surveillance: 2.2.a Biological sample collection in SE Asia:** Our longterm collaboration in the region has included qualitative and quantitative survey data, and collecting large archives of banked human sera and other biological samples from high zoonotic-risk populations. For example, under the USAID-PREDICT project, EHA has collected 9,933 and 9,269 specimens in Malaysia and Thailand respectively from people living in zoonotic disease interfaces, all of which will be available for retrospective

**Commented [KJO43]:** Emily: Will we be sampling participants more than once?

**Commented [PD44]:** I think that would be good, depending on the sample size

**Commented [KJO45]:** Need to decide if we do PCR on community samples, we can add in the questionnaire if you've been sick in the last 10 days and if so, then maybe test only this subset.

**Commented [PD46]:** Kevin's comment makes sense to me

exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in 27 countries, and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). For example, survey and biological samples were collected from: 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, China; 1,400 participants from 4 sites in Malaysia; and 678 participants from 4 sites in Thailand. Samples were tested with novel serological assays and results analyzed against risk factors from survey data (12). In China, CoV-seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), that are male (6/9). Although these results are preliminary and don't provide detailed information on routes of exposure, they identify key subpopulations to target that would likely increase the opportunity for identifying evidence of spillover for other CoVs, paramyxoviruses and filoviruses. Data from PREDICT surveys will be used to help identify target populations in Aim 2, identify strategies to better target at-risk people, and conduct focused **human animal contact surveys and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.** In Aim 2, we will use combined biological sampling and risk factor surveillance in targeted populations within the community to 1) identify risk factors correlated with seropositivity to henipaviruses, filoviruses and CoVs; 2) assess possible health effects of infection in people; and 3) where recent illness is reported, obtain clinical samples for PCR testing and potential viral isolation and characterization. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**2.2.c. Risk factors for illness:** Our preliminary data from PREDICT in Thailand, Malaysia and China revealed that frequent contact with wild (e.g. bats, rodents, non-human primates) and domestic animals (e.g. poultry, swine) among local communities was associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms. In addition, people involved in crop production, hunting and butchering of wildlife reported statistically significantly higher SARI and ILI symptoms (Li *et al.*, in prep.). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with further refining serological tools, we will be able to identify the likely routes of exposure to known or novel coronaviruses, henipaviruses, and filoviruses in the study region, as well as build data on the illnesses they cause in people.

**2.2.d. Serological platform for community surveillance:** One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. By contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes (148). However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. Henipaviruses, filovirus and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filoviruses/henipaviruses=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (149)?, developing monoclonal antibodies (150, 151) and as subunit vaccines (152, 153), is presently developing a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, filoviruses and coronaviruses. This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (149). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

**Commented [EL49R48]:** Yes (until I finish a JVM manuscript) and add this reference: [15890907](#)

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay. The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (Fig. XXX). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-related African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (77, 78). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus

henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (154-156). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity. The majority of ebolaviruses are endemic to Africa, however the discovery of Měnglà virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown pathogenicity and zoonotic potential exists. Our past work in collaboration with Duke-NUS demonstrated that three under-sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (41).

**Fig. XXX:** Validation of multiplex microsphere immunoassay

(MMIA) specificity and identification of immunologically cross-reactive viruses for Nipah (A) and Ebola (B).

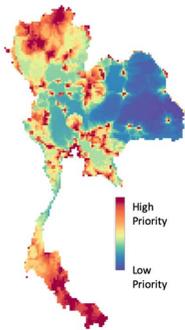

**2.3 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (Fig. XX). In Aim 2 we will conduct community-based surveillance using a brief, focused questionnaire to identify the prevalence and frequency of risk-factors for viral spillover in tandem with collection of high quality biological samples to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the communities sampled in Aim 2. Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and PCR prevalence in symptomatic patients.

**2.4 Target population & sample sizes:** We will target populations in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, that are EID hotspots, and that are well-connected through regional travel and trade hubs to the global travel network (Fig X). We will target specific communities based on our analysis of previously-collected PREDICT behavioral questionnaire data, to assess key at-risk populations and occupations with high exposure to wildlife, as well as using other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will identify populations at two sites in each of the following regions, building on our preliminary data (Table 2): Thailand (Co-I Wacharapluesadee): We will continue surveillance in bat guano harvesters and their villages in Ratchaburi province where we have identified MERS-related CoV in bat guano and rectal swabs (48, 157) and serological evidence of  $\alpha$ -CoV, HKU1-CoV in people (Wacharapluesadee in prep.). Our second site will be in Chonburi province where we have found Nipah virus (99% identity of whole genome sequence to NiV from a Bangladesh patient) in flying foxes but no outbreaks have yet been reported (REF), and have found several novel paramyxoviruses and CoVs have been found in bat feces roosting there (Wacharapluesadee in prep.).

**Commented [PD50]:** Hongying -Need a new figure that lays out the community/clinical approach – small one with pretty images.

**Commented [PD51]:** Supaporn/Kevin/ -Need sample sizes for both populations and power calculations for serology for a typical virus from one of the three families we're targeting

**Commented [PD52]:** Supaporn – please insert a reference into this comment box

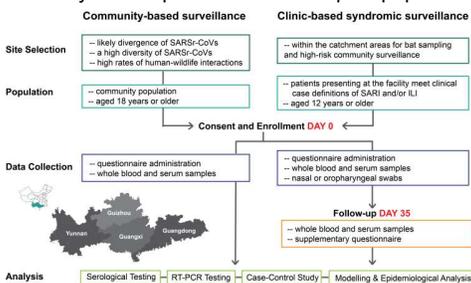

**Fig. X:** Geographic analysis to target high-risk sites for human zoonotic disease surveillance in Thailand. Our spatial analysis from Aim 1 will be extended to optimize sites for human community surveillance in Thailand and Malaysia by ranking areas with high numbers of expected viruses in wildlife, greater spillover probability based on EID risk factors, and higher levels of connectivity (measured by road density data) that may facilitate person-person spread.

**Commented [PD53]:** Need this figure for Singapore, Pen. Malaysia, Sarawak, Sabah as well – all together is best

**Peninsular Malaysia (Co-I Hughes, CM Ltd.):** We will expand our sampling of the Orang Asli indigenous communities to include additional communities in the 3 Districts we have already sampled, and additional Districts in the States of Kelantan, Pahang, and Kelantan. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled. Human samples will include serum, whole blood, throat swabs, nasal swabs, urine, and fecal sample or rectal swab. Samples will be collected in duplicate in VTM and Trizol. Samples will be stored and tested at NPHL. Participants who hunt, butcher or consume wildlife, or who rear animals will be considered suitable

for enrolment. Participants will complete a consent form and questionnaire in addition to having samples collected. During these community trips the field team will conduct community meetings to help inform the Orang Asli about the public health risk of zoonoses. **Sarawak (Co-I Tan, UNIMAS):** We will expand our sampling of the Bidayuh and Iban indigenous people to include the Dayak and Orang Ulu (“people of the interior”) because this group has a more intimate connection to remote wildlife-rich areas than the other two, albeit all are hunters. Human sampling will be led by UniMAS in collaboration with CM Ltd / EHA. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled, following the same protocols as for Peninsular Malaysia. **Sabah:** We will conduct sampling at the Madai bat and bird cave that has 200 permanent residents who harvest bird’s nests for soup, and >1,000 during the harvesting season and at Gomantong cave – one of the largest bat and cave swiftlet nesting sites in the world. Protocols follow those for Peninsular Malaysia. **Singapore:** Active human surveillance will not be conducted in Singapore, but archived human specimens e.g. from our Melaka virus serosurvey (4), will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

**Sample sizes:** From our previous work we anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so that they make up  $\geq 30\%$  of the sampled population in each community. We will stratify sampling to ensure appropriate representation of sex, demographic, and socio-economic factors at each community site. Estimating 5% overall seroprevalence in these high-exposure populations, these sample sizes are sufficient to estimate effect sizes of 2X or greater with 80% power. For community-based surveillance, we will enroll xxx individuals per county/province, pooled across two sites for each, allowing us to make county/province-level comparisons of differing effects.

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**Commented [PD54]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipaviruses, filoviruses and CoVs.

**Commented [PD55]:** Emily/Hongying Please check

**2.5 Data & sample collection:** Following enrollment of eligible participants and completion of the consent procedure, biological specimens (5ml will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 2.5ml whole blood; two 500  $\mu$ L serum samples) will be collected and a questionnaire will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported

interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent considerations for participants enrolled from clinical settings we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

#### **2.6: Laboratory analysis: 2.6.a Serological testing:**

In a previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity detected (12). **This suggests that if we can expand our serology tests to cover other bat CoVs, and that doing so may identify many more seropositive individuals.** We will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 bat SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoVs SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (12), and HKU10 is known to jump from one host bat species to another (158) so is likely to have infected people more widely. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV, at a phylogenetic distance where therapeutic or vaccine efficacy may falter. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or S1 (n-terminal domain); 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (13). Additionally, in Thailand, as an initial project on our EIDRC, we will develop serology assays to the novel CoVs found in bats at the bat guano site using LIPS assays and viral genomic data, and will screen archived specimens from 230 participants (2 years' collection in 2017-2018, a subset of the subjects have been sampled at multiple timepoints to allow us to assess seroconversion). To complement ELISA and LIPS assays we will also simultaneously screen sera for the presence of antibodies specific to henipaviruses, filoviruses and select coronaviruses using a Luminex-based platform with a multiplex microsphere immunoassay (MMIA). This proposed serological approach for biosurveillance is based on the detection, or capture, of serum antibodies specific to or cross-reactive with virus envelope receptor-binding glycoproteins from all presently described species of filoviruses (e.g. Ebola virus), henipaviruses (e.g. Nipah virus) and bat-borne SARS-CoV. The Broder lab produces soluble native-like, oligomeric virus glycoproteins that retain quaternary structures and retain conformational epitopes that can be used to detect conformational-dependent antibodies generated during a humoral immune response to viral infections. These virus glycoproteins are coupled to microspheres and combined into a multiplex immunoassay utilizing Luminex-based machine technology so that sera can be simultaneously tested for antibodies reactive with all 20 virus antigens included in this pan-filovirus/henipavirus/coronavirus immunoassay. Oligomeric antigens in combination with a MMIA have advantages in specificity and sensitivity compared to linear or monomeric antigens and traditional enzyme-linked immunosorbent assays (ELISAs), and can enhance and complement nucleic-acid based biosurveillance programs. Control sera samples for each virus antigen will be run in parallel to field sample screening to establish the expected positive and negative serological cutoffs and virus-specific antibody reactivity. Statistical approaches will be utilized to determine population level seroprevalence.

Commented [PD56]: Chris, Eric, Linfa, Dani etc. please draft some language here...

Commented [EL57]: Not sure if this is redundant from before

**2.6.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

Commented [PD58]: HELP – please add text for Henipas, filovirus

**2.6.c Biological characterization of viruses identified:** Novel viruses identified in humans will

be recovered by cultivation or from full length genome sequences using reverse genetic approaches. Viruses will be characterized for growth in primary human cell lines and in mouse models, including the Collaborative Cross Mice or humanized mice expressing human receptors from related strains. The approaches are discussed in more detail under Aim 1.

**2.7 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for Henipavirus, Filoviruses, and CoVs spillover. “Cases” are defined as participants whose samples tested positive for Henipavirus, Filoviruses, or CoVs by serological tests. “Controls” will be selected from the pool of participants admitted to the studies and whose samples tested negative for Henipavirus, Filoviruses, or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between Henipavirus, Filoviruses, or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%).

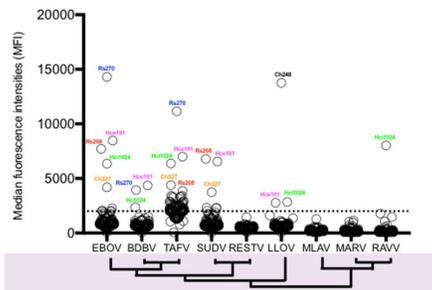

Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, paramyxoviruses, and influenza viruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may not match known viruses due to recombination events, particularly for CoVs.**

Commented [CB59]: Eric, insert mention of Malay preliminary sero positive data and your SIN data %

We will use the three-tiered serological testing system outline in 2.6.a to try to improve specificity of detecting and interpreting the presence of antibodies that bind to known viruses targeted in this project. Furthermore, we must also consider that identify these ‘novel’ viruses likely exist and that exposure to these viruses generates antisera that is cross-reactive with known, related virus antigens, which is a serious challenge of serological surveillance and diagnostics. Our collaborations have already demonstrated that SE Asia bat sera samples screened with our pan-filovirus MMIA have been exposed to an Ebola-like virus, that is antigenically-distinct from known Asiatic filoviruses, Reston virus and Mengla virus (Figure XXX) (Lainq, Mendnehall 2018).

Commented [EL60]: Why highlight a very specific challenge for only CoVs?

Formatted: Font: Bold

**Figure XXX. Serological evidence of ‘novel’ Ebola-like virus in three bat genera sampled in Peninsular Malaysia.** Colors indicate likely cross-reactivity across related filovirus antigens within the same bat serum samples (Hughes et. al. in prep)

Using these three serological platforms we will be able to address inherent challenges of indirect virus surveillance through antibody capture by testing multiple binding assay platforms and antigens and using positive control samples to establish serological profiles against known viruses that will aid in our interpretations of cross-reactive antisera responses likely representative of ‘novel’ viruses.

—however, we will also remain flexible on interpretation of data to ensure we account for recombination.

**Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research (Table 1) and other data suggests that there are substantial numbers of outbreaks or clinical cases for which the etiologic agent is not diagnosed, e.g. (159, 160). To investigate this in SE. Asia, we will work directly with clinics and outbreak control organizations to identify the causes of some ‘cryptic’ outbreaks or cases in the region. Specifically, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and who present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We conduct novel viral discovery assays on patients who present with symptoms indicative of a high-risk zoonotic virus. If novel pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the pathogen, using the *in vitro* and *in vivo* strategy laid out in Aim 1.

**3.2 Preliminary data clinical surveillance: 3.2.a. Clinical surveys and outbreak investigations:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes: **Peninsular Malaysia: At the time of writing, there is an outbreak of suspected viral undiagnosed illness in the indigenous Batek Orang Asli (“people of the forest”) community living at Gua Musang (“civet cat cave”) district, in Kelantan, Malaysia, close to Taman Negara – a National Park containing the oldest known rainforest. This community is one where we have conducted prior routine surveillance and biological sampling, demonstrating proof-of-concept that our two-pronged high-risk community/clinic approach will work.** Dozens of people are affected and the outbreak is currently being investigated by our collaborators at the Malaysian NPHL. The Orang Asli live in remote villages in the rainforest of Malaysia, with limited access to modern health care and extensive contact hunting, butchering, and eating wildlife as their primary source of protein. This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC - to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia. **Investigating this outbreak be a key priority if EID-SEARCH is funded.** **Sabah:** Co-I Kamruddin (BMHRC) is leading an asymptomatic leptospirosis study on sanitation workers, an ILI study in a Kota Kinabalu clinic and diarrheal study in children under 5 yrs. Co-Is William, Tan and others have conducted clinical observational studies to determine the etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah. Co-Is Tan,

Formatted: Font: Bold

Commented [KJO61]: Make this more general. There’s a greater challenge of interpretation of serological data, esp. if we’re using many platforms (each will have its own problems that our lab colleagues are probably more familiar with). Noam may be able to generally comment on a solution here from a statistical perspective.

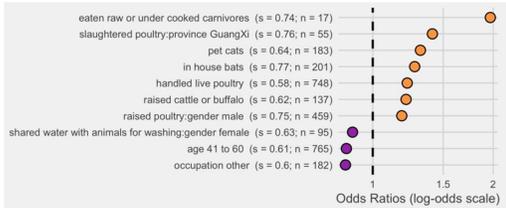

Commented [PD62]: Kevin – please modify according to your comment

William have collaborated with Co-I Wang to enroll 90 adult and over 100 pediatric participants with central nervous system infections, negative tests for malaria and dengue from 3 district hospitals in Sabah to determine the various etiologies. While a high proportion tested positive for rickettsial agents, the majority had no clear diagnosis. *Sarawak*: Dr Tan (UNIMAS) is conducting a survey of high-risk female Kelabit indigenous people and has found 8% with HPV52 as the dominant strain. He is working on clinical cohorts of hand, foot and mouth disease and will recruit patients from that study in the current proposed work. Finally, he is conducting a longterm study of rotavirus and other viral etiologies of acute gastroenteritis in Kuching, Sarawak that will include swine herders and farmers. These are an important group in Malaysia because pig farms are shunned by the government and local villagers to they are placed far away from town centers, deep in the forest, and it is this scenario that led to the emergence of Nipah virus in 1998-9 (18, 161). *Thailand*: The Chulalongkorn Univ. TRC-EID laboratory works in coordination with the Thailand Ministry of Health to investigate outbreak etiology, including the first case of imported MERS-CoV in Thailand, **for which we produced sequence confirmation within 24 hours from acquiring the specimen (Fig. X)**. Three imported MERS cases have been detected in Thailand since 2015, and all cases were confirmed at the TRC-EID. We worked during the Zika outbreak to identify > 500 PCR-positive Zika patients with sequence confirmation. We have also worked on returning and suspected Ebola travelers, syndromic surveillance for SARI, Encephalitis, Hand Foot and Mouth disease in children and Viral diarrhea. Working with the US CDC (Thailand), between 1998 and 2002 we enrolled a large cohort of children from Kamphaeng Phet Province to examine Dengue virus and JE epidemiology (162, 163). Among the 784/2,574 convalescent sera Henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence), suggesting prior exposure to endemic henipaviruses or a related paramyxovirus in rural Thailand. *Singapore*: Duke-NUS has worked with the Ministry of Health to investigate Zika cases (164), and with EcoHealth and others, Duke-NUS has developed novel CoV assays for clinical surveillance, and for expedited analysis during outbreaks. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing is as rapid as several months, with the development of novel serological assays from sequence data in 7 days (13). **For example, with the discovery of SADS-CoV, we identified and fully sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (*Rhinolophus* spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (13).**

Commented [PD63]: Fig coming from Hongying

**3.2.b Analysis of self-reported illness:** In addition to biological outcomes we have developed a standardized approach in PREDICT for analyzing data on self-reported symptoms related to targeted illnesses; of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), fever with muscle aches (fevers of unknown origin (FUO) and, cough or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI and/or SARI symptoms and demographics, occupation, and contact with animals in the last year. Results have clear biological relevance. In Yunnan, China, salient associated variables or combination of variables were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (Fig. 11). We will expand this approach for all syndromes in Aim 3, and use more granular targeted questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country.

**Fig. 11:** Associated variables of self-reported ILI and/or SARI in prior 12 months (s = bootstrap support; n = number +ve out of 1,585 respondents). **Orange circles** = odds ratios > 1 (positively associated with the outcome); **purple** = odds ratios <1 (negatively associated with the outcome).

**3.3 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms

typical of high-impact emerging viruses. We will collect survey data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.4 Clinical cohorts. 3.4.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at 2 town-level clinics and 2 provincial-level hospitals in Thailand, Peninsular Malaysia, Sabah and Sarawak. These all serve as the catchment healthcare facility for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients  $\geq 12$  years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, fevers of unknown origin, or hemorrhagic fever will be recruited into the study. We will enroll a total of xxxx individuals for clinical syndromic surveillance, which accounts for up to 40% loss from follow-up. Study data will be pooled across country sites, as clinical patients are limited by the number of individuals presenting at hospitals. Sites: *Thailand:* XXXXX | *Peninsular Malaysia:* Focusing immediately on the current outbreak in Orang Asli, we will work closely with the Malaysian Ministry of Health to support their investigation. We will also work with 6 Orang Asli clinics which focus solely on this indigenous community. *Sarawak:* XXXXXX *Sabah:* XXXXXXXXXX | *Singapore:* XXXXX

**3.4.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever of unknown etiology; or 6) severe diarrhea. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance of PCR detection of viruses (165). We will follow up 35 days after enrollment to collect an additional two 500  $\mu$ L serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs  $<28$  days after onset of symptoms for SARS patients (166). These samples may prove valuable to collaborators in that the PBMC could be used in production of therapeutic antibodies.

### 3.4.c Sampling:

Following enrollment with signed consent form, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500  $\mu$ L whole blood; two 500  $\mu$ L serum samples) including two nasal or oropharyngeal swabs will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

**3.5 Sample testing:** PCR, Serol to link symptoms to etiologic agents

**Commented [PD64]:** Supaporn, Kevin – we need information!

**Commented [PD65]:** Tom, Kevin – we need information.

**Commented [PD66]:** Hongying Emily

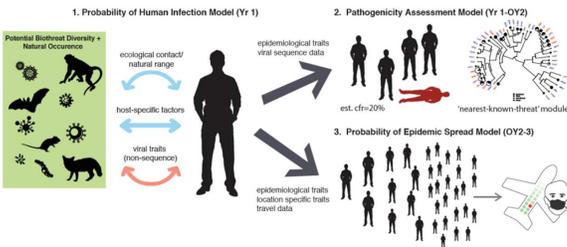

**Commented [PD67]:** Need data for Nipah and filovirus patients

**Commented [PD68]:** Ralph: PBMC could be valuable for making therapeutic antibodies through collaborations?

The standard syndromic diagnostic PCR assay for the common pathogens will be conducted and the results will be shared to the hospital with 48 hours. Specimens will be further tested for 3 viral families; CoV, PmV and filovirus by consensus PCR. Appropriate specimen from dead case will be further conducted by NGS if the previous PCR tests are negative to identified cause of infection. The serology panel assay will be conducted from paired serum.

Commented [PD69]: This is v. weak – can someone strengthen it please!

**3.5 Assessing potential for pandemic spread:** We will use statistical models built from collated biological, ecological, and genetic data to predict the likelihood of human infection (or spillover) and pathogenicity for a the range of diverse viruses we will characterize. The aim is to quickly identify and assess which viruses pose the most significant risk to human health and thus prioritize additional resources to more fully characterize, better understand pathogenicity, and invest in therapeutic development for those pathogens. We will combine two independent but related statistical models to predict pathogen spillover risk and pathogenicity. First, we will expand a simple generalized additive modeling approach (91) to assess spillover risk probability to a new virus that is currently not known to infect people, when we have only limited genetic data from initial PCR screening and sequencing. Additional data from receptor binding protein homology and cell line infection experiments can be incorporated into the model framework as available. Second, given high likelihood to spillover and infect humans, or direct evidence of human infection from our clinical surveillance, we will then predict pathogenicity using nearest neighbor phylogenetic analyses as a first approximation and by incorporating more detailed data from genomic characterization and animal model experiments. For the pathogenicity model, human epidemiological data for ~300 viral species known to infect people (case fatality rate, global estimates of number of human cases per year or decade,  $R_0$ , infectious period, and primary symptoms) will be aggregated including from previous reviews [Woolhouse ref] to use as predictor variables. Thirdly, we will build off EHA's previous DTRA and DHS supported research to predict pandemic spread for viruses we identify by integrating surveillance site data, global flight models (167), as well as additional datasets (road networks, shipping routes, cell phone data) to measure human movement and connectivity across Southeast Asia.

**Fig. XXXXX:** Conceptual framework highlighting 3 underlying models to estimate: 1) probability of human infection, or spillover, the first necessary step to understand pathogenicity when status of human infection is unknown; 2) pathogenicity, i.e. probability of causing clinical signs, case fatality rate estimates, and other metrics relevant to humans; and 3) probability of pathogen spread based on ecological, epidemiological, and airline connectivity and human migration data.

Commented [PD70]: Hongying – please work with Kevin to come up with something of relevance here. Also, make the text brief, bold and large so it's readable

**approaches: Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases.** Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (165). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the potential public health importance of discovering active spillover of a new henipavirus, filovirus or CoV infection.

Commented [PD71]: Add data for Nipah and filo infections

**Additional Instructions – Specific to the EIDRC FOA:**

**4. Administrative Plan**

In a clearly labeled section entitled “**Administrative Plan**”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.

Chula TRC-EID is National reference laboratory for diagnostic and confirmation of EIDs pathogen along with the National public health laboratory at the Department of Medical Science and the WHO Collaborating Centre for Research and Training on Viral Zoonoses. We have built a EID laboratory network in-country among three Ministry including Ministry of Public Health (Department of Medical Science and Department of Disease Control), Department of Livestock and Development, and Department of National Parks, Wildlife and Plant Conservation and Universities and among SEARO countries. Our clinicians provide case consultation for Thailand and SEARO countries. The laboratory and clinic training are regularly conducted.

**For Malaysia –**

**NPHL –** Molecular and serological screening (BioPlex) of PM Orang Asli samples, serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval)

**PERHILITAN molecular zoonosis laboratory, at the National Wildlife Forensic Laboratory -** Molecular and serological screening (BioPlex) of PM wildlife samples

**UPM Faculty of Veterinary Medicine -** Molecular and serological screening (BioPlex) of PM livestock samples

**KKPHL -** Molecular of syndromic samples from Sabah (already done) and Sarawak (would need approval)

**SWD WHGFL -** Molecular screening of Sabah wildlife samples

**BMHRC -** Molecular and serological screening (BioPlex) of Sabah livestock samples, serological screening (BioPlex) of Sabah wildlife samples, Molecular and serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval). BMHRC will need renovations and BioPlex to do this work – Menzies team might have funds for BioPlex that they would base here as part of DTRA project.

- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

**List out all of our involvement with outbreak investigations, ministries of health surveillance etc.**

If possible the clean or summarized answers from the questionnaire should be shared to the hospital Infectious Control team and Bureau of Epidemiology for their information for controlling the outbreak.

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging

**Commented [PD72]:** All – I’ve started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**Commented [PD73]:** From Supaporn

**Commented [PD74]:** From Supaporn – do same for all countries

infectious diseases in an international setting.

CM/EHA helped establish and manages with SWD the Wildlife Health, Genetic and Forensic Laboratory (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications) that has all the equipment necessary to store samples, run extractions, PCR and analysis on biological samples for wildlife disease surveillance. The lab is used to conduct health checks on rescued and relocated wildlife before being released into new areas or sanctuaries, to screen samples for the PREDICT and Deep Forest Project and for genetic research and forensic investigations. CM/EHA also helped establish the new molecular zoonosis laboratories (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications), at DWNP's National Wildlife Forensic Laboratory. The lab is used to screen samples for the PREDICT & DTRA projects. In addition CM/EHA also has access to NPHL and KKPFL for screening human samples and the Virology lab at FVMUPM for screening Livestock samples.

The Borneo Medical and Health Research Centre (BMHRC) is a centre of excellence that conducts teaching and scientific researches on communicable diseases, outbreak investigations, and ethnomedicine. BMHRC has offices space including a meeting room and seven laboratories which including preparation lab, parasitology lab, cell culture lab, bacteriology lab, natural product lab, virology lab, and molecular biology lab. BMHRC is supported by an administration staff, medical lab technologist, and research assistants who are available to work on projects. Through this project we will help to establish a certified BSL-2 lab at the BMHRC. This lab can then be used for human testing to elevate pressure at KKPFL and QEH labs. It would also be an ideal location for a Luminex platform as human, wildlife and livestock samples could all be screened here. Co-Is Hughes and Kamruddin will be starting outbreak response training in August 2019 with a team from Sabah CDC, KKPFL and BMHRC. (Dr. Maria Suleiman now in PM But still collaborating with us, Dr. Muhammad Jikal current Director CDC working with us and Dato' Dr Cristina Rundi Director Sabah state health Dept is supportive) this collaborative group is working to develop a Sabah outbreak response team that will help support SSHD/ CDC outbreak team and also conduct sampling for disease surveillance to be based at BMHRC and we will develop this as part of this proposal. In addition the UMS hospital will come in line in 2021 providing additional opportunities for cohort studies and capacity building.

FROM DARPA grant:

**Section 1.03 MANAGEMENT PLAN**

Project DEFUSE lead institution is EcoHealth Alliance, New York, an international research organization focused on emerging zoonotic diseases. The PI, Dr. Daszak, has 25+ years' experience

Commented [KJ075]: Figure like this would be good, but instead of breaking down by TA, maybe by country or Specific Aim. Per FOA, Need to also show how we'll link in with the Coordinating Center and other EIDRCs.

managing lab, field and modeling research projects on emerging zoonoses. Dr. Daszak will commit 2 months annually (one funded by DEFUSE, one funded by core EHA funds) to oversee and coordinate all project activities, with emphasis on modeling and fieldwork in TA1. Dr. Karesh has 40+ years' experience leading zoonotic and wildlife disease projects, and will commit 1 month annually to manage partnership activities and outreach. Dr. Epstein, with 20 years' experience working emerging bat zoonoses will coordinate animal trials across partners. Drs. Olival and Ross will manage modeling approaches for this project. Support staff includes

a field surveillance team, modeling analysts, developers, data managers, and field consultants in Yunnan Province, China. The EHA team has worked extensively with other collaborators: Prof. Wang (15+ yrs); Dr. Shi (15+ yrs); Prof. Baric (5+ yrs) and Dr. Rocke (15+ yrs).

**Subcontracts:** #1 to Prof. Baric, UNC, to oversee reverse engineering of SARS-CoVs, BSL-3 humanized mouse experimental infections, design and testing of targeted immune boosting treatments; #2 to Prof. Wang, Duke-NUS, to oversee broadscale immune boosting, captive bat experiments, and analyze immunological and virological responses to immune modulators; #3 to Dr. Shi, Wuhan Inst. Virol., to conduct PCR testing, viral discovery and isolation from bat samples collected in China, spike protein binding assays, humanized mouse work, and experimental trials on *Rhinolophus* bats; #4 to Dr. Rocke, USGS NWHC, to refine delivery mechanisms for immune boosting treatments. Dr. Rocke will use a captive colony of bats at NWHC for initial trials, and oversee cave experiments in the US and China. #5 to Dr. Unidad, PARC, to develop innovative aerosol platform into a field-deployable device for large-scale inoculation of the bats. Dr. Unidad will collaborate closely with Dr. Rocke in developing a field deployable prototype for both initial trials and cave experiments in China.

**Collaborator Coordination:** All key personnel will join regularly-scheduled web conferencing and conference calls in addition to frequent ad hoc email and telephone interactions between individuals and groups of investigators. Regular calls will include:

- Weekly meetings between the PI and Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.
- Monthly web conferences between key personnel (research presentations/coordination)
- Four in-person partner meetings annually with key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

Evaluation metrics will include the generation of high-quality data, successful achievement of milestones and timelines, scientific interaction and collaboration, the generation of high quality publications, and effective budget management. The PI and subawardee PIs will attend a kickoff meeting and the PI will meet regularly with DAPRA at headquarters and at site visits.

**Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by Dr. Daszak and the Project Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation. Should a resolution not be forthcoming, consultation with our technical advisors and DARPA Program staff may be warranted.

**Risk management:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. A project of this nature requires a different mindset from that typically associated with basic research activities that move at an incremental pace with investigators gradually optimizing experimental systems, refining data, or waiting for additional data before moving ahead with an analysis approach. To maintain our timeline, we will continually evaluate these trade-offs to make decisions about when iteration is appropriate and when necessary to move forward with current information.

#### **Biographies:**

**Dr. Peter Daszak** is President and Chief Scientist of EcoHealth Alliance, Chair of the NASEM Forum on Microbial Threats, member of the Executive Committee and the EHA institutional lead for the \$130 million USAID-EPT-PREDICT. His >300 scientific papers include the first global map of EID hotspots, estimates of unknown viral diversity, predictive models of virus-host relationships, and evidence of the bat origin of SARS-CoV and other emerging viruses.

**Prof. Ralph Baric** is a Professor in the UNC-Chapel Hill Dept. of Epidemiology and Dept. of Microbiology & Immunology. His work focuses on coronaviruses as models to study RNA virus transcription, replication,

**Commented [PD76]:** Some of references in this section are duplicates

persistence, cross species transmission and pathogenesis. His group has developed a platform strategy to assess and evaluate countermeasures of the potential “pre-epidemic” risk associated with zoonotic virus cross species transmission.

**Prof. Linfa Wang** is the Emerging Infectious Diseases Programme Director at Duke-NUS Medical School. His research focuses on emerging bat viruses, including SARS-CoV, SADS-CoV, henipaviruses, and others and genetic work linking bat immunology, flight, and viral tolerance. A 2014 recipient of the Eureka Prize for Research in Infectious Diseases, he currently heads a Singapore National Research Foundation grant “Learning from bats” (\$9.7M SGD).

**Current list of contacts at key human (especially) and wildlife orgs in every SE Asian country from map above – please add to this if we’ve missed any**

Indonesia – EHA: Eijkman (Dodi Safari), IPB (Imung Joko Pamungkas); **CM Ltd**: IPB (Imung Joko Pamungkas), Bogor Agricultural University (Diah Iskandriati)

SE China – EHA: Yunnan CDC (XX), Wuhan Inst. Virol. (Zhengli Shi);

Myanmar – Chulalongkorn (Thiravat and Supaporn) have collaborated extensively with Win Min Thit, MD (Yangon General Hospital, Myanmar); Khin Yi Oo (National Health Laboratory, Myanmar) and also in training PREDICT Myanmar veterinarians in bat sampling under PREDICT.

Japan – **BMHRC**: Oita University (Hidekatsu Iha, Kiyoshi Aoyagi), Nagasaki University (Koichi Morita, Kazuhiko Moji)

Cambodia -

Laos - **CM Ltd**: Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (Matthew Robinson)

Bangladesh – EHA: IEDCR (Meerjady Sabrina Flora, Ariful Islam), icddr,b (Mohammed Ziaur)

Malaysia – **CM Ltd**: Borneo Medical and Health Research Center (Ahmed Kamruddin), Department of Wildlife and National Parks Peninsular Malaysia (Frankie Sitam, Jeffrine Japning, Rahmat Topani, Kadir Hashim, Hatta Musa), Hospital Universiti Malaysia Sabah (Helen Lasimbang), Faculty of Medicine, Universiti of Malaya (Sazaly Abu Bakar), Kota Kinabalu Public Health Laboratory (Jiloris Dony, Joel Jaimin), Ministry of Health (Chong Chee Kheong, Khebir Verasahib, Maria Suleiman), National Public Health Laboratory (Hani Mat Hussin, Noorliza Noordin, Yu Kie Chem), Queen Elizabeth Hospital (Giri Rajahram, Heng Gee Lee), Sabah State Health Department (Christina Rundi, Mohammad Jikal), Sabah Wildlife Department (Rosa Sipangkui, Senthilvel Nathan, Augustine Tuuga, Jumrafiah Sukor), Gleneagles Hospital Kota Kinabalu (Timothy William); **BMHRC**: **CM Ltd** (Tom Hughes), HQEII (Shahnaz Sabri), Kota Kinabalu Public Health Laboratory (Jiloris Dony), Sabah State Health Department (Mohammad Jikal)

Thailand – **CM Ltd**: Department of Disease Control, Ministry of Public Health (Rome Buathong, Pawinee Doungngern, Pongtorn Chartpituck), Department of National Park, Wildlife and Plant Conservation (Pattarapol Manee-On), Faculty of Forestry, Kasetsart University (Prateep Duengkae), Mahidol-Oxford Tropical Medicine Research Unit, (Stuart Blacksell, Richard Maude), Chulalongkorn University (Supaporn Wacharapluesadee).

Chulalongkorn lab is a WHO Collaborating Centre for Research and Training on Viral Zoonoses, we work closely with WHO SEARO and SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste. We had conducted the PREDICT lab training for Veterinary lab in the Southeast Asia region for FAO. We conducted (transferred?) the bat sampling technique for scientists from Malaysia, Myanmar, the Philippines, and China.

## 5. Data Management Plan

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system

### Language from NIH CoV grant:

Data Sharing Plan: Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited in long-term public scientific repositories – all sequence data will be made publicly available via GenBank, species location data via the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestricted MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Viral isolates will remain at the Wuhan Institute of Virology initially. Isolates, reagents and any other products, should they be developed, will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

Sharing Model Organisms: We do not anticipate the development of any model organisms from this study. Should any be developed, they will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

Genomic Data Sharing: We anticipate obtaining genetic sequence data for 100s of novel coronavirus genotypes, including RNA-dependent RNA polymerase (RdRp) and Spike genes for all strains/genotypes. In addition, we will generate full viral genomes for a subset of the bat SARSr-CoVs that we identify. All sequence data will be deposited in the NIH genetic sequence database, GenBank. We will ensure that all meta-data

associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also submitted. The genotype data will be made publicly available no later than the date of initial publication or six months after the receipt of final sequencing data, whichever comes first. We anticipate sequence generation will occur over the 5 year proposed project period.

Genome Wide Association Studies (GWAS): Not applicable.

Commented [KJ077]: From CoV NIH grant

Thailand TRC-EID Chulalongkorn lab: Specimen management and BioBank: The software called PACS (Pathogen Asset Control System) supported by BTRP DTRA, is now used for managing the specimen from specimen registration (barcoding, and may move to use QR code system soon), aliquoting, tracking, short patient history record, data summary, searching, test reporting and etc. Our biobank system contains 28 freezers (-80C) and liquid N2 system. Its size is around 120 sq meters. There is a separate electric generator for our lab and biobank. There are CC TV cameras at the biobank and laboratory.

Chula TRC-EID has our own server for data management and analysis. We have the necessary software including Bioinformatic tools (Blast Standalone, SAMTOOL, GATK, AliVIEW, RaxML, FigTREE, MAFFT, Guppy, Megan, PoreChop, MEGA), Database (MySQL, MongoDB) Web, jQuery, Node.js, Express.js React, API, PHP, Ruby, Python, Java, C#, HTML5, Bootstrap, CSS, Responsive, Cloud, Linux Command, PACS (sample management system), Virtualbox virtual machines, R programming languages, Perl scripts, Bash shell scripts, Open source software, Microsoft Office running on both Apple Mac OS X, Ubuntu, Linux, and Windows Operating Systems. Chula TRC-EID has a dedicated 16-core Ram 64GB Linux server with 4TB hard drives, dual quad-core Mac Pro Server with 2TB hard drives and another dedicated iMac Pro (Retina 4K, 21.5-inch, 2017) Processor 3.6GHz quad-core Intel Core i7 (Turbo Boost up to 4.2GHz) Ra, 16GB with 512GB hard drives. TRC-EID also has HPC Linux server CPU: 4 x 26cores Intel Xeon = 104 cores 2.1GHz with 52 TB HDD and 2x3.84TB SSD with GPU 2x Tesla v100 (CUDA core = 5120 cores/GPU, Tensor core = 640 cores/GPU). TRC-EID has a dedicated 10/100/1000 of LAN (Local Area Network), 2.4G / 5G Gigabit Wi-Fi 802.11ac.

Commented [KJ078]: From Supaporn for their lab, some may go in Facilities doc?

From DARPA:

**Data Management and Sharing:** EcoHealth Alliance will maintain a central database of data collected and generated via all project field, laboratory, and modeling work. The database will use secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations, and enable compliance with DARPA data requests and disclosure requirements. All archived human sample data will be de-identified. Partners will provide raw and processed data to the central database throughout the course of the project. Project partners will have access to the data they generate in the database at all times, and maintain control over local copies. Release of any data from the database to non-DARPA outside parties or for public release or publication will occur only after consultations with all project partners. EHA has extensive experience in managing data for multi-partner projects (PREDICT, USAID IDEEAL, the Global Ranavirus Reporting System).

Commented [KJ079]: Text from DARPA Preempt

## 6. Clinical Management Plan

### Clinical site selection

Our consortium partners have been conducting lab and human surveillance research, inclusive of human surveillance during outbreaks, for over the past two decades and in that time have developed strong relationships with local clinical facilities and processes. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1. These are regions where we will sample wildlife due to the high potential of zoonotic viral diversity. Additionally, these will be clinical sites that serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. In PREDICT we developed successful working relationships with the major healthcare facilities the hotspot areas in 6 different countries, including Thailand and Malaysia and we will continue to work with these sites going forward. Continuing to

Commented [EH80]: Is that true

work with these hospitals means we will begin this project with successfully established partners and we can begin data collection quickly. This also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites for this study is limited. All that is required of sites will be the ability to enroll patients that meet the clinical case definitions of interest, capacity to collect and temporarily store biological samples, and follow standards for data management and protection. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently site staff. These will be persons who are locally trained and certified to collect biological specimen from participants including blood draw technique, e.g. doctor or nurse. Last, the clinical site will need the capacity to securely store all personal health information and personally identifiable research data, this will include locked offices with locked filing cabinets to store all paper records and an encrypted computer. Training on project procedures will be provided for all local project staff by local country project management staff and partners from headquarters. The study at clinical sites will begin by developing relationships with local stakeholders at the hospitals and clinics in our geographic areas of interest that serve as catchment facilities for people of within the community surveillance study. We will recruit hospital staff that will be extensively trained for project procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data management plans. During the Development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data (e.g. locked filing cabinet, dry shipper, secure laptop). [Did not specifically address CONDUCT]. Oversight for clinical sites will be managed by the country coordinator for each country. This will be done with regular site visits to the clinical sites and annual visits by headquarter research staff. Site visits will include monitoring and evaluating the process for patient enrollment, collecting and storage of samples, administration of the questionnaire, and secure and data management procedures for secure personal health information and research data. During these visits any additional training will also be provided.

#### **Standardized approach oversight and implementation**

Management and oversight for all study sites will be managed by the local country coordinator who is supported by staff at headquarters. Implementation of a standardized approach across all study sites, community and clinical, will begin by extensive training of staff on procedures on requirements of the project, this includes: enrollment, data collection, and data management. Our research team has over 5 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research. This includes SOPs for screening, enrollment, and retention of participants. In addition to yearly monitoring reports the country coordinator will regularly visit each clinical site to ensure quality standards and compliance of procedures are being met. Through our work with clinical sites in PREDICT we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical research staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll, allowing for minimal disruption and prevents potential enrollees from being overlooked if the research staff is not on duty. At clinical sites that do scheduled outpatient days we may have a trained member of the research staff with the intake nurse to monitor the patients coming to the clinic more rapidly to no delay screening or enrollment in such a fast pace environment. Using the screening tools, we will recruit and enroll patients who present with symptoms that meet the clinical case definitions of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology within the past 10 days. These patients will be enrolled, samples collected and survey conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; 3) environment biosecurity. With permission from each clinic, and consent from participants, we will review clinical records to

collect data on medical history, clinical syndromes, and patient etiology. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either coronaviruses, henipavirus, or filoviruses, serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between coronaviruses, henipavirus, or filoviruses in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. [How do these cohorts be leveraged for new emerging pathogens] Achieving the adequate numbers will be attained through duration of the as clinical participant enrollment. While patient's enrollment is limited by the number of individuals presenting at hospitals, during the PREDICT project we had an average of 105 patients enrolled per year, ranging from 77-244. The country coordinator will be continually monitoring the project database to be sure that we are on track to reach our target.

#### Clinical cohort setup, recruitment, enrollment

We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology for symptoms reported onset of illness to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 2\* 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples and two nasal or oropharyngeal swabs will be collected. The cases are defined as participants whose samples tested positive for Henipaviruses, Filoviruses, or CoVs by PCR or serological tests. The controls will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500 µL serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms for coronaviruses, henipavirus, or filoviruses infected patients to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

#### Utilization of collected data

Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses the are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire allows us to assess relative measures of human-wildlife contact from our survey work that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk.

The biological specimens to be collected (2\*5mL whole blood for whole blood and serum analysis and nasal or oropharyngeal swabs) from all eligible participants and follow up specimen 35 days (3mL of whole blood for serum) after enrollment with the standardized questionnaire. Capacity for specimen is collection is not more than standard phlebotomy skills and we will collected by locally trained and certified personnel that are part of the research team in country. Staff we will trainline on ethical guidelines for conducting human subjects

**Commented [EH81]:** Will these cohort fulfill the goals of the EIDRC.

**Commented [EH82]:** PREDICT we also make the stipulation that we will collective relative samples if available from treatment collection, eg CSF if the MD is doing a spinal tap we will request an aliquot if possible

**Commented [EH83]:** Please add any information that might address: types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

**Commented [EH84]:** Please add any information that might address: Describe methods that might be applied to elucidate a zoonotic source

research and survey data collection methods. Collection of whole blood, serum, and nasal or oropharyngeal swabs allows us to test the samples for PCR to detect viruses in our priority viral families, serologically test for immunological response and historical exposure to zoonotic diseases of relevance, and the questionnaire will assess individuals evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

#### **Potential expansion**

Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research or an outbreak in the region. If expansion is required we could rapidly implement research activities in additional clinical or community sites through the same process we on-boarded the initial locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transportation, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provided necessary information for granular understand of disease spread.

In a clearly labeled section entitled "**Clinical Management Plan**":

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment. including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen

collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

#### Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics
2. Tekada Sanofi Pasteur dengue
3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

### 7. Statistical Analysis Plan

In a clearly labeled section within the Research Strategy entitled "**Statistical Analysis Plan**":

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

### 8. Project Milestones and Timelines

In a clearly labeled section entitled "**Project Milestones and Timelines**":

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

**Project Management & Timeline**

PI Daszak will oversee all aspects of the project. Dr. Daszak has two decades of experience managing international, multidisciplinary research in disease ecology, including successful multi-year projects funded by NSF, NIH and USAID. He will conduct monthly conference calls with all co-PIs, including the China team (see Activity schedule below). He will be assisted by EHA Sr. Personnel Li, who is a US-based Chinese national with fluent

	Results Publication	■	■	■	■	■

■ China-US Joint Activity    ■ China-Led Activity    ■ US-Led Activity

Mandarin. Co-PI Olival will oversee Aim 1 working closely with China PI Tong, who will test samples. Co-PI Ma (China team) will coordinate and lead all Chinese experimental infections, with guidance from co-PI Saif, who will coordinate and lead all US experiments with co-PI Qihong Wang. Sr. Personnel Ross will conduct all modeling activities in Aim 2, working closely with co-PI Saif to parameterize the models. Co-PI Baric and Sr. Personnel Sims will lead infectious clone, recombinant viral and culture experiments. Consultant Linfa Wang will advise on serology, PCR and other assays. China team co-PIs Shi and Zhou will oversee viral characterization in Aim 1. Sr. Personnel Feferholtz will oversee the economic modeling in close collaboration with Ross.

Commented [KJO85]: Text and figure From NSF-NIH SADS grant. Peter will adapt

Another Example of Milestones and specific tasks from a prev DHS (unfunded) proposal:

**Expand existing databases to include predictor variables for pathogenicity risk model**

**Task 1:** Collate available human clinical information from the literature for ~300 viral pathogens known to infect humans (Contract Award Date to 6 month)

**Task 2:** Update EHA host-viral association database to include new data for mammalian and avian species from literature 2015-present (Contract Award Date to 3 month)

**Task 3:** Extract and curate full and partial genomic data from Genbank for 5-6 viral families with a high proportion of human-infectious pathogens for phylogenetic analyses – e.g. ‘nearest-known-threat module’. (Month 2 to 6 month)

**Develop underlying pathogenicity and spillover risk assessment models**

**Task 4:** Fit generalized linear models in Stan for multiple response variables to measure pathogen impact (Month 7 to 10 month)

**Task 5:** Fit generalized linear models to estimate risk of human infection (spillover) based on host, ecological, and location specific traits (Month 4 to 8 month)

**Task 6:** Validate model effectiveness by simulating early-outbreak, limited-information scenarios from known pandemics to confirm model behavior (Month 8 to 10 month)

Commented [KJO86]: Just example, but probably just want to use a Gantt chart format per most of our grants, depending on space.

## II. Research Strategy:

### 1. Significance:

Southeast Asia is a critical hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of key ecological and socioeconomic drivers of emergence (**Fig. 1**) (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is also undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread.

**Fig. 1:** Southeast Asia, and in particular, parts of Thailand and Malaysia are hotspots of risk for disease emergence (**left**), and predicted high diversity of 'missing' or as-yet undiscovered viruses, yellow = highest diversity (**left**). From (1, 2).

Not surprisingly a number of novel viruses, including near-neighbors of known agents, have emerged in the region leading to sometimes

unusual clinical presentations (**Table 1**). These factors are also behind a significant background burden of repeated Dengue virus outbreaks in the region (16), and over 30 known *Flavivirus* species circulating throughout S. and SE Asia (17). The events in Table 1 are dominated by three viral families: coronaviruses, henipaviruses and filoviruses, which serve as initial examples of our team's research focus and capabilities. These viral groups have led to globally important emerging zoonoses (18-29). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (30-32). Furthermore, relatives and near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium: henipaviruses in bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (33-39); a novel henipavirus, Mojiang virus, in wild rats in Yunnan (10); serological evidence of filoviruses in bats in Bangladesh (40) and Singapore (41); Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (Hughes *et al.*, in prep.); evidence of novel filoviruses in bats in China (42-44), including Mēnglà virus that appears capable of infecting human cells (45); novel paramyxoviruses in bats and rodents consumed as bushmeat in Vietnam (46); a lineage C  $\beta$ -

172 novel  $\beta$ -CoVs (52 novel SARSr-CoVs) and a new  $\beta$ -CoV clade ("lineage E") in bat species in S. China that are also found throughout the region (20, 47, 49, 50); and 9 and 27 novel wildlife-origin CoVs and

**Commented [MOU1]:** Should include Olival *et al.* 2017 for missing zoonoses, not Jones. Or Jones, Allen, and Olival papers.

**Commented [MOU2]:** Shouldn't we add the emergence of Nipah in Malaysia Singapore in 1999 at the top of the table!?

paramyxoviruses in Thailand (respectively) and 9 novel CoVs in Malaysia identified as part our work under USAID-PREDICT funding (49, 51). These discoveries underscore the clear and present danger of future zoonotic events in the region. Furthermore, the wide diversity of potentially pathogenic viral strains has significant potential to help in the development of broadly active vaccines, immunotherapeutics and drugs (47). Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 2). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (29, 52). However, these regions tend to be in the developing world, where nations often lack the resources to investigate novel zoonotic events, or wildlife reservoirs of zoonoses, and prioritize more immediate public health concerns such as Dengue virus or NTDs (16). Zoonotic disease surveillance and control is also hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (53). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in x/xx (x%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (12, 54). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (3) as well as 12/856 (1.4%) people screened in Singapore (4). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (7), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (55). In pPreliminary screening in Malaysia with funding from DTRA for serological surveillance of Henipaviruses and Filoviruses spillover found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in non-human primates (NHPs) and people (Hughes, in prep.) we found serological evidence of exposure to Henipaviruses (Hendra, Nipah and Cedar) in 14 bats and 6 human samples, and Ebola (Zaire and Sudan) antigenically-related viruses in 11 bats, 2 non-human primates (NHP) and 3 human samples (Hughes, in prep.)

Commented [PD3]: Peter will correct

Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70% (56). Nipah virus has been reported in people in West Bengal, India, which borders Bangladesh (26), in bats in Central North India (57), and now in people in Kerala, South India in 2018 and 2019, raising the specter of future spillover at other sites in the region (14, 58).

Commented [T4]: Can save space by abbreviating throughout

**Fig. 2: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks

(green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (52).

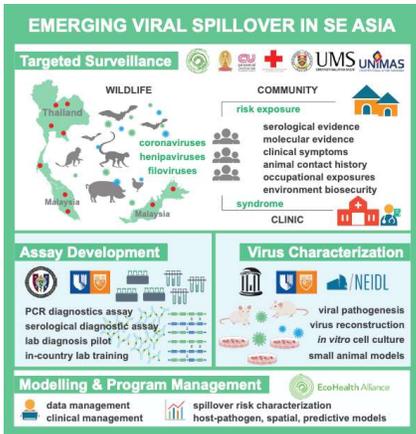

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (59), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (20, 47, 49, 50, 60-62). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-**

Commented [PD5]: Peter to do

**concept for an early warning approach that we will expand in this EIDRC to target key viral groups in one of the world's most high-risk EID hotspots.**

The overall premise for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. To scale-up this approach, we propose to launch EID-SEARCH (the **E**merging **I**nfectious **D**iseases - **S**outh **E**ast **A**sia **R**esearch **C**ollaboration **H**ub), to better understand the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and novel CoVs, henipaviruses, and filoviruses in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development, and cross-training in surveillance and novel diagnostic platforms. We will develop and transfer technology to test these viruses' capacity to infect human cells and mouse models, develop new specific and sensitive serological and molecular diagnostic tools, conduct surveillance of human communities with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover of viruses causing previously 'cryptic' clinical syndromes in people. We will test the capacity of novel viruses we isolate, or genetically characterize, to infect human cells and/or mouse models, and thus assess potential for spillover and spread which will feed into our risk models. Our group also has extensive experience in other viruses, including vector-borne flaviviruses, and alphaviruses, and will use this experience to provide robust long-term surveillance, diagnostics, human capacity building and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EID-SEARCH is poised to rapidly respond to any new emerging outbreak. Thus, filoviruses, henipaviruses and coronaviruses are examples of sentinel surveillance systems in place that can capture, identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.

**2. Innovation:** Previous work by our consortium has developed strategies to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses. In the EID-SEARCH we scale up this approach in a central research "hub" made up of leading laboratories, clinics and surveillance sites in three critically high-risk EID hotspot countries in SE Asia. EID-SEARCH's reach is expanded through its regional network of collaborators that covers nearly all of the greater SE Asia region. The innovation of the EID-SEARCH is in: 1) Its multidisciplinary approach that combines modeling to target

geographic and taxonomic sampling targets with on-the-ground zoonotic disease surveillance in human and wildlife populations; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). **In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. We will use *in silico* methods (inovel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains),

**Commented [BR56]:** Statement should be in the aims. ...Our center covers the worlds most high risk EID hotspot?

**Commented [KJ07]:** Hongying to add in "genetic sequencing" under Virus Characterization, and also Aim 1 + 3 for Virus Characterization and Aim 1 + 2 for Assay Development

cell culture, and animal models to assess their potential for spillover into

**Fig. 2:** EID-SEARCH approach, core members, and roles.

high-risk human populations. **In Aim 2, we will conduct focused, targeted cross-sectional surveys of and sampling of human communities with high levels of animal contact exposure to wildlife and other animals to identify occupational and other risk factors for zoonotic virus exposure.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. Serological findings will be analyzed together with clinical metadata (including a simple animal-contact survey, location data, viral sequence/isolates etc.) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise 'cryptic' outbreaks.** We will enroll and collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and [follow-up](#) serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs. Our US partner BSL-4 laboratory, NEIDL, will attempt isolation and characterize any viruses requiring high levels of containment (e.g. any novel filoviruses discovered).

### 3. Approach

**Research team:** The EID-SEARCH builds on long-term collaboration among world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (**Fig. 2**). Over the past two decades, our consortium partners have conducted high profile research on EIDs within the region and globally, including identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (20, 25, 57, 59, 63-65), discovering SADS-CoV (13), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (60-62, 66-79). Our team has substantial experience conducting human surveillance in the community and during outbreaks (See sections 2.x.x, 3.x.x), including: USAID-PREDICT, and DTRA-funded viral surveillance of indigenous communities in Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah (Co-I Hughes); collection of >2,000 serum samples from healthy blood donors and sanitation workers, febrile and influenza like illness (ILI), and diarrheal stool samples from children under 5 years of age (Co-I Kamruddin); collaboration on the MONKEYBAR project with the London School of Hygiene and Tropical Medicine to analyze risk and prevalence of the zoonotic malaria *Plasmodium knowlesi* through case control and cross-sectional studies in Sabah villages (~800, 10,000 participants resp.) and clinical observational studies to determine the etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah. (Co-Is William, Rajahram, Yeo); (Co-Is William, [Toek Hing]); case control and cross-sectional studies in Sabah villages (~800, 10,000 participants resp.) (Co-Is GR, TYW); and community-based surveillance of hundreds of bat-exposed villagers in Thailand (Co-Is Wacharapluesedee and Hemachudha). As a proof-of-concept of how our team can rapidly scale up resources for diagnostics and surveillance in the face of a new EID, in 2016, we discovered a novel bat-origin HKU-2 CoV (80, 81) killing >20,000 pigs in S. China, designed PCR and LIPS serology tests, then surveyed pig farmers for evidence of exposure, and conducted experimental infections, pathogenesis and molecular studies, **all in the span of 3 months** (13, 82).

The administration of this center (**See section X**) will be led by PI Daszak, who has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5-20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival and Zambrana are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesedee, Hughes and collaborators have coordinated surveillance of people,

**Commented [KJ08]:** And pathogenicity? Could argue for those we use animal models on.

**Commented [PD9]:** Hongying – Figure needs edits to text: top panel, 'wildlife' should read "Aim 1: WILDLIFE", "AIM 2: COMMUNITY", "AIM 3: CLINIC". Right hand side: "Clinical symptoms" should be "Clinical history", "Occupational exposures" should be "Occupational exposure", "environment biosecurity" should be "environmental risk factors"

Middle panel: "Assay Development" and "Virus Characterization" should have "(Aim 1)" after them. Left hand side: should read "PCR diagnostics", "serology", "piloting diagnostics" and the last one is ok. Right hand side bullets should be "receptor binding characterization" "in vitro characterization" and "mouse models"

Bottom panel: all good

**Commented [PD10]:** PD will get stronger letter from Jerry Keusch: opportunity for visiting scholars to be certified for BSL-4 research, strong Ebola person at NEIDL to conduct characterization if we find filoviruses.

**Commented [T11]:** Prof Chua is not part of this proposal

wildlife, and livestock within Thailand and Malaysia for the past 150 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from NIH, DoD, USAID, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to our EIDRC.

**Geographical focus:** The three core (hub) countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people

otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH, DTRA, and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our core member's extensive network of collaborators in clinics, research institutes and public health laboratories in almost every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in XX-10 countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic

potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Fig.3 :** Map of Southeast Asia indicating three hub countries for this proposed EIDRC (Red: Thailand, Singapore, Malaysia) and countries in which Key Personnel have collaborating partners (Green), indicating that EID-SEARCH provides access to key collaborators throughout the region.

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and non-human primates (NHP) (83). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (Fig. 1) (2). In Aim 1, we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates (NHP)) in these regions and apply novel predictive models to estimate viral diversity and host range to identify wildlife species that have been ignored or under-sampled by previous zoonotic disease surveillance efforts. We will strategically collect specimens from these species and screen them, together with some of the tens of thousands of recently collected samples we have archived in freezers in our labs, for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel virus in high risk RNA viral families, *Coronaviridae* (CoV), *Paramyxoviridae* (PMV), and *Filoviridae* (FV). We will expand to other groups of pathogens, including arboviruses, pending available resources and priorities established with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation. On this subset of viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, gene edited humanized transgenic mice and the collaborative cross genetic reference mouse population) previously developed and widely used by our team to predict capacity of novel viruses to

**Commented [KJO12]:** Including those in green on map, plus Australia.

**Commented [PD13]:** Hongying – “EIDRC Program Countries” should be “EID-SEARCH core countries” and “External Partner Countries” should be “Collaborating Partners”

**Commented [PD14]:** PD to Remember to correct specific aims with same titles

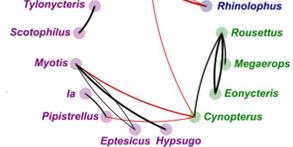

**Commented [KJO15]:** Can/should save space by abbreviating throughout after first mention.

**Commented [PD16]:** From Kevin - we need to specify in the methods below how many viruses (number of) we will have resources to do this on

infect people and spillover (61, 84-87). These high-risk viruses and their close relatives will be targets for human community serosurveys and clinical sampling in Aim 2 and 3, respectively.

**1.2 Preliminary data: 1.2.a. Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a major high risk location for pathogen emergence (1, 2). For Southeast Asia, these EID hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (Fig 1). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (2). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 1). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (88). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data and flight model software we have produced with Dept Homeland Security funds (89). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

**1.2.b. Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primates-NHP represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential(90). Thus, the bulk of our proposed wildlife sampling and testing will consist of these three taxa with a focus on bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses PMVs and FVs (48, 91-93). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (2), and are exceedingly diverse in Southeast Asia (~500 species). To further prioritize taxonomic sampling targets within these diverse geographic hotspots, we have used a novel, Bayesian phylogeographic analysis to identify host taxa that are the most important centers of evolutionary diversity for a given viral group, e.g. bat genera for  $\beta$ -CoVs using an extensive CoV sequence dataset from our NIH-funded research (Fig. 5) (49). This approach will be extended to other mammal taxa and viral families of interest, allowing us to identify the ancestral wildlife hosts of specific zoonotic viral groups, where their diversity is likely highest.

**Fig 5:** Preliminary analysis to identify the most important bat genera in Southeast Asia as hosts for beta-CoV evolutionary diversities using our previously-collected CoV sequence data collected under our NIH-funded research. Line thickness is proportional to the probability of virus sharing between two genera, with in-inter-family switches are highlighted in red. We will apply this Bayesian discrete phylogeographic model to identify taxonomic and geographic centers of viral diversification and sharing for relevant paramyxovirus PMV, CoV, coronavirus, and other virus clades.

Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (94, 95) (Fig. 6). Using prior data for bat, rodent and primate-NHP viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively identify new strains to support experimental infection studies and risk assessment.

**Commented [KJO17]:** Wrong ref! Should be Olival et al. 2017.

**Commented [KJO18]:** This is currently in Aim 3.

**Commented [KJO19]:** Olival et al appears twice in refs, fix.

**Commented [BRS20]:** I would say we focus on these three species (plus vectors?). To demonstrate the capability of the team, this proposal will focus on bat surveillance (for a variety of reasons), noting that this approach will also be applied to other zoonotic vectors during the 5 year program throughout the region.

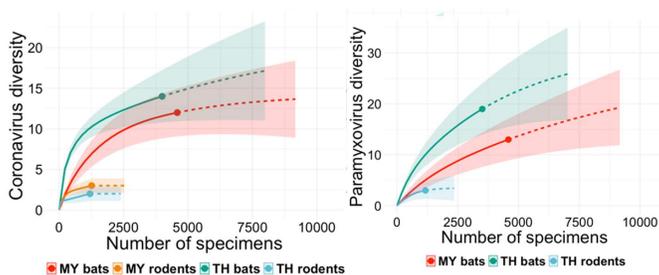

**Commented [PD21]:** Ralph – have we done this well enough now? If not, please add text/edit

**Commented [PD22]:** Kevin - Can you get rid of the shading on the background to this figure and change the colors so the circles and genus names are more visible (esp. the green). Colors should be darker and more contrasty

**Commented [MOU23R22]:** Revised figure inserted.

**Commented [KJO24]:** We can show just a single curve per country (aggregating all wildlife species) for simplicity, and could fit CoVs and PMVs on one graph.

**Commented [PD25]:** Evan/Hongying/Kevin, please send that also and I'll choose one

**Fig. 6:** Estimated coronavirus-CoV (left) and paramyxovirus-PMV (right) putative viral 'species' diversity in bats and rodents for from Thailand and Malaysia, using data from PCR screening and RdRp gene-sequences preliminary data from >103,000 PCR tests specimens in bats and 4,500 tests in rodents. Bats in Thailand and Malaysia have 4X the number of viruses than rodent species, controlling for sampling effort. CoV and paramyxovirus diversity estimates are

comparable, but discovery has not yet saturated in any taxonomic group or location. We estimate that additional collection of 5k-9k bat specimens sampling of ~5,000 bats and testing of our archived rodents specimens alone will identify >80% of remaining CoV and paramyxovirus-PMV viral species in these key reservoirs, yielding >800 unique viral strains. We will use this approach to define sampling targets for other wildlife taxa, and for viral strain diversity.

**1.2.c. Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. Under the 10-year PREDICT program globally, we identified 912 novel and 210 known viruses, more than the total number of viruses previously recognized in mammals by the International Committee on Taxonomy of Viruses. This work included collecting nearly 300,000 individual mammal samples from 14 EHA-led PREDICT countries and PCR-screening more than 60,000 individual specimens (51). In southern China alone, this sampling led to the identification of 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARS-CoVs). Included were members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus, SADS-CoV, responsible for killing >20,000 pigs in Guangdong Province (13). Many of the identified bat species are found across the region. We have collected 28,957 samples from bats, rodents and primates in Thailand and 47,178/51,373 in Malaysia, conducting 146,527 PCR tests on a large proportion of these specimens. We have archived duplicate samples which are now available for use in this project, including fecal, oral, urogenital, and serum samples and biopsies from bats, rodents, and non-human primates NHP, and primate biopsies. In Thailand this screening has identified 100 novel viruses and 37 known viruses in wildlife reservoirs. In Malaysia this screening has identified 77 novel viruses and 23 known viruses in wildlife reservoirs (66 novel and 19 known in Sabah and 11 novel and 9 known from Peninsular Malaysia). We used Using family level primers for henipaviruses PMV, filoviruses-FV, and CoVs, we and have already discovered 9 novel and 7 known CoVs and 26 novel and 2 known paramyxoviruses-PMV in Thailand; and This is in addition to 13 novel and 5 known CoVs and 15 novel and 1 known paramyxovirus-PMV in Malaysia from wildlife. In the current proposed work, we will attempt to sequence, isolate and characterize those viruses that our analyses below suggest are most likely to be able to infect humans.

Our collaborative group has worked together on these projects, as well as other DTRA funded projects in Singapore/Thailand (Co-Is Broder, Wacharapleusadee, Wang) to design, cross-train, and use novel serological and molecular platforms to investigate virus infection dynamics in bats and examine potential spillover events with or without human disease (see Aim 2). For serology, Co-Is Wang and Anderson (Duke-NUS) will develop a phage-display method to screen antibodies for all known and related bat-borne viruses, focusing on henipaviruses, filoviruses-FV and coronaviruses-CoV. Once various "trends" are discovered, additional platforms (including Luminex and LIPS) will be used for verification and expanded surveillance. For molecular investigation, we will combine targeted PCR approach with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified. In Malaysia (Co-Is Hughes, Broder, Laing) we have transferred the Luminex serology platform to partner laboratories for screening of wildlife, livestock and human samples to investigate the spillover of henipaviruses and FV filoviruses at high risk interfaces. These interfaces include farms near the forest and indigenous communities with lots of subsistence hunting in Peninsular Malaysia, and preliminary screening has found

**Commented [PD26]:** Kevin – please get someone to check EIDITH – I think I just gestimated these numbers...

**Commented [MOU27R26]:** These are correct, based on EIDITH P1 + P2 for EHA countries.

**Commented [T28]:** This is right number based on our records.

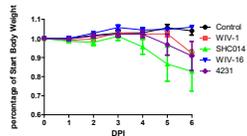

**Commented [KJ029]:** Leave this out as it may look like we've already done a bulk of the work?

**Commented [MOU30]:** Think we need to abbreviate these viral families throughout, should Find/Replace. Also, henipa is not a viral family, so changing back to PMVs.

serological evidence of past exposure to viruses antigenically-related to Nipah and Ebola in humans, bats and non-human primates (NHPs). In Thailand, Co-Is Broder, Laing and Wacharapluesadee have transferred a Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses (FV) and known henipaviruses in wildlife and human samples, with testing underway and currently being validated in our Chulalongkorn University laboratory (See also section 2.2.d).

**1.2.d. In vitro & in vivo characterization of viral potential for human infection:** Using Coronaviridae as an example, we have conducted *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3-7% (20, 59, 96). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (59). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of two different variants. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in those without ACE2 (20, 59, 96). We used the SARS-CoV reverse genetics system (70) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (60). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry.** The Baric lab has a well-established hACE2 and DPP4 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect (84, 97). We used this chimera approach to demonstrate that pathogenicity of bat SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the value of this model in assessing novel SARSr-CoV pathogenicity.** Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity, nor after challenge following vaccination against SARS-CoV (60).** We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they are unable to use the ACE2 receptor.** Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines.

A similar approach to the above pipeline for CoVs will be applied to novel henipaviruses and filoviruses (FV) we discover during our research. The broad mammalian tropism of Hendra virus and Nipah virus (66) is likely mediated by their usage of highly conserved ephrin ligands for cell entry (15, 98). A third isolated henipavirus, Cedar virus does not cause pathogenesis in animal models. Recently, **Co-Is Broder and Laing** have developed a reverse genetics system and rescued a recombinant CedV to test ephrin receptor usage/tropism and pathogenicity during henipavirus infections (75). CedV is unable to use the Ephrin-B3 receptor (75, 99) which is found in spinal cord and may underlie NiV encephalitis (100) and that pathogenesis also involves virulence factors V and W proteins. The putative henipaviruses, Ghana virus and Mojiang virus, predict V and W protein expression, with GhV able to bind to ephrin-B2, but not -B2 (101), and the receptor for MoJV remaining unknown (102) but is likely ephrin-B2 (103). Primary human lung endothelial cells are highly susceptible to Ebolavirus infection (104). Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (105) Huh7 cells also offer advantages for reverse genetic recovery of novel filoviruses (106). Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G).

**Fig. 7:** Body weight change in hACE2 transgenic mice after SARSr-CoV infection, demonstrating that bat-origin SARSr-CoVs cause similar clinical presentation to outbreak strain (4231). From (60, 61).

**Models of Outbred Populations.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments (107). We have used this model for CoV, ~~filo-FV~~ (Ebola), Flaviviruses, and alphaviruses

**Commented [KJ031]:** Move to Aim 2? I think it's good to have some flexibility to test wildlife sera using these assays, but not readily clear how this fits in with our PCR screening? We could do a broader survey of a smaller number of wildlife samples from more species, and those with high seroprev, we can follow up w molecular assays – though not sure this is necessary. All the serology in this section can prob go to Aim 2.

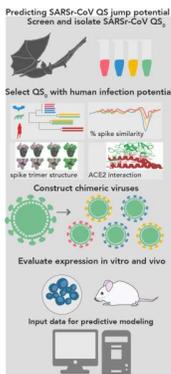

**Commented [T32R31]:** All samples from concurrent Orang Asli sampling will be screened this year using Luminex under our current DTRA project as well as most of our concurrent farm samples. Doing PCR and serology on wildlife and livestock sample sets allows us to see what viruses were circulating at time of sampling while serology will show what has been circulating in past and provide indication of what novel viruses might be out there that we have yet to find in viremic animal or person.

**Commented [PD33]:** Ralph/Danielle/Eric/Chris – need something substantial here on filovirus binding that shows we have a valid approach for novel filoviruses

**Commented [PD34]:** Ralph – I think I mis-spoke in this fig. description – please correct.

infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection (85-87, 108-111). Bat Models. Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (112).

**1.3. General Approach:** We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new sampling of wildlife in high risk locales. We will use viral family level PCR screening-assays to identify and partially characterize viruses, then follow up sequencing of relevant receptor binding proteins to assess homology and predict binding affinity, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will follow this with *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease (Fig. 8). EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses, as well as cross-training and tech transfer to the hub labs in Thailand and Malaysia. This will include via support of one Malaysian Ph.D student, Mei-Ho Lee (CM Ltd.) who has worked with the EID-SEARCH collaborators for 9 years. The focus of her study will be infection potential of novel CoVs and paramyxoviruses-PMV already found in bats in Malaysia under preliminary data for this proposal.

**Fig. 8:** Schematic showing EID-SEARCH approach to selection of sampling, viral testing, prioritization and characterization to identify novel, high zoonotic-risk viruses in wildlife.

**1.4 Wildlife samples: 1.4.a. Geographic and taxonomic targeting for newly collected wildlife samples:** We will prioritize sites within each country that rank highest for both the risk of zoonotic disease emergence (113) and the predicted number of 'missing' zoonotic viruses (90). Our preliminary analysis (Fig. 1) suggests priority areas include: the Kra Isthmus and the forests of northern Peninsular Malaysia, of Kra (S. Thailand and N. Peninsular Malaysia), NW Thailand (near the Myanmar-Laos border), and the lowland rainforests of Sarawak and Sabah. In each of these 'hottest of the hotspots' regions, we will identify 2-4 distinct sampling sites based on the geographic distribution of key hosts we prioritize for intensive-additional wildlife sampling. We will priority rank bat, rodent, and primate-NHP species using analysis-of-host-trait-data-for-the-highest-predicted-number-of-viruses-based-host-trait-based-models (90). We will also identify species predicted to be centers of evolutionary diversity for Corona-, Paramyxo-, and Filoviridae using ancestral host reconstruction of available sequence data and Bayesian discrete phylogeographic models (114-116). We will ensure wildlife sampling is complimentary to specimens archived in our extensive freezer banks. We will collect only the additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes given predicted levels of viral richness and rates of discovery (see 1.4.b). We will leverage our strong collaborations with wildlife experts in Malaysia and Thailand to ground-truth geographic and taxonomic model outputs with local expert knowledge to ensure the sampling plan is realistic based on current species distributions, population size estimates, seasonality, and accessibility to sites.

Recognizing that most zoonotic viruses are multi-host, i.e. naturally harbored by multiple wildlife species, and that the phylogenetic relatedness of those hosts is predictable and varies across viral families (90) – we will use a combined network analysis and a phylogeographic model also apply a generalizable phylogenetic and spatial modeling approach to rapidly predict and prioritize new (unsampled) hosts for important, novel viruses we discover during our research. We will use a combined network analysis and a phylogeographic model to estimate a viruses' host range and to We have shown this relatively simple model prioritize additional wildlife species for sampling and testing for viruses we discover. Our recently developed model of viral sharing uses just two phylogeographic traits (using just wildlife species range overlap and phylogenetic similarity between host species) is both generalizable to estimate host range for all mammalian and avian viruses and robust –

**Commented [PD35]:** Ralph – please add data from the CC mouse re. filoviruses, to beef up the image of us as a filovirus group

**Commented [PD36]:** Linfa/Danielle – please draft a brief para explaining how we'll use these two models

**Commented [PD37]:** Hongying – this is a placeholder from DARPA proposal. We need a new one with Stages: 1) Geographic and taxonomic modeling to maximize discovery of potential zoonotic viruses; 2) PCR screening and partial RNA sequencing; 3) Full genome or RBD and Glycoprotein sequencing to model receptor binding based on sequence similarity; 4) Cell line infections (for prioritized viruses); 5) animal model infections (for prioritized); 6) High priority viruses ranked based on data (red, yellow, green) schematic.

**Commented [T38]:** Kra Isthmus is in Thailand

**Formatted:** Font: Italic

accurately predicting hosts 98% of the time when cross-validated using data from known viruses to successfully predict host species in the top 2% of all 4,200 possible mammal species (117).

**1.4.b. Sample size justifications for testing new and archived wildlife specimens:** We calculate initial We will sample sizes targets using e-our preliminary data on average PCR prevalence from screening tens of thousands of bat, rodent and primate specimens for CoV and Paramyxoviruses-PMVs under the USAID-PREDICT project in Malaysia and Thailand. We will refine these sample size targets, in real-time, over the course of our project using viral discovery curve analyses (Fig. 6) to either scale-up or scale-back new sampling and testing of archived specimens for each species depending on their viral diversity/capture rates. We will only collect additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes and to complement our archived specimens. For example, *Rousettus* spp. bats, known filovirus

Commented [PD39]: Kevin - That doesn't make clear sense straight away – please re-word better without increasing length

reservoirs, were not adequately sampled under PREDICT research in Thailand. Preliminary analysis indicates we will require ~14,000 new samples to identify 80% of remaining viral species diversity in our study region, ~5,000 samples from

Formatted: Font: Italic

Thailand and ~9,000 samples from Malaysia (Fig. 9). Viral strain discovery diversity from a sampling effort this size is expected to number in the hundreds of strains. For example, given ~6% prevalence of CoVs in bat species previously sampled under the PREDICT project, a target of 14,000 individuals would yield ~800 PCR positive individuals, representing, conservatively, an estimated ~200600 novel CoV strains/sequences/strains. Similarly, for paramyxoviruses, which have an average PCR detection prevalence of ~1.5%, sampling of 14,000 individuals would yield ~200 positives and an estimated ~50150 novel paramyxovirus strains. From each mammal, we will collect serum, whole blood, throat swabs, urine and fecal samples or rectal swab using our previously-validated

Commented [KJO40]: Just assumed that 75% of detections would = unique sequences/strains. We can lower this to be more conservative.

Commented [MOU41]: Kevin will work with Noam and Evan to fill in these numbers.

For example, given 5-12% prevalence of CoVs in the most common bat species we previously sampled in Thailand and Malaysia, a target of XXX individuals per species would yield XX (± x) PCR positive individual bats, and an estimated ~xx novel strains. Similarly, for paramyxoviruses with an average PCR detection rate of X%, we would need XX individuals per species to detect 80% of predicted viral strain diversity with 80% power. Preliminary analysis indicates we will require XX,000 samples to identify 80% of remaining viral diversity (Fig. 9). All wildlife sampling will be nondestructive methods (see Vertebrate Animals section) [REFS]. In the event that an animal is found dead or needs to be euthanized due to injury we will collect biopsy-necropsy samples for screening.

Commented [KJO42]: PREDICT sampling protocols? Jon's FAO bat book manual, and other published for rodents and primates (from Bangladesh?)

**Fig. 9.** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMV species s from high-risk bat and rodent taxa in Malaysia and Thailand

Commented [PD43]: Hongying/KEvin Need less text on the figure, but larger font size, or crisper text to make it all visible at this size.

We estimate the following sampling effort, broken down for each region: *Peninsular Malaysia:* Wildlife sampling will be led by CM Ltd / EHA in collaboration with PERHILITAN. Archive bat, rodent and NHP samples will be screened serologically using the BioPlex and other serology techniques identified through this project. New wildlife sampling will focus on bats but it is expected that rodents and NHPs will be sample as well. Wildlife sampling will be conducted around Orang Asli communities sampled as part of aim 2. Three new communities will be identified in the districts we have already sampled in. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at PERHILITAN's NWFL and screened using molecular and serological techniques. *Sarawak, Malaysia:* Archive bat, rodent and NHP samples will be screened serologically using the BioPlex and other serology techniques identified through this project. Wildlife sampling will be led by CM Ltd / EHA in collaboration with UniMAS (Co-Is Faisal Faculty of Resource Science and Technology). Wildlife sampling will be conducted around Dyak indigenous communities sampled as part of aim 2. One community will be identified. Concurrent sampling trip will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab

and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and initially tested at UniMAS or BMHRC using molecular and serological techniques. If over the course of the project we are able to develop the laboratory at the Faculty of Medicine and Health Sciences or Faculty of Resource Science and Technology molecular screening will be carried at UniMAS. *Sabah, Malaysia:* Bat sampling will be led by CM Ltd / EHA in collaboration with SWD and WHU. Bat sampling will initially focus on 3 caves. Batu Supu Sabah low disturbance cave and surrounding area, Madai medium disturbance cave and surrounding area, Gomantong cave high disturbance cave and surrounding area. Each cave will be sampled twice once in wet season and once in dry season targeting 500 bats at each cave on each trip for a total of 3000 bats. Wildlife samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored at WHGFL, molecular testing will be conducted at WHGFL and serology screening at BMHRC. In addition at Madi cave the community that lives in the mouth of the cave will also be sampled targeting 150 people, while at Gomantong cave 25 workers involved in the bird next farming will be enrolled into the study.

Thailand: XXXXXXXXXX New bat specimens will be collected from bat species that was not collected during PREDICT2 study for example *Rousettus* bats (targeted species for Filovirus study), *Taphozous* bat (targeted species for MERS-CoV), *Rhinolophus* (targeted species for SARS-CoV) for serology and PCR assays (n=100 for each species).

Thailand: XXXXXXXXXX

**1.4.c. Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C. PCR screening will be performed with pan-coronavirus, filovirus and paramyxovirus primers, in addition to virus specific primers where additional sensitivity is warranted in key viral reservoirs, i.e. Nipah virus specific primers [REF]. PCR products will be gel purified and sequenced. We will attempt isolation on samples that contain viruses of interest (determined in **1.4, below**), using Vero cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). [This includes the over 30 bat cell lines maintained at Duke-NUS] from four different bat species.

**1.4.d. Moving beyond RNA viruses:** To detect pathogens from other families, such as non-RNA viruses we will combine conserved PCR assays with NGS. We will perform either unbiased NGS, or use a pan-viral enrichment library to sequence full-length genomes. We will conduct this work via EID-CC research projects or as part of outbreak detection/investigation in the region from DNA viruses or other agents.

**1.4.e. Sequencing Spike Glycoproteins:** Based on earlier studies, our working hypothesis is that zoonotic coronaviruses CoV, filoviruses FV and henipaviruses PMV encode receptor binding glycoproteins that elicit efficient infection of primary human cells (e.g., lung, liver, etc.) (12, 59, 60). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (**Fig. 4**) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are under sampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (20, 60, 118), suggesting that existing vaccines and immunotherapeutics could easily fail against future emerging SARS-like CoV. Moreover, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic receptor binding protein genes of MERS-related, Ebola-related and Nipah/Hendra-related viruses will also program efficient entry via human ortholog receptors. For all novel virus strains, we will sequence the complete entry spike genes by amplifying overlapping fragments using degenerate primers as shown previously (20, 59). Full-length genomes of selected CoV strains (representative across subclades) will be sequenced using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer.

**Commented [T44]:** I have just seen Dr Tan's lab – no -80 freezer, no biosafety cabinets.

**Commented [PD45]:** Kevin – who can write this bits?

**Commented [KJO46]:** I think all this could be deleted. Doesn't fit with the overall plan, or is redundant. We may want to call out a few specific sites Tom mentions (but won't that depend on the modeling!?), and you may want to keep the partner info Tom provided and call that out - maybe more in Aim 2 since its about people too?

**Commented [T47R46]:** These sites fit into geographic areas described above. If we want to sample a large number of bats the Sabah caves are our best bet. We could target caves in PM as well as in Sarawak. But based on earlier discussions I thought this was plan for PM and Sarawak?

In PM we could target –

1. A cave we found near OA GM but only around 300 bats and we sampled 171 already.
2. Gua payong, kelantan
3. Gua tempurug, perak
4. Gua kandu, perak
5. Buah cave, terengganu
6. Cave kalam, perlis

In Sarawak we could target Niah, Mulu, Fairy, Deer, Wind caves. These are tourist attractions with many native settlements around the areas and hunting bushmeat for protein source is still a norm.

**Commented [T48]:** Will we not use throat swabs as well – thought this was where we had found the most viruses then in fecal samples?

**Commented [MOU49]:** Supaporn: From my DTRA study, specific Nipah primers and WHO 2C CoV primers is more sensitive than consensus PCR if we want to find the specific virus.

**Commented [PD50]:** Linfa – can you give a v. brief description of these please, e.g.: "This includes 13 primary lung, 5 primary gut epithelial, and 1 primary liver cell line. In addition we have 12 immortalized cell lines, 7 of which are intestinal, and therefore suitable for CoVs. Cell lines are derived from insectivorous and frugivorous bats (genera.....)"

PCR or Minlon sequencing will be performed to fill gaps in the genome. The full length spike gene sequences, including the amount of variation in the receptor binding residues that bind the appropriate human receptor will be used to select strains for Aim 3 experiments.

**1.5. Assessing risk for spillover. 1.5.a. Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, [filoviruses-FV](#) and [henipaviruses-PMV](#), we will use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (60, 61, 119). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs or other test [filoviruses-FV](#) or [henipaviruses-PMV](#) to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other viruses (62, 69). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (61, 120) or monoclonal antibodies targeting the Ebola or Marburg E glycoprotein (Available through BEI), or Nipah or Hendra viruses (121). As controls or if antisera is not available, the S genes of novel SARSr-CoV or spike entry genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (122). Polyclonal sera against SARS-related viruses will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (61, 123, 124). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (125) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (126-128). Similar approaches will be applied to novel MERS-related viruses, other CoV, [filoviruses-FV](#) or [henipaviruses-PMV](#). While most wildlife-origin viruses with unknown transmission potential or pathogenicity in people are BSL-2 or -3, cell culture for potentially BSL-4 pathogens will be undertaken at collaborating institute NEIDL. To facilitate this, duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (See letter of support) for culture, characterization and sharing with other approved agencies including NIH [Rocky Mountain Laboratories RML](#) where our [EID-SEARCH team has ongoing collaborations](#). When appropriate of feasible, training opportunities at NEIDL for in-country staff will be given.

**1.5.b. Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the [intraspecific](#) scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (68). [A lot of variation](#) in the NPC1 receptor alters EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains (129). Signatures of positive selection in bat NPC1 were concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in *Eidolon helvum* cells. Thus NPC1 is a genetic determinant of filovirus susceptibility in bats, and some NPC1 variations likely reflect host adaptations to reduce filovirus replication and virulence (130). Nipah and Hendra use ephrin B2 or ephrin B3 as a receptor, and variation affects its ability to use human vs bat receptor molecules (101, 131).

**1.5.c. Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of [RNA-dependent RNA polymerase \(RdRp\) sequences from PCR screening \(or L-genes\)](#), receptor binding glycoproteins, and/or full genome sequence [data](#) (when available) [data](#) to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, [filoviruses-FV](#) and [henipaviruses-PMV](#) that we identify. [We will run phylogenetic and ancestral state reconstruction analyses \(Fig. 5\) to reconstruct identify host taxa and geographic sites of  \$\beta\$ -CoV, filovirus and henipavirus evolutionary origins within bats, rodents and primates using our expanded dataset and identify the host taxa and geographic regions that together define hotspots of phylo-diversity for these viruses, allowing for more targeted surveillance. For receptor binding glycoprotein](#)

Commented [BR551]: Any antibodies available? If not we can synthesize them from published co-crystals.

Commented [PD52]: Can someone answer Ralph's question please?

Commented [KJ053]: Make more specific about our plans to sequence NPC1 or Ephrin receptors, etc. Should we frame much of this as "add on projects" pending additional EIDRC-CC funding?

Commented [PD54]: Kevin/Alice – please edit this section to include relevance for filoviruses and henipaviruses as well (and other hosts)

sequence data from characterized viruses, we will apply codon usage analyses and codon adaptation indices, as used recently on Henipaviruses (132), to assess the relative contributions of natural selection and mutation pressure in shaping host adaptation and host range. We will rerun MCC analyses (Fig. 3) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (Fig. 4) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) or other virus families within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (96, 133).

**1.5.d. Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, and approximately 600 total CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (120, 133-135). For novel henipaviruses PMV, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize strains that are predicted to interact with ephrin-B2 and expression VWV proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models. We will assess ability to infect human cells using a continuous lung epithelial cell line, Calu3, that our group has previously used to generate data on NiV and HeV growth curves and a variety of host expression changes after infection (136). We will also use primary human airway cultures to assess human infection for Henipavirus-PMV and MERS- and SARS-related CoV (137) (138). There is some evidence for Nipah and Hendra virus replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (139, 140). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted Ebola infections (85-87).

**1.5.e. Animal models:** We will use transgenic mouse models and the UNC Collaborative Cross model to assess spillover potential of viruses. For work on CoVs, we will follow the protocols in the transgenic mouse model used by the Baric lab previously. Briefly, in the BSL3 lab, n=8 10- to 20-week old hACE2 or hDPP4 transgenic mice will be intranasally inoculated with  $5 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins or MERS-CoV and MERS-related CoV, respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV or MERS-CoV mAbs (141, 142) will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (119, 143). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and

Commented [KJO55]: I suggested we could get up to 600 CoV "strains" (all seqs, not just SARSr-CoVs) in section 1.4b, but we can reduce that.

evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (61, 119). For the Collaborative Cross model, we will....

Finally, for more detailed pathogenesis studies in the natural reservoir, we will use the bat models (natural and transgenic mouse model) at Duke-NUS. Both animal systems can be used to test susceptibility, pathogenesis and immune responses of any newly discovered viruses.

**1.6. Potential problems/alternative approaches:** Challenges with logistics or obtaining permission to for wildlife sampling in sites we select~~sample bats in sites or provinces we select~~. We have a >20-year track record of successful field work in Malaysia, ~~Thailand and and~~ >10 years in ~~Thailand~~Singapore, and have ~~worked with~~strong established partnerships with local wildlife authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based ~~on a range of PCR data and are fairly conservative in our approach~~on realistic detection rates from our extensive preliminary data, and are confident that we will detect and identify large numbers of potentially zoonotic pathogens, particularly for CoVs and PMVs. However, as a back-up, we already have identified dozens of novel viruses that are near neighbors to known high impact agents, and will continue characterizing these should discovery efforts yield few novel viruses~~We acknowledge that FV strain diversity may be harder to capture, given relatively low seroprevalence in bat populations – suggesting lower levels of viral circulations (40, 41). However, our team was the first and among the only groups to sequence FV RNA from Asian wildlife species(44, 45, 55), and we are confident that with our targeted sampling and testing strategy will identify additional strains of Ebola and related viruses.~~ The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (144), do not suggest a strong pattern of seasonality in CoV shedding, ~~although there are studies that suggest this~~and where seasonal patterns do occur, i.e. for in henipaviruses and filovirus (MARV?) shedding (REFS?)in Thailand (145) or can be predicted from wildlife serology data, we will be sure to. ~~Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province at different timepoints throughout the year to account for this.~~

**Aim 2: Test evidence of viral spillover in high-risk communities using novel serological assays.**

**Commented [PD56]:** Ralph – please insert a couple of sentences on how we'll use the cc mouse and what we'd expect

**Commented [PD57]:** Linfa/Danielle – could you put a couple of sentences in on what we might do with the models. Remember – this could be an additional short project from the EIDCC extra funding.

**Commented [KJ058]:** Emily and Noam reworking this section significantly, so not touching it much.

Country, site	Lead	# enrolled, focus	Findings
Peninsular Malaysia <a href="#">PREDICT</a>	Hughes	1,390 Orang Asli indigenous population, <a href="#">9813 samples for viral PCR/serol.</a>	<del>25+ novel</del> <u>Ongoing, 4 known</u> CoVs, 1 influenza, Nipah ab+ve, filovirus ab+ve

**Commented [T59]:** These serology findings were from UM OA samples not our OA samples. We have not started screening ours yet.

Malaysia Sabah	Kamruddin	1,283 serology	40% JE, 5% ZIKV ab+ve
Malaysia Sabah	William	10,800 zoonotic malaria	High burden of macaque-origin malaria
Malaysia Sabah	Hughes	150 bat cave workers	Ongoing
Malaysia Sarawak	Tan	500 Bidayuh and Iban people	8% PCR prevalence HPV in women
Malaysia PREDICT	Hughes	9,933 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Thailand	Wacharaplu-esadee	1,000 bat guano harvesters/villagers	Novel HKU1-CoV assoc. clinical findings
Thailand PREDICT	Wacharaplu-esadee	9,269 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Singapore	Wang	856, Melaka virus	7-11% ab+ve

**2.1 Rationale/Innovation:** Rapid response requires early detection. Thus, assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that interface frequently with wildlife that harbor high risk emerging viral strains. To enhance the low statistical probability of identifying these rare events, we will target rural human communities inhabiting regions of high wildlife biodiversity, that also engage in practices that increase the risk of

**Commented [T60]:** This is something we are proposing to do under this proposal not something we have started.

**Commented [KJO61]:** Check these numbers, don't think we have 9000 people sampled, if this represents individuals! Per below, we say we have 9000 specimens, not people, so need to adjust.

**Commented [KJO62]:** Emily: Will we be sampling participants more than once?

**Commented [PD63]:** I think that would be good, depending on the sample size

**Commented [KJO64]:** Need to decide if we do PCR on community samples, we can add in the questionnaire if you've been sick in the last 10 days and if so, then maybe test only this subset.

**Commented [PD65]:** Kevin's comment makes sense to me

**Commented [T66R65]:** Agree

**Commented [T67]:** 9813 samples from OA 120 samples from Syndromic Surveillance in Sabah

**Commented [KJO68]:** Don't match table numbers, need to change table header to # specimens, not # enrolled.

**Commented [T69]:** Community near one of our sites and we are not investigating just provided some informal advice on sampling, PPE etc

**Commented [T70]:** This needs to go under table – I can't fix formatting.

spillover (e.g. hunting and butchering wildlife). In Aim 2 we will build and expand on our preliminary biological sampling and enroll large cross-sectional samples in human populations with high behavioral risk of exposure to wildlife-origin viruses and that live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will initially identify 2 sites in each of Thailand, 3 in Peninsular Malaysia, 1 in Sarawak, and 1 in Sabah for repeated biological sampling. We will design and deploy behavioral risk factor questionnaires, and specific and sensitive serological assays to identify the baseline frequency, and causes of, spillover of known and related novel viral pathogens in these populations. In participants where symptoms are reported in the last 10 days, paired serum specimens (acute and 21 days after fever) will be collected to determine titer of positive antibody. Samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses PMV and filoviruses FV, and for isolation and biological characterization of potential pathogens, using the approach laid out in Aim 1.

**2.2 Preliminary data on high-zoonotic risk human community surveillance: 2.2.a Biological sample collection in SE Asia:** Our longterm collaboration in the region has included qualitative and quantitative survey data, and collecting large archives of banked human sera and other biological samples from high zoonotic-risk populations. For example, under the USAID-PREDICT project, EHA has collected 9,933-813 and 9,269 specimens in Malaysia and Thailand respectively from people living in zoonotic disease interfaces, all of which will be available for retrospective serological testing by EID-SEARCH. Our core group has collected and tested many thousand additional specimens from other important community cohorts (Table 2), and some of these will continue under EID-SEARCH (See section 2.4). Of particular interest is the access to indigenous communities in Peninsular Malaysia (Orang Asli) and Sarawak (Bidayuh, Iban people), and the bat guano harvesters in Thailand. These communities hunt, butcher and eat wildlife daily, and work in supremely high-risk zoonotic interfaces (e.g. bat caves). One of our indigenous community sites is experiencing an ongoing outbreak of unknown etiology that we are investigating currently (See section 3.2.a).

**Table 2:** Current or recent biological sample collection from healthy populations conducted by members of our consortium in EID-SEARCH hub countries

**2.2.b Human Contact Risk Factors:** EHA is the lead organization across all 27 USAID-PREDICT project countries for collecting data on, and analyzing the human aspects of, zoonotic spillover risk (146, 147). We conducted exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities, using these data to assess local social and cultural norms underlying wildlife contact (147). We then developed a risk factor survey to accompany human biological sampling to evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in 27 countries, and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal

swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). For example, survey and biological samples were collected from: 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, China; 1,400 participants from 4 sites in Malaysia; and 678 participants from 4 sites in Thailand. Samples were tested with novel serological assays and results analyzed against risk factors from survey data (12). In China, CoV-seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), that are male (6/9). Although these results are preliminary and don't provide detailed information on routes of exposure, they identify key subpopulations to target that would likely increase the opportunity for identifying evidence of spillover for other CoVs, paramyxoviruses-PMV and filovirusesFV. Data from PREDICT surveys will be used to help identify target populations in Aim 2, identify strategies to better target at-risk people, and conduct focused **human animal contact surveys and serosurveys to produce statistically significant findings for henipavirusesPMV, CoVs and filovirusesFV**. In Aim 2, we will use combined biological sampling and risk factor surveillance in targeted populations within the community to 1) identify risk factors correlated with seropositivity to henipavirusesPMV, filoviruses-FV and CoVs; 2) assess possible health effects of infection in people; and 3) where recent illness is reported, obtain clinical samples for PCR testing and potential viral isolation and characterization. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**Commented [T71]:** This includes 10 people from Syndromic surveillance in Sabah

1390 participants from 3 districts in Peninsular Malaysia – not yet serologically screened but will be this year.

**2.2.c. Risk factors for illness:** Our preliminary data from PREDICT in Thailand, Malaysia and China revealed that frequent contact with wild (e.g. bats, rodents, non-human primatesNHP) and domestic animals (e.g. poultry, swine) among local communities was associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms. In addition, people involved in crop production, hunting and butchering of wildlife reported statistically significantly higher SARI and ILI symptoms (Li *et al.*, in prep.). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with further refining serological tools, we will be able to identify the likely routes of exposure to known or novel coronavirusesCOV, henipavirusesPMV, and filovirusesFV in the study region, as well as build data on the illnesses they cause in people.

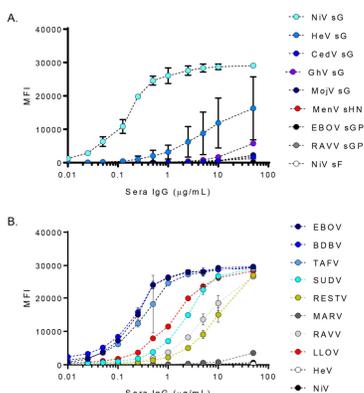

**Commented [KJ072]:** Peter, sent over LASSO figure for ILI from Thailand and Malaysia for you to consider.

**2.2.d. Serological platform for community surveillance:** One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. By contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes (148). However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. HenipavirusesPMV, filovirus-FV and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filovirusesFV / henipavirusesPMV=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (149)?, developing monoclonal antibodies (150, 151) and as subunit vaccines (152, 153), is presently developing a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipavirusesPMV, filovirusesFV and coronavirusesCoV. This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (149). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

**Commented [PD73]:** Chris/Eric Is this the right ref?

**Commented [KJ074]:** See my comment in Aim 1 that some of that serology platform stuff can be moved here.

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay. The known diversity of [henipaviruses-PMV](#) includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (**Fig. XXX**). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-related African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (76, 77). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus

henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (154-156). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity. The majority of ebolaviruses are endemic to Africa, however the discovery of Měnglà virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown pathogenicity and zoonotic potential exists. Our past work in collaboration with Duke-NUS demonstrated that three under-sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (41).

**Fig. XXX:** Validation of multiplex microsphere immunoassay

(MMIA) specificity and identification of immunologically cross-reactive viruses for Nipah (A) and Ebola (B).

**2.3 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (**Fig. XX**). In Aim 2 we will conduct community-based surveillance using a brief, focused questionnaire to identify the prevalence and frequency of risk-factors for viral spillover in tandem with collection of high quality biological samples to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the communities sampled in Aim 2. Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and PCR prevalence in symptomatic patients.

**2.4 Target population & sample sizes:** We will target populations in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, that are EID hotspots, and that are well-connected through regional travel and trade hubs to the global travel network (**Fig X**). We will target specific communities based on our analysis of previously-collected PREDICT behavioral questionnaire data, to assess key at-risk populations and occupations with high exposure to wildlife, as well as using other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will identify populations at two sites in each of the following regions, building on our preliminary data (**Table 2**): *Thailand (Co-I Wacharapluesadee)*: We will continue surveillance in bat guano harvesters and their villages in Ratchaburi province where we have identified MERS-related CoV in bat guano and rectal swabs (48, 157) and serological evidence of  $\alpha$ -CoVs, HKU1-CoV in people (Wacharapluesadee in prep.). Our second site will be in Chonburi province where we have found Nipah virus (99% identity of whole genome sequence to NiV from a Bangladesh patient) in flying foxes but no outbreaks have yet been reported ([REFThai MOPH, unpublished](#)), and have found several novel paramyxoviruses and CoVs have been found in bat feces roosting there ((158, 159) Wacharapluesadee in prep.).

**Commented [PD75]:** Hongying -Need a new figure that lays out the community/clinical approach – small one with pretty images.

**Commented [PD76]:** Supaporn/Kevin/ -Need sample sizes for both populations and power calculations for serology for a typical virus from one of the three families we're targeting

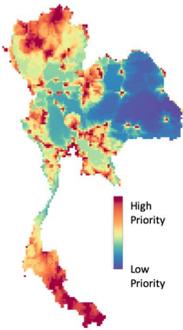

**Commented [KJ077R76]:** I pasted in info from Supaporn below.

**Commented [PD78]:** Supaporn – please insert a reference into this comment box

**Commented [KJ079]:** Added in a couple more of her refs.

Sample size: Serological exposure likely low due to low risk of onward transmission. High risk occupational groups vs. community sample at each site. Need to stratify sampling in villages based on

Thailand: 100 subjects of healthy high-risk community from 2 study sites (Chonburi and Ratchaburi) will be enrolled on Year 2 and tested for antibody, and specimen from ill subject will be collected and test by PCR and serology assays. Specimens from same subject will be collected on Y3 and Y4 for serology re-testing.

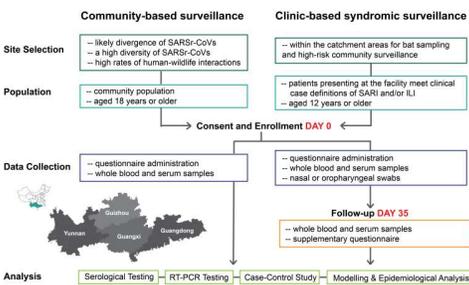

**Fig. X:** Geographic analysis to target high-risk sites for human zoonotic disease surveillance in Thailand. Our spatial analysis from Aim 1 will be extended to optimize sites for human community surveillance in Thailand and Malaysia by ranking areas with high numbers of expected viruses in wildlife, greater spillover probability based on EID risk factors, and higher levels of connectivity (measured by road density data) that may facilitate person-person spread.

**Peninsular Malaysia (Co-I Hughes, CM Ltd.):** We will expand our sampling of the Orang Asli indigenous communities to include additional communities in the 3 Districts we have already sampled, and additional Districts in the States of Kelantan Perak, Pahang, and KelantanKedah. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled. Human samples will include serum, whole blood, throat swabs, and nasal swabs, urine, and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and extracted at PERHILITAN's NWFL and tested at NPHL. Participants who hunt, butcher or consume

wildlife, or who rear animals will be considered suitable for enrolment. Participants will complete a consent form and questionnaire in addition to having samples collected. During these community trips the field team will conduct community meetings to help inform the Orang Asli about the public health risk of zoonoses. **Sarawak (Co-I Tan, Faculty of Medicine and Health Sciences UNIMAS):** We will expand our sampling of the Bidayuh and Iban indigenous people to include the Dayak and Orang Ulu ("people of the interior") -because this group has a more intimate connection to remote wildlife-rich areas than the other two, albeit all are hunters. Human sampling will be led by UniMAS in collaboration with CM Ltd / EHA. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled, following the same protocols as for Peninsular Malaysia. **Sabah:** We will conduct sampling at the Madai bat and bird cave that has 200 permanent residents who harvest bird's nests for soup, and >1,000 during the harvesting season and at Gomantong cave – one of the largest bat and cave swiftlet nesting sites in the world. Protocols follow those for Peninsular Malaysia. **Singapore:** Active human surveillance will be not be conducted in Singapore, but archived human specimens e.g. from our Melaka virus serosurvey (4), will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

**Sample sizes:** From our previous work we anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so that they make up ≥30% of the sampled population in each community. We will stratify sampling to ensure appropriate representation of sex, demographic, and socio-economic factors at each community site. Estimating 5% overall seroprevalence in these high-exposure populations, these sample sizes are sufficient to estimate effect sizes of risk factors of 2X or greater with 80% power. For community-based surveillance, we will enroll xxxx individuals per

**Commented [S80]:** I think the animal and human specimen collection should be in a same format for Thailand and Malaysia.

**Commented [PD81]:** Need this figure for Singapore, Pen. Malaysia, Sarawak, Sabah as well – all together is best

**Commented [KJO82R81]:** Sam is going to send a combined figure tomorrow AM.

**Commented [T83]:** We don't think we will be able to collect urine or fecal samples from OA communities. Might be possible in Sarawak we have no idea about Madai.

county/province, pooled across two sites for each, allowing us to make county/province-level comparisons of differing effects.

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**2.5 Data & sample collection:** Following enrollment of eligible participants and completion of the consent procedure, biological specimens (up to 32ml of blood (on average we collect 15ml separated into 1ml of whole blood and 3-5ml of serum, 2 throat swabs and 2 nasal swabs)(one in VTM and one in Trizol)) 5ml will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 2.5ml whole blood; two 500 µL serum samples) will be collected and a questionnaire will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent considerations for participants enrolled from clinical settings we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

#### **2.6: Laboratory analysis: 2.6.a Serological testing:**

In a previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity detected (12). **This suggests that if we can expand our serology tests to cover other bat CoVs, and that doing so may identify many more seropositive individuals.** We will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 bat SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the α-CoVs SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (12), and HKU10 is known to jump from one host bat species to another (160) so is likely to have infected people more widely. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV, at a phylogenetic distance where therapeutic or vaccine efficacy may falter. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or S1 (n-terminal domain); 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (13). Additionally, in Thailand, as an initial project on our EIDRC, we will develop serology assays to the novel CoVs found in bats at the bat guano site using LIPS assays and viral genomic data, and will screen archived specimens from 230 participants (2 years' collection in 2017-2018, a subset of the subjects have been sampled at multiple timepoints to allow us to assess seroconversion).

**2.6.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b.4.c for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E, NiV, HeV, Ebola (WHO PCR protocol) based on the symptom as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

**Commented [PD84]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipas, filoviruses and CoVs.

**Commented [T85]:** Malaysia protocol – I suggest we don't change so easy to amend ethical approval

**Commented [PD86]:** Emily/Hongying Please check

**Commented [PD87]:** Chris, Eric, Linfa, Dani etc. please draft some language here...

**Commented [PD88]:** HELP – please add text for Henipavirus, filoviruses

**Commented [MOU89]:** Supaporn: These should be depending on the viruses found in wildlife animal from the studied countries.

**2.6.c Biological characterization of viruses identified:** Novel viruses identified in humans will be recovered by cultivation or from full length genome sequences using reverse genetic approaches. Viruses will be characterized for growth in primary human cell lines and in mouse models, including the Collaborative Cross Mice or humanized mice expressing human receptors from related strains. The approaches are discussed in more detail under Aim 1.

**2.7 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for [HenipavirusPMV](#), [FilovirusesFV](#), and CoVs spillover. “Cases” are defined as participants whose samples tested positive for [HenipavirusPMV](#), [FilovirusesFV](#), or CoVs by serological tests. “Controls” will be selected from the pool of participants admitted to the studies and whose samples tested negative for [HenipavirusPMV](#), [FilovirusesFV](#), or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between [HenipavirusPMV](#), [FilovirusesFV](#), or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, [paramyxovirusesPMV](#), and influenza viruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may not match known viruses due to recombination events, particularly for CoVs.** We will use the three-tiered serological testing system outline in **2.6.a** to try to identify these ‘novel’ viruses, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

### **Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research (**Table 1**) and other data suggests that there are substantial numbers of outbreaks or clinical cases for which the etiologic agent is not diagnosed, e.g. (161, 162). To investigate this in SE. Asia, we will work directly with clinics and outbreak control organizations to identify the causes of some ‘cryptic’ outbreaks or cases in the region. Specifically, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and who present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We conduct novel viral discovery assays on patients who present with symptoms indicative of a high-risk zoonotic virus. If novel pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the pathogen, using the *in vitro* and *in vivo* strategy laid out in Aim 1.

**3.2 Preliminary data clinical surveillance: 3.2.a. Clinical surveys and outbreak investigations:** Our [longterm/long-term](#) collaboration in the region has included the following activities investigating clinical syndromes: *Peninsular Malaysia: At the time of writing, there is an outbreak of a suspected undiagnosed*

**Commented [KJO90]:** Make this more general. There’s a greater challenge of interpretation of serological data, esp. if we’re using many platforms (each will have its own problems that our lab colleagues are probably more familiar with). Noam may be able to generally comment on a solution here from a statistical perspective.

**Commented [PD91]:** Kevin – please modify according to your comment

**Commented [KJO92R91]:** Noam is working on this section, so can review after/tomorrow.

viral undiagnosed illness in the indigenous Batek people, one of Malaysia's Orang Asli (indigenous) ("people of the forest") communities living at in the Gua Musang ("civet-cat-cave") district, in Kelantan, Malaysia, close to Taman Negara – a National Park containing the oldest known rainforest. This Orang Asli community is- neighbors one where we have conducted prior routine surveillance and biological sampling, demonstrating proof-of-concept that our two-pronged high-risk community/clinic approach will work. Dozens of people are affected and the outbreak is currently being investigated by our collaborators at the Malaysian NPHL. The Orang Asli- continue to practice traditional and in many cases subsistence hunting of wild animals – including bats, rodents, nonhuman primates, and raise domestic animals such as chickens and hunting dogs around their villages. These communities are remotely located, in heavily forested areas, with limited access to medical services, live in remote villages in the rainforest of Malaysia, with limited access to modern health care and extensive contact hunting, butchering, and eating wildlife as their primary source of protein. This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC - to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia. ~~Investigating this outbreak be a key priority if EID SEARCH is funded.~~ Sabah: Co-I Kamruddin (BMHRC) is leading an asymptomatic leptospirosis study on sanitation workers, an ILI study in a Kota Kinabalu clinic and diarrheal study in children under 5 yrs. Co-Is William, ~~Tan Rajahram~~ and ~~others Yeo~~ have conducted clinical observational studies to determine the etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah. Co-Is ~~Tan Yeo~~, William have collaborated with Co-I Wang to enroll 90 adult and over 100 pediatric participants with central nervous system infections, negative tests for malaria and dengue from 3 district hospitals in Sabah to determine the various etiologies. While a ~~high~~ proportion tested positive for rickettsial agents, the majority had no clear diagnosis. Sarawak: Dr Tan (UNIMAS) is conducting a survey of high-risk female Kelabit indigenous people and has found 8% with HPV52 as the dominant strain. He is working on clinical cohorts of hand, foot and mouth disease and will recruit patients from that study in the current proposed work. Finally, he is conducting a long-term study of rotavirus and other viral etiologies of acute gastroenteritis in Kuching, Sarawak in collaboration with Co-Is Kamruddin that will include ~~swine herders and pig~~ farmers. These are an important group in Malaysia because pig farmers are ~~shunned by wary of~~ the government and ~~local villagers to they~~ are placed far away from town centers, ~~deep in on the edge of~~ the forest, and it is this scenario that led to the emergence of Nipah virus in 1998-9 (18, 163). Thailand: The Chulalongkorn Univ. TRC-EID laboratory works in coordination with the Thailand Ministry of Health to investigate outbreak etiology, including the first case of imported MERS-CoV in Thailand, **for which we produced sequence confirmation within 24 hours from acquiring the specimen (Fig. X)**. Three imported MERS cases have been detected in Thailand since 2015, and all cases were confirmed at the TRC-EID. We worked during the Zika outbreak to identify > 500 PCR-positive Zika patients with sequence confirmation. We have also worked on returning and suspected Ebola travelers, syndromic surveillance for SARI, Encephalitis, Hand Foot and Mouth disease in children and Viral diarrhea. Working with the US CDC (Thailand), between 1998 and 2002 we enrolled a large cohort of children from Kamphaeng Phet Province to examine Dengue virus and JE epidemiology (164, 165). Among the 784/2,574 convalescent sera Henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence), suggesting prior exposure to endemic henipaviruses or a related paramyxovirus in rural Thailand. Singapore: Duke-NUS has worked with the Ministry of Health to investigate Zika cases (166), and with EcoHealth and others, Duke-NUS has developed novel CoV assays for clinical surveillance, and for expedited analysis during outbreaks. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing is as rapid as several months, with the development of novel serological assays from sequence data in 7 days (13). **For example, with the discovery of SADS-CoV, we identified and fully sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (Rhinolophus spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (13).**

Commented [T93]: I would not include these

Commented [T94]: If we want to be accurate

Formatted: Underline

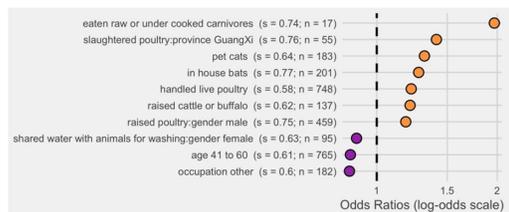

Commented [KJO95]: Deleted sentence below, because reality is, not likely an issue in ~4-6 months when we get funded and seems to be measles. Should play up as an example, but not an actual item for follow up..

**3.2.b Analysis of self-reported illness:** In addition to biological outcomes we have developed a standardized approach in PREDICT for analyzing data on self-reported symptoms related to targeted illnesses; of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), fever with muscle aches (fevers of unknown origin (FUO) and, cough or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI and/or SARI symptoms and demographics, occupation,

and contact with animals in the last year. Results have clear biological relevance. In Yunnan, China, salient associated variables or combination of variables were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (Fig. 11). We will expand this approach for all syndromes in Aim 3, and use more granular targeted questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country.

Commented [MOU96]: Replace w Malaysia or Thailand LASSO

**Fig. 11:** Associated variables of self-reported ILI and/or SARI in prior 12 months (s = bootstrap support; n = number +ve out of 1,585 respondents). **Orange circles** = odds ratios > 1 (positively associated with the outcome); **purple** = odds ratios <1 (negatively associated with the outcome).

**3.3 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms

typical of high-impact emerging viruses. We will collect survey data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.4 Clinical cohorts. 3.4.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at 2 town-level level clinics and 2 provincial-level hospitals in Thailand, Peninsular Malaysia, and two hospitals in Sabah and Sarawak. These all serve as the catchment healthcare facility for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients ≥ 12 years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, fevers of unknown origin, or hemorrhagic fever will be recruited into the study. We will enroll a total of xxxx individuals for clinical syndromic surveillance, which accounts for up to 40% loss from follow-up. Study data will be pooled across country sites, as clinical patients are limited by the number of individuals presenting at hospitals. Sites: Thailand: Two new district hospitals at the same site of high-risk community will be included to the study to collect specimens (PREDICT sample protocol) from patients with respiratory and/or encephalitis symptom during 3 years of the study (Year 2 to Year 4), at least 100 patients from each hospital will be enrolled and laboratory tested by PCR and serology assays. The second blood after 21 days of fever will be collected for serology testing. ~~XXXXX~~ Peninsular Malaysia: Focusing immediately on the current outbreak in Orang Asli, we will work closely with the Malaysian Ministry of Health to support their investigation. We will also work with 6 Orang Asli clinics which focus solely on this indigenous community. No clinical study. Sarawak: No clinical study. ~~XXXXXX~~ Sabah: Clinical study at QEH and HUMS: Patients will be identified in the intake area, the emergency room, in the ward, or in the intensive care unit of each participating hospital by clinic staff according to standard operating procedures at Queen Elizabeth Hospital and Hospital UMS. Staff will identify potential participants that fit undiagnosed syndromes in patients. Patients will be screened for eligibility according to the inclusion / exclusion criteria based on available clinical information, and the research study will be explained to participants by trained staff. Biological samples will be collected from the patients, and the patients or his/her designate will complete a short questionnaire. Over two years this study aims to enroll 200 patients at QEH and 100 at HUMS. Collection of patient's specimens must take place whilst the patient is still in the viraemic / febrile phase of the disease. Therefore, this study is relying on the clinical judgement of the treating clinicians to make the decision whether to include the patients into the study at the earliest point possible so that sampling process can take place during the targeted viraemic / febrile phase while not interrupting the treatment of the patients. Patients will complete consent form and answer a short questionnaire. Human

Commented [T97]: I would make this over 18 for Malaysia it is what we have approval for and dealing with minors is a huge complication – we need to keep this study as simple as possible for hospital staff or they won't recruit people if it is too complicated and time consuming.

Commented [KJO98]: Pasted in from Supaporn.

Commented [KJO99]: Make sure this matches our timeline and target numbers. Noam to calculate minimum samples size for detection assuming 1-3% ?? viral prev. Need some refs or data on detection rate for "novel" etiological agents.

Commented [T100]: Need to make this very short – general consensus is PREDICT syndromic study failed as questionnaire was too labor intensive for staff and patients.

samples will include serum, whole blood, throat swabs, nasal swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored at QEH until there is a sufficient number to move to BMHRC for screening.

~~XXXXXXXXXX~~ Singapore: ~~XXXXX~~ Given budget constraints we will not do clinical cohorts, however in the event of a suspected outbreak we have close relationships with xxxxx xxxxx hospitals and central reference lab.

**3.4.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever of unknown etiology; or 6) severe diarrhea. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance of PCR detection of viruses (167). Where possible we will follow up 35 days after enrollment to collect an additional two 500 µL serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs <28 days after onset of symptoms for SARS patients (168). These samples may prove valuable to collaborators in that the PBMC could be used in production of therapeutic antibodies.

#### 3.4.c Sampling:

Following enrollment with signed consent form, biological specimens ((up to 23ml of blood (on average we collect 15ml separated into 1ml of whole blood and 3-5ml of serum, 2 x Oropharyngeal swab or throat swab, 2 x Nasopharyngeal swab or nasal swab, urine sample or two urogenital swabs 2 x Rectal swab or Fecal sample (for all swabs one in VTM and one in Trizol) 5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples) including two nasal or oropharyngeal swabs will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

#### 3.5 Sample testing: PCR, Serology to link symptoms to etiologic agents

The objective is to detect novel CoV, PMV and FV viruses that are causing diseases in patients without known aetiology. Therefore, the tests carried out for this project cannot be relied on as a diagnostic tool, nor should it overlap or duplicate any of the routine diagnostic testing carried at the hospitals or clinics. Since the usually-suspected diseases such as dengue, leptospirosis and malaria will be diagnosed within 6 hours, recruitment of patients will happen only after these diseases have been ruled out by the routine rapid diagnosis. If a patient is not diagnosed through rapid diagnostics and is enrolled in the study but is later diagnosed through routine diagnostics the participant will remain in the study and will have their samples tested regardless of any normative diagnosis result, as we know that coinfection is possible and could be scientifically interesting.

Collection of patient's specimens must take place whilst the patient is still in the viraemic / febrile phase of the disease. Therefore, this study is relying on the clinical judgement of the treating clinicians to make the decision whether to include the patients into the study at the earliest point possible so that sampling process can take place during the targeted viraemic / febrile phase while not interrupting the treatment of the patients. PCR and serology results will often not be available for months after patient is admitted. The results will help us to detect and prevent potential epidemics involving emerging zoonotic agents, as well as to eventually counsel communities on practices that could reduce exposure and related health risks. These sentinel populations will be very important in providing cost-effective and timely information on disease emergence. The study will also

Commented [PD101]: Tom, Kevin – we need information.

Commented [T102R101]: We do not have budget to do clinical study in PM or Sarawak.

Commented [KJO103]: Linfa/Dani?

Commented [PD104]: Hongying Emily

Commented [PD105]: Need data for Nipah and filovirus patients

Commented [PD106]: Ralph: PBMC could be valuable for making therapeutic antibodies through collaborations?

Commented [T107]: Malaysia protocol suggest we stick to this for Malaysia as we have approval for this.

Commented [KJO108]: Blood just during 35 day follow up, or both? I guess both ideally, but weigh against IRB.

increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control worldwide.

The standard syndromic diagnostic PCR assay for the common pathogens will be conducted and the results will be shared to the hospital with 48 hours. Specimens will be further tested for 3 viral families; CoV, PmV and filovirus by consensus PCR. Appropriate specimen from dead case will be further conducted by NGS if the previous PCR tests are negative to identified cause of infection. The serology panel assay will be conducted from paired serum.

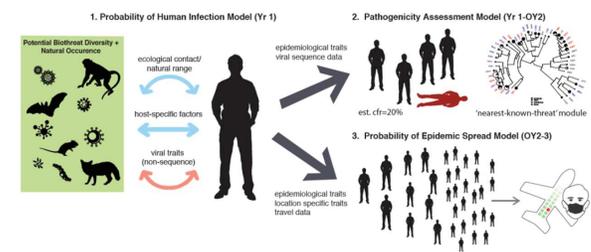

**Serology:** Panel serology assay will be performed from paired serum to determine the four fold raising antibody. The specific primer PCR of the virus antibody positive case will be further tested from acute specimens to confirm for infection.

Commented [PD109]: This is v. weak – can someone strengthen it please!

Commented [KJO110]: Text from Supaporn

Commented [PD111]: This is v. weak – can someone strengthen it please!

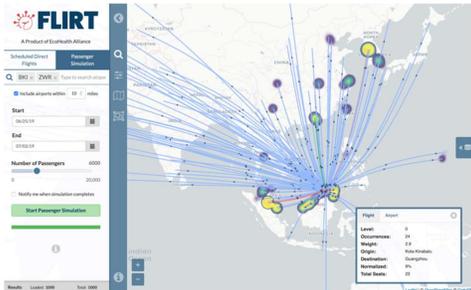

**3.5 Assessing potential for pandemic spread:** Building off our spillover risk characterization in Aim 1, we will use statistical models built from collated biological, ecological, and genetic data to predict further assess the likelihood of human infection (or spillover) and also pathogenicity for a the range of diverse viruses we will characterize. The aim is to quickly identify and assess which viruses pose the most significant risk to human health and thus prioritize additional resources to more fully characterize, better understand pathogenicity, and invest in therapeutic development for those pathogens. We will combine two independent but related statistical models to predict pathogen spillover risk and pathogenicity. First, we will expand a simple generalized additive modeling approach (90) to assess spillover risk probability to a new virus that is currently not known to infect people, when we have only limited genetic data from initial PCR screening and sequencing. Additional data from receptor binding protein homology and cell line infection experiments can will be incorporated into the model framework as available. Second, given high likelihood to spillover and infect humans, or direct evidence of human infection from our clinical surveillance, we will then predict pathogenicity using nearest neighbor phylogenetic analyses as a first approximation and by incorporating more detailed data from genomic characterization and animal model experiments (Aim 1). For the pathogenicity model, human epidemiological trait data for ~300 viral species known to infect people (e.g. case fatality rate, global estimates of number of human cases per year or decade,  $R_0$ , infectious period, and primary symptoms) will be aggregated including from have been collated by recent studies previous and will be used as reviews [Woolhouse ref] to use as predictor variables. Thirdly, we will build off apply tools already developed, and being refined by EHA under's previous DTRA and DHS supported research, to predict pandemic spread for viruses we identify by integrating surveillance site data, using global flight models (169), as well as additional datasets (road networks, shipping routes, cell phone data) to measure on human movement and connectivity across Southeast Asia.

**Fig. XXXXX:** Conceptual framework highlighting 3 underlying models to estimate: 1) probability of human infection, or spillover, the first necessary step to understand pathogenicity when status of human infection is unknown; 2) pathogenicity, i.e. probability of causing clinical signs, case fatality rate estimates, and other metrics relevant to humans; and 3) probability of pathogen spread based on ecological, epidemiological, and airline connectivity and human migration data.

Commented [PD112]: Hongying – please work with Kevin to come up with something of relevance here. Also, make the text brief, bold and large so it's readable

Commented [KJO113]: See also FLIRT flight simulator figure below. Peter, let's decide if I should rework this figure to combine both, or how to proceed with this section.

**3.7 Potential problems/alternative approaches:** Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases. Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (167). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the

Commented [PD114]: Add data for Nipah and filio infections

potential public health importance of discovering active spillover of a new henipavirus, filiovirus or CoV infection.

**Additional Instructions – Specific to the EIDRC FOA:**

**4. Administrative Plan**

In a clearly labeled section entitled “Administrative Plan”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.

Commented [PD115]: All – I’ve started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

Chula TRC-EID is National reference laboratory for diagnostic and confirmation of EIDs pathogen along with the National public health laboratory at the Department of Medical Science and the WHO Collaborating Centre for Research and Training on Viral Zoonoses. We have built a EID laboratory network in-country among three Ministry including Ministry of Public Health (Department of Medical Science and Department of Disease Control), Department of Livestock and Development, and Department of National Parks, Wildlife and Plant Conservation and Universities and among SEARO countries. Our clinicians provide case consultation for Thailand and SEARO countries. The laboratory and clinic training are regularly conducted.

Commented [PD116]: From Supaporn

For Peninsular Malaysia this project will be administered through the Zoonosis Technical Working Committee established under the PREDICT project – a working technical committee comprising appointed and authorized officers from MOH, DVS, PERHILITAN, EHA who will work together in coordinating and monitoring the implementation of the Study as well as to prepare a report on the progress of the Study pursuant to the existing MOA. **NPHL – is National reference laboratory for diagnostic and confirmation of EIDs pathogen.** Molecular and serological screening (BioPlex) of PM Orang Asli samples, serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval). **PERHILITAN molecular zoonosis laboratory, at the National Wildlife Forensic Laboratory – Storage ad extraction of all PM samples.** Molecular and serological screening (BioPlex) of PM wildlife samples. **UPM Faculty of Veterinary Medicine -** Molecular and serological screening (BioPlex) of PM livestock samples

For Sabah this project will be administered through the Sabah Zoonotic Diseases Committee. A working

technical committee comprising appointed and authorized officers from SSHD, DVS, SWD, UMS and EHA who will work together in coordinating and monitoring the implementation of the Study as well as to prepare a report on the progress of the Study pursuant to the existing agreement. **KKPHL** - Molecular screening of syndromic samples from Sabah (already done) and Sarawak (would need approval), **SWD WHGFL** - Molecular screening of Sabah wildlife samples, **BMHRC** — Once the lab is renovated the BMHRC will be used for the mMolecular and serological screening (BioPlex) of Sabah livestock samples, serological screening (BioPlex) of Sabah wildlife samples, Molecular and serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval). BMHRC will need renovations and BioPlex to do this work – Menzies team might have funds for BioPlex that they would base here as part of DTRA project.

Coordination between PM, Sabah and Sarawak will follow the model used for PREDICT. For PM the relevant authority approves the results for release for example for Livestock samples this is DVS, these results will then be shared with the Ministry of Health and PERHILITAN under the terms of our agreement. After Ministry of Health and PERHILITAN approves the release, these results will be shared with Sabah and Sarawak partners and more widely through the EIDRC network. For Sabah once wildlife results are approved for release by SWD they will be shared with all partners and once human results are approved for release by Sabah State Health Department they will be shared with all partners. It is assumed that a similar arrangement will be made in Sarawak.

Results from human screening will be shared with participants when they become available. Only country coordinator will know which participant number links to which name and the results. A doctor from each District for community surveillance and from QEH and HUMS will be provided with patient name, project ID number or IC number of positive participants so they can look up these individual results in the t report and share results with patient and update their record.

- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

**List out all of our involvement with outbreak investigations, ministries of health surveillance etc.**

If possible the clean or summarized answers from the questionnaire should be shared to the hospital Infectious Control team and Bureau of Epidemiology for their information for controlling the outbreak.

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

CM/EHA helped establish and manages with SWD the Wildlife Health, Genetic and Forensic Laboratory (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications) that has all the equipment necessary to store samples, run extractions, PCR and analysis on biological samples for wildlife disease surveillance. The lab is used to conduct health checks on rescued and relocated wildlife before being released into new areas or sanctuaries, to screen samples for the PREDICT and Deep Forest Project and for genetic research and forensic investigations. CM/EHA also helped establish the new molecular zoonosis laboratories (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications), at DWNP's National Wildlife Forensic Laboratory. The lab is used to screen samples for the PREDICT & DTRA

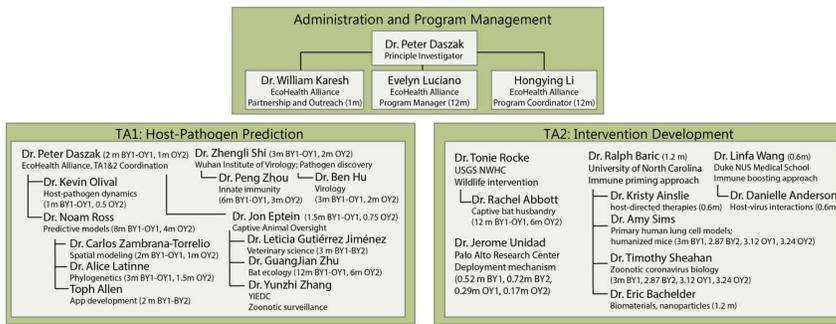

Commented [PD117]: From Supaporn – do same for all countries

projects. In addition CM/EHA also has access to NPHL and KKP HL for screening human samples and the Virology lab at FVMUPM for screening Livestock samples.

The Borneo Medical and Health Research Centre (BMHRC) is a centre of excellence that conducts teaching and scientific researches on communicable diseases, outbreak investigations, and ethnomedicine. BMHRC has offices space including a meeting room and seven laboratories which including preparation lab, parasitology lab, cell culture lab, bacteriology lab, natural product lab, virology lab, and molecular biology lab. BMHRC is supported by an administration staff, medical lab technologist, and research assistants who are available to work on projects. Through this project we will help to establish a certified BSL-2 lab at the BMHRC. This lab can then be used for human testing to elevate pressure at KKP HL and QEHL labs. It would also be an ideal location for a Luminex platform as human, wildlife and livestock samples could all be screened here. Co-Is Hughes and Kamruddin will be starting outbreak response training in August 2019 with a team from Sabah CDC, KKP HL and BMHRC. (Dr. Maria Suleiman now in PM But still collaborating with us, Dr. Muhammad Jikal current Director CDC working with us and Dato' Dr Cristina Rundi Director Sabah state health Dept is supportive) this collaborative group is working to develop a Sabah outbreak response team that will help support SSHD/ CDC outbreak team and also conduct sampling for disease surveillance to be based at BMHRC and we will develop this as part of this proposal. In addition the UMS hospital will come in line in 2021 providing additional opportunities for cohort studies and capacity building.

FROM DARPA grant:

**Section 1.03 MANAGEMENT PLAN**

Project DEFUSE lead institution is EcoHealth Alliance, New York, an international research organization focused on emerging zoonotic diseases. The PI, Dr. Daszak, has 25+ years' experience

Commented [KJO118]: Figure like this would be good, but instead of breaking down by TA, maybe by country or Specific Aim. Per FOA, Need to also show how we'll link in with the Coordinating Center and other EIDRCs.

managing lab, field and modeling research projects on emerging zoonoses. Dr. Daszak will commit 2 months annually (one funded by DEFUSE, one funded by core EHA funds) to oversee and coordinate all project activities, with emphasis on modeling and fieldwork in TA1. Dr. Karesh has 40+ years' experience leading zoonotic and wildlife disease projects, and will commit 1 month annually to manage partnership activities and outreach. Dr. Epstein, with 20 years' experience working emerging bat zoonoses will coordinate animal trials across partners. Drs. Olival and Ross will manage modeling approaches for this project. Support staff includes a field surveillance team, modeling analysts, developers, data managers, and field consultants in Yunnan Province, China. The EHA team has worked extensively with other collaborators: Prof. Wang (15+ yrs); Dr. Shi (15+ yrs); Prof. Baric (5+ yrs) and Dr. Roche (15+ yrs).

**Subcontracts: #1** to Prof. Baric, UNC, to oversee reverse engineering of SARSr-CoVs, BSL-3 humanized mouse experimental infections, design and testing of targeted immune boosting treatments; **#2** to Prof. Wang, Duke-NUS, to oversee broadscale immune boosting, captive bat experiments, and analyze immunological and virological responses to immune modulators; **#3** to Dr. Shi, Wuhan Inst. Virol., to conduct PCR testing, viral discovery and isolation from bat samples collected in China, spike protein binding assays, humanized mouse work, and experimental trials on *Rhinolophus* bats; **#4** to Dr. Roche, USGS NWHC, to refine delivery mechanisms for immune boosting treatments. Dr. Roche will use a captive colony of bats at NWHC for initial

trials, and oversee cave experiments in the US and China. #5 to Dr. Unidad, PARC, to develop innovative aerosol platform into a field-deployable device for large-scale inoculation of the bats. Dr. Unidad will collaborate closely with Dr. Roche in developing a field deployable prototype for both initial trials and cave experiments in China.

**Collaborator Coordination:** All key personnel will join regularly-scheduled web conferencing and conference calls in addition to frequent ad hoc email and telephone interactions between individuals and groups of investigators. Regular calls will include:

- Weekly meetings between the PI and Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.
- Monthly web conferences between key personnel (research presentations/coordination)
- Four in-person partner meetings annually with key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

Evaluation metrics will include the generation of high-quality data, successful achievement of milestones and timelines, scientific interaction and collaboration, the generation of high quality publications, and effective budget management. The PI and subawardee PIs will attend a kickoff meeting and the PI will meet regularly with DAPRA at headquarters and at site visits.

**Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by Dr. Daszak and the Project Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation. Should a resolution not be forthcoming, consultation with our technical advisors and DARPA Program staff may be warranted.

**Risk management:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. A project of this nature requires a different mindset from that typically associated with basic research activities that move at an incremental pace with investigators gradually optimizing experimental systems, refining data, or waiting for additional data before moving ahead with an analysis approach. To maintain our timeline, we will continually evaluate these trade-offs to make decisions about when iteration is appropriate and when necessary to move forward with current information.

#### **Biographies:**

**Dr. Peter Daszak** is President and Chief Scientist of EcoHealth Alliance, Chair of the NASEM Forum on Microbial Threats, member of the Executive Committee and the EHA institutional lead for the \$130 million USAID-EPT-PREDICT. His >300 scientific papers include the first global map of EID hotspots, estimates of unknown viral diversity, predictive models of virus-host relationships, and evidence of the bat origin of SARS-CoV and other emerging viruses.

**Prof. Ralph Baric** is a Professor in the UNC-Chapel Hill Dept. of Epidemiology and Dept. of Microbiology & Immunology. His work focuses on coronaviruses as models to study RNA virus transcription, replication, persistence, cross species transmission and pathogenesis. His group has developed a platform strategy to assess and evaluate countermeasures of the potential “pre-epidemic” risk associated with zoonotic virus cross species transmission.

**Prof. Linfa Wang** is the Emerging Infectious Diseases Programme Director at Duke-NUS Medical School. His research focuses on emerging bat viruses, including SARS-CoV, SADS-CoV, henipaviruses, and others and genetic work linking bat immunology, flight, and viral tolerance. A 2014 recipient of the Eureka Prize for Research in Infectious Diseases, he currently heads a Singapore National Research Foundation grant “Learning from bats” (\$9.7M SGD).

**Tom Hughes** is trained in ecology, international development and public health. For the past 10 years he has acted as the Malaysian Project Coordinator for EcoHealth Alliance. He has designed, initiated and managed

**Commented [PD119]:** Some of references in this section are duplicates

**Formatted: Font: Bold**

collaborative projects on surveillance, viral discovery and ecology of wildlife reservoirs of zoonoses. He has worked closely with partners from the Ministry of Health, the Department of Wildlife and National Parks, and the Department of Veterinary Services, over the last 14 years and with Sabah Wildlife Department, Sabah State Health Department and UMS over the last 8 years to develop personnel and laboratory capacity and establish sustainable disease surveillance systems for wildlife and people with high exposure to wildlife.

**Current list of contacts at key human (especially) and wildlife orgs in every SE Asian country from map above – please add to this if we've missed any**

Indonesia – EHA: Eijkman (Dodi Safari), IPB (Imung Joko Pamungkas); **CM Ltd:** IPB (Imung Joko Pamungkas), Bogor Agricultural University (Diah Iskandriati)

SE China – EHA: Yunnan CDC (XX), Wuhan Inst. Virol. (Zhengli Shi);

Myanmar – Chulalongkorn (Thiravat and Supaporn) have collaborated extensively with Win Min Thit, MD (Yangon General Hospital, Myanmar); Khin Yi Oo (National Health Laboratory, Myanmar) and also in training PREDICT Myanmar veterinarians in bat sampling under PREDICT.

Japan – **BMHRC:** Oita University (Hidekatsu Iha, Kiyoshi Aoyagi), Nagasaki University (Koichi Morita, Kazuhiko Moji)

Cambodia -

Laos - **CM Ltd:** Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (Matthew Robinson)

Bangladesh – EHA: IEDCR (Meerjady Sabrina Flora, Ariful Islam), icddr,b (Mohammed Ziaur)

India – EHA: Jon's collaborators;

Vietnam – Wellcome CRU ? Liaison with Zhengli Shi for Serol assays etc.?

Philippines – EHA, **CM Ltd:** Biodiversity Management Bureau, Department of Environment and Natural Resources (Anson Tagtag), Bureau of Animal Industry (Davinio Catbagan), Research Institute of Tropical Medicine (Catalino Demetria).

Malaysia – **CM Ltd:** Borneo Medical and Health Research Center (Ahmed Kamruddin), Department of Wildlife and National Parks Peninsular Malaysia (Frankie Sitam, Jeffrine Japning, Rahmat Topani, Kadir Hashim, Hatta Musa), Hospital Universiti Malaysia Sabah (Helen Lasimbang), Faculty of Medicine, Universiti of Malaya (Sazaly Abu Bakar), Kota Kinabalu Public Health Laboratory (Jiloris Dony, Joel Jaimin), Ministry of Health (Chong Chee Kheong, Khebir Verasahib, Maria Suleiman), National Public Health Laboratory (Hani Mat Hussin, Noorliza Noordin, Yu Kie Chem), Queen Elizabeth Hospital (Giri Rajahram, Heng Gee Lee), Sabah State Health Department (Christina Rundi, Mohammad Jikal), Sabah Wildlife Department (Rosa Sipangkui, Senthilvel Nathan, Augustine Tuuga, Jumrafiah Sukor), Gleneagles Hospital Kota Kinabalu (Timothy William); **BMHRC:** CM Ltd (Tom Hughes), HQEII (Shahnaz Sabri), Kota Kinabalu Public Health Laboratory (Jiloris Dony), Sabah State Health Department (Mohammad Jikal)

Thailand – **CM Ltd:** Department of Disease Control, Ministry of Public Health (Rome Buathong, Pawinee Dounngern, Pongtorn Chartpituck), Department of National Park, Wildlife and Plant Conservation (Pattarapol Manee-On), Faculty of Forestry, Kasetsart University (Prateep Duengkae), Mahidol-Oxford Tropical Medicine Research Unit, (Stuart Blacksell, Richard Maude), Chulalongkorn University (Supaporn Wacharapluesadee).

Chulalongkorn lab is a WHO Collaborating Centre for Research and Training on Viral Zoonoses, we work closely with WHO SEARO and SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste.

We had conducted the PREDICT lab training for Veterinary lab in the Southeast Asia region for FAO. We conducted (transferred?) the bat sampling technique for scientists from Malaysia, Myanmar, the Philippines, and China.

## 5. Data Management Plan

Data and Specimen Management: All research procedures will be conducted in accordance with local laws and IRB regulations (and/or other relevant governing authority regulations for human ethics as appropriate). Only the project coordinator in each country will have access to identifiable human subjects' data. All questionnaire data and biological samples will be labeled with a unique alphanumeric identification code, assigned to each enrolled, sampled individual that does not identify the individual from whom data are collected. No personal identifying information will be recorded on the sample vials or on the questionnaires.

For community sampling, biological samples will be stored in liquid nitrogen dry shippers following collection in the field and during transported to the corresponding Laboratory as detailed above. Samples will be stored in a locked -80C freezer at corresponding Laboratory. Only trained staff and project personnel will have access to the specimens. Subject privacy and confidentiality practices will be addressed during training of all study personnel.

Safety Precautions: The project has standardized protocols, SOPs, and training to ensure the safety of staff involved in research activities, including biological specimen collection. Specimens will be collected by trained clinic staff wearing appropriate PPE, including gloves, fitted and tested N95 masks, gowns, and closed toed shoes. Following agreement from government partners, any specimens transported by air to regional or reference laboratories for testing that cannot be carried out in country will follow safety and International Air Transport Association (IATA) guidelines provided to staff. Samples will be packed frozen into dry shippers designed for shipment approved by IATA with appropriate permits and approvals to allow for shipping of biological specimens and infectious substances, under which shipping of samples must also comply with the Safe Sample Transport guidelines.

Training oversight will be provided by the Project Coordinators in each country. All project personnel handling specimens and involved in their transport are trained annually with documentation of training maintained by PREDICT through the PREDICT internal database, the Emerging Infectious Disease Information and Technology Hub (EIDITH).

Data Quality Control: All data are examined at entry and later upon integration into the study database, for complete de-identification, completeness, accuracy, and logical consistency. Once all test results (e.g. initial detection by PCR, subsequent sequencing of viruses, and serology) are available for a given specimen, the results are interpreted in light of all available scientific literature and previous findings by team scientists.

Data Identification: Data will be identified by a unique identification code assigned to each sampled individual. Participants' names and codes will be recorded in the confidential participant logbook, which is completed in the field by field staff and retained and locked in the office of the country Coordinator. All records that contain names or other personal identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the country headquarters in locked filing cabinets, with access limited to study staff. Only the Project Coordinator will have access to identifiable human subjects' data. All other collaborators will have access only to coded data that cannot be linked to identifiable information.

Data and Specimen Protection during Transport: All data collected on paper forms will be transported from the study site to the local collaborating laboratory or collaborating institute in secured containers. A password-protected laptop will be used to collect coded data only. Personal identifying information will not be stored in electronic form. All data transmitted electronically will be 128-bit encrypted. Email will not be used to transmit personal identifiable data. All coded electronic data will be backed-up to secure servers maintained by a secure, 128-bit encrypted and password-protected centralized database.

#### Data Storage:

Human specimens will be banked at the corresponding Laboratory and locked in an ultralow laboratory freezer. Access is restricted to trained personnel. Human questionnaire responses will have restricted access and will only be accessed by trained project personnel. Data will utilize the secure, 128-bit encrypted and password-protected centralized database being developed by EHA to store data for access by the consortium (whose access has been approved by our Malaysian, Thai and Singapore government partners) only for surveillance data analysis. The database is maintained by the EHA information management team. There is no public access to the database.

Commented [T120]: Noam

Data and/or Specimen Banking: Specimen and data will be stored following data collection in secure research facilities. Personal identifying information will be kept in a secure manner and no personally identifiable information will be stored with participants' questionnaire or biological specimen data. Participants will be given a study code. Participants' names and study codes will be kept in a separate locked file from any questionnaire or biological data. Blood and swab samples will be stored securely in labs and labeled with the de-identified study code number.

Data and specimens will be securely stored for up to ten years with personal identifying information kept in a secure manner. This study could be extended by five-year increments in perpetuity. If participants agreed during the consent process, they may be contacted about having their samples or questionnaire data used for future separate studies about new animal infections discovered in the future, and factors that may affect their chances of getting these animal infections. No data will be released for other purposes without full consent from participants.

Upon completion of the project, personal identifying information will be destroyed unless this protocol is extended or amended for a maximum of ten years of sample and data storage.

Provision to Monitor the Data to Ensure the Safety of Subjects: The data collected and the procedures performed are within the scope of Good Clinical Practice and pose no more than minimal risk to the volunteer. Trained health professionals will perform all specimen collection under the supervision of the country Coordinator. The personnel tasked with conducting these procedures will be well-trained in project protocols and in Universal Precaution Practices to ensure safe sample collection, and to ensure that the sample collection process causes the least discomfort possible to the participant. In addition, the administration of questionnaires will be supervised as appropriate. These individuals will be trusted members of the community and will have often treated the participants or their family members before. Every effort will be made by trained project teams to make sure the respondent is comfortable when answering sensitive questions. Participation in this study will not alter the medical evaluation or therapy provided to the participant by the clinical or medical officer and will be based on the typical standards of care.

As described above, no identifying information will be stored with or paired with questionnaire data or biological specimens. As the data samples will be coded within the database for the life of the study and the on-site data log will be stored in a secure manner, the risk of a loss of confidentiality is minimized for the study volunteers. Results will be shared with the Ministries of Health in the form of the official government report generated by EHA that contains all test results but no identifiable information. When questionnaires are moved to the country headquarters, records will only contain

coded data to ensure the safety and confidentiality of participants and will be maintained in a secure database. The only documents that will link the participant with a unique ID number is the first page of the questionnaire that will be separated in the field and kept with the consent form and Participant Log (which will be stored in a locked file separately from participant data in the offices of the Country Project Coordinator).

At the completion of each surveillance period, generally on a calendar year schedule, a data and safety review will be conducted at each site with the clinical staff and the EcoHealth Alliance country team. At this review, safety information and adverse effects collected during the performance period will be discussed and addressed. Data may include case report forms, notes from study visits, and or any telephone calls to the PI from participants. Adverse effects from sampling protocols are expected to be exceedingly rare, but if any unusual conditions are observed by the team, it will trigger a notification within 5 working days, to assure that additional data collection and investigations are initiated.

Report summaries of the data generated from the project will be provided to the Ministries of Health and to other in-country collaborating investigators, at their request. Adverse or serious adverse events included in report summaries to the Ministry of Health and other in-country collaborators.

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

**This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system**

**Language from NIH CoV grant:**

**Data Sharing Plan:** Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited for in long-term public scientific repositories – all sequence data will be made publicly available via GenBank, species location data via the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestricted MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Viral isolates will remain at the Wuhan Institute of Virology initially. Isolates, reagents and any other products, should they be developed, will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Sharing Model Organisms:** We do not anticipate the development of any model organisms from this study. Should any be developed, they will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Genomic Data Sharing:** We anticipate obtaining genetic sequence data for 100s of novel coronavirus genotypes, including RNA-dependent RNA polymerase (RdRp) and Spike genes for all strains/genotypes. In addition, we will generate full viral genomes for a subset of the bat SARS-CoVs that we identify. All sequence data will be deposited in the NIH genetic sequence database, GenBank. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also be submitted. The genotype data will be made publicly available no later than the date of initial publication or six months after the receipt of final sequencing data, whichever comes first. We anticipate sequence generation will occur over the 5 year proposed project period.

**Genome Wide Association Studies (GWAS):** Not applicable.

Commented [KJO121]: From CoV NIH grant

**Thailand TRC-EID Chulalongkorn lab: Specimen management and BioBank:** The software called PACS (Pathogen Asset Control System) supported by BTRP DTRA, is now used for managing the specimen from specimen registration (barcoding, and may move to use QR code system soon), aliquoting, tracking, short patient history record, data summary, searching, test reporting and etc. Our biobank system contains 28 freezers (-80C) and liquid N2 system. Its size is around 120 sq meters. There is a separate electric generator for our lab and biobank. There are CC TV cameras at the biobank and laboratory.

Chula TRC-EID has our own server for data management and analysis. We have the necessary software including Bioinformatic tools (Blast Standalone, SAMTOOL, GATK, AliVIEW, RaxML, FigTREE, MAFFT, Guppy, Megan, PoreChop, MEGA), Database (MySQL, MongoDB) Web, jQuery, Node.js, Express.js React, API, PHP, Ruby, Python, Java, C#, HTML5, Bootstrap, CSS, Responsive, Cloud, Linux Command, PACS (sample management system), Virtualbox virtual machines, R programming languages, Perl scripts, Bash shell scripts, Open source software, Microsoft Office running on both Apple Mac OS X, Ubuntu, Linux, and Windows Operating Systems. Chula TRC-EID has a dedicated 16-core Ram 64GB Linux server with 4TB hard drives, dual quad-core Mac Pro Server with 2TB hard drives and another dedicated iMac Pro (Retina 4K, 21.5-inch, 2017) Processor 3.6GHz quad-core Intel Core i7 (Turbo Boost up to 4.2GHz) Ra, 16GB with 512GB hard drives. TRC-EID also has HPC Linux server CPU: 4 x 26cores Intel Xeon = 104 cores 2.1GHz with 52 TB HDD and 2x3.84TB SSD with GPU 2x Tesla v100 (CUDA core = 5120 cores/GPU, Tenser core = 640 cores/GPU). TRC-EID has a dedicated 10/100/1000 of LAN (Local Area Network), 2.4G / 5G Gigabit Wi-Fi 802.11ac.

Commented [KJO122]: From Supaporn for their lab, some may go in Facilities doc?

From DARPA:

**Data Management and Sharing:** EcoHealth Alliance will maintain a central database of data collected and generated via all project field, laboratory, and modeling work. The database will use secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations, and enable compliance with DARPA data requests and disclosure requirements. All archived human sample data will be de-identified. Partners will provide raw and processed data to the central database throughout the course of the project. Project partners will have access to the data they generate in the database at all times, and maintain control over local copies. Release of any data from the database to non-DARPA outside parties or for public release or publication will occur only after consultations with all project partners. EHA has extensive experience in managing data for multi-partner partner projects (PREDICT, USAID IDEEAL, the Global Ranavirus Reporting System).

Commented [KJO123]: Text from DARPA Preempt

## 6. Clinical Management Plan

### Clinical site selection

Our consortium partners have been conducting lab and human surveillance research, inclusive of human surveillance during outbreaks, for over the past two decades and in that time have developed strong relationships with local clinical facilities and processes. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1. These are regions where we will sample wildlife due to the high potential of zoonotic viral diversity. Additionally, these will be clinical sites that serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. In PREDICT we developed successful working relationships with the major healthcare facilities the hotspot areas in 6 different countries, including Thailand and Malaysia and we will continue to work with these sites going forward. Continuing to work with these hospitals means we will begin this project with successfully established partners and we can begin data collection quickly. This also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites for this study is limited. All that is required of sites will be the ability to enroll patients that meet the clinical case definitions of interest, capacity to collect and temporarily store biological samples, and follow standards for data management and protection. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently site staff. These will be persons who are locally trained and certified to collect biological specimen from participants including blood draw technique, e.g. doctor or nurse. Last, the clinical site will need the capacity to securely store all personal health information and personally identifiable research data, this will include locked offices with locked filing cabinets to store all paper records and an encrypted computer. Training on project procedures will be provided for all local project staff by local country project management staff and partners from headquarters. The study at clinical sites will begin by developing relationships with local stakeholders at the hospitals and clinics in our geographic areas of interest that serve as catchment facilities for people of within the community surveillance study. We will recruit hospital staff that will be extensively trained for project procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data management plans. During the Development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data (e.g. locked filing cabinet, dry shipper, secure laptop). [Did not specifically address CONDUCT]. Oversight for clinical sites will be managed by the country coordinator for each country. This will be done with regular site visits to the clinical sites and annual visits by headquarter research staff. Site visits will include monitoring and evaluating the process for patient enrollment, collecting and storage of samples, administration of the questionnaire, and secure and data management procedures for secure personal health information and research data. During these visits any additional training will also be provided.

Commented [EH124]: Is that true

### Standardized approach oversight and implementation

Management and oversight for all study sites will be managed by the local country coordinator who is supported by staff at headquarters. Implementation of a standardized approach across all study sites, community and clinical, will begin by extensive training of staff on procedures on requirements of the project, this includes: enrollment, data collection, and data management. Our research team has over 5 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research. This includes SOPs for screening, enrollment, and retention of participants. In addition to yearly monitoring reports the country coordinator will regularly visit each clinical site to ensure quality standards and compliance of procedures are being met. Through our work with clinical sites in PREDICT we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical research staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll, allowing for

minimal disruption and prevents potential enrollees from being overlooked if the research staff is not on duty. At clinical sites that do scheduled outpatient days we may have a trained member of the research staff with the intake nurse to monitor the patients coming to the clinic more rapidly to no delay screening or enrollment in such a fast pace environment. Using the screening tools, we will recruit and enroll patients who present with symptoms that meet the clinical case definitions of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology within the past 10 days. These patients will be enrolled, samples collected and survey conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; 3) environment biosecurity. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either coronaviruses, henipavirus, or filoviruses, serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between coronaviruses, henipavirus, or filoviruses in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. **How do these cohorts be leveraged for new emerging pathogens?** Achieving the adequate numbers will be attained through duration of the as clinical participant enrollment. While patient's enrollment is limited by the number of individuals presenting at hospitals, during the PREDICT project we had an average of 105 patients enrolled per year, ranging from 77-244. The country coordinator will be continually monitoring the project database to be sure that we are on track to reach our target.

#### Clinical cohort setup, recruitment, enrollment

We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology for symptoms reported onset of illness to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 2\* 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples and two nasal or oropharyngeal swabs will be collected. The cases are defined as participants whose samples tested positive for Henipaviruses, Filoviruses, or CoVs by PCR or serological tests. The controls will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500 µL serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms for coronaviruses, henipavirus, or filoviruses infected patients to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

#### Utilization of collected data

Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses they are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire allows us to assess

**Commented [EH125]:** Will these cohort fulfill the goals of the EIDRC.

**Commented [EH126]:** PREDICT we also make the stipulation that we will collective relative samples if available from treatment collection, eg CSF if the MD is doing a spinal tap we will request an aliquot if possible

**Commented [EH127]:** Please add any information that might address: types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

relative measures of human-wildlife contact from our survey work that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk.

The biological specimens to be collected (2\*5mL whole blood for whole blood and serum analysis and nasal or oropharyngeal swabs) from all eligible participants and follow up specimen 35 days (3mL of whole blood for serum) after enrollment with the standardized questionnaire. Capacity for specimen collection is not more than standard phlebotomy skills and we will collect by locally trained and certified personnel that are part of the research team in country. Staff we will trainline on ethical guidelines for conducting human subjects research and survey data collection methods. Collection of whole blood, serum, and nasal or oropharyngeal swabs allows us to test the samples for PCR to detect viruses in our priority viral families, serologically test for immunological response and historical exposure to zoonotic diseases of relevance, and the questionnaire will assess individuals evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

#### **Potential expansion**

Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research or an outbreak in the region. If expansion is required we could rapidly implement research activities in additional clinical or community sites through the same process we on-boarded the initial locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transpiration, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provided necessary information for granular understand of disease spread.

In a clearly labeled section entitled "**Clinical Management Plan**":

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment. including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be

**Commented [EH128]:** Please add any information that might address: Describe methods that might be applied to elucidate a zoonotic source

utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics

2. Tekada Sanofi Pasteur dengue

3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

## 7. Statistical Analysis Plan

Analysis of questionnaire data will involve calculation of metrics of contact for each risk group under study, such as the proportion of respondents indicating they have butchered live animals, seen wildlife in their homes, been bitten or scratched by animals, etc. Comparisons of metrics of contact between men and women, as well as different study communities will be conducted in order to explore the environmental and social factors (gender, age, occupation/religion, socioeconomic status (SES)) that influence contact with animals and to determine who is most at risk. Statistics will be computed to identify differences between groups that are significant at  $P < 0.05$ . Various metrics of contact related to different activities within specific groups will be compared to determine the activities that put groups at most risk. Finally, multivariate analysis as appropriate for the outcome measure (e.g. ordinary linear regression, logistic regression, generalized estimating equations that correct for cluster effects and non-normal distributions of outcome, etc.) will be employed to explore the relationship between key metrics of contact and the factors that influence frequency and types of human-animal contact.

Test results and viral sequences obtained from human and animal (wildlife and livestock) samples will be compared and phylogenetic analysis performed to document viral sharing between animals and humans. The test results data will be analyzed in the context of the questionnaire data to identify high-risk human-animal interactions and behaviors or practices that are associated with viral spillover and/or sharing. Specifically, we will calculate odds ratios for demographic and behavioral risk factors associated with the outcomes of viral infection or exposure among communities sampled. Self-report of medical history and illnesses collected through the questionnaires will also be evaluated for associations with demographic and behavioral risk factors. Regression analyses will allow for statistical assessment of both categorical and continuous predictor variables and hierarchical aggregation of data to adjust for correlated factors within communities. Data on self-reporting of illnesses will be triangulated with biological data from the concurrent animal and human sampling to identify symptoms and illnesses that could be correlated with potential pathogens.

In a clearly labeled section within the Research Strategy entitled "**Statistical Analysis Plan**":

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

## 8. Project Milestones and Timelines

In a clearly labeled section entitled “**Project Milestones and Timelines**”:

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

### Project Management & Timeline

PI Daszak will oversee all aspects of the project. Dr. Daszak has two decades of experience managing international, multidisciplinary research in disease ecology, including successful multi-year projects funded by NSF, NIH and USAID. He will conduct monthly conference calls with all co-PIs, including the China team (see **Activity schedule below**). He will be assisted by EHA Sr. Personnel Li, who is a US-based Chinese national with fluent

■ China-US Joint Activity    ■ China-Led Activity    ■ US-Led Activity

Mandarin. Co-PI Olival will oversee Aim 1 working closely with China PI Tong, who will test samples. Co-PI Ma (China team) will coordinate and lead all Chinese experimental infections, with guidance from co-PI Saif, who will coordinate and lead all US experiments with co-PI Qihong Wang. Sr. Personnel Ross will conduct all modeling activities in Aim 2, working closely with co-PI Saif to parameterize the models. Co-PI Baric and Sr. Personnel Sims will lead infectious clone, recombinant viral and culture experiments. Consultant Linfa Wang will advise on serology, PCR and other assays. China team co-PIs Shi and Zhou will oversee viral characterization in Aim 1. Sr. Personnel Feferholtz will oversee the economic modeling in close collaboration with Ross.

Commented [KJ0129]: Text and figure From NSF-NIH SADS grant. Peter will adapt

Another Example of Milestones and specific tasks from a prev DHS (unfunded) proposal:

### Expand existing databases to include predictor variables for pathogenicity risk model

**Task 1:** Collate available human clinical information from the literature for ~300 viral pathogens known to infect humans (Contract Award Date to 6 month)

**Task 2:** Update EHA host-viral association database to include new data for mammalian and avian species from literature 2015-present (Contract Award Date to 3 month)

**Task 3:** Extract and curate full and partial genomic data from Genbank for 5-6 viral families with a high proportion of human-infectious pathogens for phylogenetic analyses – e.g. 'nearest-known-threat module'. (Month 2 to 6 month)

#### **Develop underlying pathogenicity and spillover risk assessment models**

**Task 4:** Fit generalized linear models in Stan for multiple response variables to measure pathogen impact (Month 7 to 10 month)

**Task 5:** Fit generalized linear models to estimate risk of human infection (spillover) based on host, ecological, and location specific traits (Month 4 to 8 month)

**Task 6:** Validate model effectiveness by simulating early-outbreak, limited-information scenarios from known pandemics to confirm model behavior (Month 8 to 10 month)

**Commented [KJO130]:** Just example, but probably just want to use a Gantt chart format per most of our grants, depending on space.

## II. Research Strategy:

### 1. Significance:

Southeast Asia is a critical hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of key ecological and socioeconomic drivers of emergence (**Fig. 1**) (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is also undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread.

**Fig. 1:** Southeast Asia, and in particular, parts of Thailand and Malaysia are hotspots of risk for disease emergence (**left**), and predicted high diversity of 'missing' or as-yet undiscovered viruses, yellow = highest diversity (**left**). From (1, 2).

Not surprisingly a number of novel viruses, including near-neighbors of known agents, have emerged in the region leading to sometimes

unusual clinical presentations (**Table 1**). These factors are also behind a significant background burden of repeated Dengue virus outbreaks in the region (16), and over 30 known *Flavivirus* species circulating throughout S. and SE Asia (17). The events in Table 1 are dominated by three viral families: coronaviruses, henipaviruses and filoviruses, which serve as initial examples of our team's research focus and capabilities. These viral groups have led to globally important emerging zoonoses (18-29). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (30-32). Furthermore, relatives and near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium: henipaviruses in bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (33-39); a novel henipavirus, Mojiang virus, in wild rats in Yunnan (10); serological evidence of filoviruses in bats in Bangladesh (40) and Singapore (41); Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (Hughes *et al.*, in prep.); evidence of novel filoviruses in bats in China (42-44), including Mēnglà virus that appears capable of infecting human cells (45); novel paramyxoviruses in bats and rodents consumed as bushmeat in Vietnam (46); a lineage C β-

Viral agent	Site, date	Impact	Novelty of event	Ref.	CoV in bats in China that uses the same cell receptor as MERS-CoV and can infect human cells <i>in vitro</i> (47); MERSr-CoVs in dry bat guano being harvested as fertilizer in Thailand (48), and directly in bats (Wacharapluesadee <i>et al.</i> , in prep.);
Melaka & Kampar virus	Malaysia 2006	SARI in family group, individual	1 <sup>st</sup> disease due to bat-origin reoviruses, also Singapore, Vietnam etc.	(3-6)	<b>Table 1:</b> Recent emergence events in SE Asia indicating potential for novel pathways of emergence, or unusual
Reston filovirus	Philippines 2008	Seropositive people killed pigs,	No prior findings of filoviruses in pigs	(7)	
Thrombocytopenia Syndrome virus	E. Asia 2009	100s of deaths in people	Novel tick-borne zoonosis with large caseload	(8)	
Reston filovirus	Shanghai 2011	PCR positive pigs	Further evidence of pig RESTV infection	(9)	
Mojiang virus	Yunnan 2012	Death of 3 mineworkers	1 <sup>st</sup> evidence of rodent origin henipavirus in people	(10)	
Nipah-like virus	Philippines 2015	Killed horses	No prior horse infection for NiV, known for HeV	(11)	
SARSr-CoV & HKU10-CoV	S. China 2015	Seropositive people	1 <sup>st</sup> evidence human infection HKU10 & SARSr-CoV	(12)	
SADS-CoV	China 2017	>25,000 pig deaths seronegative people	Novel emergence of bat-origin CoV	(13)	
Nipah virus	Kerala 2018, 2019	Killed 17/19 people	1 <sup>st</sup> outbreak of NiV outside Bangladesh, W. Bengal focus	(14, 15)	

presentations for known or close relatives of known viruses.

172 novel β-CoVs (52 novel SARSr-CoVs) and a new β-CoV clade ("lineage E") in bat species in S. China that are also found throughout the region (20, 47, 49, 50); and 9 and 27 novel wildlife-origin CoVs and

**Commented [MOU1]:** Should include Olival *et al.* 2017 for missing zoonoses, not Jones. Or Jones, Allen, and Olival papers.

**Commented [MOU2]:** Shouldn't we add the emergence of Nipah in Malaysia Singapore in 1999 at the top of the table!?

paramyxoviruses in Thailand (respectively) and 9 novel CoVs in Malaysia identified as part our work under USAID-PREDICT funding (49, 51). These discoveries underscore the clear and present danger of future zoonotic events in the region. Furthermore, the wide diversity of potentially pathogenic viral strains has significant potential to help in the development of broadly active vaccines, immunotherapeutics and drugs (47). Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 2). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (29, 52). However, these regions tend to be in the developing world, where nations often lack the resources to investigate novel zoonotic events, or wildlife reservoirs of zoonoses, and prioritize more immediate public health concerns such as Dengue virus or NTDs (16). Zoonotic disease surveillance and control is also hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (53). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in x/xx (x%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (12, 54). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (3) as well as 12/856 (1.4%) people screened in Singapore (4). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (7), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (55). In pPreliminary screening in Malaysia with funding from DTRA for serological surveillance of Henipaviruses and Filoviruses spillover found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in non-human primates (NHPs) and people (Hughes, in prep.)- we found serological evidence of exposure to Henipaviruses (Hendra, Nipah and Cedar) in 14 bats and 6 human samples, and Ebola (Zaire and Sudan) antigenically-related viruses in 11 bats, 2 NHP and 3 human samples (Hughes, in prep.).

Commented [PD3]: Peter will correct

Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70% (56). Nipah virus has been reported in people in West Bengal, India, which borders Bangladesh (26), in bats in Central North India (57), and now in people in Kerala, South India in 2018 and 2019, raising the specter of future spillover at other sites in the region (14, 58).

**Fig. 2: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In

some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (52).

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (59), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (20, 47, 49, 50, 60-62). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-**

Commented [PD4]: Peter to do

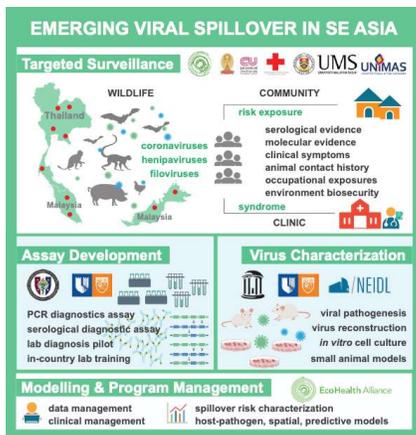

concept for an early warning approach that we will expand in this EIDRC to target key viral groups in one of the world's most high-risk EID hotspots.

Commented [BR55]: Statement should be in the aims. ...Our center covers the worlds most high risk EID hotspot?

The overall premise for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. To scale-up this approach, we propose to launch EID-SEARCH (the Emerging Infectious Diseases - South East Asia Research Collaboration Hub), to better understand the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and novel CoVs, henipaviruses, and filoviruses in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development, and cross-training in surveillance and novel diagnostic platforms. We will develop and transfer technology to test these viruses' capacity to infect human cells and mouse models, develop new specific and sensitive serological and molecular diagnostic tools, conduct surveillance of human communities with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover of viruses causing previously 'cryptic' clinical syndromes in people. We will test the capacity of novel viruses we isolate, or genetically characterize, to infect human cells and/or mouse models, and thus assess potential for spillover and spread which will feed into our risk models. Our group also has extensive experience in other viruses, including vector-borne flaviviruses, and alphaviruses, and will use this experience to provide robust long-term surveillance, diagnostics, human and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EID-SEARCH is poised to rapidly respond to any new emerging outbreak. Thus, filoviruses, henipaviruses and coronaviruses are examples of sentinel surveillance systems in place that can capture, identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.

**2. Innovation:** Previous work by our consortium has developed strategies to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses. In the EID-SEARCH we scale up this approach in a central research "hub" made up of leading laboratories, clinics and surveillance sites in three critically high-risk EID hotspot countries in SE Asia. EID-SEARCH's reach is expanded through its regional network of collaborators that covers nearly all of the greater SE Asia region. The innovation of the EID-SEARCH is in: 1) Its multidisciplinary approach that combines modeling to target geographic and taxonomic sampling targets with on-the-ground zoonotic disease surveillance in human and wildlife populations; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people. We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. We will use *in silico* methods (novel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into

Commented [KJ06]: Hongying to add in "genetic sequencing" under Virus Characterization, and also Aim 1 + 3 for Virus Characterization and Aim 1 + 2 for Assay Development

that identifies how likely viruses are to be able to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people. We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. We will use *in silico* methods (novel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into

Commented [KJ07]: And pathogenicity? Could argue for those we use animal models on.

**Fig. 2:** EID-SEARCH approach, core members, and roles.

high-risk human populations. **In Aim 2, we will conduct focused, targeted cross-sectional surveys of and sampling of human communities with high levels of animal contact exposure to wildlife and other animals to identify occupational and other risk factors for zoonotic virus exposure.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. Serological findings will be analyzed together with clinical metadata (including a simple animal-contact survey, location data, viral sequence/isolates etc.) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise ‘cryptic’ outbreaks.** We will enroll and collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and [follow-up](#) serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs. Our US partner BSL-4 laboratory, NEIDL, will attempt isolation and characterize any viruses requiring high levels of containment (e.g. any novel filoviruses discovered).

### 3. Approach

**Research team:** The EID-SEARCH builds on long-term collaboration among world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (**Fig. 2**). Over the past two decades, our consortium partners have conducted high profile research on EIDs within the region and globally, including identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (20, 25, 57, 59, 63-65), discovering SADS-CoV (13), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (60-62, 66-79). Our team has substantial experience conducting human surveillance in the community and during outbreaks (See sections 2.x.x, 3.x.x), including: USAID-PREDICT, and DTRA-funded viral surveillance of indigenous communities in Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah (Co-I Hughes); collection of >2,000 serum samples from healthy blood donors and sanitation workers, febrile and influenza like illness (ILI), and diarrheal stool samples from children under 5 years of age (Co-I Kamruddin); collaboration on the MONKEYBAR project with the London School of Hygiene and Tropical Medicine to analyze risk and prevalence of the zoonotic malaria *Plasmodium knowlesi* (Co-Is William, Tock Hing); case control and cross-sectional studies in Sabah villages (~800, 10,000 participants resp.) (Co-Is GR, TYW); and community-based surveillance of hundreds of bat-exposed villagers in Thailand (Co-Is Wacharapluesedee and Hemachudha). As a proof-of-concept of how our team can rapidly scale up resources for diagnostics and surveillance in the face of a new EID, in 2016, we discovered a novel bat-origin HKU-2 CoV (80, 81) killing >20,000 pigs in S. China, designed PCR and LIPS serology tests, then surveyed pig farmers for evidence of exposure, and conducted experimental infections, pathogenesis and molecular studies, **all in the span of 3 months** (13, 82).

The administration of this center (**See section X**) will be led by PI Daszak, who has >20 years’ experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5–20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival and Zambrana are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesedee, Hughes and collaborators have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from NIH, DoD, USAID, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to our EIDRC.

**Commented [PD8]:** Hongying – Figure needs edits to text: top panel, ‘wildlife’ should read “Aim 1: WILDLIFE”, “AIM 2: COMMUNITY”, “AIM 3: CLINIC”. Right hand side: “Clinical symptoms” should be “Clinical history”, “Occupational exposures” should be “Occupational exposure”, “environment biosecurity” should be “environmental risk factors”

Middle panel: “Assay Development” and “Virus Characterization” should have “(Aim 1)” after them. Left hand side: should read “PCR diagnostics”, “serology”, “piloting diagnostics” and the last one is ok. Right hand side bullets should be “receptor binding characterization” “in vitro characterization” and “mouse models”

Bottom panel: all good

**Commented [PD9]:** PD will get stronger letter from Jerry Keusch: opportunity for visiting scholars to be certified for BSL-4 research, strong Ebola person at NEIDL to conduct characterization if we find filoviruses.

**Geographical focus:** The three core (hub) countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people

otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH, DTRA, and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our core member's extensive network of collaborators in clinics, research institutes and public health laboratories in almost every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in >10 countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic

**Commented [KJO10]:** Including those in green on map, plus Australia.

potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Fig.3 :** Map of Southeast Asia indicating three hub countries for this proposed EIDRC (Red: Thailand, Singapore, Malaysia) and countries in which Key Personnel have collaborating partners (Green), indicating that EID-SEARCH provides access to key collaborators throughout the region.

**Commented [PD11]:** Hongying – “EIDRC Program Countries” should be “EID-SEARCH core countries” and “External Partner Countries” should be “Collaborating Partners”

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and non-human primates (83). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (Fig. 1) (2). In Aim 1, we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and apply novel predictive models to estimate viral diversity and host range to identify wildlife species that have been ignored or under-sampled by previous zoonotic disease surveillance efforts. We will strategically collect specimens from these species and screen them, together with some of the tens of thousands of recently collected samples we have archived in freezers in our labs, for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel virus in high risk RNA viral families, *Coronaviridae* (CoV), *Paramyxoviridae* (PMV), and *Filoviridae* (FV). We will expand to other groups of pathogens, including arboviruses, pending available resources and priorities established with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation. On this subset of viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, gene edited humanized transgenic mice and the collaborative cross genetic reference mouse population) previously developed and widely used by our team to predict capacity of novel viruses to infect people and spillover (61, 84-87). These high-risk viruses and their close relatives will be targets for human community serosurveys and clinical sampling in Aim 2 and 3, respectively.

**Commented [PD12]:** PD to Remember to correct specific aims with same titles

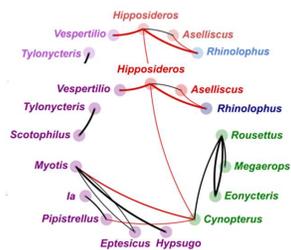

**Commented [KJO13]:** Can/should save space by abbreviating throughout after first mention.

**Commented [PD14]:** From Kevin - we need to specify in the methods below how many viruses (number of) we will have resources to do this on

**1.2 Preliminary data: 1.2.a. Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a

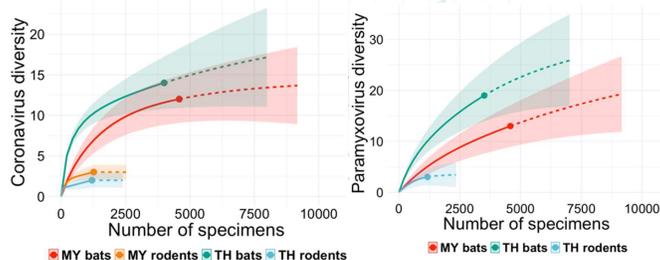

major high risk location for pathogen emergence (1, 2). For Southeast Asia, these EID hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (Fig 1). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (2). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 1). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (88). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data and flight model software we have produced with Dept Homeland Security funds (89). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

**1.2.b. Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primates represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential(90). Thus, the bulk of our proposed wildlife sampling and testing will consist of these three taxa with a focus on bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, **henipaviruses and filoviruses** PMVs and FVs (48, 91-93). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (2), and are exceedingly diverse in Southeast Asia (~500 species). To further prioritize taxonomic sampling targets within these diverse geographic hotspots, we have used a novel, Bayesian phylogeographic analysis to identify host taxa that are the most important centers of evolutionary diversity for a given viral group, e.g. bat genera for  $\beta$ -CoVs **using an extensive CoV sequence dataset from our NIH funded research** (Fig. 5) (49). This approach will be extended to other mammal taxa and viral families of interest, allowing us to identify the ancestral wildlife hosts of specific zoonotic viral groups, where their diversity is likely highest.

**Fig 5:** Preliminary analysis to identify the most important bat genera in Southeast Asia as hosts for beta-CoV evolutionary diversitys using our previously-collected-CoV sequence data collected under our NIH-funded research. Line thickness is proportional to the probability of virus sharing between two genera, with in-inter-family switches are highlighted in red. We will apply this Bayesian discrete phylogeographic model to identify taxonomic and geographic centers of viral diversification and sharing for relevant paramyxovirus PMV, CoV, coronavirus, and other virus clades.

Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (94, 95) (Fig. 6). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively identify new strains to support experimental infection studies and risk assessment.

**Fig. 6:** Estimated coronavirus-CoV (left) and paramyxovirus-PMV (right) putative viral 'species' diversity in bats and rodents for from Thailand and Malaysia, using data from PCR screening and RdRp gene sequences preliminary data from >103,000 PCR test specimens in bats and 4,500 tests in rodents. Bats in Thailand and Malaysia have 4X the number of viruses than rodent species, controlling for sampling effort. CoV and paramyxovirus diversity estimates are comparable, but discovery has not yet saturated in any taxonomic group or location. We estimate that additional collection

**Commented [KJO15]:** Wrong ref! Should be Olival et al. 2017.

**Commented [KJO16]:** This is currently in Aim 3.

**Commented [KJO17]:** Olival et al appears twice in refs, fix.

**Commented [BRS18]:** I would say we focus on these three species (plus vectors?). To demonstrate the capability of the team, this proposal will focus on bat surveillance (for a variety of reasons), noting that this approach will also be applied to other zoonotic vectors during the 5 year program throughout the region.

**Commented [PD19]:** Ralph – have we done this well enough now? If not, please add text/edit

**Commented [PD20]:** Kevin - Can you get rid of the shading on the background to this figure and change the colors so the circles and genus names are more visible (esp. the green). Colors should be darker and more contrasty

**Commented [MOU21R20]:** Revised figure inserted.

**Commented [KJO22]:** We can show just a single curve per country (aggregating all wildlife species) for simplicity, and could fit CoVs and PMVs on one graph.

**Commented [PD23]:** Evan/Hongying/Kevin, please send that also and I'll choose one

of 5k-9k bat specimens sampling of ~5,000 bats and testing of our archived rodents specimens alone will identify >80% of remaining CoV and paramyxovirus PMV viral species in these key reservoirs, yielding >800 unique viral strains. We will use this approach to define sampling targets for other wildlife taxa, and for viral strain diversity.

**1.2.c. Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. Under the 10-year PREDICT program globally, we identified 912 novel and 210 known viruses, more than the total number of viruses previously recognized in mammals by the International Committee on Taxonomy of Viruses. This work included collecting nearly 300,000 individual mammal samples from 14 EHA-led PREDICT countries and PCR-screening more than 60,000 individual specimens (51). In southern China alone, this sampling led to the identification of 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARSr-CoVs). Included were members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus, SADS-CoV, responsible for killing >20,000 pigs in Guangdong Province (13). Many of the identified bat species are found across the region. We have collected 28,957 samples from bats, rodents and primates in Thailand and 51,373 in Malaysia, conducting 146,527 PCR tests on a large proportion of these specimens. We have archived duplicate samples which are now available for use in this project, including fecal, oral, urogenital and serum samples from bats, rodents, and non-human primates, and primate biopsies. In Thailand this screening has identified 100 novel viruses and 37 known viruses in wildlife reservoirs. In Malaysia this screening has identified 77 novel viruses and 23 known viruses in wildlife reservoirs (66 novel and 19 known in Sabah and 11 novel and 9 known from Peninsular Malaysia). We used Using family level primers for henipaviruses PMV, filoviruses-FV, and CoVs, we and have already discovered 9 novel and 7 known CoVs and 26 novel and 2 known paramyxoviruses in Thailand; and, This is in addition to 13 novel and 5 known CoVs and 15 novel and 1 known paramyxovirus in Malaysia from wildlife. In the current proposed work, we will attempt to sequence, isolate and characterize those viruses that our analyses below suggest are most likely to be able to infect humans.

Our collaborative group has worked together on these projects, as well as other DTRA funded projects in Singapore/Thailand (Co-Is Broder, Wacharapleusadee, Wang) to design, cross-train, and use novel serological and molecular platforms to investigate virus infection dynamics in bats and examine potential spillover events with or without human disease (see Aim 2). For serology, Co-Is Wang and Anderson (Duke-NUS) will develop a phage-display method to screen antibodies for all known and related bat-borne viruses, focusing on henipaviruses, filoviruses and coronaviruses. Once various "trends" are discovered, additional platforms (including Luminex and LIPS) will be used for verification and expanded surveillance. For molecular investigation, we will combine targeted PCR approach with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified. In Malaysia (Co-Is Hughes, Broder, Laing) we have transferred the Luminex serology platform to partner laboratories for screening of wildlife, livestock and human samples to investigate the spillover of henipaviruses and filoviruses at high risk interfaces. These interfaces include farms near the forest and indigenous communities with lots of subsistence hunting in Peninsular Malaysia, and preliminary screening has found serological evidence of past exposure to viruses antigenically-related to Nipah and Ebola in humans, bats and non-human primates (NHPs). In Thailand, Co-Is Broder, Laing and Wacharapleusadee have transferred a Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses and known henipaviruses in wildlife and human samples, with testing underway and currently being validated in our Chulalongkorn University laboratory (See also section 2.2.d).

**1.2.d. In vitro & in vivo characterization of viral potential for human infection:** Using Coronaviridae as an example, we have conducted *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3-7% (20, 59, 96). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (59). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of

**Commented [PD24]:** Kevin – please get someone to check EIDITH – I think I just guesstimated these numbers...

**Commented [MOU25R24]:** These are correct, based on EIDITH P1 + P2 for EHA countries.

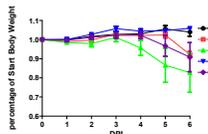

**Commented [KJO26]:** Leave this out as it may look like we've already done a bulk of the work?

**Commented [MOU27]:** Think we need to abbreviate these viral families throughout, should Find/Replace. Also, henipa is not a viral family, so changing back to PMVs.

**Commented [KJO28]:** Move to Aim 2? I think it's good to have some flexibility to test wildlife sera using these assays, but not readily clear how this fits in with our PCR screening? We could do a broader survey of a smaller number of wildlife samples from more species, and those with high seroprev, we can follow up w molecular assays – though not sure this is necessary. All the serology in this section can prob go to Aim 2.

two different variants. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in those without ACE2 (20, 59, 96). We used the SARS-CoV reverse genetics system (70) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (60). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry**. The Baric lab has a well-established hACE2 and DPP4 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect (84, 97). We used this chimera approach to demonstrate that pathogenicity of bat SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the value of this model in assessing novel SARSr-CoV pathogenicity**. Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity, nor after challenge following vaccination against SARS-CoV** (60). We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they are unable to use the ACE2 receptor**. Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines.

A similar approach to the above pipeline for CoVs will be applied to novel henipaviruses and filoviruses we discover during our research. The broad mammalian tropism of Hendra virus and Nipah virus (66) is likely mediated by their usage of highly conserved ephrin ligands for cell entry (15, 98). A third isolated henipavirus, Cedar virus does not cause pathogenesis in animal models. Recently, **Co-Is Broder and Laing** have developed a reverse genetics system and rescued a recombinant CedV to test ephrin receptor usage/tropism and pathogenicity during henipavirus infections (75). CedV is unable to use the Ephrin-B3 receptor (75, 99) which is found in spinal cord and may underlie NiV encephalitis (100) and that pathogenesis also involves virulence factors V and W proteins. The putative henipaviruses, Ghana virus and Mojiang virus, predict V and W protein expression, with GhV able to bind to ephrin-B2, but not -B2 (101), and the receptor for MoJV remaining unknown (102) but is likely ephrin-B2 (103). Primary human lung endothelial cells are highly susceptible to Ebolavirus infection (104). Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (105) Huh7 cells also offer advantages for reverse genetic recovery of novel filoviruses (106). Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G).

**Fig. 7:** Body weight change in hACE2 transgenic mice after SARSr-CoV infection, demonstrating that bat-origin SARSr-CoVs cause similar clinical presentation to outbreak strain (4231). From (60, 61).

**Models of Outbred Populations.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments (107). We have used this model for CoV, ~~filo-FV~~ (Ebola), Flaviviruses, and alphaviruses infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection (85-87, 108-111). **Bat Models.** Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (112).

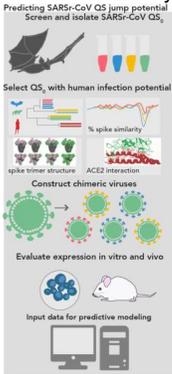

**Commented [PD29]:** Ralph/Danielle/Eric/Chris – need something substantial here on filovirus binding that shows we have a valid approach for novel filoviruses

**Commented [PD30]:** Ralph – I think I mis-spoke in this fig. description – please correct.

**Commented [PD31]:** Ralph – please add data from the CC mouse re. filoviruses, to beef up the image of us as a filovirus group

**Commented [PD32]:** Linfa/Danielle – please draft a brief para explaining how we'll use these two models

**1.3. General Approach:** We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new sampling of wildlife in high risk locales. We will use viral family level PCR [screening-assays](#) to identify and partially characterize viruses, then follow up sequencing of relevant receptor binding proteins to assess homology and predict binding affinity, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will follow this with *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease (**Fig. 8**). EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses, as well as cross-training and tech transfer to the hub labs in Thailand and Malaysia. This will include via support of one Malaysian Ph.D student, Mei-Ho Lee (CM Ltd.) who has worked with the EID-SEARCH collaborators for 9 years. The focus of her study will be infection potential of novel CoVs and paramyxoviruses already found in bats in Malaysia under preliminary data for this proposal.

**Fig. 8:** Schematic showing EID-SEARCH approach to selection of sampling, viral testing, prioritization and characterization to identify novel, high zoonotic-risk viruses in wildlife.

**1.4 Wildlife samples: 1.4.a. Geographic and taxonomic targeting for newly collected wildlife samples:** We will prioritize sites within each country that rank highest for both the risk of zoonotic disease emergence (113) and the predicted number of 'missing' zoonotic viruses (90). Our preliminary analysis (**Fig. 1**) suggests priority areas include: the [Kra Isthmus of Kra](#) (S. Thailand and N. Peninsular Malaysia), NW Thailand (near the Myanmar-Laos border), and the lowland rainforests of Sarawak and Sabah. In each of these 'hottest of the hotspots' regions, we will identify 2-4 distinct sampling sites based on the geographic distribution of key hosts we prioritize for [intensive-additional](#) wildlife sampling. We will priority rank bat, rodent, and primate species using [analysis of host trait data for the highest-predicted number of viruses based on host trait-based models](#) (90). We will also identify species predicted to be centers of evolutionary diversity for Corona-, Paramyxo-, and Filoviridae using ancestral host reconstruction of available sequence data and Bayesian discrete phylogeographic models (114-116). ~~We will ensure wildlife sampling is complimentary to specimens archived in our extensive freezer banks. We will collect only the additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes given predicted levels of viral richness and rates of discovery (see 1.4.b).~~ We will leverage our strong collaborations with wildlife experts in Malaysia and Thailand to ground-truth geographic and taxonomic model outputs with local expert knowledge to ensure the sampling plan is realistic based on current species distributions, population size estimates, seasonality, and accessibility to sites.

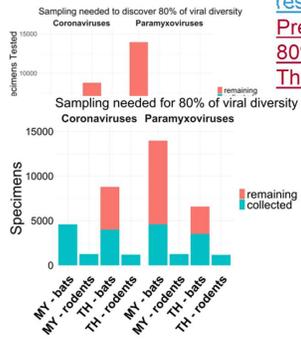

Recognizing that most zoonotic viruses are multi-host, i.e. naturally harbored by multiple wildlife species, and that the phylogenetic relatedness of those hosts is predictable and varies across viral families (90) – we will ~~use a combined network analysis and a phylogeographic model also apply a generalizable phylogenetic and spatial modeling approach~~ to rapidly predict ~~and prioritize~~ new (unsampled) hosts for ~~important~~, novel viruses we discover during our research. ~~We will use a combined network analysis and a phylogeographic model to estimate a viruses' host range and to~~ We have shown this relatively simple model ~~prioritize additional wildlife species for sampling and testing for viruses we discover. Our recently developed model of viral sharing uses just two phylogeographic traits (using just~~ wildlife species range overlap and phylogenetic similarity between host species) ~~is both generalizable to estimate host range for all mammalian and avian viruses and robust – accurately predicting hosts 98% of the time when cross-validated using data from known viruses to successfully predict host species in the top 2% of all 4,200 possible mammal species~~ (117).

**Commented [PD33]:** Hongying – this is a placeholder from DARPA proposal. We need a new one with Stages: 1) Geographic and taxonomic modeling to maximize discovery of potential zoonotic viruses; 2) PCR screening and partial RNA sequencing; 3) Full genome or RBD and Glycoprotein sequencing to model receptor binding based on sequence similarity; 4) Cell line infections (for prioritized viruses); 5) animal model infections (for prioritized); 6) High priority viruses ranked based on data (red, yellow, green) schematic.

**Formatted:** Font: Italic

**Commented [PD34]:** Kevin - That doesn't make clear sense straight away – please re-word better without increasing length

**1.4.b. Sample size justifications for testing new and archived wildlife specimens:** We calculate initial We will sample sizes targets using e-our preliminary data on average PCR prevalence from screening tens of thousands of bat, rodent and primate specimens for CoV and Paramyxoviruses-PMVs under the USAID-PREDICT project in Malaysia and Thailand. We will refine these sample size targets, in real-time, over the course of our project using viral discovery curve analyses (Fig. 6) to either scale-up or scale-back new sampling and testing of archived specimens for each species depending on their viral diversity capture rates. We will only collect additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes and to complement our archived specimens. For example, *Rousettus* spp. bats, known filovirus reservoirs, were not adequately sampled under PREDICT research in Thailand.

Preliminary analysis indicates we will require ~14,000 new samples to identify 80% of remaining viral species diversity in our study region. ~5,000 samples from Thailand and ~9,000 samples from Malaysia (Fig. 9). Viral strain discovery diversity from a sampling effort this size is expected to number in the hundreds of strains. For example, given ~6% prevalence of CoVs in bat species previously sampled under the PREDICT project, a target of 14,000 individuals would yield ~800 PCR positive individuals, representing, conservatively, an estimated ~200600 novel CoV strains/sequences/strains. Similarly, for paramyxoviruses, which have an average PCR detection prevalence of ~1.5%, sampling of 14,000 individuals would yield ~200 positives and an estimated ~60150 novel paramyxovirus strains. From each mammal, we will collect serum, whole blood, throat swabs, urine and fecal samples or rectal swab using our previously-validated. For example, given 5-

12% prevalence of CoVs in the most common bat species we previously sampled in Thailand and Malaysia, a target of XXX individuals per species would yield XX (± x) PCR positive individual bats, and an estimated ~xx novel strains. Similarly, for paramyxoviruses with an average PCR detection rate of X%, we would need XX individuals per species to detect 80% of predicted viral strain diversity with 80% power. Preliminary analysis indicates we will require XX,000 samples to identify 80% of remaining viral diversity (Fig. 9). All wildlife sampling will be nondestructive methods (see Vertebrate Animals section) [REFS]. In the event that an animal is found dead or needs to be euthanized due to injury we will collect biopsy-necropsy samples for screening.

**Fig. 9.** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMV species s-from high-risk bat and rodent taxa in Malaysia and Thailand

We estimate the following sampling effort, broken down for each region: **Peninsular Malaysia:** Wildlife sampling will be led by CM Ltd / EHA in collaboration with PERHILITAN. Archive bat, rodent and NHP samples will be screened serologically using the BioPlex and other serology techniques identified through this project. New wildlife sampling will focus on bats but it is expected that rodents and NHPs will be sample as well. Wildlife sampling will be conducted around Orang Asli communities sampled as part of aim 2. Three new communities will be identified in the districts we have already sampled in. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at PERHILITAN's NWFL. **Sarawak, Malaysia:** Wildlife sampling will be led by CM Ltd / EHA in collaboration with UniMAS. Wildlife sampling will be conducted around Dyak communities sampled as part of aim 2. One community will be identified. Concurrent sampling trip will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at UniMAS or BMHRC. **Sabah, Malaysia:** Bat sampling will be led by CM Ltd / EHA in collaboration with SWD and WHU. Bat sampling will initially focus on 3 caves. Batu Supu Sabah low disturbance cave and surrounding area, Madai medium disturbance cave and surrounding area, Gomantong cave high disturbance cave and surrounding area. Each cave will be sampled

Formatted: Font: Italic

Commented [KJO35]: Just assumed that 75% of detections would = unique sequences/strains. We can lower this to be more conservative.

Commented [MOU36]: Kevin will work with Noam and Evan to fill in these numbers.

Commented [KJO37]: PREDICT sampling protocols? Jon's FAO bat book manual, and other published for rodents and primates (from Bangladesh?)

Commented [PD38]: Hongying/KEvin Need less text on the figure, but larger font size, or crisper text to make it all visible at this size.

Commented [T39]: Will dig into budget tomorrow to confirm numbers.

Commented [T40]: With Dr Tan and possibly Dr Faisal - still waiting for Dr Faisal paper work and details of samples he has in storage will discuss with Dr Tan tomorrow.

Commented [T41]: Will dig into budget tomorrow to confirm numbers.

Commented [T42]: Discussing with Tam tomorrow.

twice once in wet season and once in dry season targeting 500 bats at each cave on each trip for a total of 3000 bats. Wildlife samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored at WHGFL, molecular testing will be conducted at WHGFL and serology screening at BMHRC. In addition at Madi cave the community that lives in the mouth of the cave will also be sampled targeting 150 people, while at Gomantong cave 25 workers involved in the bird next farming will be enrolled into the study.

Thailand: XXXXXXXXXX New bat specimens will be collected from bat species that was not collected during PREDICT2 study for example *Rousettus* bats (targeted species for Filovirus study), *Taphozous* bat (targeted species for MERS-CoV), *Rhinolophus* (targeted species for SARS-CoV) for serology and PCR assays (n=100 for each species).

Thailand: XXXXXXXXXX

**1.4.c. Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs ~~with High Pure Viral RNA Kit (Roche)~~. RNA will be aliquoted, and stored at -80C. PCR screening will be performed with pan-coronavirus, filovirus and paramyxovirus primers, in addition to virus specific primers where additional sensitivity is warranted in key viral reservoirs, i.e. Nipah virus specific primers [REF]. PCR products will be gel purified and sequenced. We will attempt isolation on samples that contain viruses of interest (determined in 1.4, below), using Vero cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). [This includes the over 30 bat cell lines maintained at Duke-NUS] from four different bat species.

**1.4.d. Moving beyond RNA viruses:** To detect pathogens from other families, such as non-RNA viruses we will combine conserved PCR assays with NGS. We will perform either unbiased NGS, or use a pan-viral enrichment library to sequence full-length genomes. We will conduct this work via EID-CC research projects or as part of outbreak detection/investigation in the region from DNA viruses or other agents.

**1.4.e. Sequencing Spike Glycoproteins:** Based on earlier studies, our working hypothesis is that zoonotic coronaviruses, filoviruses and henipaviruses encode receptor binding glycoproteins that elicit efficient infection of primary human cells (e.g., lung, liver, etc.) (12, 59, 60). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (Fig. 4) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are undersampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (20, 60, 118), suggesting that existing vaccines and immunotherapeutics could easily fail against future emerging SARS-like CoV. Moreover, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic receptor binding protein genes of MERS-related, Ebola-related and Nipah/Hendra-related viruses will also program efficient entry via human ortholog receptors. For all novel virus strains, we will sequence the complete entry spike genes by amplifying overlapping fragments using degenerate primers as shown previously (20, 59). Full-length genomes of selected CoV strains (representative across subclades) will be sequenced using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR or Minlon sequencing will be performed to fill gaps in the genome. The full length spike gene sequences, including the amount of variation in the receptor binding residues that bind the appropriate human receptor will be used to select strains for Aim 3 experiments.

**1.5. Assessing risk for spillover. 1.5.a. Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, filoviruses and henipaviruses, we will use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-

Commented [T43]: Will dig into budget tomorrow to confirm numbers.

Commented [PD44]: Kevin – who can write this bits?

Commented [KJO45]: I think all this could be deleted. Doesn't fit with the overall plan, or is redundant. We may want to call out a few specific sites Tom mentions (but won't that depend on the modeling!?), and you may want to keep the partner info Tom provided and call that out - maybe more in Aim 2 since its about people too?

Commented [MOU46]: Supaporn: From my DTRA study, specific Nipah primers and WHO 2C CoV primers is more sensitive than consensus PCR if we want to find the specific virus.

Commented [PD47]: Linfa – can you give a v. brief description of these please, e.g.: “This includes 13 primary lung, 5 primary gut epithelial, and 1 primary liver cell line. In addition we have 12 immortalized cell lines, 7 of which are intestinal, and therefore suitable for CoVs. Cell lines are derived from insectivorous and frugivorous bats (genera.....)”

ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (60, 61, 119). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs or other test filoviruses or henipaviruses to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other viruses (62, 69). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (61, 120) or monoclonal antibodies targeting the Ebola or Marburg E glycoprotein (Available through BEI), or Nipah or Hendra viruses (121). As controls or if antisera is not available, the S genes of novel SARSr-CoV or spike entry genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (122). Polyclonal sera against SARS-related viruses will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (61, 123, 124). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (125) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (126-128). Similar approaches will be applied to novel MERS-related viruses, other CoV, filoviruses or henipaviruses. While most wildlife-origin viruses with unknown transmission potential or pathogenicity in people are BSL-2 or -3, cell culture for potentially BSL-4 pathogens will be undertaken at collaborating institute NEIDL. To facilitate this, duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (See letter of support) for culture, characterization and sharing with other approved agencies including NIH Rocky Mountain Laboratories RML where our EID-SEARCH team has ongoing collaborations. When appropriate of feasible, training opportunities at NEIDL for in-country staff will be given.

**1.5.b. Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the *intraspecific* scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (68). A lot of variation in the NPC1 receptor alters EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains (129). Signatures of positive selection in bat NPC1 were concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in *Eidolon helvum* cells. Thus NPC1 is a genetic determinant of filovirus susceptibility in bats, and some NPC1 variations likely reflect host adaptations to reduce filovirus replication and virulence (130). Nipah and Hendra use ephrin B2 or ephrin B3 as a receptor, and variation affects its ability to use human vs bat receptor molecules (101, 131).

**1.5.c. Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RNA-dependent RNA polymerase (RdRp) sequences from PCR screening (or L-genes), receptor binding glycoproteins, and/or full genome sequence data (when available) data to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, filoviruses and henipaviruses that we identify. We will run phylogenetic and ancestral state reconstruction analyses (Fig. 5) to reconstruct identify host taxa and geographic sites of  $\beta$ -CoV, filovirus and henipavirus evolutionary origins within bats, rodents and primates using our expanded dataset and identify the host taxa and geographic regions that together define hotspots of phylo-diversity for these viruses, allowing for more targeted surveillance. For receptor binding glycoprotein sequence data from characterized viruses, we will apply codon usage analyses and codon adaptation indices, as used recently on Henipaviruses (132), to assess the relative contributions of natural selection and mutation pressure in shaping host adaptation and host range. We will rerun MCC analyses (Fig. 3) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (Fig. 4) to monitor progress towards

Commented [BRS48]: Any antibodies available? If not we can synthesize them from published co-crystals.

Commented [PD49]: Can someone answer Ralph's question please?

Commented [KJ050]: Make more specific about our plans to sequence NPC1 or Ephrin receptors, etc. Should we frame much of this as "add on projects" pending additional EIDRC-CC funding?

Commented [PD51]: Kevin/Alice – please edit this section to include relevance for filoviruses and henipaviruses as well (and other hosts)

~~discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) or other virus families within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (96, 133).~~

**1.5.d. Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, and approximately 600 total CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (120, 133-135). For novel henipaviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize strains that are predicted to interact with ephrin-B2 and expression V/W proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models. We will assess ability to infect human cells using a continuous lung epithelial cell line, Calu3, that our group has previously used to generate data on NiV and HeV growth curves and a variety of host expression changes after infection (136). We will also use primary human airway cultures to assess human infection for Henipavirus and MERS- and SARS-related CoV (137) (138). There is some evidence for Nipah and Hendra virus replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (139, 140). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted Ebola infections (85-87).

**1.5.e. Animal models:** We will use transgenic mouse models and the UNC Collaborative Cross model to assess spillover potential of viruses. For work on CoVs, we will follow the protocols in the transgenic mouse model used by the Baric lab previously. Briefly, in the BSL3 lab, n=8 10- to 20-week old hACE2 or hDPP4 transgenic mice will be intranasally inoculated with  $5 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins or MERS-CoV and MERS-related CoV, respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV or MERS-CoV mAbs (141, 142) will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (119, 143). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (61, 119). For the Collaborative Cross model, we will....

Finally, for more detailed pathogenesis studies in the natural reservoir, we will use the bat models (natural and transgenic mouse model) at Duke-NUS. Both animal systems can be used to test susceptibility, pathogenesis and immune responses of any newly discovered viruses.

**Commented [KJ052]:** I suggested we could get up to 600 CoV "strains" (all seqs, not just SARSr-CoVs) in section 1.4b, but we can reduce that.

**Commented [PD53]:** Ralph – please insert a couple of sentences on how we'll use the cc mouse and what we'd expect

**Commented [PD54]:** Linfa/Danielle – could you put a couple of sentences in on what we might do with the models. Remember – this could be an additional short project from the EIDCC extra funding.

**1.6. Potential problems/alternative approaches:** Challenges with logistics or obtaining permission to for wildlife sampling in sites we select~~sample bats in sites or provinces we select~~. We have a >20-year track record of successful field work in Malaysia, ~~Thailand and and~~ >10 years in ~~Thailand~~Singapore, and have ~~worked with~~strong established partnerships with local wildlife authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based ~~on a range of PCR data and are fairly conservative in our approach~~on realistic detection rates from our extensive preliminary data, and are confident that we will detect and identify large numbers of potentially zoonotic pathogens, particularly for CoVs and PMVs. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses~~We acknowledge that FV strain diversity may be harder to capture, given relatively low seroprevalence in bat populations – suggesting lower levels of viral circulations (40, 41). However, our team was the first and among the only groups to sequence FV RNA from Asian wildlife species(44, 45, 55), and we are confident that with our targeted sampling and testing strategy will identify additional strains of Ebola and related viruses.~~ The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (144), do not suggest a strong pattern of seasonality in CoV shedding, ~~although there are studies that suggest this and where seasonal patterns do occur, i.e. for in henipaviruses and filovirus (MARV?) shedding (REFS?) in Thailand (145) or can be predicted from wildlife serology data, we will be sure to~~ ~~Nonetheless to account for this we will~~ conduct sampling ~~evenly on quarterly basis within each province at different timepoints throughout the year to account for this.~~

**Aim 2: Test evidence of viral spillover in high-risk communities using novel serological assays.**

Commented [KJ055]: Emily and Noam reworking this section significantly, so not touching it much.

Country, site	Lead	# enrolled, focus	Findings
Peninsular Malaysia	Hughes	1,390 Orang Asli indigenous population, PCR/serol.	25+ novel CoVs, influenza, Nipah ab+ve, filovirus ab+ve
Malaysia Sabah	Kamruddin	1,283 serology	40% JE, 5% ZIKV ab+ve
Malaysia Sabah	William	10,800 zoonotic malaria	High burden of macaque-origin malaria
Malaysia Sabah	Hughes	150 bat cave workers	Ongoing
Malaysia Sarawak	Tan	500 Bidayuh and Iban people	8% PCR prevalence HPV in women

Malaysia PREDICT	Hughes	9,933 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Thailand	Wacharapluesadee	1,000 bat guano harvesters/villagers	Novel HKU1-CoV assoc. clinical findings
Thailand PREDICT	Wacharapluesadee	9,269 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Singapore	Wang	856, Melaka virus	7-11% ab+ve

**2.1 Rationale/Innovation:** Rapid response requires early detection. Thus, assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that interface frequently with wildlife that harbor high risk emerging viral strains.

To enhance the low statistical probability of identifying these rare events, we will target rural human communities inhabiting regions of high wildlife biodiversity, that also engage in practices that increase the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will build and expand on our preliminary biological sampling and enroll large cross-sectional samples in human populations with high behavioral risk of exposure to wildlife-origin viruses and that live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will initially identify 2 sites in each of Thailand, Peninsular Malaysia, Sarawak, and Sabah for repeated biological sampling. We will design and deploy behavioral risk factor questionnaires, and specific and sensitive serological assays to identify the baseline frequency, and causes of, spillover of known and related novel viral pathogens in these populations. In participants where symptoms are reported in the last 10 days, paired serum specimens (acute and 21 days after fever) will be collected to determine titer of positive antibody. Samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, and for isolation and biological characterization of potential pathogens, using the approach laid out in Aim 1.

**2.2 Preliminary data on high-zoonotic risk human community surveillance: 2.2.a Biological sample collection in SE Asia:** Our longterm collaboration in the region has included qualitative and quantitative survey data, and collecting large archives of banked human sera and other biological samples from high zoonotic-risk populations. For example, under the USAID-PREDICT project, EHA has collected 9,933 and 9,269 specimens in Malaysia and Thailand respectively from people living in zoonotic disease interfaces, all of which will be available for retrospective serological testing by EID-SEARCH. Our core group has collected and tested many thousand additional specimens from other important community cohorts (Table 2), and some of these will continue under EID-SEARCH (See section 2.4). Of particular interest is the access to indigenous communities in Peninsular Malaysia (Orang Asli) and Sarawak (Bidayuh, Iban people), and the bat guano harvesters in Thailand. These communities hunt, butcher and eat wildlife daily, and work in supremely high-risk zoonotic interfaces (e.g. bat caves). One of our indigenous community sites is experiencing an ongoing outbreak of unknown etiology that we are investigating currently (See section 3.2.a).

**Table 2:** Current or recent biological sample collection from healthy populations conducted by members of our consortium in EID-SEARCH hub countries

**2.2.b Human Contact Risk Factors:** EHA is the lead organization across all 27 USAID-PREDICT project countries for collecting data on, and analyzing the human aspects of, zoonotic spillover risk (146, 147). We conducted exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities, using these data to assess local social and cultural norms underlying wildlife contact (147). We then developed a risk factor survey to accompany human biological sampling to evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in 27 countries, and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). For example, survey and biological samples were collected from: 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, China; 1,400 participants from 4 sites in Malaysia; and 678 participants from 4 sites in Thailand. Samples were tested with novel serological assays and results analyzed against risk factors from survey data (12). In China, CoV-seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan

**Commented [KJ056]:** Check these numbers, don't think we have 9000 people sampled, if this represents individuals! Per below, we say we have 9000 specimens, not people, so need to adjust.

**Commented [KJ057]:** Emily: Will we be sampling participants more than once?

**Commented [PD58]:** I think that would be good, depending on the sample size

**Commented [KJ059]:** Need to decide if we do PCR on community samples, we can add in the questionnaire if you've been sick in the last 10 days and if so, then maybe test only this subset.

**Commented [PD60]:** Kevin's comment makes sense to me

**Commented [KJ061]:** Don't match table numbers, need to change table header to # specimens, not # enrolled.

province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), that are male (6/9). Although these results are preliminary and don't provide detailed information on routes of exposure, they identify key subpopulations to target that would likely increase the opportunity for identifying evidence of spillover for other CoVs, paramyxoviruses and filoviruses. Data from PREDICT surveys will be used to help identify target populations in Aim 2, identify strategies to better target at-risk people, and conduct focused **human animal contact surveys and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.** In Aim 2, we will use combined biological sampling and risk factor surveillance in targeted populations within the community to 1) identify risk factors correlated with seropositivity to henipaviruses, filoviruses and CoVs; 2) assess possible health effects of infection in people; and 3) where recent illness is reported, obtain clinical samples for PCR testing and potential viral isolation and characterization. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**2.2.c. Risk factors for illness:** Our preliminary data from PREDICT in Thailand, Malaysia and China revealed that frequent contact with wild (e.g. bats, rodents, non-human primates) and domestic animals (e.g. poultry, swine) among local communities was associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms. In addition, people involved in crop production, hunting and butchering of wildlife reported statistically significantly higher SARI and ILI symptoms (Li *et al.*, in prep.). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with further refining serological tools, we will be able to identify the likely routes of exposure to known or novel coronaviruses, henipaviruses, and filoviruses in the study region, as well as build data on the illnesses they cause in people.

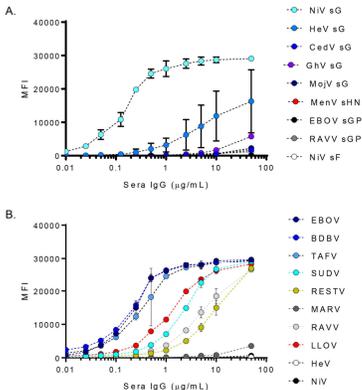

**2.2.d. Serological platform for community surveillance:** One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. By contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes (148). However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. Henipaviruses, filovirus and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filoviruses/henipaviruses=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (149)?, developing monoclonal antibodies (150, 151) and as subunit vaccines (152, 153), is presently developing a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, filoviruses and coronaviruses. This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (149). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

Commented [KJO62]: Peter, sent over LASSO figure for ILI from Thailand and Malaysia for you to consider.

Commented [PD63]: Chris/Eric Is this the right ref?

Commented [KJO64]: See my comment in Aim 1 that some of that serology platform stuff can be moved here.

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay. The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (Fig. XXX). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-related African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (76, 77). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus

henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (154-156). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity. The majority of ebolaviruses are endemic to Africa, however the discovery of Měnglà virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown pathogenicity and zoonotic potential exists. Our past work in collaboration with Duke-NUS demonstrated that three under-sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (41).

**Fig. XXX:** Validation of multiplex microsphere immunoassay

(MMIA) specificity and identification of immunologically cross-reactive viruses for Nipah (A) and Ebola (B).

**2.3 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (Fig. XX). In Aim 2 we will conduct community-based surveillance using a brief, focused questionnaire to identify the prevalence and frequency of risk-factors for viral spillover in tandem with collection of high quality biological samples to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the communities sampled in Aim 2. Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and PCR prevalence in symptomatic patients.

**2.4 Target population & sample sizes:** We will target populations in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, that are EID hotspots, and that are well-connected through regional travel and trade hubs to the global travel network (Fig X). We will target specific communities based on our analysis of previously-collected PREDICT behavioral questionnaire data, to assess key at-risk populations and occupations with high exposure to wildlife, as well as using other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will identify populations at two sites in each of the following regions, building on our preliminary data (Table 2): *Thailand (Co-I Wacharapluesadee)*: We will continue surveillance in bat guano harvesters and their villages in Ratchaburi province where we have identified MERS-related CoV in bat guano and rectal swabs (48, 157) and serological evidence of  $\alpha$ -CoVs, HKU1-CoV in people (Wacharapluesadee in prep.). Our second site will be in Chonburi province where we have found Nipah virus (99% identity of whole genome sequence to NiV from a Bangladesh patient) in flying foxes but no outbreaks have yet been reported (REFThai MOPH, unpublished), and have found several novel paramyxoviruses and CoVs have been found in bat feces roosting there ((158, 159) Wacharapluesadee in prep.).

**Commented [PD65]:** Hongying -Need a new figure that lays out the community/clinical approach – small one with pretty images.

**Commented [PD66]:** Supaporn/Kevin/ -Need sample sizes for both populations and power calculations for serology for a typical virus from one of the three families we're targeting

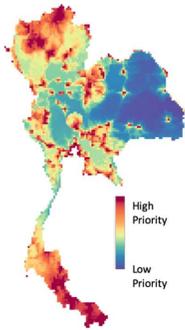

**Commented [KJO67R66]:** I pasted in info from Supaporn below.

**Commented [PD68]:** Supaporn – please insert a reference into this comment box

**Commented [KJO69]:** Added in a couple more of her refs.

Sample size: Serological exposure likely low due to low risk of onward transmission. High risk occupational groups vs. community sample at each site. Need to stratify sampling in villages based on

Thailand: 100 subjects of healthy high-risk community from 2 study sites (Chonburi and Ratchaburi) will be enrolled on Year 2 and tested for antibody, and specimen from ill subject will be collected and tested by PCR and serology assays. Specimens from same subject will be collected on Y3 and Y4 for serology re-testing.

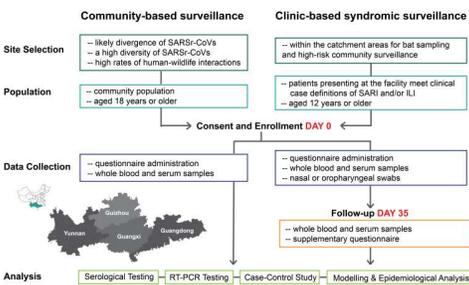

**Fig. X:** Geographic analysis to target high-risk sites for human zoonotic disease surveillance in Thailand. Our spatial analysis from Aim 1 will be extended to optimize sites for human community surveillance in Thailand and Malaysia by ranking areas with high numbers of expected viruses in wildlife, greater spillover probability based on EID risk factors, and higher levels of connectivity (measured by road density data) that may facilitate person-person spread.

**Peninsular Malaysia (Co-I Hughes, CM Ltd.):** We will expand our sampling of the Orang Asli indigenous communities to include additional communities in the 3 Districts we have already sampled, and additional Districts in the States of Kelantan Perak, Pahang, and Kelantan. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled. Human samples will include serum, whole blood, throat swabs, nasal swabs, urine, and fecal sample or rectal swab. Samples will be collected in duplicate in VTM and Trizol. Samples will be stored and tested at NPHL. Participants who hunt, butcher or consume wildlife, or who rear animals will be considered suitable

for enrolment. Participants will complete a consent form and questionnaire in addition to having samples collected. During these community trips the field team will conduct community meetings to help inform the Orang Asli about the public health risk of zoonoses. **Sarawak (Co-I Tan, UNIMAS):** We will expand our sampling of the Bidayuh and Iban indigenous people to include the Dayak and Orang Ulu ("people of the interior") because this group has a more intimate connection to remote wildlife-rich areas than the other two, albeit all are hunters. Human sampling will be led by UniMAS in collaboration with CM Ltd / EHA. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled, following the same protocols as for Peninsular Malaysia. **Sabah:** We will conduct sampling at the Madai bat and bird cave that has 200 permanent residents who harvest bird's nests for soup, and >1,000 during the harvesting season and at Gomantong cave – one of the largest bat and cave swiftlet nesting sites in the world. Protocols follow those for Peninsular Malaysia. **Singapore:** Active human surveillance will not be conducted in Singapore, but archived human specimens e.g. from our Melaka virus serosurvey (4), will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

**Sample sizes:** From our previous work we anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so

that they make up  $\geq 30\%$  of the sampled population in each community. We will stratify sampling to ensure appropriate representation of sex, demographic, and socio-economic factors at each community site. Estimating 5% overall seroprevalence in these high-exposure populations, these sample sizes are sufficient to estimate effect sizes of risk factors of 2X or greater with 80% power. For community-based surveillance, we will enroll xxx individuals per county/province, pooled across two sites for each, allowing us to make county/province-level comparisons of differing effects.

**Commented [S70]:** I think the animal and human specimen collection should be in a same format for Thailand and Malaysia.

**Commented [PD71]:** Need this figure for Singapore, Pen. Malaysia, Sarawak, Sabah as well – all together is best

**Commented [KJ072R71]:** Sam is going to send a combined figure tomorrow AM.

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**2.5 Data & sample collection:** Following enrollment of eligible participants and completion of the consent procedure, biological specimens (5ml will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 2.5ml whole blood; two 500 µL serum samples) will be collected and a questionnaire will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent considerations for participants enrolled from clinical settings we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

**2.6: Laboratory analysis: 2.6.a Serological testing:**

In a previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity detected (12). **This suggests that if we can expand our serology tests to cover other bat CoVs, and that doing so may identify many more seropositive individuals.** We will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 bat SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoVs SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (12), and HKU10 is known to jump from one host bat species to another (160) so is likely to have infected people more widely. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV, at a phylogenetic distance where therapeutic or vaccine efficacy may falter. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or S1 (n-terminal domain); 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (13). Additionally, in Thailand, as an initial project on our EIDRC, we will develop serology assays to the novel CoVs found in bats at the bat guano site using LIPS assays and viral genomic data, and will screen archived specimens from 230 participants (2 years' collection in 2017-2018, a subset of the subjects have been sampled at multiple timepoints to allow us to assess seroconversion).

**2.6.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b.4.c for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E, NiV, HeV, Ebola (WHO PCR protocol) based on the symptom as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

**2.6.c Biological characterization of viruses identified:** Novel viruses identified in humans will be recovered by cultivation or from full length genome sequences using reverse genetic approaches. Viruses will be characterized for growth in primary human cell lines and in mouse models, including the Collaborative Cross

**Commented [PD73]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipas, filoviruses and CoVs.

**Commented [PD74]:** Emily/Hongying Please check

**Commented [PD75]:** Chris, Eric, Linfa, Dani etc. please draft some language here...

**Commented [PD76]:** HELP – please add text for Henipas, filoviruses

**Commented [MOU77]:** Supaporn: These should be depending on the viruses found in wildlife animal from the studied countries.

Mice or humanized mice expressing human receptors from related strains. The approaches are discussed in more detail under Aim 1.

**2.7 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for Henipavirus, Filoviruses, and CoVs spillover. “Cases” are defined as participants whose samples tested positive for Henipavirus, Filoviruses, or CoVs by serological tests. “Controls” will be selected from the pool of participants admitted to the studies and whose samples tested negative for Henipavirus, Filoviruses, or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between Henipavirus, Filoviruses, or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, paramyxoviruses, and influenza viruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may not match known viruses due to recombination events, particularly for CoVs.** We will use the three-tiered serological testing system outline in 2.6.a to try to identify these ‘novel’ viruses, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

**Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research (Table 1) and other data suggests that there are substantial numbers of outbreaks or clinical cases for which the etiologic agent is not diagnosed, e.g. (161, 162). To investigate this in SE. Asia, we will work directly with clinics and outbreak control organizations to identify the causes of some ‘cryptic’ outbreaks or cases in the region. Specifically, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and who present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We conduct novel viral discovery assays on patients who present with symptoms indicative of a high-risk zoonotic virus. If novel pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the pathogen, using the *in vitro* and *in vivo* strategy laid out in Aim 1.

**3.2 Preliminary data clinical surveillance: 3.2.a. Clinical surveys and outbreak investigations:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes: ***Peninsular Malaysia: At the time of writing, there is an outbreak of suspected viral undiagnosed illness in the indigenous Batek Orang Asli (“people of the forest”) community living at Gua Musang (“civet cat cave”) district, in Kelantan, Malaysia, close to Taman Negara – a National Park containing the oldest known rainforest. This community is one where we have conducted prior routine surveillance and biological***

**Commented [KJ078]:** Make this more general. There’s a greater challenge of interpretation of serological data, esp. if we’re using many platforms (each will have its own problems that our lab colleagues are probably more familiar with). Noam may be able to generally comment on a solution here from a statistical perspective.

**Commented [PD79]:** Kevin – please modify according to your comment

**Commented [KJ080R79]:** Noam is working on this section, so can review after/tomorrow.

sampling, demonstrating proof-of-concept that our two-pronged high-risk community/clinic approach will work. Dozens of people are affected and the outbreak is currently being investigated by our collaborators at the Malaysian NPHL. The Orang Asli live in remote villages in the rainforest of Malaysia, with limited access to modern health care and extensive contact hunting, butchering, and eating wildlife as their primary source of protein. This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC - to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia. **Investigating this outbreak be a key priority if EID-SEARCH is funded.** *Sabah:* Co-I Kamruddin (BMHRC) is leading an asymptomatic leptospirosis study on sanitation workers, an ILI study in a Kota Kinabalu clinic and diarrheal study in children under 5 yrs. Co-Is William, Tan and others have conducted clinical observational studies to determine the etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah. Co-Is Tan, William have collaborated with Co-I Wang to enroll 90 adult and over 100 pediatric participants with central nervous system infections, negative tests for malaria and dengue from 3 district hospitals in Sabah to determine the various etiologies. While a high proportion tested positive for rickettsial agents, the majority had no clear diagnosis. *Sarawak:* Dr Tan (UNIMAS) is conducting a survey of high-risk female Kelabit indigenous people and has found 8% with HPV52 as the dominant strain. He is working on clinical cohorts of hand, foot and mouth disease and will recruit patients from that study in the current proposed work. Finally, he is conducting a longterm study of rotavirus and other viral etiologies of acute gastroenteritis in Kuching, Sarawak that will include swine herders and farmers. These are an important group in Malaysia because pig farms are shunned by the government and local villagers to they are placed far away from town centers, deep in the forest, and it is this scenario that led to the emergence of Nipah virus in 1998-9 (18, 163). *Thailand:* The Chulalongkorn Univ. TRC-EID laboratory works in coordination with the Thailand Ministry of Health to investigate outbreak etiology, including the first case of imported MERS-CoV in Thailand, **for which we produced sequence confirmation within 24 hours from acquiring the specimen** ~~(Fig. X)~~. Three imported MERS cases have been detected in Thailand since 2015, and all cases were confirmed at the TRC-EID. We worked during the Zika outbreak to identify > 500 PCR-positive Zika patients with sequence confirmation. We have also worked on returning and suspected Ebola travelers, syndromic surveillance for SARI, Encephalitis, Hand Foot and Mouth disease in children and Viral diarrhea. Working with the US CDC (Thailand), between 1998 and 2002 we enrolled a large cohort of children from Kamphaeng Phet Province to examine Dengue virus and JE epidemiology (164, 165). Among the 784/2,574 convalescent sera Henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence), suggesting prior exposure to endemic henipaviruses or a related paramyxovirus in rural Thailand. *Singapore:* Duke-NUS has worked with the Ministry of Health to investigate Zika cases (166), and with EcoHealth and others, Duke-NUS has developed novel CoV assays for clinical surveillance, and for expedited analysis during outbreaks. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing is as rapid as several months, with the development of novel serological assays from sequence data in 7 days (13). **For example, with the discovery of SADS-CoV, we identified and fully sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (*Rhinolophus* spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (13).**

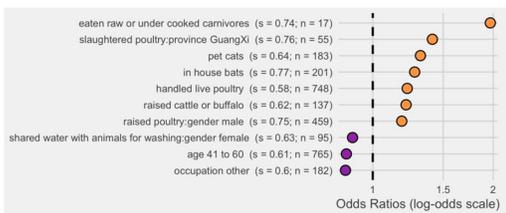

**3.2.b Analysis of self-reported illness:** In addition to biological outcomes we have developed a standardized approach in PREDICT for analyzing data on self-reported symptoms related to targeted illnesses; of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), fever with muscle aches (fevers of unknown origin (FUO) and, cough or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI and/or SARI symptoms and demographics, occupation, and contact with animals in the last year. Results have clear biological relevance. In Yunnan, China, salient associated variables or combination of variables were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (Fig. 11). We will expand this approach for all syndromes in Aim 3, and use more granular targeted questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country.

Formatted: Underline

Commented [KJO81]: Deleted sentence below, because reality is, not likely an issue in ~4-6 months when we get funded and seems to be measles. Should play up as an example, but not an actual item for follow up..

Commented [MOU82]: Replace w Malaysia or Thailand LASSO

**Fig. 11:** Associated variables of self-reported ILI and/or SARI in prior 12 months ( $s$  = bootstrap support;  $n$  = number +ve out of 1,585 respondents). **Orange circles** = odds ratios > 1 (positively associated with the outcome); **purple** = odds ratios <1 (negatively associated with the outcome).

**3.3 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms

typical of high-impact emerging viruses. We will collect survey data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.4 Clinical cohorts. 3.4.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at 2 town-level level clinics and 2 provincial-level hospitals in Thailand, Peninsular Malaysia, Sabah and Sarawak. These all serve as the catchment healthcare facility for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients  $\geq 12$  years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, fevers of unknown origin, or hemorrhagic fever will be recruited into the study. We will enroll a total of xxxx individuals for clinical syndromic surveillance, which accounts for up to 40% loss from follow-up. Study data will be pooled across country sites, as clinical patients are limited by the number of individuals presenting at hospitals. Sites: Thailand: Two new district hospitals at the same site of high-risk community will be included to the study to collect specimens (PREDICT sample protocol) from patients with respiratory and/or encephalitis symptom during 3 years of the study (Year 2 to Year 4), at least 100 patients from each hospital will be enrolled and laboratory tested by PCR and serology assays. The second blood after 21 days of fever will be collected for serology testing. -XXXXX Peninsular Malaysia: Focusing immediately on the current outbreak in Orang Asli, we will work closely with the Malaysian Ministry of Health to support their investigation. We will also work with 6 Orang Asli clinics which focus solely on this indigenous community. Sarawak: XXXXXX Sabah: XXXXXXXXXX. Singapore: XXXXX Given budget constraints we will not do clinical cohorts, however in the event of a suspected outbreak we have close relationships with xxxxx xxxxx hospitals and central reference lab.

**3.4.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever of unknown etiology; or 6) severe diarrhea. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance of PCR detection of viruses (167). We will follow up 35 days after enrollment to collect an additional two 500  $\mu$ L serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs  $\leq 28$  days after onset of symptoms for SARS patients (168). These samples may prove valuable to collaborators in that the PBMC could be used in production of therapeutic antibodies.

**3.4.c Sampling:**

Commented [KJO83]: Pasted in from Supaporn.

Commented [KJO84]: Make sure this matches our timeline and target numbers. Noam to calculate minimum samples size for detection assuming 1-3% ?? viral prev. Need some refs or data on detection rate for "novel" etiological agents.

Commented [PD85]: Tom, Kevin – we need information.

Commented [KJO86]: Linfa/Dani?

Commented [PD87]: Hongying Emily

Commented [PD88]: Need data for Nipah and filovirus patients

Commented [PD89]: Ralph: PBMC could be valuable for making therapeutic antibodies through collaborations?

Following enrollment with signed consent form, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples) including two nasal or oropharyngeal swabs will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

Commented [KJO90]: Blood just during 35 day follow up, or both? I guess both ideally, but weigh against IRB.

### 3.5 Sample testing: PCR, Serol to link symptoms to etiologic agents

The standard syndromic diagnostic PCR assay for the common pathogens will be conducted and the results will be shared to the hospital with 48 hours. Specimens will be further tested for 3 viral families; CoV, PmV and filovirus by consensus PCR. Appropriate specimen from dead case will be further conducted by NGS if the previous PCR tests are negative to identified cause of infection. The serology panel assay will be conducted from paired serum.

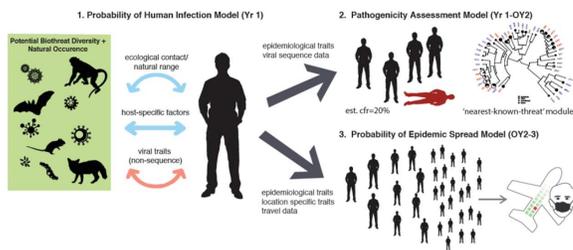

Commented [PD91]: This is v. weak – can someone strengthen it please!

Serology: Panel serology assay will be performed from paired serum to determine the four fold raising antibody. The specific primer PCR of the virus antibody positive case will be further tested from acute specimens to confirm for infection.

Commented [KJO92]: Text from Supaporn

Commented [PD93]: This is v. weak – can someone strengthen it please!

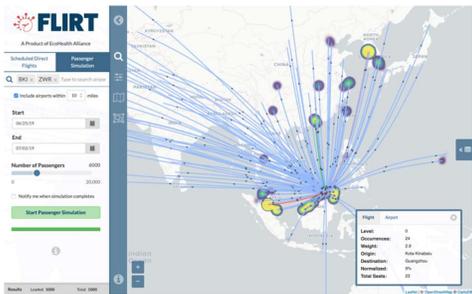

**3.5 Assessing potential for pandemic spread:** Building off our spillover risk characterization in Aim 1, wWe will use statistical models built from collated biological, ecological, and genetic data to predict further assess the likelihood of human infection (or spillover) and also pathogenicity for a the range of diverse viruses we will characterize. The aim is to quickly identify and assess which viruses pose the most significant risk to human health and thus prioritize additional resources to more fully characterize, better understand pathogenicity, and invest in therapeutic development for those pathogens. We will combine two independent but related statistical models to predict pathogen spillover risk and pathogenicity. First, we will expand a simple generalized additive modeling approach (90) to assess spillover risk probability to a new virus that is currently not known to infect people, when we have only limited genetic data from initial PCR screening and sequencing. Additional data from receptor binding protein homology and cell line infection experiments can will be incorporated into the model framework as available. Second, given high likelihood to spillover and infect humans, or direct evidence of human infection from our clinical surveillance, we will then predict pathogenicity using nearest neighbor phylogenetic analyses as a first approximation and by incorporating more detailed data from genomic characterization and animal model experiments (Aim 1). For the pathogenicity model, hEuman epidemiological trait data for ~300 viral species known to infect people (e.g. case fatality rate, global estimates of number of human cases per year or decade, R<sub>0</sub>, infectious period, and primary symptoms) will be aggregated including from have been collated by recent studies -previous and will be used as reviews [Woolhouse ref] to use as predictor variables. Thirdly, we will build off apply tools already developed, and being refined by EHA under's previous DTRA and DHS supported research, to predict pandemic spread for viursesviruses we identify by integrating surveillance site data using global flight models (169), as well as additional datasets (road networks, shipping routes, cell phone data) to measure on human movement and connectivity across Southeast Asia.

**Fig. XXXX:** Conceptual framework highlighting 3 underlying models to estimate: 1) probability of human infection, or spillover, the first necessary step to understand pathogenicity when status of human infection is unknown; 2) pathogenicity, i.e. probability of causing clinical signs, case fatality rate estimates, and other metrics relevant to humans; and 3) probability of pathogen spread based on ecological, epidemiological, and airline connectivity and human migration data.

**Commented [PD94]:** Hongying – please work with Kevin to come up with something of relevance here. Also, make the text brief, bold and large so it's readable

**Commented [KJO95]:** See also FLIRT flight simulator figure below. Peter, let's decide if I should rework this figure to combine both, or how to proceed with this section.

**3.7 Potential problems/alternative approaches:** Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases. Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (167). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the

**Commented [PD96]:** Add data for Nipah and filio infections

potential public health importance of discovering active spillover of a new henipavirus, filiovirus or CoV infection.

**Additional Instructions – Specific to the EIDRC FOA:**

**4. Administrative Plan**

In a clearly labeled section entitled “Administrative Plan”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.

Chula TRC-EID is National reference laboratory for diagnostic and confirmation of EIDs pathogen along with the National public health laboratory at the Department of Medical Science and the WHO Collaborating Centre for Research and Training on Viral Zoonoses. We have built a EID laboratory network in-country among three Ministry including Ministry of Public Health (Department of Medical Science and Department of Disease Control), Department of Livestock and Development, and Department of National Parks, Wildlife and Plant Conservation and Universities and among SEARO countries. Our clinicians provide case consultation for Thailand and SEARO countries. The laboratory and clinic training are regularly conducted.

**Commented [PD97]:** All – I've started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**Commented [PD98]:** From Supaporn

**For Malaysia –**

**NPHL** – Molecular and serological screening (BioPlex) of PM Orang Asli samples, serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval)

**PERHILITAN molecular zoonosis laboratory, at the National Wildlife Forensic Laboratory** - Molecular and serological screening (BioPlex) of PM wildlife samples

**UPM Faculty of Veterinary Medicine** - Molecular and serological screening (BioPlex) of PM livestock samples

**KKPHL** - Molecular of syndromic samples from Sabah (already done) and Sarawak (would need approval)

**SWD WHGFL** - Molecular screening of Sabah wildlife samples

**BMHRC** - Molecular and serological screening (BioPlex) of Sabah livestock samples, serological screening (BioPlex) of Sabah wildlife samples, Molecular and serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval). BMHRC will need renovations and BioPlex to do this work – Menzies team might have funds for BioPlex that they would base here as part of DTRA project.

- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

**List out all of our involvement with outbreak investigations, ministries of health surveillance etc.**

If possible the clean or summarized answers from the questionnaire should be shared to the hospital Infectious Control team and Bureau of Epidemiology for their information for controlling the outbreak.

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

CM/EHA helped establish and manages with SWD the Wildlife Health, Genetic and Forensic Laboratory (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications) that has all the equipment necessary to store samples, run extractions, PCR and analysis on biological samples for wildlife disease surveillance. The lab is used to conduct health checks on rescued and relocated wildlife before being released into new areas or sanctuaries, to screen samples for the PREDICT and Deep Forest Project and for genetic research and forensic investigations. CM/EHA also helped establish the new molecular zoonosis laboratories (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications), at DWNP's National Wildlife Forensic Laboratory. The lab is used to screen samples for the PREDICT & DTRA projects. In addition CM/EHA also has access to NPHL and KKPHL for screening human samples and the Virology lab at FVMUPM for screening Livestock samples.

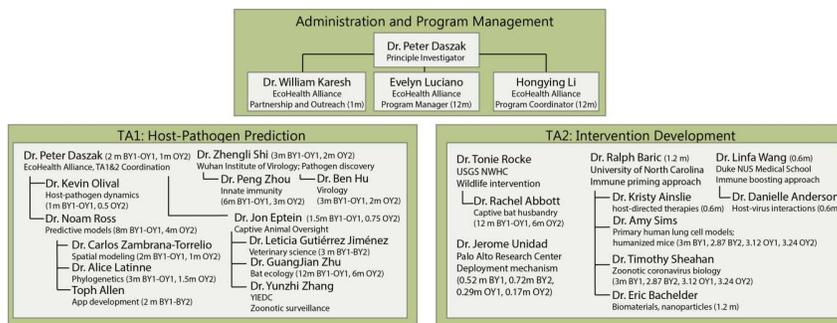

The Borneo Medical and Health Research Centre (BMHRC) is a centre of excellence that conducts teaching and scientific researches on communicable diseases, outbreak investigations, and ethnomedicine. BMHRC has offices space including a meeting room and seven laboratories which including preparation lab, parasitology lab, cell culture lab, bacteriology lab, natural product lab, virology lab, and molecular biology lab.

**Commented [PD99]:** From Supaporn – do same for all countries

BMHRC is supported by an administration staff, medical lab technologist, and research assistants who are available to work on projects. Through this project we will help to establish a certified BSL-2 lab at the BMHRC. This lab can then be used for human testing to elevate pressure at KKP HL and QEHL labs. It would also be an ideal location for a Luminex platform as human, wildlife and livestock samples could all be screened here. Co-Is Hughes and Kamruddin will be starting outbreak response training in August 2019 with a team from Sabah CDC, KKP HL and BMHRC. (Dr. Maria Suleiman now in PM But still collaborating with us, Dr. Muhammad Jikal current Director CDC working with us and Dato' Dr Cristina Rundi Director Sabah state health Dept is supportive) this collaborative group is working to develop a Sabah outbreak response team that will help support SSSH/ CDC outbreak team and also conduct sampling for disease surveillance to be based at BMHRC and we will develop this as part of this proposal. In addition the UMS hospital will come in line in 2021 providing additional opportunities for cohort studies and capacity building.

FROM DARPA grant:

**Section 1.03 MANAGEMENT PLAN**

Project DEFUSE lead institution is EcoHealth Alliance, New York, an international research organization focused on emerging zoonotic diseases. The PI, Dr. Daszak, has 25+ years' experience

Commented [KJO100]: Figure like this would be good, but instead of breaking down by TA, maybe by country or Specific Aim. Per FOA, Need to also show how we'll link in with the Coordinating Center and other EIDRCs.

managing lab, field and modeling research projects on emerging zoonoses. Dr. Daszak will commit 2 months annually (one funded by DEFUSE, one funded by core EHA funds) to oversee and coordinate all project activities, with emphasis on modeling and fieldwork in TA1. Dr. Karesh has 40+ years' experience leading zoonotic and wildlife disease projects, and will commit 1 month annually to manage partnership activities and outreach. Dr. Epstein, with 20 years' experience working emerging bat zoonoses will coordinate animal trials across partners. Drs. Olival and Ross will manage modeling approaches for this project. Support staff includes a field surveillance team, modeling analysts, developers, data managers, and field consultants in Yunnan Province, China. The EHA team has worked extensively with other collaborators: Prof. Wang (15+ yrs); Dr. Shi (15+ yrs); Prof. Baric (5+ yrs) and Dr. Roche (15+ yrs).

**Subcontracts: #1** to Prof. Baric, UNC, to oversee reverse engineering of SARSr-CoVs, BSL-3 humanized mouse experimental infections, design and testing of targeted immune boosting treatments; **#2** to Prof. Wang, Duke-NUS, to oversee broadscale immune boosting, captive bat experiments, and analyze immunological and virological responses to immune modulators; **#3** to Dr. Shi, Wuhan Inst. Virol., to conduct PCR testing, viral discovery and isolation from bat samples collected in China, spike protein binding assays, humanized mouse work, and experimental trials on *Rhinolophus* bats; **#4** to Dr. Roche, USGS NWHC, to refine delivery mechanisms for immune boosting treatments. Dr. Roche will use a captive colony of bats at NWHC for initial trials, and oversee cave experiments in the US and China. **#5** to Dr. Unidat, PARC, to develop innovative aerosol platform into a field-deployable device for large-scale inoculation of the bats. Dr. Unidat will collaborate closely with Dr. Roche in developing a field deployable prototype for both initial trails and cave experiments in China.

**Collaborator Coordination:** All key personnel will join regularly-scheduled web conferencing and conference calls in addition to frequent ad hoc email and telephone interactions between individuals and groups of investigators. Regular calls will include:

- Weekly meetings between the PI and Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.
- Monthly web conferences between key personnel (research presentations/coordination)
- Four in-person partner meetings annually with key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

Evaluation metrics will include the generation of high-quality data, successful achievement of milestones and timelines, scientific interaction and collaboration, the generation of high quality publications, and effective budget management. The PI and subawardee PIs will attend a kickoff meeting and the PI will meet regularly with DAPRA at headquarters and at site visits.

**Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by Dr. Daszak and the Project Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation. Should a resolution not be forthcoming, consultation with our technical advisors and DARPA Program staff may be warranted.

**Risk management:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. A project of this nature requires a different mindset from that typically associated with basic research activities that move at an incremental pace with investigators gradually optimizing experimental systems, refining data, or waiting for additional data before moving ahead with an analysis approach. To maintain our timeline, we will continually evaluate these trade-offs to make decisions about when iteration is appropriate and when necessary to move forward with current information.

#### **Biographies:**

**Dr. Peter Daszak** is President and Chief Scientist of EcoHealth Alliance, Chair of the NASEM Forum on Microbial Threats, member of the Executive Committee and the EHA institutional lead for the \$130 million USAID-EPT-PREDICT. His >300 scientific papers include the first global map of EID hotspots, estimates of unknown viral diversity, predictive models of virus-host relationships, and evidence of the bat origin of SARS-CoV and other emerging viruses.

**Prof. Ralph Baric** is a Professor in the UNC-Chapel Hill Dept. of Epidemiology and Dept. of Microbiology & Immunology. His work focuses on coronaviruses as models to study RNA virus transcription, replication, persistence, cross species transmission and pathogenesis. His group has developed a platform strategy to assess and evaluate countermeasures of the potential “pre-epidemic” risk associated with zoonotic virus cross species transmission.

**Prof. Linfa Wang** is the Emerging Infectious Diseases Programme Director at Duke-NUS Medical School. His research focuses on emerging bat viruses, including SARS-CoV, SADS-CoV, henipaviruses, and others and genetic work linking bat immunology, flight, and viral tolerance. A 2014 recipient of the Eureka Prize for Research in Infectious Diseases, he currently heads a Singapore National Research Foundation grant “Learning from bats” (\$9.7M SGD).

**Commented [PD101]:** Some of references in this section are duplicates

Malaysia – **CM Ltd**: Borneo Medical and Health Research Center (Ahmed Kamruddin), Department of Wildlife and National Parks Peninsular Malaysia (Frankie Sitam, Jeffrine Japning, Rahmat Topani, Kadir Hashim, Hatta Musa), Hospital Universiti Malaysia Sabah (Helen Lasimbang), Faculty of Medicine, Universiti of Malaya (Sazaly Abu Bakar), Kota Kinabalu Public Health Laboratory (Jiloris Dony, Joel Jaimin), Ministry of Health (Chong Chee Kheong, Khebir Verasahib, Maria Suleiman), National Public Health Laboratory (Hani Mat Hussin, Noorliza Noordin, Yu Kie Chem), Queen Elizabeth Hospital (Giri Rajahram, Heng Gee Lee), Sabah State Health Department (Christina Rundi, Mohammad Jikal), Sabah Wildlife Department (Rosa Sipangkui, Senthilvel Nathan, Augustine Tuuga, Jumrafiah Sukor), Gleneagles Hospital Kota Kinabalu (Timothy Wiliam); **BMHRC**: CM Ltd (Tom Hughes), HQEII (Shahnaz Sabri), Kota Kinabalu Public Health Laboratory (Jiloris Dony), Sabah State Health Department (Mohammad Jikal)

Thailand – **CM Ltd**: Department of Disease Control, Ministry of Public Health (Rome Buathong, Pawinee Doungngern, Pongtorn Chartpituck ), Department of National Park, Wildlife and Plant Conservation (Pattarapol Manee-On), Faculty of Forestry, Kasetsart University (Prateep Duengkae), Mahidol-Oxford Tropical Medicine Research Unit, (Stuart Blacksell, Richard Maude), Chulalongkorn University (Supaporn Wacharapluesadee).

Chulalongkorn lab is a WHO Collaborating Centre for Research and Training on Viral Zoonoses, we work closely with WHO SEARO and SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste. We had conducted the PREDICT lab training for Veterinary lab in the Southeast Asia region for FAO. We conducted (transferred?) the bat sampling technique for scientists from Malaysia, Myanmar, the Philippines, and China.

## 5. Data Management Plan

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe

how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.

- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system

#### Language from NIH CoV grant:

**Data Sharing Plan:** Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited for in long-term public scientific repositories – all sequence data will be made publicly available via GenBank, species location data via the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestricted MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Viral isolates will remain at the Wuhan Institute of Virology initially. Isolates, reagents and any other products, should they be developed, will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Sharing Model Organisms:** We do not anticipate the development of any model organisms from this study. Should any be developed, they will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Genomic Data Sharing:** We anticipate obtaining genetic sequence data for 100s of novel coronavirus genotypes, including RNA-dependent RNA polymerase (RdRp) and Spike genes for all strains/genotypes. In addition, we will generate full viral genomes for a subset of the bat SARSr-CoVs that we identify. All sequence data will be deposited in the NIH genetic sequence database, GenBank. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also be submitted. The genotype data will be made publicly available no later than the date of initial publication or six months after the receipt of final sequencing data, whichever comes first. We anticipate sequence generation will occur over the 5 year proposed project period.

**Genome Wide Association Studies (GWAS):** Not applicable.

Commented [KJO102]: From CoV NIH grant

Thailand TRC-EID Chulalongkorn lab: Specimen management and BioBank: The software called PACS (Pathogen Asset Control System) supported by BTRP DTRA, is now used for managing the specimen from specimen registration (barcoding, and may move to use QR code system soon), aliquoting, tracking, short patient history record, data summary, searching, test reporting and etc. Our biobank system contains 28 freezers (-80C) and liquid N2 system. Its size is around 120 sq meters. There is a separate electric generator for our lab and biobank. There are CC TV cameras at the biobank and laboratory.

Chula TRC-EID has our own server for data management and analysis. We have the necessary software including Bioinformatic tools (Blast Standalone, SAMTOOL, GATK, AliVIEW, RaxML, FigTREE, MAFFT, Guppy, Megan, PoreChop, MEGA), Database (MySQL, MongoDB) Web, jQuery, Node.js, Express.js React,

API, PHP, Ruby, Python, Java, C#, HTML5, Bootstrap, CSS, Responsive, Cloud, Linux Command, PACS (sample management system), Virtualbox virtual machines, R programming languages, Perl scripts, Bash shell scripts, Open source software, Microsoft Office running on both Apple Mac OS X, Ubuntu, Linux, and Windows Operating Systems. Chula TRC-EID has a dedicated 16-core Ram 64GB Linux server with 4TB hard drives, dual quad-core Mac Pro Server with 2TB hard drives and another dedicated iMac Pro (Retina 4K, 21.5-inch, 2017) Processor 3.6GHz quad-core Intel Core i7 (Turbo Boost up to 4.2GHz) Ra, 16GB with 512GB hard drives. TRC-EID also has HPC Linux server CPU: 4 x 26cores Intel Xeon = 104 cores 2.1GHz with 52 TB HDD and 2x3.84TB SSD with GPU 2x Tesla v100 (CUDA core = 5120 cores/GPU, Tenser core = 640 cores/GPU). TRC-EID has a dedicated 10/100/1000 of LAN (Local Area Network), 2.4G / 5G Gigabit Wi-Fi 802.11ac.

Commented [KJO103]: From Supaporn for their lab, some may go in Facilities doc?

From DARPA:

**Data Management and Sharing:** EcoHealth Alliance will maintain a central database of data collected and generated via all project field, laboratory, and modeling work. The database will use secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations, and enable compliance with DARPA data requests and disclosure requirements. All archived human sample data will be de-identified. Partners will provide raw and processed data to the central database throughout the course of the project. Project partners will have access to the data they generate in the database at all times, and maintain control over local copies. Release of any data from the database to non-DARPA outside parties or for public release or publication will occur only after consultations with all project partners. EHA has extensive experience in managing data for multi-partner partner projects (PREDICT, USAID IDEEAL, the Global Ranavirus Reporting System).

Commented [KJO104]: Text from DARPA Preempt

## 6. Clinical Management Plan

### Clinical site selection

Our consortium partners have been conducting lab and human surveillance research, inclusive of human surveillance during outbreaks, for over the past two decades and in that time have developed strong relationships with local clinical facilities and processes. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1. These are regions where we will sample wildlife due to the high potential of zoonotic viral diversity. Additionally, these will be clinical sites that serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. In PREDICT we developed successful working relationships with the major healthcare facilities the hotspot areas in 6 different countries, including Thailand and Malaysia and we will continue to work with these sites going forward. Continuing to work with these hospitals means we will begin this project with successfully established partners and we can begin data collection quickly. This also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites for this study is limited. All that is required of sites will be the ability to enroll patients that meet the clinical case definitions of interest, capacity to collect and temporarily store biological samples, and follow standards for data management and protection. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently site staff. These will be persons who are locally trained and certified to collect biological specimen from participants including blood draw technique, e.g. doctor or nurse. Last, the clinical site will need the capacity to securely store all personal health information and personally identifiable research data, this will include locked offices with locked filing cabinets to store all paper records and an encrypted computer. Training on project procedures will be provided for all local project staff by local country project management staff and partners from headquarters. The study at clinical sites will begin by developing relationships with local stakeholders at the hospitals and clinics in our geographic areas of interest that serve as catchment facilities for people of within the community surveillance study. We will recruit hospital staff that will be extensively trained for project procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data

Commented [EH105]: Is that true

management plans. During the Development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data (e.g. locked filing cabinet, dry shipper, secure laptop). [Did not specifically address CONDUCT]. Oversight for clinical sites will be managed by the country coordinator for each country. This will be done with regular site visits to the clinical sites and annual visits by headquarter research staff. Site visits will include monitoring and evaluating the process for patient enrollment, collecting and storage of samples, administration of the questionnaire, and secure and data management procedures for secure personal health information and research data. During these visits any additional training will also be provided.

### **Standardized approach oversight and implementation**

Management and oversight for all study sites will be managed by the local country coordinator who is supported by staff at headquarters. Implementation of a standardized approach across all study sites, community and clinical, will begin by extensive training of staff on procedures on requirements of the project, this includes: enrollment, data collection, and data management. Our research team has over 5 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research. This includes SOPs for screening, enrollment, and retention of participants. In addition to yearly monitoring reports the country coordinator will regularly visit each clinical site to ensure quality standards and compliance of procedures are being met. Through our work with clinical sites in PREDICT we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical research staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll, allowing for minimal disruption and prevents potential enrollees from being overlooked if the research staff is not on duty. At clinical sites that do scheduled outpatient days we may have a trained member of the research staff with the intake nurse to monitor the patients coming to the clinic more rapidly to no delay screening or enrollment in such a fast pace environment. Using the screening tools, we will recruit and enroll patients who present with symptoms that meet the clinical case definitions of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology within the past 10 days. These patients will be enrolled, samples collected and survey conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; 3) environment biosecurity. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either coronaviruses, henipavirus, or filoviruses, serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between coronaviruses, henipavirus, or filoviruses in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. [How do these cohorts be leveraged for new emerging pathogens] Achieving the adequate numbers will be attained through duration of the as clinical participant enrollment. While patient's enrollment is limited by the number of individuals presenting at hospitals, during the PREDICT project we had an average of 105 patients enrolled per year, ranging from 77-244. The country coordinator will be continually monitoring the project database to be sure that we are on track to reach our target.

### Clinical cohort setup, recruitment, enrollment

We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology for symptoms reported onset of illness to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 2\* 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples and two nasal or oropharyngeal swabs will be collected. The cases are defined as participants whose samples tested positive for Henipaviruses, Filoviruses, or CoVs by PCR or serological tests. The controls will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500 µL serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms for coronaviruses, henipavirus, or filoviruses infected patients to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

**Commented [EH106]:** Will these cohort fulfill the goals of the EIDRC.

**Commented [EH107]:** PREDICT we also make the stipulation that we will collective relative samples if available from treatment collection, eg CSF if the MD is doing a spinal tap we will request an aliquot if possible

### Utilization of collected data

Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses the are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire allows us to assess relative measures of human-wildlife contact from our survey work that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk.

**Commented [EH108]:** Please add any information that might address: types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

The biological specimens to be collected (2\*5mL whole blood for whole blood and serum analysis and nasal or oropharyngeal swabs) from all eligible participants and follow up specimen 35 days (3mL of whole blood for serum) after enrollment with the standardized questionnaire. Capacity for specimen is collection is not more than standard phlebotomy skills and we will collected by locally trained and certified personnel that are part of the research team in country. Staff we will trainline on ethical guidelines for conducting human subjects research and survey data collection methods. Collection of whole blood, serum, and nasal or oropharyngeal swabs allows us to test the samples for PCR to detect viruses in our priority viral families, serologically test for immunological response and historical exposure to zoonotic diseases of relevance, and the questionnaire will assess individuals evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

**Commented [EH109]:** Please add any information that might address: Describe methods that might be applied to elucidate a zoonotic source

### Potential expansion

Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research or an outbreak in the region. If expansion is required we could rapidly implement research activities in additional clinical or community sites through the same process we on-boarded the initial locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital

settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transpiration, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provided necessary information for granular understand of disease spread.

In a clearly labeled section entitled "**Clinical Management Plan**":

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment. including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics

2. Tekada Sanofi Pasteur dengue

3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

## 7. Statistical Analysis Plan

In a clearly labeled section within the Research Strategy entitled "**Statistical Analysis Plan**":

- Describe the overall plan for statistical analysis of preliminary research data, including observational

cohort data.

- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

### 8. Project Milestones and Timelines

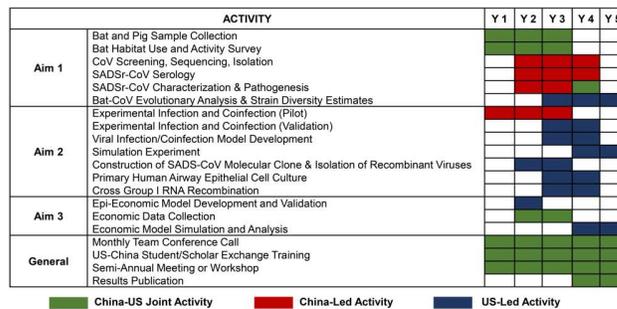

In a clearly labeled section entitled “Project Milestones and Timelines”:

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

#### Project Management & Timeline

PI Daszak will oversee all aspects of the project. Dr. Daszak has two decades of experience managing international, multidisciplinary research in disease ecology, including successful multi-year projects funded by NSF, NIH and USAID. He will conduct monthly conference calls with all co-PIs, including the China team (see Activity schedule below). He will be assisted by EHA Sr. Personnel Li, who is a US-based Chinese national with fluent

Mandarin. Co-PI Olival will oversee Aim 1 working closely with China PI Tong, who will test samples. Co-PI Ma (China team) will coordinate and lead all Chinese experimental infections, with guidance from co-PI Saif, who will coordinate and lead all US experiments with co-PI Qihong Wang. Sr. Personnel Ross will conduct all modeling activities in Aim 2, working closely with co-PI Saif to parameterize the models. Co-PI Baric and Sr. Personnel Sims will lead infectious clone, recombinant viral and culture experiments. Consultant Linfa Wang will advise on serology, PCR and other assays. China team co-PIs Shi and Zhou will oversee viral characterization in Aim 1. Sr. Personnel Feferholtz will oversee the economic modeling in close collaboration with Ross.

Commented [KJO110]: Text and figure From NSF-NIH SADS grant. Peter will adapt

Another Example of Milestones and specific tasks from a prev DHS (unfunded) proposal:

#### Expand existing databases to include predictor variables for pathogenicity risk model

Task 1: Collate available human clinical information from the literature for ~300 viral pathogens known to infect humans (Contract Award Date to 6 month)

**Task 2:** Update EHA host-viral association database to include new data for mammalian and avian species from literature 2015-present (Contract Award Date to 3 month)

**Task 3:** Extract and curate full and partial genomic data from Genbank for 5-6 viral families with a high proportion of human-infectious pathogens for phylogenetic analyses – e.g. 'nearest-known-threat module'. (Month 2 to 6 month)

#### **Develop underlying pathogenicity and spillover risk assessment models**

**Task 4:** Fit generalized linear models in Stan for multiple response variables to measure pathogen impact (Month 7 to 10 month)

**Task 5:** Fit generalized linear models to estimate risk of human infection (spillover) based on host, ecological, and location specific traits (Month 4 to 8 month)

**Task 6:** Validate model effectiveness by simulating early-outbreak, limited-information scenarios from known pandemics to confirm model behavior (Month 8 to 10 month)

**Commented [KJO111]:** Just example, but probably just want to use a Gantt chart format per most of our grants, depending on space.

## II. Research Strategy:

### 1. Significance:

Southeast Asia is a critical hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of key ecological and socioeconomic drivers of emergence (**Fig. 1**) (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is also undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread.

**Fig. 1:** Southeast Asia, and in particular, parts of Thailand and Malaysia are hotspots of risk for disease emergence (**left**), and predicted high diversity of 'missing' or as-yet undiscovered viruses, yellow = highest diversity (**left**). From (1, 2).

Not surprisingly a number of novel viruses, including near-neighbors of known agents, have emerged in the region leading to sometimes unusual clinical presentations (**Table 1**). These factors are also behind a significant background burden of repeated Dengue virus outbreaks in the region (16), and over 30 known *Flavivirus* species circulating throughout S. and SE Asia (17). The events in Table 1 are dominated by three viral families: coronaviruses, henipaviruses and filoviruses, which serve as initial examples of team research focus and capabilities. These viral groups have led to globally important emerging zoonoses (18-29). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (30-32). Furthermore, relatives and near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium: henipaviruses in bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (33-39); a novel henipavirus, Mojiang virus, in wild rats in Yunnan (10); serological evidence of filoviruses in bats in Bangladesh (40) and Singapore (41); Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (Hughes *et al.*, in prep.); evidence of novel filoviruses in bats in China (42-44), including Mēnglà virus that appears capable of infecting human cells (45); novel paramyxoviruses in bats and rodents consumed as bushmeat in Vietnam (46); a lineage C  $\beta$ -

Viral agent	Site, date	Impact	Novelty of event	Ref.	
Melaka & Kampar virus	Malaysia 2006	SARI in family group, individual	1 <sup>st</sup> disease due to bat-origin reoviruses, also Singapore, Vietnam etc.	(3-6)	CoV in bats in China that uses the same cell receptor as MERS-CoV and can infect human cells <i>in vitro</i> (47);
Reston filovirus	Philippines 2008	Seropositive people killed pigs,	No prior findings of filoviruses in pigs	(7)	MERSr-CoVs in dry bat guano being harvested as fertilizer in Thailand (48), and directly in bats (Wacharapluesadee <i>et al.</i> , in prep.);
Thrombocytopenia Syndrome virus	E. Asia 2009	100s of deaths in people	Novel tick-borne zoonosis with large caseload	(8)	
Reston filovirus	Shanghai 2011	PCR positive pigs	Further evidence of pig RESTV infection	(9)	
Mojiang virus	Yunnan 2012	Death of 3 mineworkers	1 <sup>st</sup> evidence of rodent origin henipavirus in people	(10)	
Nipah-like virus	Philippines 2015	Killed horses	No prior horse infection for NiV, known for HeV	(11)	
SARSr-CoV & HKU10-CoV	S. China 2015	Seropositive people	1 <sup>st</sup> evidence human infection HKU10 & SARSr-CoV	(12)	<b>Table 1:</b> Recent emergence events in SE Asia indicating potential for novel pathways of emergence, or unusual presentations for known or
SADS-CoV	China 2017	>25,000 pig deaths seronegative people	Novel emergence of bat-origin CoV	(13)	
Nipah virus	Kerala 2018, 2019	Killed 17/19 people 2018, 1 infected 2019	1 <sup>st</sup> outbreak of NiV outside Bangladesh, W. Bengal focus	(14, 15)	

close relatives of known viruses.

172 novel  $\beta$ -CoVs (52 novel SARSr-CoVs) and a new  $\beta$ -CoV clade ("lineage E") in bat species in S. China that are also found throughout the region (20, 47, 49, 50); and 9 and 27 novel wildlife-origin CoVs and

paramyxoviruses in Thailand (respectively) and 9 novel CoVs in Malaysia identified as part our work under USAID-PREDICT funding (49, 51). These discoveries underscore the clear and present danger of future zoonotic events in the region. Furthermore, the wide diversity of potentially pathogenic viral strains has significant potential to help in the development of broadly active vaccines, immunotherapeutics and drugs (47).

Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 2). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (29, 52). However, these regions tend to be in the developing world, where nations often lack the resources to investigate novel zoonotic events, or wildlife reservoirs of zoonoses, and prioritize more immediate public health concerns such as Dengue virus or NTDs (16). Zoonotic disease surveillance and control is also hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (53). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in x/xx (x%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (12, 54). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (3) as well as 12/856 (1.4%) people screened in Singapore (4). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (7), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (55). Preliminary

Commented [PD1]: Peter will correct

screening in Malaysia with funding from DTRA for serological surveillance of Henipaviruses and Filoviruses spillover found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in non-human primates (NHPs) and people (Hughes, in prep.). Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70% (56). Nipah virus has been reported in people in West Bengal, India, which borders Bangladesh (26), in bats in Central North India (57), and now in people in Kerala, South India in 2018 and 2019, raising the specter of future spillover at other sites in the region (14, 58).

**Fig. 2: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC

proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (52).

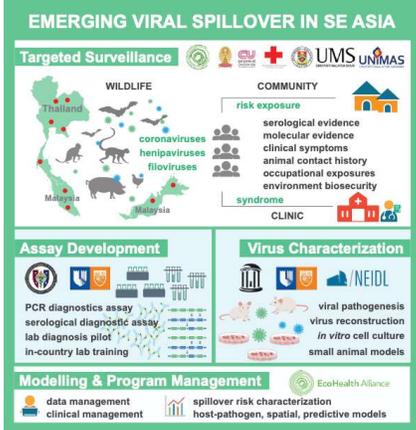

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (59), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (20, 47, 49, 50, 60-62). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-concept for an early warning approach that we will expand in this EIDRC to target key viral groups in**

Commented [PD2]: Peter to do

**one of the world's most high-risk EID hotspots.**

The overall premise for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. To scale-up this approach, we propose to launch **EID-SEARCH** (the **E**merging **I**nfectious **D**iseases - **S**outh **E**ast **A**sia **R**esearch **C**ollaboration **H**ub), to better understand the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and novel CoVs, henipaviruses, and filoviruses in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development, and cross-training in surveillance and novel diagnostic platforms. We will develop and transfer technology to test these viruses' capacity to infect human cells and mouse models, develop new specific and sensitive serological and molecular diagnostic tools, conduct surveillance of human communities with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover of viruses causing previously 'cryptic' clinical syndromes in people. We will test the capacity of novel viruses we isolate, or genetically characterize, to infect human cells and/or mouse models, and thus assess potential for spillover and spread which will feed into our risk models. Our group also has extensive experience in other viruses, including vector-borne flaviviruses, and alphaviruses, and will use this experience to provide robust long-term surveillance, diagnostics, human and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EID-SEARCH is poised to rapidly respond to any new emerging outbreak. Thus, filoviruses, henipaviruses and coronaviruses are examples of sentinel surveillance systems in place that can capture, identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.

**2. Innovation:** Previous work by our consortium has developed strategies to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses. In the EID-SEARCH we scale up this approach in a central research "hub" made up of leading laboratories, clinics and surveillance sites in three critically high-risk EID hotspot countries in SE Asia. EID-SEARCH's reach is expanded through its regional network of collaborators that covers nearly all of the greater SE Asia region. The innovation of the EID-SEARCH is in: 1) Its multidisciplinary approach that combines modeling to target geographic and taxonomic sampling targets with on-the-ground zoonotic disease surveillance in human and wildlife populations; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). **In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. We will use *in silico* methods (inovel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into

to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). **In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. **Fig. 2:** EID-SEARCH approach, core members, and roles.

**Commented [BRS3]:** Statement should be in the aims. ...Our center covers the worlds most high risk EID hostspot?

**Commented [PD4]:** Hongying – Figure needs edits to text: top panel, 'wildlife' should read "Aim 1: WILDLIFE", "AIM 2: COMMUNITY", "AIM 3: CLINIC". Right hand side: "Clinical symptoms" should be "Clinical history", "Occupational exposures" should be "Occupational exposure", "environment biosecurity" should be "environmental risk factors"

Middle panel: "Assay Development" and "Virus Characterization" should have "(Aim 1)" after them. Left hand side: should read "PCR diagnostics", "serology", "piloting diagnostics" and the last one is ok. Right hand side bullets should be "receptor binding characterization" "in vitro characterization" and "mouse models"

Bottom panel: all good

high-risk human populations. **In Aim 2, we will conduct focused, targeted surveys and sampling of human communities with high exposure to wildlife and other animals.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. Serological findings will be analyzed together with clinical metadata (including a simple animal-contact survey, location data, viral sequence/isolates etc.) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise 'cryptic' outbreaks.** We will enroll and collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs. Our US partner BSL-4 laboratory, NEIDL, will attempt isolation and characterize any viruses requiring high levels of containment (e.g. any novel filoviruses discovered).

### 3. Approach

**Research team:** The EID-SEARCH builds on long-term collaboration among world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (**Fig. 2**). Over the past two decades, our consortium partners have conducted high profile research on EIDs within the region and globally, including identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (20, 25, 59, 63-66), discovering SADS-CoV (13), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (60-62, 67-80). Our team has substantial experience conducting human surveillance in the community and during outbreaks (See sections 2.x.x, 3.x.x), including: USAID-PREDICT, and DTRA-funded viral surveillance of indigenous communities in Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah (Co-I Hughes); collection of >2,000 serum samples from healthy blood donors and sanitation workers, febrile and influenza like illness (ILI), and diarrheal stool samples from children under 5 years of age (Co-I Kamruddin); collaboration on the MONKEYBAR project with the London School of Hygiene and Tropical Medicine to analyze risk and prevalence of the zoonotic malaria *Plasmodium knowlesi* (Co-Is William, Tock Hing); case control and cross-sectional studies in Sabah villages (~800, 10,000 participants resp.) (Co-Is GR, TYW). As a proof-of-concept of how our team can rapidly scale up resources for diagnostics and surveillance in the face of a new EID, in 2016, we discovered a novel bat-origin HKU-2 CoV (81, 82) killing >20,000 pigs in S. China, designed PCR and LIPS serology tests, then surveyed pig farmers for evidence of exposure, and conducted experimental infections, pathogenesis and molecular studies, **all in the span of 3 months** (13, 83).

The administration of this center (**See section X**) will be led by PI Daszak, who has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5- 20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival and Zambrana are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesadee, Hughes and collaborators have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from NIH, DoD, USAID, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to our EIDRC.

**Geographical focus:** The three core (hub) countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses diverse cultural and

**Commented [PD5]:** PD will get stronger letter from Jerry Keusch: opportunity for visiting scholars to be certified for BSL-4 research, strong Ebola person at NEIDL to conduct characterization if we find filoviruses.

socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH, DTRA, and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our core member's extensive network of collaborators in clinics, research institutes and public health laboratories in almost every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in XX countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

Fig.3 : Map of Southeast Asia indicating three hub countries for this proposed EIDRC (Red: Thailand, Singapore, Malaysia) and countries in which Key Personnel have collaborating partners (Green), indicating that EID-SEARCH provides access to key collaborators throughout the region.

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and non-human primates (84). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (Fig. 1) (2). In Aim 1, we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and apply novel predictive models to estimate viral diversity and host range to identify wildlife species that have been ignored or under-sampled by previous zoonotic disease surveillance efforts. We will strategically collect specimens from these species and screen them, together with some of the tens of thousands of recently collected samples we have archived in freezers in our labs, for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel virus in high risk RNA viral families, *Coronaviridae*, *Paramyxoviridae*, and *Filoviridae*. We will expand to other groups of pathogens, pending available resources and priorities established with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation. On this subset of viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, gene edited humanized transgenic mice and the collaborative cross genetic reference mouse population) previously developed and widely used by our team to predict capacity of novel viruses to infect people and spillover (61, 85-88). These high-risk viruses and their close relatives will be targets for human community and clinical sampling in Aim 2 and 3, respectively.

**1.2 Preliminary data: 1.2.a. Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a major high risk location for pathogen emergence (1, 2). For Southeast Asia, these EID hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (Fig 1). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (2). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 1). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate)

Commented [PD6]: Hongying – “EIDRC Program Countries” should be “EID-SEARCH core countries” and “External Partner Countries” should be “Collaborating Partners”

Commented [PD7]: PD to Remember to correct specific aims with same titles

Commented [KJO8]: Will we? If so, make sure we mention primates more and include in vert animal sections.

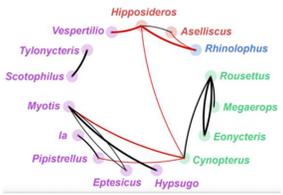

Commented [PD9]: PD will discuss both of these comments with Kevin

Commented [KJO10]: Do you think we need to add in or mention vectors (arthropods)? We don't have big banks of these as far as I know, so maybe best not too?

Commented [PD11]: From Kevin - we need to specify in the methods below how many viruses (number of) we will have resources to do this on

differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (89). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data and flight model software we have produced with Dept Homeland Security funds (90). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

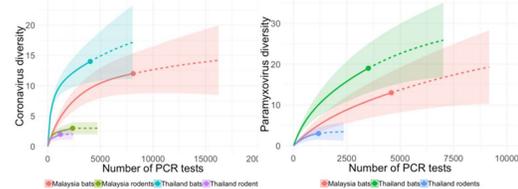

**1.2.b. Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primates represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential(91). Thus, the bulk of our proposed wildlife sampling and testing will consist of these three taxa with a focus on bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses (48, 92-94). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (2), and are exceedingly diverse in Southeast Asia (~500 species). To further prioritize taxonomic sampling targets within these diverse geographic hotspots, we have used a novel, Bayesian phylogeographic analysis to identify host taxa that are the most important centers of evolutionary diversity for a given viral group, e.g. bat genera for  $\beta$ -CoVs using an extensive CoV sequence dataset from our NIH-funded research (Fig. 5) (49). This approach will be extended to other mammal taxa and viral families of interest, allowing us to identify the ancestral wildlife hosts of specific zoonotic viral groups, where their diversity is likely highest.

**Fig 5:** Preliminary analysis to identify the most important bat genera in Southeast Asia as hosts for beta-CoVs using our previously-collected CoV sequence data. Line thickness is proportional to the probability of virus sharing between two genera. Inter-family switches are highlighted in red. We will apply this Bayesian discrete phylogeographic model to identify taxonomic and geographic centers of viral

diversification and sharing for relevant paramyxovirus, coronavirus, and other virus clades.

Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (95, 96) (Fig. 6). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively identify new strains to support experimental infection studies and risk assessment.

**Fig. 6:** Estimated coronavirus (left) and paramyxovirus (right) putative viral 'species' diversity in bats and rodents for Thailand and Malaysia, using RdRp gene sequence preliminary data from >13,000 PCR tests in bats and 4,500 in rodents. Bats in Thailand and Malaysia have 4X the number of viruses than rodent species, controlling for sampling effort. CoV and paramyxovirus diversity estimates are comparable, but discovery has not yet

saturated in any taxonomic group or location. We estimate that additional sampling of ~5,000 bats and testing of our archived rodents specimens alone will identify >80% of remaining CoV and paramyxovirus viral species in these key reservoirs. We will use this approach to define sampling targets for other wildlife taxa, and for viral strain diversity.

**1.2.c. Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. Under the 10-year PREDICT program globally, we identified 912 novel and 210 known viruses, more than the total number of viruses previously recognized in mammals by the International Committee on Taxonomy of Viruses. This work included collecting nearly 300,000 individual mammal samples from 14 EHA-led PREDICT countries and PCR-screening more than 60,000 individual specimens(51). In southern China alone, this sampling lead to the identification of 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARS-CoVs). Included were members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus, SADS-CoV, responsible for killing >20,000 pigs in Guangdong Province (13). Many of the identified bat species are

**Commented [BRS12]:** I would say we focus on these three species (plus vectors?). To demonstrate the capability of the team, this proposal will focus on bat surveillance (for a variety of reasons), noting that this approach will also be applied to other zoonotic vectors during the 5 year program throughout the region.

**Commented [PD13]:** Ralph – have we done this well enough now? If not, please add text/edit

**Commented [PD14]:** Kevin - Can you get rid of the shading on the background to this figure and change the colors so the circles and genus names are more visible (esp. the green). Colors should be darker and more contrasty

**Commented [KJO15]:** We can show just a single curve per country (aggregating all wildlife species) for simplicity, and could fit CoVs and PMVs on one graph.

**Commented [PD16]:** Evan/Hongying/Kevin, please send that also and I'll choose one

**Commented [PD17]:** Kevin – please get someone to check EIDITH – I think I just guesstimated these numbers...

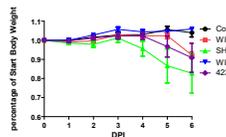

found across the region. We have collected 28,957 samples from bats, rodents and primates in Thailand and 51,373 in Malaysia, conducting 146,527 PCR tests on a large proportion of these specimens. We have **archived duplicate samples which are now available for use in this project**, including fecal, oral, urogenital and serum samples from bats, rodents, and non-human primates, and primate biopsies. In Thailand this screening has identified 100 novel viruses and 37 known viruses in wildlife reservoirs. In Malaysia this screening has identified 77 novel viruses and 23 known viruses in wildlife reservoirs (66 novel and 19 known in Sabah and 11 novel and 9 known from Peninsular Malaysia). We used family level primers for henipaviruses, filoviruses and CoVs and have already discovered 9 novel and 7 known CoVs and 26 novel and 2 known paramyxoviruses in Thailand. This is in addition to 13 novel and 5 known CoVs and 15 novel and 1 known paramyxovirus in Malaysia from wildlife. In the current proposed work, we will attempt to sequence, isolate and characterize those viruses that our analyses below suggest are most likely to be able to infect humans.

Our collaborative group has worked together on these projects, as well as other DTRA funded projects in Singapore/Thailand (Co-Is Broder, Wacharapleusadee, Wang) to design, cross-train, and use novel serological and molecular platforms to investigate virus infection dynamics in bats and examine potential spillover events with or without human disease. For serology, Co-Is Wang and Anderson (Duke-NUS) will develop a phage-display method to screen antibodies for all known and related bat-borne viruses, focusing on henipaviruses, filoviruses and coronaviruses. Once various “trends” are discovered, additional platforms (including Luminex and LIPS) will be used for verification and expanded surveillance. For molecular investigation, we will combine targeted PCR approach with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified. In Malaysia (Co-Is Hughes, Broder, Laing) we have transferred the Luminex serology platform to partner laboratories for screening of wildlife, livestock and human samples to investigate the spillover of henipaviruses and filoviruses at high risk interfaces. These interfaces include farms near the forest and indigenous communities with lots of subsistence hunting in Peninsular Malaysia, and preliminary screening has found serological evidence of past exposure to viruses antigenically-related to Nipah and Ebola in humans, bats and non-human primates (NHPs). In Thailand, Co-Is Broder, Laing and Wacharapleusadee have transferred a Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses and known henipaviruses in wildlife and human samples, with testing underway and currently being validated in our Chulalongkorn University laboratory (**See also section 2.2.d**).

**1.2.d. *In vitro* & *in vivo* characterization of viral potential for human infection:** Using Coronaviridae as an example, we have conducted *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3-7% (20, 59, 97). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (59). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of two different variants. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in those without ACE2 (20, 59, 97). We used the SARS-CoV reverse genetics system (71) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (60). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry**. The Baric lab has a well-established hACE2 and DPP4 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect (85, 98). We used this chimera approach to demonstrate that pathogenicity of bat SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the value of this model in assessing novel SARSr-CoV pathogenicity**. Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity, nor after challenge following vaccination against SARS-CoV** (60). We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they**

are unable to use the ACE2 receptor. Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines.

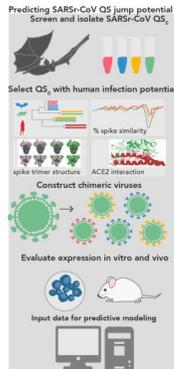

A similar approach to the above pipeline for CoVs will be applied to novel henipaviruses and filoviruses we discover during our research. The broad mammalian tropism of Hendra virus and Nipah virus (67) is likely mediated by their usage of highly conserved ephrin ligands for cell entry (15, 99). A third isolated henipavirus, Cedar virus does not cause pathogenesis in animal models. Recently, **Co-Is Broder and Laing** have developed a reverse genetics system and rescued a recombinant CedV to test ephrin receptor usage/tropism and pathogenicity during henipavirus infections (76). CedV is unable to use the Ephrin-B3 receptor (76, 100) which is found in spinal cord and may underlie NiV encephalitis (101) and that pathogenesis also involves virulence factors V and W proteins. The putative henipaviruses, Ghana virus and Mojiang virus, predict V and W protein expression, with GhV able to bind to ephrin-B2, but not -B2 (102), and the receptor for MoJV remaining unknown (103) but is likely ephrin-B2 (104). Primary human lung endothelial cells are highly susceptible to Ebolavirus infection (105). Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (106) Huh7 cells also offer advantages for reverse genetic recovery of novel filoviruses (107). Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G).

**Fig. 7:** Body weight change in hACE2 transgenic mice after SARSr-CoV infection, demonstrating that bat-origin SARSr-CoVs cause similar clinical presentation to outbreak strain (4231). From (60, 61).

**Models of Outbred Populations.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments (108). We have used this model for CoV, filo (Ebola), Flaviviruses, and alphaviruses infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection (86-88, 109-112). **Bat Models.** Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (113).

**1.3. General Approach:** We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new sampling of wildlife in high risk locales. We will use viral family level PCR screening to identify and partially characterize viruses, then follow up sequencing of relevant receptor binding proteins to assess homology and predict binding affinity, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will follow this with *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease (Fig. 8). EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses, as well as cross-training and tech transfer to the hub labs in Thailand and Malaysia. This will include via support of one Malaysian Ph.D student, Mei-Ho Lee (CM Ltd.) who has worked with the EID-SEARCH collaborators for 9 years. The focus of her study will be infection potential of novel CoVs and paramyxoviruses already found in bats in Malaysia under preliminary data for this proposal.

**Fig. 8:** Schematic showing EID-SEARCH approach to selection of sampling, viral testing,

prioritization and characterization to identify novel, high zoonotic-risk viruses in wildlife.

**1.4 Wildlife samples: 1.4.a. Geographic and taxonomic targeting for newly collected wildlife samples:** We will prioritize sites within each country that rank highest for both the risk of zoonotic disease emergence

**Commented [PD18]:** Ralph/Danielle/Eric/Chris – need something substantial here on filovirus binding that shows we have a valid approach for novel filoviruses

**Commented [PD19]:** Ralph – I think I mis-spoke in this fig. description – please correct.

**Commented [PD20]:** Ralph – please add data from the CC mouse re. filoviruses, to beef up the image of us as a filovirus group

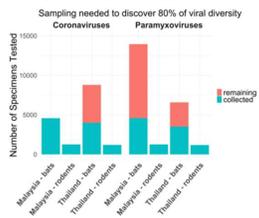

**Commented [PD21]:** Linfa/Danielle – please draft a brief para explaining how we'll use these two models

**Commented [PD22]:** Hongying – this is a placeholder from DARPA proposal. We need a new one with Stages: 1) Geographic and taxonomic modeling to maximize discovery of potential zoonotic viruses; 2) PCR screening and partial RNA sequencing; 3) Full genome or RBD and Glycoprotein sequencing to model receptor binding based on sequence similarity; 4) Cell line infections (for prioritized viruses); 5) animal model infections (for prioritized); 6) High priority viruses ranked based on data (red, yellow, green) schematic.

(114) and the predicted number of 'missing' zoonotic viruses (91). Our preliminary analysis (Fig. 1) suggests priority areas include: the Isthmus of Kra (S. Thailand and N. Peninsular Malaysia), NW Thailand (near the Myanmar-Laos border), and the lowland rainforests of Sarawak and Sabah. In each of these 'hottest of the hotspots' regions, we will identify 2-4 distinct sampling sites based on the geographic distribution of key hosts we prioritize for intensive wildlife sampling. We will priority rank bat, rodent, and primate species using analysis of host trait data for the highest predicted number of viruses based (91). We will also identify species predicted to be centers of evolutionary diversity for Corona-, Paramyxo-, and Filoviridae using ancestral host reconstruction of available sequence data and Bayesian discrete phylogeographic models (115-117). We will ensure wildlife sampling is complimentary to specimens archived in our extensive freezer banks. We will collect only the additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes given predicted levels of viral richness and rates of discovery (see 1.4.b). We will leverage our strong collaborations with wildlife experts in Malaysia and Thailand to ground-truth geographic and taxonomic model outputs with local expert knowledge to ensure the sampling plan is realistic based on current species distributions, population size estimates, seasonality, and accessibility to sites.

Recognizing that most zoonotic viruses are multi-host, i.e. naturally harbored by multiple wildlife species, and that the phylogenetic relatedness of those hosts is predictable and varies across viral families (91) – we will also apply a generalizable phylogenetic and spatial modeling approach to rapidly predict new (unsampled) hosts for novel viruses we discover during our research. We will use a combined network analysis and a phylogeographic model to estimate a viruses' host range and to prioritize additional wildlife species for sampling and testing for viruses we discover. Our recently developed model of viral sharing uses just two phylogeographic traits (wildlife species range overlap and phylogenetic similarity between host species) to successfully predict host species in the top 2% of all 4,200 possible mammal species (118).

**1.4.b. Sample size justifications for testing new and archived wildlife specimens:** We will use our preliminary data on average PCR prevalence from screening tens of thousands of bat, rodent and primate specimens for CoV and Paramyxoviruses under the USAID-PREDICT project in Malaysia and Thailand. We will refine these sample size targets, in real-time, over the course of our project using viral discovery curve analyses (Fig. 6) to either scale-up or scale-back sampling and testing of archived specimens for each species depending on their viral diversity. For example, given 5-12% prevalence of CoVs in the most common bat species we previously-sampled in Thailand and Malaysia, a target of XXX individuals per species would yield XX (± x) PCR positive individual bats, and an estimated ~xx novel strains. Similarly, for paramyxoviruses with an average PCR detection rate of X%, we would need XX individuals per species to detect 80% of predicted viral strain diversity with 80% power. Preliminary analysis indicates we will require XX,000 samples to identify 80% of remaining viral diversity (Fig. 9). All wildlife sampling will be nondestructive. In the event that an animal is found dead or needs to be euthanized due to injury we will collect biopsy samples for screening.

**Fig. 9.** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMVs from high-risk bat and rodent taxa in Malaysia and Thailand

We estimate the following sampling effort, broken down for each region: **Peninsular Malaysia:** Wildlife sampling will be led by CM Ltd / EHA in collaboration with PERHILITAN. Archive bat, rodent and NHP samples will be screened serologically using the BioPlex and other serology techniques identified through this project. New wildlife sampling will focus on bats but it is expected that rodents and NHPs will be sample as well. Wildlife sampling will be conducted around Orang Asli communities sampled as part of aim 2. Three new communities will be identified in the districts we have already sampled in. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at PERHILITAN's NWFL. **Sarawak, Malaysia:** Wildlife sampling will be led by CM Ltd / EHA in collaboration with UniMAS. Wildlife sampling will be conducted around Dyak communities sampled as part of aim 2. One community will be identified. Concurrent sampling trip will be

**Commented [PD23]:** Kevin - That doesn't make clear sense straight away – please re-word better without increasing length

**Commented [MOU24]:** Kevin will work with Noam and Evan to fill in these numbers.

**Commented [PD25]:** Hongying/KEvin Need less text on the figure, but larger font size, or crisper text to make it all visible at this size.

**Commented [T26]:** Will dig into budget tomorrow to confirm numbers.

**Commented [T27]:** With Dr Tan and possibly Dr Faisal – still waiting for Dr Faisal paper work and details of samples he has in storage will discuss with Dr Tan tomorrow.

conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at UniMAS or BMHRC. Sabah, Malaysia: Bat sampling will be led by CM Ltd / EHA in collaboration with SWD and WHU. Bat sampling will initially focus on 3 caves. Batu Supu Sabah low disturbance cave and surrounding area, Madai medium disturbance cave and surrounding area, Gomantong cave high disturbance cave and surrounding area. Each cave will be sampled twice once in wet season and once in dry season targeting 500 bats at each cave on each trip for a total of 3000 bats. Wildlife samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored at WHGFL, molecular testing will be conducted at WHGFL and serology screening at BMHRC. In addition at Madi cave the community that lives in the mouth of the cave will also be sampled targeting 150 people, while at Gomantong cave 25 workers involved in the bird next farming will be enrolled into the study. Thailand: XXXXXXXXXXXX

Commented [T29]: Discussing with Tam tomorrow.

Commented [T30]: Will dig into budget tomorrow to confirm numbers.

Commented [PD31]: Kevin – who can write this bits?

**1.4.c. Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C. PCR will be performed with pan-coronavirus, filovirus and paramyxovirus primers. PCR products will be gel purified and sequenced. We will attempt isolation on samples that contain viruses of interest (determined in 1.4, below), using Vero cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). This includes the over 30 bat cell lines maintained at Duke-NUS from four different bat species.

Commented [PD32]: Linfa – can you give a v. brief description of these please, e.g.: “This includes 13 primary lung, 5 primary gut epithelial, and 1 primary liver cell line. In addition we have 12 immortalized cell lines, 7 of which are intestinal, and therefore suitable for CoVs. Cell lines are derived from insectivorous and frugivorous bats (genera.....)”

**1.4.d. Moving beyond RNA viruses:** To detect pathogens from other families, such as non-RNA viruses we will combine conserved PCR assays with NGS. We will perform either unbiased NGS, or use a pan-viral enrichment library to sequence full-length genomes. We will conduct this work via EID-CC research projects or as part of outbreak detection/investigation in the region from DNA viruses or other agents.

**1.4.e. Sequencing Spike Glycoproteins:** Based on earlier studies, our working hypothesis is that zoonotic coronaviruses, filoviruses and henipaviruses encode receptor binding glycoproteins that elicit efficient infection of primary human cells (e.g., lung, liver, etc.) (12, 59, 60). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (Fig. 4) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are undersampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (20, 60, 119), suggesting that existing vaccines and immunotherapeutics could easily fail against future emerging SARS-like CoV. Moreover, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic receptor binding protein genes of MERS-related, Ebola-related and Nipah/Hendra-related viruses will also program efficient entry via human ortholog receptors. For all novel virus strains, we will sequence the complete entry spike genes by amplifying overlapping fragments using degenerate primers as shown previously (20, 59). Full-length genomes of selected CoV strains (representative across subclades) will be sequenced using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR or Minlon sequencing will be performed to fill gaps in the genome. The full length spike gene sequences, including the amount of variation in the receptor binding residues that bind the appropriate human receptor will be used to select strains for Aim 3 experiments.

**1.5. Assessing risk for spillover. 1.5.a. Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, filoviruses and henipaviruses, we will

use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (60, 61, 120). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs or other test filoviruses or henipaviruses to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other viruses (62, 70). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (61, 121) or monoclonal antibodies targeting the Ebola or Marburg E glycoprotein (Available through BEI), or Nipah or Hendra viruses (122). As controls or if antisera is not available, the S genes of novel SARSr-CoV or spike entry genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (123). Polyclonal sera against SARS-related viruses will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (61, 124, 125). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (126) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (127-129). Similar approaches will be applied to novel MERS-related viruses, other CoV, filoviruses or henipaviruses. While most wildlife-origin viruses with unknown transmission potential or pathogenicity in people are BSL-2 or -3, cell culture for potentially BSL-4 pathogens will be undertaken at collaborating institute NEIDL. To facilitate this, duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (See letter of support) for culture, characterization and sharing with other approved agencies including NIH RML. When appropriate of feasible, training opportunities at NEIDL for in-country staff will be given.

**1.5.b. Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the *intraspecific* scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (69). A lot of variation in the NPC1 receptor alters EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains (130). Signatures of positive selection in bat NPC1 were concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in *Eidolon helvum* cells. Thus NPC1 is a genetic determinant of filovirus susceptibility in bats, and some NPC1 variations likely reflect host adaptations to reduce filovirus replication and virulence (131). Nipah and Hendra use ephrin B2 or ephrin B3 as a receptor, and variation affects its ability to use human vs bat receptor molecules (102, 132).

**1.5.c. Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RdRp (or L genes), receptor binding glycoproteins, and full genome sequence (when available) data to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, filoviruses and henipaviruses that we identify. We will rerun MCC analyses (Fig. 3) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR-positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (Fig. 4) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) or other virus families within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (96, 133).

**1.5.d. Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have

Commented [BR533]: Any antibodies available? If not we can synthesize them from published co-crystals.

Commented [PD34]: Can someone answer Ralph's question please?

Commented [PD35]: Kevin/Alice – please edit this section to include relevance for filoviruses and henipaviruses as well (and other hosts)

recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (121, 134-136). For novel henipaviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize strains that are predicted to interact with ephrin-B2 and expression V/W proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models. We will assess ability to infect human cells using a continuous lung epithelial cell line, Calu3, that our group has previously used to generate data on NiV and HeV growth curves and a variety of host expression changes after infection (137). We will also use primary human airway cultures to assess human infection for Henipavirus and MERS- and SARS-related CoV (138) (139). There is some evidence for Nipah and Hendra virus replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (140, 141). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted Ebola infections (86-88).

**1.5.e. Animal models:** We will use transgenic mouse models and the UNC Collaborative Cross model to assess spillover potential of viruses. For work on CoVs, we will follow the protocols in the transgenic mouse model used by the Baric lab previously. Briefly, in the BSL3 lab, n=8 10- to 20-week old hACE2 or hDPP4 transgenic mice will be intranasally inoculated with  $5 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins or MERS-CoV and MERS-related CoV, respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV or MERS-CoV mAbs (142, 143) will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (120, 144). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (61, 120). For the Collaborative Cross model, we will....

Finally, for more detailed pathogenesis studies in the natural reservoir, we will use the bat models (natural and transgenic mouse model) at Duke-NUS. Both animal systems can be used to test susceptibility, pathogenesis and immune responses of any newly discovered viruses.

**1.6. Potential problems/alternative approaches:** **to sample bats in sites or provinces we select.** We have a >20-year track record of successful field work in Malaysia, Thailand and >10 years in Singapore, and have worked with local authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample

**Commented [PD36]:** Ralph – please insert a couple of sentences on how we'll use the cc mouse and what we'd expect

**Commented [PD37]:** Linfa/Danielle – could you put a couple of sentences in on what we might do with the models. Remember – this could be an additional short project from the EIDCC extra funding.

**Commented [PD38]:** Kevin – please edit/check

**Commented [PD39]:** Kevin – please check the veracity of these comments

sizes based on a range of PCR data and are fairly conservative in our approach. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses. The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (145), do not suggest a strong pattern of seasonality in CoV shedding, although there are studies that suggest this occurs in henipavirus and filovirus (MARV?) shedding (REFS?). Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province.

**Aim 2: Test evidence of viral spillover in high-risk communities using novel serological assays.**

**2.1 Rationale/Innovation:** Rapid response requires early detection. Thus, assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that interface frequently with wildlife that harbor high risk emerging viral strains. To enhance the low statistical probability of identifying these rare events, we will target rural human communities inhabiting regions of high wildlife biodiversity, that also engage in practices that increase the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will build and expand on our preliminary biological sampling and enroll large cross-sectional samples in human populations with high behavioral risk of exposure to wildlife-origin viruses and that live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will initially identify 2 sites in each of Thailand, Peninsular Malaysia, Sarawak, and Sabah for repeated biological sampling. We will design and deploy behavioral risk factor questionnaires, and specific and sensitive serological assays to identify the baseline frequency, and causes of, spillover of known and related novel viral pathogens in these populations. In participants where symptoms are reported in the last 10 days, paired serum specimens (acute and 21 days after fever) will be collected to determine titer of positive antibody. Samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, and for isolation and biological characterization of potential pathogens, using the approach laid out in Aim 1.

Country, site	Lead	# enrolled, focus	Findings
Peninsular Malaysia	Hughes	1,390 Orang Asli indigenous population, PCR/serol.	25+ novel CoVs, influenza, Nipah ab+ve, filovirus ab+ve
Malaysia Sabah	Kamruddin	1,283 serology	40% JE, 5% ZIKV ab+ve
Malaysia Sabah	William	10,800 zoonotic malaria	High burden of macaque-origin malaria
Malaysia Sabah	Hughes	150 bat cave workers	Ongoing
Malaysia Sarawak	Tan	500 Bidayuh and Iban people	8% PCR prevalence HPV in women
Malaysia PREDICT	Hughes	9,933 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Thailand	Wacharapluesadee	1,000 bat guano harvesters/villagers	Novel HKU1-CoV assoc. clinical findings
Thailand PREDICT	Wacharapluesadee	9,269 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Singapore	Wang	856, Melaka virus	7-11% ab+ve

**2.2 Preliminary data on high-zoonotic risk human community surveillance: 2.2.a Biological sample collection in SE Asia:**

Our longterm collaboration in the region has included qualitative and quantitative survey data, and collecting large archives of banked human sera and other biological samples from high zoonotic-risk populations. For example, under the USAID-PREDICT project, EHA has collected 9,933 and 9,269 specimens in Malaysia and Thailand respectively from people living in zoonotic disease interfaces, all of which will be available for retrospective serological testing by EID-SEARCH. Our core group has

collected and tested many thousand additional specimens from other important community cohorts (Table 2), and some of these will continue under EID-SEARCH (See section 2.4). Of particular interest is the access to indigenous communities in Peninsular Malaysia (Orang Asli) and Sarawak (Bidayuh, Iban people), and the bat guano harvesters in Thailand. These communities hunt, butcher and eat wildlife daily, and work in supremely high-risk zoonotic interfaces (e.g. bat caves). One of our indigenous community sites is experiencing an ongoing outbreak of unknown etiology that we are investigating currently (See section 3.2.a).

Commented [KJO40]: Emily: Will we be sampling participants more than once?

Commented [PD41]: I think that would be good, depending on the sample size

Commented [KJO42]: Need to decide if we do PCR on community samples, we can add in the questionnaire if you've been sick in the last 10 days and if so, then maybe test only this subset.

Commented [PD43]: Kevin's comment makes sense to me

**Table 2:** Current or recent biological sample collection from healthy populations conducted by members of our consortium in EID-SEARCH hub countries

**2.2.b Human Contact Risk Factors:** EHA is the lead organization across all 27 USAID-PREDICT project countries for collecting data on, and analyzing the human aspects of, zoonotic spillover risk (146, 147). We conducted exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities, using these data to assess local social and cultural norms underlying wildlife contact (147). We then developed a risk factor survey to accompany human biological sampling to evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in 27 countries, and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). For example, survey and biological samples were collected from: 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, China; 1,400 participants from 4 sites in Malaysia; and 678 participants from 4 sites in Thailand. Samples were tested with novel serological assays and results analyzed against risk factors from survey data (12). In China, CoV-seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), that are male (6/9). Although these results are preliminary and don't provide detailed information on routes of exposure, they identify key subpopulations to target that would likely increase the opportunity for identifying evidence of spillover for other CoVs, paramyxoviruses and filoviruses. Data from PREDICT surveys will be used to help identify target populations in Aim 2, identify strategies to better target at-risk people, and conduct focused **human animal contact surveys and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.** In Aim 2, we will use combined biological sampling and risk factor surveillance in targeted populations within the community to 1) identify risk factors correlated with seropositivity to henipaviruses, filoviruses and CoVs; 2) assess possible health effects of infection in people; and 3) where recent illness is reported, obtain clinical samples for PCR testing and potential viral isolation and characterization. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

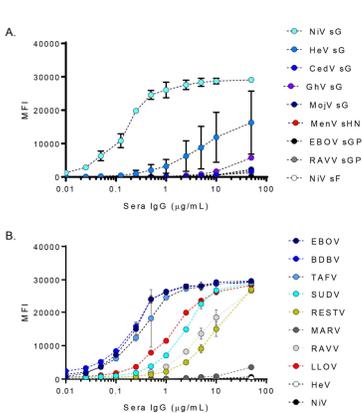

**2.2.c. Risk factors for illness:** Our preliminary data from PREDICT in Thailand, Malaysia and China revealed that frequent contact with wild (e.g. bats, rodents, non-human primates) and domestic animals (e.g. poultry, swine) among local communities was associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms. In addition, people involved in crop production, hunting and butchering of wildlife reported statistically significantly higher SARI and ILI symptoms (Li *et al.*, in prep.). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with further refining serological tools, we will be able to identify the likely routes of exposure to known or novel coronaviruses, henipaviruses, and filoviruses in the study region, as well as build data on the illnesses they cause in people.

**2.2.d. Serological platform for community surveillance:** One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. By contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes (148). However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. Henipaviruses, filovirus and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filoviruses/henipaviruses=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (149)?, developing monoclonal antibodies (150, 151) and as subunit vaccines (152, 153), is presently developing a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, filoviruses and coronaviruses. This MMIA uses a Luminex-based

Commented [PD44]: Chris/Eric Is this the right ref?

multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (149). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay. The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (Fig. XXX). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-related African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (77, 78). To strengthen serological data

interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (154-156). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity. The majority of ebolaviruses are endemic to Africa, however the discovery of Mēnglà virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown pathogenicity and zoonotic potential exists. Our past work in collaboration with Duke-NUS demonstrated that three under-sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (41).

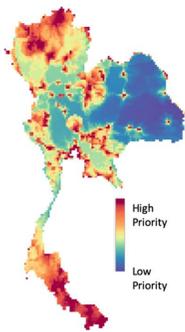

**Fig. XXX:** Validation of multiplex microsphere immunoassay (MMIA) specificity and identification of immunologically cross-reactive viruses for Nipah (A) and Ebola (B).

**2.3 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (Fig. XX). In Aim 2 we will conduct community-based surveillance using a brief, focused questionnaire to identify the prevalence and frequency of risk-factors for viral spillover in tandem with collection of high quality biological samples to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the communities sampled in Aim 2. Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and PCR prevalence in symptomatic patients.

**2.4 Target population & sample sizes:** We will target populations in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, that are EID hotspots, and that are well-connected through regional travel and trade hubs to the global travel network (Fig X). We will target specific communities based on our analysis of previously-collected PREDICT behavioral questionnaire data, to assess key at-risk populations and occupations with high exposure to wildlife, as well as using other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will identify populations at two sites in each of the following regions, building on our preliminary data (Table 2): Thailand (Co-I Wacharaplusadee): We will continue surveillance in bat guano harvesters and their villages in Ratchaburi province where we have identified MERS-related CoV in bat guano and rectal swabs

**Commented [PD45]:** Hongying -Need a new figure that lays out the community/clinical approach – small one with pretty images.

(48, 157) and serological evidence of  $\alpha$ -CoVs, HKU1-CoV in people (Wacharapluesadee in prep.). Our second site will be in Chonburi province where we have found Nipah virus (99% identity of whole genome sequence to NiV from a Bangladesh patient) in flying foxes but no outbreaks have yet been reported (REF), and have found several novel paramyxoviruses and CoVs have been found in bat feces roosting there (Wacharapluesadee in prep.).

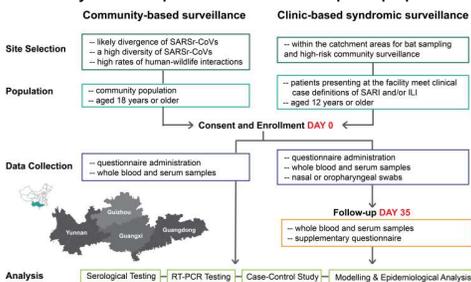

**Fig. X:** Geographic analysis to target high-risk sites for human zoonotic disease surveillance in Thailand. Our spatial analysis from Aim 1 will be extended to optimize sites for human community surveillance in Thailand and Malaysia by ranking areas with high numbers of expected viruses in wildlife, greater spillover probability based on EID risk factors, and higher levels of connectivity (measured by road density data) that may facilitate person-person spread.

**Peninsular Malaysia (Co-I Hughes, CM Ltd.):** We will expand our sampling of the Orang Asli indigenous communities to include additional communities in the 3 Districts we have already sampled, and additional Districts in the States of Kelantan Perak, Pahang, and Kelantan. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled. Human samples will include serum, whole blood, throat swabs, nasal swabs, urine, and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at NPHL. Participants who hunt, butcher or consume wildlife, or who rear animals will be considered suitable

for enrolment. Participants will complete a consent form and questionnaire in addition to having samples collected. During these community trips the field team will conduct community meetings to help inform the Orang Asli about the public health risk of zoonoses. **Sarawak (Co-I Tan, UNIMAS):** We will expand our sampling of the Bidayuh and Iban indigenous people to include the Dayak and Orang Ulu (“people of the interior”) because this group has a more intimate connection to remote wildlife-rich areas than the other two, albeit all are hunters. Human sampling will be led by UNIMAS in collaboration with CM Ltd / EHA. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled, following the same protocols as for Peninsular Malaysia. **Sabah:** We will conduct sampling at the Madai bat and bird cave that has 200 permanent residents who harvest bird’s nests for soup, and >1,000 during the harvesting season and at Gomantong cave – one of the largest bat and cave swiftlet nesting sites in the world. Protocols follow those for Peninsular Malaysia. **Singapore:** Active human surveillance will be not be conducted in Singapore, but archived human specimens e.g. from our Melaka virus serosurvey (4), will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

**Sample sizes:** From our previous work we anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so that they make up  $\geq 30\%$  of the sampled population in each community. We will stratify sampling to ensure

appropriate representation of sex, demographic, and socio-economic factors at each community site. Estimating 5% overall seroprevalence in these high-exposure populations, these sample sizes are sufficient to estimate effect sizes of risk factors of 2X or greater with 80% power. For community-based surveillance, we will enroll xxx individuals per county/province, pooled across two sites for each, allowing us to make county/province-level comparisons of differing effects.

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**Commented [PD46]:** Supaporn/Kevin/ -Need sample sizes for both populations and power calculations for serology for a typical virus from one of the three families we’re targeting

**Commented [PD47]:** Supaporn – please insert a reference into this comment box

**Commented [PD48]:** Need this figure for Singapore, Pen. Malaysia, Sarawak, Sabah as well – all together is best

**Commented [PD49]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipus, filus and CoVs.

**2.5 Data & sample collection:** Following enrollment of eligible participants and completion of the consent procedure, biological specimens (5ml will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 2.5ml whole blood; two 500 µL serum samples) will be collected and a questionnaire will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent considerations for participants enrolled from clinical settings we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

Commented [PD50]: Emily/Hongying Please check

**2.6: Laboratory analysis: 2.6.a Serological testing:**

In a previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity detected (12). **This suggests that if we can expand our serology tests to cover other bat CoVs, and that doing so may identify many more seropositive individuals.** We will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 bat SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoVs SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (12), and HKU10 is known to jump from one host bat species to another (158) so is likely to have infected people more widely. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV, at a phylogenetic distance where therapeutic or vaccine efficacy may falter. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or S1 (n-terminal domain); 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (13). Additionally, in Thailand, as an initial project on our EIDRC, we will develop serology assays to the novel CoVs found in bats at the bat guano site using LIPS assays and viral genomic data, and will screen archived specimens from 230 participants (2 years' collection in 2017-2018, a subset of the subjects have been sampled at multiple timepoints to allow us to assess seroconversion).

Commented [PD51]: Chris, Eric, Linfa, Dani etc. please draft some language here...

**2.6.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

Commented [PD52]: HELP – please add text for Henipap, filop

**2.6.c Biological characterization of viruses identified:** Novel viruses identified in humans will be recovered by cultivation or from full length genome sequences using reverse genetic approaches. Viruses will be characterized for growth in primary human cell lines and in mouse models, including the Collaborative Cross Mice or humanized mice expressing human receptors from related strains. The approaches are discussed in more detail under Aim 1.

**2.7 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for Henipavirus, Filoviruses, and CoVs spillover. “Cases” are defined as participants whose samples tested positive for Henipavirus, Filoviruses, or CoVs by serological tests. “Controls” will be selected from the pool of participants admitted to the studies and whose samples tested negative for Henipavirus, Filoviruses, or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between Henipavirus, Filoviruses, or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, paramyxoviruses, and influenza viruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may not match known viruses due to recombination events, particularly for CoVs.** We will use the three-tiered serological testing system outline in 2.6.a to try to identify these ‘novel’ viruses, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

**Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research (Table 1) and other data suggests that there are substantial numbers of outbreaks or clinical cases for which the etiologic agent is not diagnosed, e.g. (159, 160). To investigate this in SE. Asia, we will work directly with clinics and outbreak control organizations to identify the causes of some ‘cryptic’ outbreaks or cases in the region. Specifically, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and who present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We conduct novel viral discovery assays on patients who present with symptoms indicative of a high-risk zoonotic virus. If novel pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the pathogen, using the *in vitro* and *in vivo* strategy laid out in Aim 1.

**3.2 Preliminary data clinical surveillance: 3.2.a. Clinical surveys and outbreak investigations:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes: ***Peninsular Malaysia: At the time of writing, there is an outbreak of suspected viral undiagnosed illness in the indigenous Batek Orang Asli (“people of the forest”) community living at Gua Musang (“civet cat cave”) district, in Kelantan, Malaysia, close to Taman Negara – a National Park containing the oldest known rainforest. This community is one where we have conducted prior routine surveillance and biological sampling, demonstrating proof-of-concept that our two-pronged high-risk community/clinic approach will work.*** Dozens of people are affected and the outbreak is currently being investigated by our collaborators at the

**Commented [KJ053]:** Make this more general. There’s a greater challenge of interpretation of serological data, esp. if we’re using many platforms (each will have its own problems that our lab colleagues are probably more familiar with). Noam may be able to generally comment on a solution here from a statistical perspective.

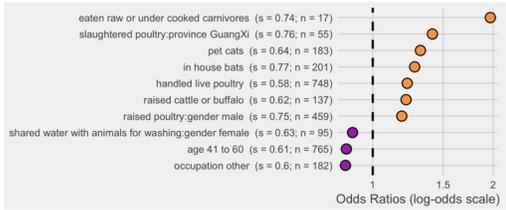

**Commented [PD54]:** Kevin – please modify according to your comment

Malaysian NPHL. The Orang Asli live in remote villages in the rainforest of Malaysia, with limited access to modern health care and extensive contact hunting, butchering, and eating wildlife as their primary source of protein. This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC - to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia. **Investigating this outbreak be a key priority if EID-SEARCH is funded.** *Sabah:* Co-I Kamruddin (BMHRC) is leading an asymptomatic leptospirosis study on sanitation workers, an ILI study in a Kota Kinabalu clinic and diarrheal study in children under 5 yrs. Co-Is William, Tan and others have conducted clinical observational studies to determine the etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah. Co-Is Tan, William have collaborated with Co-I Wang to enroll 90 adult and over 100 pediatric participants with central nervous system infections, negative tests for malaria and dengue from 3 district hospitals in Sabah to determine the various etiologies. While a high proportion tested positive for rickettsial agents, the majority had no clear diagnosis. *Sarawak:* Dr Tan (UNIMAS) is conducting a survey of high-risk female Kelabit indigenous people and has found 8% with HPV52 as the dominant strain. He is working on clinical cohorts of hand, foot and mouth disease and will recruit patients from that study in the current proposed work. Finally, he is conducting a longterm study of rotavirus and other viral etiologies of acute gastroenteritis in Kuching, Sarawak that will include swine herders and farmers. These are an important group in Malaysia because pig farms are shunned by the government and local villagers to they are placed far away from town centers, deep in the forest, and it is this scenario that led to the emergence of Nipah virus in 1998-9 (18, 161). *Thailand:* The Chulalongkorn Univ. TRC-EID laboratory works in coordination with the Thailand Ministry of Health to investigate outbreak etiology, including the first case of imported MERS-CoV in Thailand, **for which we produced sequence confirmation within 24 hours from acquiring the specimen (Fig. X)**. Three imported MERS cases have been detected in Thailand since 2015, and all cases were confirmed at the TRC-EID. We worked during the Zika outbreak to identify > 500 PCR-positive Zika patients with sequence confirmation. We have also worked on returning and suspected Ebola travelers, syndromic surveillance for SARI, Encephalitis, Hand Foot and Mouth disease in children and Viral diarrhea. Working with the US CDC (Thailand), between 1998 and 2002 we enrolled a large cohort of children from Kamphaeng Phet Province to examine Dengue virus and JE epidemiology (162, 163). Among the 784/2,574 convalescent sera Henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence), suggesting prior exposure to endemic henipaviruses or a related paramyxovirus in rural Thailand. *Singapore:* Duke-NUS has worked with the Ministry of Health to investigate Zika cases (164), and with EcoHealth and others, Duke-NUS has developed novel CoV assays for clinical surveillance, and for expedited analysis during outbreaks. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing is as rapid as several months, with the development of novel serological assays from sequence data in 7 days (13). **For example, with the discovery of SADS-CoV, we identified and fully sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (*Rhinolophus* spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (13).**

Commented [PD55]: Fig coming from Hongying

**3.2.b Analysis of self-reported illness:** In addition to biological outcomes we have developed a standardized approach in PREDICT for analyzing data on self-reported symptoms related to targeted illnesses; of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), fever with muscle aches (fevers of unknown origin (FUO) and, cough or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI and/or SARI symptoms and demographics, occupation, and contact with animals in the last year. Results have clear biological relevance. In Yunnan, China, salient associated variables or combination of variables were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (Fig. 11). We will expand this approach for all syndromes in Aim 3, and use more granular targeted questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country.

**Fig. 11:** Associated variables of self-reported ILI and/or SARI in prior 12 months (s = bootstrap support; n = number +ve out of 1,585 respondents). **Orange circles** = odds ratios > 1 (positively associated with the outcome); **purple** = odds ratios <1 (negatively associated with the outcome).

**3.3 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms

typical of high-impact emerging viruses. We will collect survey data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.4 Clinical cohorts. 3.4.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at 2 town-level level clinics and 2 provincial-level hospitals in Thailand, Peninsular Malaysia, Sabah and Sarawak. These all serve as the catchment healthcare facility for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients  $\geq 12$  years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, fevers of unknown origin, or hemorrhagic fever will be recruited into the study. We will enroll a total of xxxx individuals for clinical syndromic surveillance, which accounts for up to 40% loss from follow-up. Study data will be pooled across country sites, as clinical patients are limited by the number of individuals presenting at hospitals. Sites: *Thailand:* XXXXX | *Peninsular Malaysia:* Focusing immediately on the current outbreak in Orang Asli, we will work closely with the Malaysian Ministry of Health to support their investigation. We will also work with 6 Orang Asli clinics which focus solely on this indigenous community. *Sarawak:* XXXXXX *Sabah:* XXXXXXXXXX. *Singapore:* XXXXX

**3.4.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever of unknown etiology; or 6) severe diarrhea. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance of PCR detection of viruses (165). We will follow up 35 days after enrollment to collect an additional two 500  $\mu$ L serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs  $<28$  days after onset of symptoms for SARS patients (166). These samples may prove valuable to collaborators in that the PBMC could be used in production of therapeutic antibodies.

**3.4.c Sampling:**

Following enrollment with signed consent form, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500  $\mu$ L whole blood; two 500  $\mu$ L serum samples) including two nasal or oropharyngeal swabs will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

**Commented [PD56]:** Supaporn, Kevin – we need information!

**Commented [PD57]:** Tom, Kevin – we need information.

**Commented [PD58]:** Hongying Emily

**Commented [PD59]:** Need data for Nipah and filovirus patients

**Commented [PD60]:** Ralph: PBMC could be valuable for making therapeutic antibodies through collaborations?

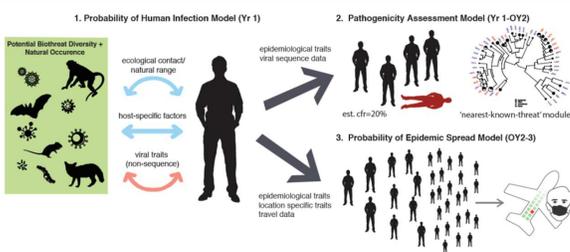

**3.5 Sample testing:** PCR, Serol to link symptoms to etiologic agents

The standard syndromic diagnostic PCR assay for the common pathogens will be conducted and the results will be shared to the hospital with 48 hours. Specimens will be further tested for 3 viral families; CoV, PmV and filovirus by consensus PCR. Appropriate specimen from dead case will be further conducted by NGS if the previous PCR tests are negative to identified cause of infection. The serology panel assay will be conducted from paired serum.

Commented [PD61]: This is v. weak – can someone strengthen it please!

**3.5 Assessing potential for pandemic spread:** We will use statistical models built from collated biological, ecological, and genetic data to predict the likelihood of human infection (or spillover) and pathogenicity for a the range of diverse viruses we will characterize. The aim is to quickly identify and assess which viruses pose the most significant risk to human health and thus prioritize additional resources to more fully characterize, better understand pathogenicity, and invest in therapeutic development for those pathogens. We will combine two independent but related statistical models to predict pathogen spillover risk and pathogenicity. First, we will expand a simple generalized additive modeling approach (91) to assess spillover risk probability to a new virus that is currently not known to infect people, when we have only limited genetic data from initial PCR screening and sequencing. Additional data from receptor binding protein homology and cell line infection experiments can be incorporated into the model framework as available. Second, given high likelihood to spillover and infect humans, or direct evidence of human infection from our clinical surveillance, we will then predict pathogenicity using nearest neighbor phylogenetic analyses as a first approximation and by incorporating more detailed data from genomic characterization and animal model experiments. For the pathogenicity model, human epidemiological data for ~300 viral species known to infect people (case fatality rate, global estimates of number of human cases per year or decade,  $R_0$ , infectious period, and primary symptoms) will be aggregated including from previous reviews [Woolhouse ref] to use as predictor variables. Thirdly, we will build off EHA's previous DTRA and DHS supported research to predict pandemic spread for viruses we identify by integrating surveillance site data, global flight models (167), as well as additional datasets (road networks, shipping routes, cell phone data) to measure human movement and connectivity across Southeast Asia.

Commented [PD62]: Hongying – please work with Kevin to come up with something of relevance here. Also, make the text brief, bold and large so it's readable

**Fig. XXXXX:** Conceptual framework highlighting 3 underlying models to estimate: 1) probability of human infection, or spillover, the first necessary step to understand pathogenicity when status of human infection is unknown; 2) pathogenicity, i.e. probability of causing clinical signs, case fatality rate estimates, and other metrics relevant to humans; and 3) probability of pathogen spread based on ecological, epidemiological, and airline connectivity and human migration data.

**3.7 Potential problems/alternative approaches: Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases.** Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (165). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the potential public health importance of discovering active spillover of a new henipavirus, filovirus or CoV infection.

Commented [PD63]: Add data for Nipah and filo infections

**Additional Instructions – Specific to the EIDRC FOA:**

**4. Administrative Plan**

In a clearly labeled section entitled “**Administrative Plan**”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.

Chula TRC-EID is National reference laboratory for diagnostic and confirmation of EIDs pathogen along with the National public health laboratory at the Department of Medical Science and the WHO Collaborating Centre for Research and Training on Viral Zoonoses. We have built a EID laboratory network in-country among three Ministry including Ministry of Public Health (Department of Medical Science and Department of Disease Control), Department of Livestock and Development, and Department of National Parks, Wildlife and Plant Conservation and Universities and among SEARO countries. Our clinicians provide case consultation for Thailand and SEARO countries. The laboratory and clinic training are regularly conducted.

**Commented [PD64]:** All – I’ve started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**For Malaysia –**

**NPHL –** Molecular and serological screening (BioPlex) of PM Orang Asli samples, serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval)

**PERHILITAN molecular zoonosis laboratory, at the National Wildlife Forensic Laboratory -** Molecular and serological screening (BioPlex) of PM wildlife samples

**UPM Faculty of Veterinary Medicine -** Molecular and serological screening (BioPlex) of PM livestock samples

**KKPHL -** Molecular of syndromic samples from Sabah (already done) and Sarawak (would need approval)

**SWD WHGFL -** Molecular screening of Sabah wildlife samples

**BMHRC -** Molecular and serological screening (BioPlex) of Sabah livestock samples, serological screening (BioPlex) of Sabah wildlife samples, Molecular and serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval). BMHRC will need renovations and BioPlex to do this work – Menzies team might have funds for BioPlex that they would base here as part of DTRA project.

- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

**List out all of our involvement with outbreak investigations, ministries of health surveillance etc.**

If possible the clean or summarized answers from the questionnaire should be shared to the hospital Infectious Control team and Bureau of Epidemiology for their information for controlling the outbreak.

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.

**Commented [PD65]:** From Supaporn

**Commented [PD66]:** From Supaporn – do same for all countries

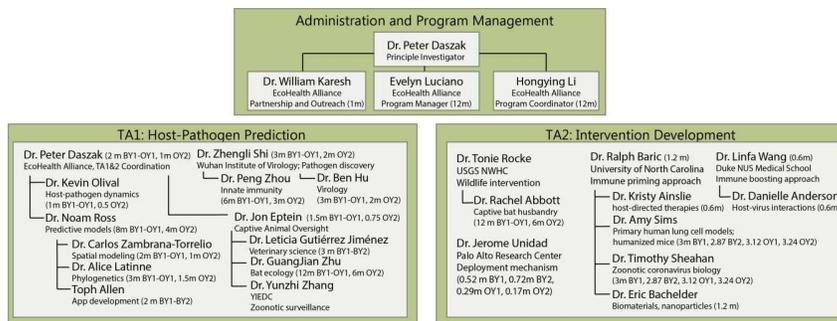

- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

CM/EHA helped establish and manages with SWD the Wildlife Health, Genetic and Forensic Laboratory (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications) that has all the equipment necessary to store samples, run extractions, PCR and analysis on biological samples for wildlife disease surveillance. The lab is used to conduct health checks on rescued and relocated wildlife before being released into new areas or sanctuaries, to screen samples for the PREDICT and Deep Forest Project and for genetic research and forensic investigations. CM/EHA also helped establish the new molecular zoonosis laboratories (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications), at DWNP's National Wildlife Forensic Laboratory. The lab is used to screen samples for the PREDICT & DTRA projects. In addition CM/EHA also has access to NPHL and KKPFL for screening human samples and the Virology lab at FVMUPM for screening Livestock samples.

The Borneo Medical and Health Research Centre (BMHRC) is a centre of excellence that conducts teaching and scientific researches on communicable diseases, outbreak investigations, and ethnomedicine. BMHRC has offices space including a meeting room and seven laboratories which including preparation lab, parasitology lab, cell culture lab, bacteriology lab, natural product lab, virology lab, and molecular biology lab. BMHRC is supported by an administration staff, medical lab technologist, and research assistants who are available to work on projects. Through this project we will help to establish a certified BSL-2 lab at the BMHRC. This lab can then be used for human testing to elevate pressure at KKPFL and QEHL labs. It would also be an ideal location for a Luminex platform as human, wildlife and livestock samples could all be screened here. Co-Is Hughes and Kamruddin will be starting outbreak response training in August 2019 with a team from Sabah CDC, KKPFL and BMHRC. (Dr. Maria Suleiman now in PM But still collaborating with us, Dr. Muhammad Jikal current Director CDC working with us and Dato' Dr Cristina Rundi Director Sabah state health Dept is supportive) this collaborative group is working to develop a Sabah outbreak response team that will help support SSHD/ CDC outbreak team and also conduct sampling for disease surveillance to be based at BMHRC and we will develop this as part of this proposal. In addition the UMS hospital will come in line in 2021 providing additional opportunities for cohort studies and capacity building.

FROM DARPA grant:

### Section 1.03 MANAGEMENT PLAN

Project DEFUSE lead institution is EcoHealth Alliance, New York, an international research organization focused on emerging zoonotic diseases. The PI, Dr. Daszak, has 25+ years' experience

Commented [KJO67]: Figure like this would be good, but instead of breaking down by TA, maybe by country or Specific Aim. Per FOA, Need to also show how we'll link in with the Coordinating Center and other EIDRCs.

managing lab, field and modeling research projects on emerging zoonoses. Dr. Daszak will commit 2 months annually (one funded by DEFUSE, one funded by core EHA funds) to oversee and coordinate all project activities, with emphasis on modeling and fieldwork in TA1. Dr. Karesh has 40+ years' experience leading zoonotic and wildlife disease projects, and will commit 1 month annually to manage partnership activities and

outreach. Dr. Epstein, with 20 years' experience working emerging bat zoonoses will coordinate animal trials across partners. Drs. Olival and Ross will manage modeling approaches for this project. Support staff includes a field surveillance team, modeling analysts, developers, data managers, and field consultants in Yunnan Province, China. The EHA team has worked extensively with other collaborators: Prof. Wang (15+ yrs); Dr. Shi (15+ yrs); Prof. Baric (5+ yrs) and Dr. Rocke (15+ yrs).

**Subcontracts:** #1 to Prof. Baric, UNC, to oversee reverse engineering of SARSr-CoVs, BSL-3 humanized mouse experimental infections, design and testing of targeted immune boosting treatments; #2 to Prof. Wang, Duke-NUS, to oversee broadscale immune boosting, captive bat experiments, and analyze immunological and virological responses to immune modulators; #3 to Dr. Shi, Wuhan Inst. Virol., to conduct PCR testing, viral discovery and isolation from bat samples collected in China, spike protein binding assays, humanized mouse work, and experimental trials on *Rhinolophus* bats; #4 to Dr. Rocke, USGS NWHC, to refine delivery mechanisms for immune boosting treatments. Dr. Rocke will use a captive colony of bats at NWHC for initial trials, and oversee cave experiments in the US and China. #5 to Dr. Unidad, PARC, to develop innovative aerosol platform into a field-deployable device for large-scale inoculation of the bats. Dr. Unidad will collaborate closely with Dr. Rocke in developing a field deployable prototype for both initial trails and cave experiments in China.

**Collaborator Coordination:** All key personnel will join regularly-scheduled web conferencing and conference calls in addition to frequent ad hoc email and telephone interactions between individuals and groups of investigators. Regular calls will include:

- Weekly meetings between the PI and Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.
- Monthly web conferences between key personnel (research presentations/coordination)
- Four in-person partner meetings annually with key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

Evaluation metrics will include the generation of high-quality data, successful achievement of milestones and timelines, scientific interaction and collaboration, the generation of high quality publications, and effective budget management. The PI and subawardee PIs will attend a kickoff meeting and the PI will meet regularly with DAPRA at headquarters and at site visits.

**Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by Dr. Daszak and the Project Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation. Should a resolution not be forthcoming, consultation with our technical advisors and DARPA Program staff may be warranted.

**Risk management:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. A project of this nature requires a different mindset from that typically associated with basic research activities that move at an incremental pace with investigators gradually optimizing experimental systems, refining data, or waiting for additional data before moving ahead with an analysis approach. To maintain our timeline, we will continually evaluate these trade-offs to make decisions about when iteration is appropriate and when necessary to move forward with current information.

#### **Biographies:**

**Dr. Peter Daszak** is President and Chief Scientist of EcoHealth Alliance, Chair of the NASEM Forum on Microbial Threats, member of the Executive Committee and the EHA institutional lead for the \$130 million USAID-EPT-PREDICT. His >300 scientific papers include the first global map of EID hotspots, estimates of unknown viral diversity, predictive models of virus-host relationships, and evidence of the bat origin of SARS-CoV and other emerging viruses.

**Commented [PD68]:** Some of references in this section are duplicates

**Prof. Ralph Baric** is a Professor in the UNC-Chapel Hill Dept. of Epidemiology and Dept. of Microbiology & Immunology. His work focuses on coronaviruses as models to study RNA virus transcription, replication, persistence, cross species transmission and pathogenesis. His group has developed a platform strategy to assess and evaluate countermeasures of the potential “pre-epidemic” risk associated with zoonotic virus cross species transmission.

**Prof. Linfa Wang** is the Emerging Infectious Diseases Programme Director at Duke-NUS Medical School. His research focuses on emerging bat viruses, including SARS-CoV, SADS-CoV, henipaviruses, and others and genetic work linking bat immunology, flight, and viral tolerance. A 2014 recipient of the Eureka Prize for Research in Infectious Diseases, he currently heads a Singapore National Research Foundation grant “Learning from bats” (\$9.7M SGD).

**Current list of contacts at key human (especially) and wildlife orgs in every SE Asian country from map above – please add to this if we’ve missed any**

Indonesia – EHA: Eijkman (Dodi Safari), IPB (Imung Joko Pamungkas); **CM Ltd**: IPB (Imung Joko Pamungkas), Bogor Agricultural University (Diah Iskandriati)

SE China – EHA: Yunnan CDC (XX), Wuhan Inst. Virol. (Zhengli Shi);

Myanmar – Chulalongkorn (Thiravat and Supaporn) have collaborated extensively with Win Min Thit, MD (Yangoon General Hospital, Myanmar); Khin Yi Oo (National Health Laboratory, Myanmar) and also in training PREDICT Myanmar veterinarians in bat sampling under PREDICT.

Japan – **BMHRC**: Oita University (Hidekatsu Iha, Kiyoshi Aoyagi), Nagasaki University (Koichi Morita, Kazuhiko Moji)

Cambodia -

Laos - **CM Ltd**: Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (Matthew Robinson)

Bangladesh – EHA: IEDCR (Meerjady Sabrina Flora, Ariful Islam), icddr,b (Mohammed Ziaur)

India – EHA: Jon’s collaborators;

Vietnam – Wellcome CRU ? Liaison with Zhengli Shi for Serol assays etc.?

Philippines – EHA, **CM Ltd**: Biodiversity Management Bureau, Department of Environment and Natural Resources (Anson Tagtag), Bureau of Animal Industry (Davinio Catbagan), Research Institute of Tropical Medicine (Catalino Demetria).

Malaysia – **CM Ltd**: Borneo Medical and Health Research Center (Ahmed Kamruddin), Department of Wildlife and National Parks Peninsular Malaysia (Frankie Sitam, Jeffrine Japning, Rahmat Topani, Kadir Hashim, Hatta Musa), Hospital Universiti Malaysia Sabah (Helen Lasimbang), Faculty of Medicine, Universiti of Malaya (Sazaly Abu Bakar), Kota Kinabalu Public Health Laboratory (Jiloris Dony, Joel Jaimin), Ministry of Health (Chong Chee Kheong, Khebir Verasahib, Maria Suleiman), National Public Health Laboratory (Hani Mat Hussin, Noorliza Noordin, Yu Kie Chem), Queen Elizabeth Hospital (Giri Rajahram, Heng Gee Lee), Sabah State Health Department (Christina Rundi, Mohammad Jikal), Sabah Wildlife Department (Rosa Sipangkui, Senthilvel Nathan, Augustine Tuuga, Jumrafiah Sukor), Gleneagles Hospital Kota Kinabalu (Timothy Wiliam); **BMHRC**: **CM Ltd** (Tom Hughes), HQEII (Shahnaz Sabri), Kota Kinabalu Public Health Laboratory (Jiloris Dony), Sabah State Health Department (Mohammad Jikal)

Thailand – **CM Ltd**: Department of Disease Control, Ministry of Public Health (Rome Buathong, Pawinee Doungngern, Pongtorn Chartpituck ), Department of National Park, Wildlife and Plant Conservation (Pattarapol

Manee-On), Faculty of Forestry, Kasetsart University (Prateep Duengkae), Mahidol-Oxford Tropical Medicine Research Unit, (Stuart Blacksell, Richard Maude), Chulalongkorn University (Supaporn Wacharapluesadee).

Chulalongkorn lab is a WHO Collaborating Centre for Research and Training on Viral Zoonoses, we work closely with WHO SEARO and SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste. We had conducted the PREDICT lab training for Veterinary lab in the Southeast Asia region for FAO. We conducted (transferred?) the bat sampling technique for scientists from Malaysia, Myanmar, the Philippines, and China.

## 5. Data Management Plan

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system

Language from NIH CoV grant:

**Data Sharing Plan:** Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited for in long-term public scientific repositories – all sequence data will be made publicly available via GenBank, species location data via the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestrictive MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Viral isolates will remain at the Wuhan Institute of Virology initially. Isolates, reagents and any other products, should they be developed, will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Sharing Model Organisms:** We do not anticipate the development of any model organisms from this study. Should any be developed, they will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Genomic Data Sharing:** We anticipate obtaining genetic sequence data for 100s of novel coronavirus genotypes, including RNA-dependent RNA polymerase (RdRp) and Spike genes for all strains/genotypes. In

addition, we will generate full viral genomes for a subset of the bat SARSr-CoVs that we identify. All sequence data will be deposited in the NIH genetic sequence database, GenBank. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also be submitted. The genotype data will be made publicly available no later than the date of initial publication or six months after the receipt of final sequencing data, whichever comes first. We anticipate sequence generation will occur over the 5 year proposed project period.

**Genome Wide Association Studies (GWAS):** Not applicable.

Commented [KJ069]: From CoV NIH grant

Thailand TRC-EID Chulalongkorn lab: Specimen management and BioBank: The software called PACS (Pathogen Asset Control System) supported by BTRP DTRA, is now used for managing the specimen from specimen registration (barcoding, and may move to use QR code system soon), aliquoting, tracking, short patient history record, data summary, searching, test reporting and etc. Our biobank system contains 28 freezers (-80C) and liquid N2 system. Its size is around 120 sq meters. There is a separate electric generator for our lab and biobank. There are CC TV cameras at the biobank and laboratory.

Chula TRC-EID has our own server for data management and analysis. We have the necessary software including Bioinformatic tools (Blast Standalone, SAMTOOL, GATK, AliVIEW, RaxML, FigTREE, MAFFT, Guppy, Megan, PoreChop, MEGA), Database (MySQL, MongoDB) Web, jQuery, Node.js, Express.js React, API, PHP, Ruby, Python, Java, C#, HTML5, Bootstrap, CSS, Responsive, Cloud, Linux Command, PACS (sample management system), Virtualbox virtual machines, R programming languages, Perl scripts, Bash shell scripts, Open source software, Microsoft Office running on both Apple Mac OS X, Ubuntu, Linux, and Windows Operating Systems. Chula TRC-EID has a dedicated 16-core Ram 64GB Linux server with 4TB hard drives, dual quad-core Mac Pro Server with 2TB hard drives and another dedicated iMac Pro (Retina 4K, 21.5-inch, 2017) Processor 3.6GHz quad-core Intel Core i7 (Turbo Boost up to 4.2GHz) Ra, 16GB with 512GB hard drives. TRC-EID also has HPC Linux server CPU: 4 x 26cores Intel Xeon = 104 cores 2.1GHz with 52 TB HDD and 2x3.84TB SSD with GPU 2x Tesla v100 (CUDA core = 5120 cores/GPU, Tensor core = 640 cores/GPU). TRC-EID has a dedicated 10/100/1000 of LAN (Local Area Network), 2.4G / 5G Gigabit Wi-Fi 802.11ac.

Commented [KJ070]: From Supaporn for their lab, some may go in Facilities doc?

From DARPA:

**Data Management and Sharing:** EcoHealth Alliance will maintain a central database of data collected and generated via all project field, laboratory, and modeling work. The database will use secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations, and enable compliance with DARPA data requests and disclosure requirements. All archived human sample data will be de-identified. Partners will provide raw and processed data to the central database throughout the course of the project. Project partners will have access to the data they generate in the database at all times, and maintain control over local copies. Release of any data from the database to non-DARPA outside parties or for public release or publication will occur only after consultations with all project partners. EHA has extensive experience in managing data for multi-partner partner projects (PREDICT, USAID IDEEAL, the Global Coronavirus Reporting System).

Commented [KJ071]: Text from DARPA Preempt

## 6. Clinical Management Plan

### Clinical site selection

Our consortium partners have been conducting lab and human surveillance research, inclusive of human surveillance during outbreaks, for over the past two decades and in that time have developed strong relationships with local clinical facilities and processes. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1. These are regions where we will sample wildlife due to the high potential of zoonotic viral diversity. Additionally, these will be clinical sites that serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. In PREDICT we developed

successful working relationships with the major healthcare facilities the hotspot areas in 6 different countries, including Thailand and Malaysia and we will continue to work with these sites going forward. Continuing to work with these hospitals means we will begin this project with successfully established partners and we can begin data collection quickly. This also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites for this study is limited. All that is required of sites will be the ability to enroll patients that meet the clinical case definitions of interest, capacity to collect and temporarily store biological samples, and follow standards for data management and protection. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently site staff. These will be persons who are locally trained and certified to collect biological specimen from participants including blood draw technique, e.g. doctor or nurse. Last, the clinical site will need the capacity to securely store all personal health information and personally identifiable research data, this will include locked offices with locked filing cabinets to store all paper records and an encrypted computer. Training on project procedures will be provided for all local project staff by local country project management staff and partners from headquarters. The study at clinical sites will begin by developing relationships with local stakeholders at the hospitals and clinics in our geographic areas of interest that serve as catchment facilities for people of within the community surveillance study. We will recruit hospital staff that will be extensively trained for project procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data management plans. During the Development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data (e.g. locked filing cabinet, dry shipper, secure laptop). [Did not specifically address CONDUCT]. Oversight for clinical sites will be managed by the country coordinator for each country. This will be done with regular site visits to the clinical sites and annual visits by headquarter research staff. Site visits will include monitoring and evaluating the process for patient enrollment, collecting and storage of samples, administration of the questionnaire, and secure and data management procedures for secure personal health information and research data. During these visits any additional training will also be provided.

Commented [EH72]: Is that true

### **Standardized approach oversight and implementation**

Management and oversight for all study sites will be managed by the local country coordinator who is supported by staff at headquarters. Implementation of a standardized approach across all study sites, community and clinical, will begin by extensive training of staff on procedures on requirements of the project, this includes: enrollment, data collection, and data management. Our research team has over 5 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research. This includes SOPs for screening, enrollment, and retention of participants. In addition to yearly monitoring reports the country coordinator will regularly visit each clinical site to ensure quality standards and compliance of procedures are being met. Through our work with clinical sites in PREDICT we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical research staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll, allowing for minimal disruption and prevents potential enrollees from being overlooked if the research staff is not on duty. At clinical sites that do scheduled outpatient days we may have a trained member of the research staff with the intake nurse to monitor the patients coming to the clinic more rapidly to no delay screening or enrollment in such a fast pace environment. Using the screening tools, we will recruit and enroll patients who present with symptoms that meet the clinical case definitions of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology within the past 10 days. These patients will be enrolled, samples collected and survey conducted to assess the

participants contact with wildlife through: 1) occupational exposures; 2) animal contact; 3) environment biosecurity. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either coronaviruses, henipavirus, or filoviruses, serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between coronaviruses, henipavirus, or filoviruses in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. [How do these cohorts be leveraged for new emerging pathogens] Achieving the adequate numbers will be attained through duration of the as clinical participant enrollment. While patient's enrollment is limited by the number of individuals presenting at hospitals, during the PREDICT project we had an average of 105 patients enrolled per year, ranging from 77-244. The country coordinator will be continually monitoring the project database to be sure that we are on track to reach our target.

#### Clinical cohort setup, recruitment, enrollment

We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology for symptoms reported onset of illness to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 2\* 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples and two nasal or oropharyngeal swabs will be collected. The cases are defined as participants whose samples tested positive for Henipaviruses, Filoviruses, or CoVs by PCR or serological tests. The controls will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500 µL serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms for coronaviruses, henipavirus, or filoviruses infected patients to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

#### Utilization of collected data

Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses the are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire allows us to assess relative measures of human-wildlife contact from our survey work that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk.

The biological specimens to be collected (2\*5mL whole blood for whole blood and serum analysis and nasal or oropharyngeal swabs) from all eligible participants and follow up specimen 35 days (3mL of whole blood for serum) after enrollment with the standardized questionnaire. Capacity for specimen is collection is not more

**Commented [EH73]:** Will these cohort fulfill the goals of the EIDRC.

**Commented [EH74]:** PREDICT we also make the stipulation that we will collective relative samples if avialble from treatmean collection, eg CSF if the MD is doing a spinal tap we will request an aliquot if possible

**Commented [EH75]:** Please add any information that might address: types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

**Commented [EH76]:** Please add any information that might address: Describe methods that might be applied to elucidate a zoonotic source

than standard phlebotomy skills and we will be collected by locally trained and certified personnel that are part of the research team in country. Staff will be trained on ethical guidelines for conducting human subjects research and survey data collection methods. Collection of whole blood, serum, and nasal or oropharyngeal swabs allows us to test the samples for PCR to detect viruses in our priority viral families, serologically test for immunological response and historical exposure to zoonotic diseases of relevance, and the questionnaire will assess individuals evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and along the wildlife value chain, and unusual illnesses reported over the past 12 months. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

#### **Potential expansion**

Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research or an outbreak in the region. If expansion is required we could rapidly implement research activities in additional clinical or community sites through the same process we on-boarded the initial locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transportation, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery of cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provide necessary information for granular understanding of disease spread.

#### **In a clearly labeled section entitled "Clinical Management Plan":**

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment, including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team is incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

**EHA: ...**

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

**Ralph**

- Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics
- Tekada Sanofi Pasteur dengue
- Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

**7. Statistical Analysis Plan**

In a clearly labeled section within the Research Strategy entitled **"Statistical Analysis Plan"**:

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

**8. Project Milestones and Timelines**

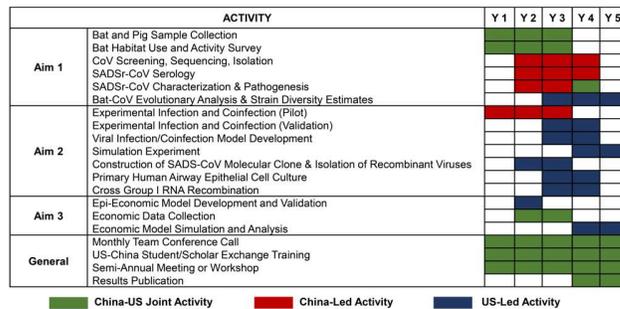

In a clearly labeled section entitled **"Project Milestones and Timelines"**:

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

**Project Management & Timeline**

PI Daszak will oversee all aspects of the project. Dr. Daszak and has two decades of experience managing international, multidisciplinary research in disease ecology, including successful multi-year projects funded by NSF, NIH and USAID. He will conduct monthly

conference calls with all co-PIs, including the China team (**see Activity schedule below**). He will be assisted by EHA Sr. Personnel Li, who is a US-based Chinese national with fluent Mandarin. Co-PI Olival will oversee Aim 1 working closely with China PI Tong, who will test samples. Co-PI Ma (China team) will coordinate and lead all Chinese experimental infections, with guidance from co-PI Saif, who will coordinate and lead all US experiments with co-PI Qihong Wang. Sr. Personnel Ross will conduct all modeling activities in Aim 2, working closely with co-PI Saif to parameterize the models. Co-PI Baric and Sr. Personnel Sims will lead infectious clone, recombinant viral and culture experiments. Consultant Linfa Wang will advise on serology, PCR and other assays. China team co-PIs Shi and Zhou will oversee viral characterization in Aim 1. Sr. Personnel Feferholtz will oversee the economic modeling in close collaboration with Ross.

**Commented [KJ077]:** Text and figure From NSF-NIH SADS grant. Peter will adapt

Another **Example of Milestones and specific tasks from a prev DHS (unfunded) proposal:**

#### **Expand existing databases to include predictor variables for pathogenicity risk model**

**Task 1:** Collate available human clinical information from the literature for ~300 viral pathogens known to infect humans (Contract Award Date to 6 month)

**Task 2:** Update EHA host-viral association database to include new data for mammalian and avian species from literature 2015-present (Contract Award Date to 3 month)

**Task 3:** Extract and curate full and partial genomic data from Genbank for 5-6 viral families with a high proportion of human-infectious pathogens for phylogenetic analyses – e.g. 'nearest-known-threat module'. (Month 2 to 6 month)

#### **Develop underlying pathogenicity and spillover risk assessment models**

**Task 4:** Fit generalized linear models in Stan for multiple response variables to measure pathogen impact (Month 7 to 10 month)

**Task 5:** Fit generalized linear models to estimate risk of human infection (spillover) based on host, ecological, and location specific traits (Month 4 to 8 month)

**Task 6:** Validate model effectiveness by simulating early-outbreak, limited-information scenarios from known pandemics to confirm model behavior (Month 8 to 10 month)

**Commented [KJ078]:** Just example, but probably just want to use a Gantt chart format per most of our grants, depending on space.

---

Hi Peter,

Built on top of Chris' suggestions. Included a preliminar data figure from Hughes et al, in prep. Double check that is ok with Tom?

Dear All,

Here's version 4. Apologies for the delay. It's in better shape now, but there are still lots of areas that need your attention. Please put in time today, and tomorrow to edit and firm up the text. I've put your names in some of the comment boxes where I need specific help but I also need you to read this critically now and edit and tighten it up. We have 30 pages of space, and our research plan is now 21 pages, so we need to lose maybe 3 or 4 pages. There are also some weak points, specifically on Filoviruses, on the details of where we'll do our clinical work, and on what we'll do with the animal models for henipias and filoviruses.

Please get comments back with me before Wednesday 26<sup>th</sup> 4pm New York time, so that I have Wednesday evening and all day Thursday to incorporate them. In the meantime, I'll be working with folks here on better figures, and all the extra sections that come after the research plan. I'll need you all to help with those on Thursday while I'm finishing off the draft.

Thanks to all of you in advance and look forward to the next round.

Cheers,

Peter

**Importance:** High

Dear all,

Thanks to everyone for comments and text for the earlier draft at the beginning of the week. Kevin's spent the last couple of days pulling all the comments together into one draft and inserting his changes, and I've now attached a v3 of the draft. It's still rough, and now too long, but it's getting there. I wanted you to look at this rough version because I'm stuck in Liberia in meetings Friday, then flying back home Saturday. I'll continue editing this draft on the plane and will be working solely on this grant from home on Sunday, Monday, Tues, Wed, Thurs.

Please work on this rapidly if possible. If you can all push your comments through, using track changes, and get them back to me **by Sunday evening New York Time**, I

will turn round a polished draft by Tuesday, giving us time for significant last go-over on Wed, Thurs. It's tight, but unfortunately, it is what it is, so please commit the time if you can!! As well as general edits (using track changes, with references in comment boxes), please do the following...

Lina/Danielle – We especially need your input in section 1.1, 1.3, 1.4 and 2.5

Ralph/Amy - Please work your magic on this draft, inserting text, editing and reducing text, and making sure the technical details of the characterization are correct and fit the proposed work on CoVs, PMVs and Henipaviruses

Chris/Eric – Eric – congratulations on your (b) (6) and thanks for working on it at this time! Chris – please help and edit/finesse the language in the relevant sections for you

Tom – Your edits crossed over with Kevin's changes, so please insert all the bits that were new in the last version you sent to me, into this version. I think these are mainly the sections and comments from the other Malaysian colleagues, but please check and re-insert all key text. We especially need to be specific about which partner in Malaysia is doing what cohorts, and where, and about who's doing the testing

Thanks again all, and I'm looking forward to non-stop work on this as soon as I get on my flight in 24 hours...

Cheers,

Peter

<EIDRC Southeast Asia v4.docx>

**II. Research Strategy:**

**1. Significance:**

South East Asia is a critical hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of key ecological and socioeconomic drivers of emergence (Fig. 1) (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is also undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread.

**Fig. 1:** Southeast Asia, and in particular, parts of Thailand and Malaysia are hotspots of risk for disease emergence (left), and predicted high diversity of 'missing' or as-yet undiscovered viruses, yellow = highest diversity (left). From (1, 2).

Not surprisingly a number of novel viruses, including near-neighbors of known agents, have emerged in the region leading to sometimes

unusual clinical presentations (Table 1). These factors are also behind a significant background burden of repeated Dengue virus outbreaks in the region (16), and over 30 known *Flavivirus* species circulating throughout S. and SE Asia (17). The events in Table 1 are dominated by three viral families: coronaviruses, henipaviruses and filoviruses, which serve as initial examples of our team's research focus and capabilities. These viral groups have led to globally important emerging zoonoses (18-29). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (30-32). Furthermore, relatives and near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium: henipaviruses in bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (33-39); a novel henipavirus, Mojiang virus, in wild rats in Yunnan (10); serological evidence of filoviruses in bats in Bangladesh (40) and Singapore (41); Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (Hughes *et al.*, in prep.); evidence of novel filoviruses in bats in China (42-44), including Mēnglà virus that appears capable of infecting human cells (45); novel paramyxoviruses in bats and rodents consumed as bushmeat in Vietnam (46); a lineage C β-

Viral agent	Site, date	Impact	Novelty of event	Ref.	CoV in bats in China that uses the same cell receptor as MERS-CoV and can infect human cells <i>in vitro</i> (47); MERSr-CoVs in dry bat guano being harvested as fertilizer in Thailand (48), and directly in bats (Wacharapluesadee <i>et al.</i> , in prep.);

172 novel β-CoVs (52 novel SARSr-CoVs) and a new β-CoV clade ("lineage E") in bat species in S. China that are also found throughout the region (20, 47, 49, 50); and 9 and 27 novel wildlife-origin CoVs and

**Commented [MOU1]:** Should include Olival *et al.* 2017 for missing zoonoses, not Jones. Or Jones, Allen, and Olival papers.

**Commented [MOU2]:** Shouldn't we add the emergence of Nipah in Malaysia Singapore in 1999 at the top of the table?

**Commented [DA3]:** Yes.  
 PMID: 10827955  
 PMID: 10520634

paramyxoviruses in Thailand (respectively) and 9 novel CoVs in Malaysia identified as part our work under USAID-PREDICT funding (49, 51). These discoveries underscore the clear and present danger of future zoonotic events in the region. Furthermore, the wide diversity of potentially pathogenic viral strains has significant potential to help in the development of broadly active vaccines, immunotherapeutics and drugs (47). Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 2). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (29, 52). However, these regions tend to be in the developing world, where nations often lack the resources to investigate novel zoonotic events, or wildlife reservoirs of zoonoses, and prioritize more immediate public health concerns such as Dengue virus or NTDs (16). Zoonotic disease surveillance and control is also hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (53). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in x/xx (x%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (12, 54). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (3) as well as 12/856 (1.4%) people screened in Singapore (4). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (7), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (55). In pPreliminary screening in Malaysia with funding from DTRA for serological surveillance of Henipaviruses and Filoviruses spillover found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in non-human primates (NHPs) and people (Hughes, in prep.) we found serological evidence of exposure to Hhenipaviruses (Hendra (HeV), Nipah- (NiV) and Cedar (CedV)) in 14 bats and 6 human samples, and Ebola (Zaire and Sudan) antigenically-related viruses in 11 bats, 2 NHP and 3 human samples (Hughes, in prep.)

Commented [PD4]: Peter will correct

Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70% (56). Nipah virus has been reported in people in West Bengal, India, which borders Bangladesh (26), in bats in Central North India (57), and now in people in Kerala, South India in 2018 and 2019, raising the specter of future spillover at other sites in the region (14, 58).

**Fig. 2: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks

(green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (52).

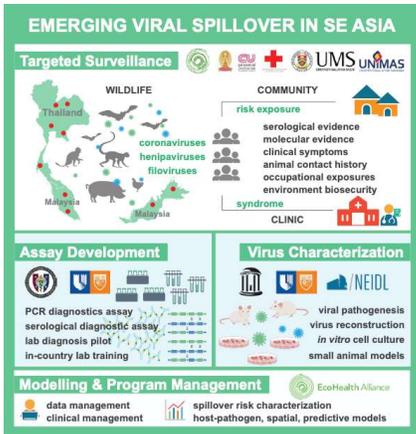

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (59), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (20, 47, 49, 50, 60-62). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-**

Commented [PD5]: Peter to do

**concept for an early warning approach that we will expand in this EIDRC to target key viral groups in one of the world's most high-risk EID hotspots.**

The overall premise for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. To scale-up this approach, we propose to launch EID-SEARCH (the **E**merging **I**nfectious **D**iseases - **S**outh **E**ast **A**sia **R**esearch **C**ollaboration **H**ub), to better understand the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and novel CoVs, henipaviruses, and filoviruses in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development, and cross-training in surveillance and novel diagnostic platforms. We will develop and transfer technology to test these viruses' capacity to infect human cells and mouse models, develop new specific and sensitive serological and molecular diagnostic tools, conduct surveillance of human communities with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover of viruses causing previously 'cryptic' clinical syndromes in people. We will test the capacity of novel viruses we isolate, or genetically characterize, to infect human cells and/or mouse models, and thus assess potential for spillover and spread which will feed into our risk models. Our group also has extensive experience in other viruses, including vector-borne flaviviruses, and alphaviruses, and will use this experience to provide robust long-term surveillance, diagnostics, human and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EID-SEARCH is poised to rapidly respond to any new emerging outbreak. Thus, filoviruses, henipaviruses and coronaviruses are examples of sentinel surveillance systems in place that can capture, identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.

**2. Innovation:** Previous work by our consortium has developed strategies to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses. In the EID-SEARCH we scale up this approach in a central research "hub" made up of leading laboratories, clinics and surveillance sites in three critically high-risk EID hotspot countries in SE Asia. EID-SEARCH's reach is expanded through its regional network of collaborators that covers nearly all of the greater SE Asia region. The innovation of the EID-SEARCH is in: 1) Its multidisciplinary approach that combines modeling to target geographic and taxonomic sampling targets with on-the-ground zoonotic disease surveillance in human and wildlife populations; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). **In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. We will use *in silico* methods (novel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into

**Commented [BR56]:** Statement should be in the aims. ...Our center covers the worlds most high risk EID hostspot?

**Commented [KJ07]:** Hongying to add in "genetic sequencing" under Virus Characterization, and also Aim 1 + 3 for Virus Characterization and Aim 1 + 2 for Assay Development

**Commented [KJ08]:** And pathogenicity? Could argue for those we use animal models on.

**Fig. 2:** EID-SEARCH approach, core members, and roles.

high-risk human populations. **In Aim 2, we will conduct focused, targeted cross-sectional surveys of and sampling of human communities with high levels of animal contact exposure to wildlife and other animalsto identify occupational and other risk factors for zoonotic virus exposure.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. Serological findings will be analyzed together with clinical metadata (including a simple animal-contact survey, location data, viral sequence/isolates etc.) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise ‘cryptic’ outbreaks.** We will enroll and collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and follow-up serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs. Our US partner BSL-4 laboratory, NEIDL, will attempt isolation and characterize any viruses requiring high levels of containment (e.g. any novel filoviruses discovered).

### 3. Approach

**Research team:** The EID-SEARCH builds on long-term collaboration among world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (**Fig. 2**). Over the past two decades, our consortium partners have conducted high profile research on EIDs within the region and globally, including identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (20, 25, 57, 59, 63-65), discovering SADS-CoV (13), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (60-62, 66-79). Our team has substantial experience conducting human surveillance in the community and during outbreaks (See sections 2.x.x, 3.x.x), including: USAID-PREDICT, and DTRA-funded viral surveillance of indigenous communities in Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah (Co-I Hughes); collection of >2,000 serum samples from healthy blood donors and sanitation workers, febrile and influenza like illness (ILI), and diarrheal stool samples from children under 5 years of age (Co-I Kamruddin); collaboration on the MONKEYBAR project with the London School of Hygiene and Tropical Medicine to analyze risk and prevalence of the zoonotic malaria *Plasmodium knowlesi* (Co-Is William, Tock Hing); case control and cross-sectional studies in Sabah villages (~800, 10,000 participants resp.) (Co-Is GR, TYW); and community-based surveillance of hundreds of bat-exposed villagers in Thailand (Co-Is Wacharapluesedee and Hemachudha). As a proof-of-concept of how our team can rapidly scale up resources for diagnostics and surveillance in the face of a new EID, in 2016, we discovered a novel bat-origin HKU-2 CoV (80, 81) killing >20,000 pigs in S. China, designed PCR and LIPS serology tests, then surveyed pig farmers for evidence of exposure, and conducted experimental infections, pathogenesis and molecular studies, **all in the span of 3 months** (13, 82).

The administration of this center (**See section X**) will be led by PI Daszak, who has >20 years’ experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5–20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival and Zambrana are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesedee, Hughes and collaborators have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from NIH, DoD, USAID, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to our EIDRC.

**Commented [PD9]:** Hongying – Figure needs edits to text: top panel, ‘wildlife’ should read “Aim 1: WILDLIFE”, “AIM 2: COMMUNITY”, “AIM 3: CLINIC”. Right hand side: “Clinical symptoms” should be “Clinical history”, “Occupational exposures” should be “Occupational exposure”, “environment biosecurity” should be “environmental risk factors”

Middle panel: “Assay Development” and “Virus Characterization” should have “(Aim 1)” after them. Left hand side: should read “PCR diagnostics”, “serology”, “piloting diagnostics” and the last one is ok. Right hand side bullets should be “receptor binding characterization” “in vitro characterization” and “mouse models”

Bottom panel: all good

**Commented [PD10]:** PD will get stronger letter from Jerry Keusch: opportunity for visiting scholars to be certified for BSL-4 research, strong Ebola person at NEIDL to conduct characterization if we find filoviruses.

**Geographical focus:** The three core (hub) countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people

otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH, DTRA, and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our core member's extensive network of collaborators in clinics, research institutes and public health laboratories in almost every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in ~~xx~~ 10 countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic

**Commented [KJO11]:** Including those in green on map, plus Australia.

potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Fig.3 :** Map of Southeast Asia indicating three hub countries for this proposed EIDRC (Red: Thailand, Singapore, Malaysia) and countries in which Key Personnel have collaborating partners (Green), indicating that EID-SEARCH provides access to key collaborators throughout the region.

**Commented [PD12]:** Hongying – “EIDRC Program Countries” should be “EID-SEARCH core countries” and “External Partner Countries” should be “Collaborating Partners”

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and non-human primates (83). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (Fig. 1) (2). In Aim 1, we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and apply novel predictive models to estimate viral diversity and host range to identify wildlife species that have been ignored or under-sampled by previous zoonotic disease surveillance efforts. We will strategically collect specimens from these species and screen them, together with some of the tens of thousands of recently collected samples we have archived in freezers in our labs, for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel virus in high risk RNA viral families, *Coronaviridae (CoV)*, *Paramyxoviridae (PMV)*, and *Filoviridae (FV)*. We will expand to other groups of pathogens, including *arboviruses*, pending available resources and priorities established with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation. On this subset of viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, gene edited humanized transgenic mice and the collaborative cross genetic reference mouse population) previously developed and widely used by our team to predict capacity of novel viruses to infect people and spillover (61, 84-87). These high-risk viruses and their close relatives will be targets for human community serosurveys and clinical sampling in Aim 2 and 3, respectively.

**Commented [PD13]:** PD to Remember to correct specific aims with same titles

**Commented [KJO14]:** Can/should save space by abbreviating throughout after first mention.

**Commented [PD15]:** From Kevin - we need to specify in the methods below how many viruses (number of) we will have resources to do this on

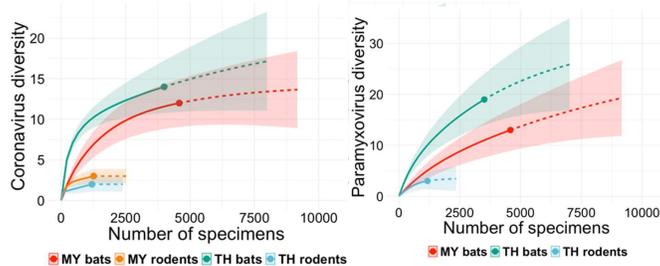

**1.2 Preliminary data: 1.2.a. Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a

major high risk location for pathogen emergence (1, 2). For Southeast Asia, these EID hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (Fig 1). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (2). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 1). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (88). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data and flight model software we have produced with Dept Homeland Security funds (89). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

**1.2.b. Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primates represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential(90). Thus, the bulk of our proposed wildlife sampling and testing will consist of these three taxa with a focus on bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses PMVs and FVs (48, 91-93). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (2), and are exceedingly diverse in Southeast Asia (~500 species). To further prioritize taxonomic sampling targets within these diverse geographic hotspots, we have used a novel, Bayesian phylogeographic analysis to identify host taxa that are the most important centers of evolutionary diversity for a given viral group, e.g. bat genera for  $\beta$ -CoVs using an extensive CoV sequence dataset from our NIH funded research (Fig. 5) (49). This approach will be extended to other mammal taxa and viral families of interest, allowing us to identify the ancestral wildlife hosts of specific zoonotic viral groups, where their diversity is likely highest.

**Fig 5:** Preliminary analysis to identify the most important bat genera in Southeast Asia as hosts for beta-CoV evolutionary diversitys using our previously-collected CoV sequence data collected under our NIH-funded research. Line thickness is proportional to the probability of virus sharing between two genera, with in-inter-family switches are highlighted in red. We will apply this Bayesian discrete phylogeographic model to identify taxonomic and geographic centers of viral diversification and sharing for relevant paramyxovirus PMV, CoV, coronavirus, and other virus clades.

Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (94, 95) (Fig. 6). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively identify new strains to support experimental infection studies and risk assessment.

**Fig. 6:** Estimated coronavirus CoV (left) and paramyxovirus PMV (right) putative viral 'species' diversity in bats and rodents for from Thailand and Malaysia, using data from PCR screening and RdRp gene sequences preliminary data from >103,000 PCR tests specimens in bats and 4,500 tests in rodents. Bats in Thailand and Malaysia have 4X the number of viruses than rodent species, controlling for sampling effort. CoV and paramyxovirus diversity estimates are comparable, but discovery has not yet saturated in any taxonomic group or location. We estimate that additional collection

Commented [KJO16]: Wrong ref! Should be Olival et al. 2017.

Commented [KJO17]: This is currently in Aim 3.

Commented [KJO18]: Olival et al appears twice in refs, fix.

Commented [BRS19]: I would say we focus on these three species (plus vectors?). To demonstrate the capability of the team, this proposal will focus on bat surveillance (for a variety of reasons), noting that this approach will also be applied to other zoonotic vectors during the 5 year program throughout the region.

Commented [PD20]: Ralph – have we done this well enough now? If not, please add text/edit

Commented [PD21]: Kevin - Can you get rid of the shading on the background to this figure and change the colors so the circles and genus names are more visible (esp. the green). Colors should be darker and more contrasty

Commented [MOU22]: Revised figure inserted.

Commented [DA23]: PMV only appears in your paper to define paramyxovirus. I will just leave it as my opinion that I don't like it, but I am not going to change it back.

Commented [KJO24]: We can show just a single curve per country (aggregating all wildlife species) for simplicity, and could fit CoVs and PMVs on one graph.

Commented [PD25]: Evan/Hongying/Kevin, please send that also and I'll choose one

of 5k-9k bat specimens sampling of ~5,000 bats and testing of our archived rodents specimens alone will identify >80% of remaining CoV and paramyxovirus PMV viral species in these key reservoirs, yielding >800 unique viral strains. We will use this approach to define sampling targets for other wildlife taxa, and for viral strain diversity.

**1.2.c. Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. Under the 10-year PREDICT program globally, we identified 912 novel and 210 known viruses, more than the total number of viruses previously recognized in mammals by the International Committee on Taxonomy of Viruses. This work included collecting nearly 300,000 individual mammal samples from 14 EHA-led PREDICT countries and PCR-screening more than 60,000 individual specimens (51). In southern China alone, this sampling led to the identification of 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARSr-CoVs). Included were members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus, SADS-CoV, responsible for killing >20,000 pigs in Guangdong Province (13). Many of the identified bat species are found across the region. We have collected 28,957 samples from bats, rodents and primates in Thailand and 51,373 in Malaysia, conducting 146,527 PCR tests on a large proportion of these specimens. We have archived duplicate samples which are now available for use in this project, including fecal, oral, urogenital and serum samples from bats, rodents, and non-human primates, and primate biopsies. In Thailand this screening has identified 100 novel viruses and 37 known viruses in wildlife reservoirs. In Malaysia this screening has identified 77 novel viruses and 23 known viruses in wildlife reservoirs (66 novel and 19 known in Sabah and 11 novel and 9 known from Peninsular Malaysia). We used Using family level primers for henipaviruses PMV, filoviruses-FV, and CoVs, we and have already discovered 9 novel and 7 known CoVs and 26 novel and 2 known paramyxoviruses in Thailand; and, This is in addition to 13 novel and 5 known CoVs and 15 novel and 1 known paramyxovirus in Malaysia from wildlife. In the current proposed work, we will attempt to sequence, isolate and characterize those viruses that our analyses below suggest are most likely to be able to infect humans.

Our collaborative group has worked together on these projects, as well as other DTRA funded projects in Singapore/Thailand (Co-Is Broder, Wacharapleusadee, Wang) to design, cross-train, and use novel serological and molecular platforms to investigate virus infection dynamics in bats and examine potential spillover events with or without human disease (see Aim 2). For serology, Co-Is Wang and Anderson (Duke-NUS) will develop a phage-display method to screen antibodies for all known and related bat-borne viruses, focusing on henipaviruses, filoviruses and coronaviruses. Once various "trends" are discovered, additional platforms (including Luminex and LIPS) will be used for verification and expanded surveillance. For molecular investigation, we will combine targeted PCR approach with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified. In Malaysia (Co-Is Hughes, Broder, Laing) we have transferred the Luminex serology platform to partner laboratories for screening of wildlife, livestock and human samples to investigate the spillover of henipaviruses and filoviruses at high risk interfaces. These interfaces include farms near the forest and indigenous communities with lots of subsistence hunting in Peninsular Malaysia, and preliminary screening has found serological evidence of past exposure to viruses antigenically-related to Nipah and Ebola in humans, bats and non-human primates (NHPs). In Thailand, Co-Is Broder, Laing and Wacharapleusadee have transferred a Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses and known henipaviruses in wildlife and human samples, with testing underway and currently being validated in our Chulalongkorn University laboratory (See also section 2.2.d).

**1.2.d. In vitro & in vivo characterization of viral potential for human infection:** Using Coronaviridae as an example, we have conducted *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3-7% (20, 59, 96). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (59). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of

**Commented [PD26]:** Kevin – please get someone to check EIDITH – I think I just guesstimated these numbers...

**Commented [MOU27]:** These are correct, based on EIDITH P1 + P2 for EHA countries.

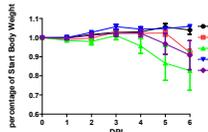

**Commented [KJO28]:** Leave this out as it may look like we've already done a bulk of the work?

**Commented [MOU29]:** Think we need to abbreviate these viral families throughout, should Find/Replace. Also, henipa is not a viral family, so changing back to PMVs.

**Commented [KJO30]:** Move to Aim 2? I think it's good to have some flexibility to test wildlife sera using these assays, but not readily clear how this fits in with our PCR screening? We could do a broader survey of a smaller number of wildlife samples from more species, and those with high seroprev, we can follow up w molecular assays – though not sure this is necessary. All the serology in this section can prob go to Aim 2.

two different variants. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in those without ACE2 (20, 59, 96). We used the SARS-CoV reverse genetics system (70) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (60). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry**. The Baric lab has a well-established hACE2 and DPP4 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect (84, 97). We used this chimera approach to demonstrate that pathogenicity of bat SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the value of this model in assessing novel SARSr-CoV pathogenicity**. Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity, nor after challenge following vaccination against SARS-CoV** (60). We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they are unable to use the ACE2 receptor**. Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines.

A similar approach to the above pipeline for CoVs will be applied to novel henipaviruses and filoviruses we discover during our research. The broad mammalian tropism of Hendra virus and Nipah virus (66) is likely mediated by their usage of highly conserved ephrin ligands for cell entry (15, 98). A third isolated henipavirus, Cedar virus does not cause pathogenesis in animal models. Recently, **Co-Is Broder and Laing** have developed a reverse genetics system and rescued a recombinant CedV to test ephrin receptor usage/tropism and pathogenicity during henipavirus infections (75). CedV is unable to use the Ephrin-B3 receptor (75, 99) which is found in spinal cord and may underlie NiV encephalitis (100) and that pathogenesis also involves virulence factors V and W proteins. The putative henipaviruses, Ghana virus and Mojiang virus, predict V and W protein expression, with GhV able to bind to ephrin-B2, but not -B2 (101), and the receptor for MoJV remaining unknown (102) but is likely ephrin-B2 (103). **Primary human lung endothelial cells are highly susceptible to Ebolavirus infection (104)**. Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (105) Huh7 cells also offer advantages for reverse genetic recovery of novel filoviruses (106). Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G).

**Fig. 7:** Body weight change in hACE2 transgenic mice after SARSr-CoV infection, demonstrating that bat-origin SARSr-CoVs cause similar clinical presentation to outbreak strain (4231). From (60, 61).

**Models of Outbred Populations.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments (107). We have used this model for CoV, **filo-FV** (Ebola), Flaviviruses, and alphaviruses infections. **In subpopulations Clinical signs such as it reproduces SARS weight loss, hemorrhage, in EBOV, encephalitis, and in WNV, acute or chronic arthritis arthritis were recapitulated in these mice following SARS, EBOV, West Nile virus and in Chikungunya infections, respectively (85-87, 108-111).** **Bat Models.** Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (112). **In a proof of concept study, Co-Is Wang and Anderson infected *E. spelaea* bats with MERS-CoV to demonstrate their susceptibility and suitability for infection with a bat borne virus under BSL3 containment. These bats and the bat mouse model will serve to complement and expand studies the UNC collaborative cross mouse.**

**Commented [PD31]:** Ralph/Danielle/Eric/Chris – need something substantial here on filovirus binding that shows we have a valid approach for novel filoviruses

**Commented [DA32]:** From here and above, see my other version.

**Commented [PD33]:** Ralph – I think I mis-spoke in this fig. description – please correct.

**Commented [DA34]:** SARS weight loss? Meaning weight loss when infected with SARS-CoV?

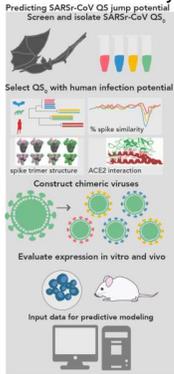

**Commented [PD35]:** Ralph – please add data from the CC mouse re. filoviruses, to beef up the image of us as a filovirus group

**Commented [PD36]:** Linfa/Danielle – please draft a brief para explaining how we'll use these two models

**Formatted:** Font: Bold

**Formatted:** Font: Italic

**1.3. General Approach:** We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new sampling of wildlife in high risk locales. We will use viral family level PCR screening assays to identify and partially characterize viruses, then follow up sequencing of relevant receptor binding proteins to assess homology and predict binding affinity, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will follow this with *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease (**Fig. 8**). EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses, as well as cross-training and tech transfer to the hub labs in Thailand and Malaysia. This will include via support of one Malaysian Ph.D student, Mei-Ho Lee (CM Ltd.) who has worked with the EID-SEARCH collaborators for 9 years. The focus of her study will be infection potential of novel CoVs and paramyxoviruses already found in bats in Malaysia under preliminary data for this proposal.

**Fig. 8:** Schematic showing EID-SEARCH approach to selection of sampling, viral testing, prioritization and characterization to identify novel, high zoonotic-risk viruses in wildlife.

**1.4 Wildlife samples: 1.4.a. Geographic and taxonomic targeting for newly collected wildlife samples:** We will prioritize sites within each country that rank highest for both the risk of zoonotic disease emergence (113) and the predicted number of 'missing' zoonotic viruses (90). Our preliminary analysis (**Fig. 1**) suggests priority areas include: the Kra Isthmus of Kra (S. Thailand and N. Peninsular Malaysia), NW Thailand (near the Myanmar-Laos border), and the lowland rainforests of Sarawak and Sabah. In each of these 'hottest of the hotspots' regions, we will identify 2-4 distinct sampling sites based on the geographic distribution of key hosts we prioritize for intensive-additional wildlife sampling. We will priority rank bat, rodent, and primate species using analysis of host trait data for the highest predicted number of viruses based on host trait-based models (90). We will also identify species predicted to be centers of evolutionary diversity for Corona-, Paramyxo-, and Filoviridae using ancestral host reconstruction of available sequence data and Bayesian discrete phylogeographic models (114-116). We will ensure wildlife sampling is complimentary to specimens archived in our extensive freezer banks. We will collect only the additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes given predicted levels of viral richness and rates of discovery (see 1.4.b). We will leverage our strong collaborations with wildlife experts in Malaysia and Thailand to ground-truth geographic and taxonomic model outputs with local expert knowledge to ensure the sampling plan is realistic based on current species distributions, population size estimates, seasonality, and accessibility to sites.

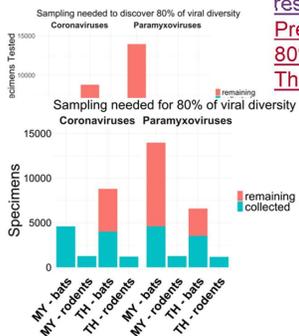

Recognizing that most zoonotic viruses are multi-host, i.e. naturally harbored by multiple wildlife species, and that the phylogenetic relatedness of those hosts is predictable and varies across viral families (90) – we will use a combined network analysis and a phylogeographic model also apply a generalizable phylogenetic and spatial modeling approach to rapidly predict and prioritize new (unsampled) hosts for important, novel viruses we discover during our research. We will use a combined network analysis and a phylogeographic model to estimate a viruses' host range and to We have shown this relatively simple model prioritize additional wildlife species for sampling and testing for viruses we discover. Our recently developed model of viral sharing uses just two phylogeographic traits (using just wildlife species range overlap and phylogenetic similarity between host species) is both generalizable to estimate host range for all mammalian and avian viruses and robust – accurately predicting hosts 98% of the time when cross-validated using data from known viruses to successfully predict host species in the top 2% of all 4,200 possible mammal species (117).

**Commented [PD37]:** Hongying – this is a placeholder from DARPA proposal. We need a new one with Stages: 1) Geographic and taxonomic modeling to maximize discovery of potential zoonotic viruses; 2) PCR screening and partial RNA sequencing; 3) Full genome or RBD and Glycoprotein sequencing to model receptor binding based on sequence similarity; 4) Cell line infections (for prioritized viruses); 5) animal model infections (for prioritized); 6) High priority viruses ranked based on data (red, yellow, green) schematic.

**Formatted:** Font: Italic

**Commented [PD38]:** Kevin - That doesn't make clear sense straight away – please re-word better without increasing length

**1.4.b. Sample size justifications for testing new and archived wildlife specimens:** We calculate initial We will sample sizes targets using e-our preliminary data on average PCR prevalence from screening tens of thousands of bat, rodent and primate specimens for CoV and Paramyxoviruses PMVs under the USAID-PREDICT project in Malaysia and Thailand. We will refine these sample size targets, in real-time, over the course of our project using viral discovery curve analyses (Fig. 6) to either scale-up or scale-back new sampling and testing of archived specimens for each species depending on their viral diversity/capture rates. We will only collect additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes and to complement our archived specimens. For example, *Rousettus* spp. bats, known filovirus

reservoirs, were not adequately sampled under PREDICT research in Thailand. Preliminary analysis indicates we will require ~14,000 new samples to identify 80% of remaining viral species diversity in our study region. ~5,000 samples from Thailand and ~9,000 samples from Malaysia (Fig. 9). Viral strain discovery/ diversity from a sampling effort this size is expected to number in the hundreds of strains. For example, given ~6% prevalence of CoVs in bat species previously sampled under the PREDICT project, a target of 14,000 individuals would yield ~800 PCR positive individuals, representing, conservatively, an estimated ~200600 novel CoV strains/sequences/strains. Similarly, for paramyxoviruses, which have an average PCR detection prevalence of ~1.5%, sampling of 14,000 individuals would yield ~200 positives and an estimated ~60150 novel paramyxovirus strains. From each mammal, we will collect serum, whole blood, throat swabs, urine and fecal samples or rectal swab using our previously-validated For example, given 5-

12% prevalence of CoVs in the most common bat species we previously sampled in Thailand and Malaysia, a target of XXX individuals per species would yield XX (± x) PCR positive individual bats, and an estimated ~xx novel strains. Similarly, for paramyxoviruses with an average PCR detection rate of X%, we would need XX individuals per species to detect 80% of predicted viral strain diversity with 80% power. Preliminary analysis indicates we will require XX,000 samples to identify 80% of remaining viral diversity (Fig. 9). All wildlife sampling will be nondestructive methods (see Vertebrate Animals section) [REFS]. In the event that an animal is found dead or needs to be euthanized due to injury we will collect biopsy/necropsy samples for screening.

**Fig. 9.** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMV species s-from high-risk bat and rodent taxa in Malaysia and Thailand

We estimate the following sampling effort, broken down for each region: *Peninsular Malaysia:* Wildlife sampling will be led by CM Ltd / EHA in collaboration with PERHILITAN. Archive bat, rodent and NHP samples will be screened serologically using the BioPlex and other serology techniques identified through this project. New wildlife sampling will focus on bats but it is expected that rodents and NHPs will be sample as well. Wildlife sampling will be conducted around Orang Asli communities sampled as part of aim 2. Three new communities will be identified in the districts we have already sampled in. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at PERHILITAN's NWFL. *Sarawak, Malaysia:* Wildlife sampling will be led by CM Ltd / EHA in collaboration with UniMAS. Wildlife sampling will be conducted around Dyak communities sampled as part of aim 2. One community will be identified. Concurrent sampling trip will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at UniMAS or BMHRC. *Sabah, Malaysia:* Bat sampling will be led by CM Ltd / EHA in collaboration with SWD and WHU. Bat sampling will initially focus on 3 caves. Batu Supu Sabah low disturbance cave and surrounding area, Madai medium disturbance cave and surrounding area, Gomantong cave high disturbance cave and surrounding area. Each cave will be sampled

Formatted: Font: Italic

Commented [KJO39]: Just assumed that 75% of detections would = unique sequences/strains. We can lower this to be more conservative.

Commented [MOU40]: Kevin will work with Noam and Evan to fill in these numbers.

Commented [KJO41]: PREDICT sampling protocols? Jon's FAO bat book manual, and other published for rodents and primates (from Bangladesh?)

Commented [PD42]: Hongying/KEvin Need less text on the figure, but larger font size, or crisper text to make it all visible at this size.

Commented [T43]: Will dig into budget tomorrow to confirm numbers.

Commented [T44]: With Dr Tan and possibly Dr Faisal - still waiting for Dr Faisal paper work and details of samples he has in storage will discuss with Dr Tan tomorrow.

Commented [T45]: Will dig into budget tomorrow to confirm numbers.

Commented [T46]: Discussing with Tam tomorrow.

twice once in wet season and once in dry season targeting 500 bats at each cave on each trip for a total of 3000 bats. Wildlife samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored at WHGFL, molecular testing will be conducted at WHGFL and serology screening at BMHRC. In addition at Madi cave the community that lives in the mouth of the cave will also be sampled targeting 150 people, while at Gomantong cave 25 workers involved in the bird next farming will be enrolled into the study.

Commented [T47]: Will dig into budget tomorrow to confirm numbers.

Thailand: XXXXXXXXXX New bat specimens will be collected from bat species that ~~were~~ not collected during PREDICT2 study for example *Rousettus* bats (targeted species for Filovirus study), *Taphozous* bat (targeted species for MERS-CoV), *Rhinolophus* (targeted species for SARS-CoV) for serology and PCR assays (n=100 for each species).

Commented [PD48]: Kevin – who can write this bits?

~~Thailand: XXXXXXXXXX~~

Commented [KJ049]: I think all this could be deleted. Doesn't fit with the overall plan, or is redundant. We may want to call out a few specific sites Tom mentions (but won't that depend on the modeling!?), and you may want to keep the partner info Tom provided and call that out - maybe more in Aim 2 since its about people too?

**1.4.c. Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs ~~with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C.~~ PCR screening will be performed with pan-coronavirus, filovirus and paramyxovirus primers, ~~in addition to virus specific primers where additional sensitivity is warranted in key viral reservoirs, i.e. Nipah virus specific primers [REF].~~ PCR products will be gel purified and sequenced. We will attempt isolation on samples that contain viruses of interest (determined in 1.4, below), using Vero cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). ~~This includes the o~~ Over 30-70 bat cell lines are maintained at Duke-NUS from four-five different bat species. ~~These include primary lung, brain, bone marrow, heart, kidney, intestine, liver, lymph node, muscle, spleen, PBMC and ovary/testes from *Eonycteris spelaea*, *Cynopterus brachyotis*, *Rhinolophus Lepidus*, *Myotis muricola* and *Pteropus alecto* bats. In addition we have 8 immortalized cell lines, including those derived from lungs, therefore suitable for the isolation of respiratory viruses.~~

Commented [MOU50]: Supaporn: From my DTRA study, specific Nipah primers and WHO 2C CoV primers is more sensitive than consensus PCR if we want to find the specific virus.

**1.4.d. Moving beyond RNA viruses:** To detect pathogens from other families, such as non-RNA viruses we will combine conserved PCR assays with NGS. We will perform either unbiased NGS, or use a pan-viral enrichment library to sequence full-length genomes. We will conduct this work via EID-CC research projects or as part of outbreak detection/investigation in the region from DNA viruses or other agents.

Commented [PD51]: Linfa – can you give a v. brief description of these please, e.g.: “This includes 13 primary lung, 5 primary gut epithelial, and 1 primary liver cell line. In addition we have 12 immortalized cell lines, 7 of which are intestinal, and therefore suitable for CoVs. Cell lines are derived from insectivorous and frugivorous bats (genera.....)”

**1.4.e. Sequencing Spike Glycoproteins:** Based on earlier studies, our working hypothesis is that zoonotic coronaviruses, filoviruses and henipaviruses encode receptor binding glycoproteins that elicit efficient infection of primary human cells (e.g., lung, liver, etc.) (12, 59, 60). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (Fig. 4) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are under sampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (20, 60, 118), suggesting that existing vaccines and immunotherapeutics could easily fail against future emerging SARS-like CoV. Moreover, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic receptor binding protein genes of MERS-related, Ebola-related and *NipahNiV*/*HeVndra*-related viruses will also program efficient entry via human ortholog receptors. For all novel virus strains, we will sequence the complete entry spike genes by amplifying overlapping fragments using degenerate primers as shown previously (20, 59). Full-length genomes of selected CoV strains (representative across subclades) will be sequenced using *NEBNext Ultra II DNA Library Prep Kit for Illumina* and sequenced on a *MiSeq* sequencer. ~~NGS. PCR or Minlon sequencing will be performed to fill gaps in the genome.~~ The full length spike gene sequences, including the amount of variation in the receptor binding residues that bind the appropriate human receptor will be used to select strains for Aim 3 experiments.

Formatted: Font: Italic

**1.5. Assessing risk for spillover. 1.5.a. Capacity to infect human cells:** [We will use a series of cell cultures](#) ~~to~~ to assess the capacity of target viruses to enter human cells. ~~For CoVs, filoviruses and henipaviruses,~~ we will use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (60, 61, 119). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs or other ~~test~~ filoviruses or henipaviruses to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other viruses (62, 69). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (61, 120) or monoclonal antibodies targeting the Ebola or Marburg E glycoprotein (Available through BEI), or NiVpah or HeVndra ~~viruses~~ glycoproteins (121). As controls or if antisera is not available, the S genes of novel SARSr-CoV or spike entry genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (122). Polyclonal sera against SARS-related viruses will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (61, 123, 124). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (125) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (126-128). Similar approaches will be applied to novel MERS-related viruses, other CoV, filoviruses or henipaviruses. While most wildlife-origin viruses with unknown transmission potential or pathogenicity in people are BSL-2 or -3, cell culture for potentially BSL-4 pathogens will be undertaken at collaborating institute NEIDL. To facilitate this, duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (**See letter of support**) for culture, characterization and sharing with other approved agencies including NIH [Rocky Mountain Laboratories RML](#) where our EID-SEARCH team has [ongoing collaborations](#). When appropriate of feasible, training opportunities at NEIDL for in-country staff will be given.

**1.5.b. Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the *intraspecific* scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (68). [A lot of variation](#) in the NPC1 receptor alters EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains (129). Signatures of positive selection in bat NPC1 were concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in *Eidolon helvum* cells. Thus NPC1 is a genetic determinant of filovirus susceptibility in bats, and some NPC1 variations likely reflect host adaptations to reduce filovirus replication and virulence (130). Nipah and Hendra use ephrin B2 or ephrin B3 as a receptor, and variation affects its ability to use human vs bat receptor molecules (101, 131).

**1.5.c. Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of [RNA-dependent RNA polymerase \(RdRp\) sequences from PCR screening \(or L-genes\)](#), receptor binding glycoproteins, and/or full genome sequence [data \(when available\) data](#) to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, filoviruses and henipaviruses that we identify. [We will run phylogenetic and ancestral state reconstruction analyses \(Fig. 5\) to reconstruct identify host taxa and geographic sites of  \$\beta\$ -CoV, filovirus and henipavirus evolutionary origins within bats, rodents and primates using our expanded dataset and identify the host taxa and geographic regions that together define hotspots of phylo-diversity for these viruses, allowing for more targeted surveillance.](#) For receptor binding glycoprotein sequence data from characterized viruses, we will apply codon usage analyses and codon adaptation indices, as used recently on Henipaviruses (132), to assess the relative contributions of natural selection and mutation

**Commented [BR52]:** Any antibodies available? If not we can synthesize them from published co-crystals.

**Commented [DA53]:** Chris has them

**Commented [PD54]:** Can someone answer Ralph's question please?

**Commented [KJ055]:** Make more specific about our plans to sequence NPC1 or Ephrin receptors, etc. Should we frame much of this as "add on projects" pending additional EIDRC-CC funding?

**Commented [PD56]:** Kevin/Alice – please edit this section to include relevance for filoviruses and henipaviruses as well (and other hosts)

pressure in shaping host adaptation and host range. We will rerun MCC analyses (Fig. 3) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (Fig. 4) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) or other virus families within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (95, 133).

**1.5.d. Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, and approximately 600 total CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (120, 134-136). For novel henipaviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize strains that are predicted to interact with ephrin-B2 and expression VW proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models. We will assess ability to infect human cells using a continuous lung epithelial cell line, Calu3, that our group has previously used to generate data on NiV and HeV growth curves and a variety of host expression changes after infection (137). We will also use primary human airway cultures to assess human infection for Henipavirus and MERS- and SARS-related CoV (138) (139). There is some evidence for Nipah and Hendra virus replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (140, 141). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted Ebola infections (85-87).

**1.5.e. Animal models:** We will use transgenic mouse models and the UNC Collaborative Cross model to assess spillover potential of viruses. For work on CoVs, we will follow the protocols in the transgenic mouse model used by the Baric lab previously. Briefly, in the BSL3 lab, n=8 10- to 20-week old hACE2 or hDPP4 transgenic mice will be intranasally inoculated with  $5 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins or MERS-CoV and MERS-related CoV, respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV or MERS-CoV mAbs (142, 143) will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (119, 144). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (61, 119). For the Collaborative Cross model, we will....

Commented [KJ057]: I suggested we could get up to 600 CoV "strains" (all seqs, not just SARSr-CoVs) in section 1.4b, but we can reduce that.

Commented [PD58]: Ralph – please insert a couple of sentences on how we'll use the cc mouse and what we'd expect

Finally, for more detailed pathogenesis studies in the natural reservoir, we will use the bat models (natural and transgenic mouse model) at Duke-NUS. Both animal systems can be used to test susceptibility, pathogenesis and immune responses of any newly discovered viruses.

**1.6. Potential problems/alternative approaches:** Challenges with logistics or obtaining permission to for wildlife sampling in sites we select~~sample bats in sites or provinces we select~~. We have a >20-year track record of successful field work in Malaysia, ~~Thailand and and~~ >10 years in ~~Thailand~~Singapore, and have ~~worked with~~strong established partnerships with local wildlife authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based ~~on a range of PCR data and are fairly conservative in our approach~~ realistic detection rates from our extensive preliminary data, and are confident that we will detect and identify large numbers of potentially zoonotic pathogens, particularly for CoVs and PMVs. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses~~We acknowledge that FV strain diversity may be harder to capture, given relatively low seroprevalence in bat populations – suggesting lower levels of viral circulations (40, 41). However, our team was the first and among the only groups to sequence FV RNA from Asian wildlife species(44, 45, 55), and we are confident that with our targeted sampling and testing strategy will identify additional strains of Ebola and related viruses.~~ The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (145), do not suggest a strong pattern of seasonality in CoV shedding, ~~although there are studies that suggest this~~and where seasonal patterns do occurs, i.e. for in henipaviruses and filovirus (MARV?) shedding (REFS?)in Thailand (146) or can be predicted from wildlife serology data, we will be sure to .~~Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province at different timepoints throughout the year to account for this.~~

**Commented [PD59]:** Linfa/Danielle – could you put a couple of sentences in on what we might do with the models. Remember – this could be an additional short project from the EIDCC extra funding.

**Commented [DA60]:** This is added above. All the SARS parts are very detailed (with temperatures and dilutions etc). We can cut the detail out if we need to cut pages.

**Aim 2: Test evidence of viral spillover in high-risk communities using novel serological assays.**

**Commented [KJO61]:** Emily and Noam reworking this section significantly, so not touching it much.

Country, site	Lead	# enrolled, focus	Findings
Peninsular Malaysia	Hughes	1,390 Orang Asli indigenous population, PCR/serol.	25+ novel CoVs, influenza, Nipah ab+ve, filovirus ab+ve
Malaysia Sabah	Kamruddin	1,283 serology	40% JE, 5% ZIKV ab+ve
Malaysia Sabah	William	10,800 zoonotic malaria	High burden of macaque-origin malaria

Malaysia Sabah	Hughes	150 bat cave workers	Ongoing
Malaysia Sarawak	Tan	500 Bidayuh and Iban people	8% PCR prevalence HPV in women
Malaysia PREDICT	Hughes	9,933 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Thailand	Wacharapluesadee	1,000 bat guano harvesters/villagers	Novel HKU1-CoV assoc. clinical findings
Thailand PREDICT	Wacharapluesadee	9,269 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Singapore	Wang	856, Melaka virus	7-11% ab+ve

**2.1 Rationale/Innovation:** Rapid response requires early detection. Thus, assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that interface frequently with wildlife that harbor high risk emerging viral strains. To enhance the low statistical probability of identifying these rare events, we will target rural human communities inhabiting

regions of high wildlife biodiversity, that also engage in practices that increase the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will build and expand on our preliminary biological sampling and enroll large cross-sectional samples in human populations with high behavioral risk of exposure to wildlife-origin viruses and that live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will initially identify 2 sites in each of Thailand, Peninsular Malaysia, Sarawak, and Sabah for repeated biological sampling. We will design and deploy behavioral risk factor questionnaires, and specific and sensitive serological assays to identify the baseline frequency, and causes of, spillover of known and related novel viral pathogens in these populations. In participants where symptoms are reported in the last 10 days, paired serum specimens (acute and 21 days after fever) will be collected to determine titer of positive antibody. Samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, and for isolation and biological characterization of potential pathogens, using the approach laid out in Aim 1.

**2.2 Preliminary data on high-zoonotic risk human community surveillance: 2.2.a Biological sample collection in SE Asia:** Our longterm collaboration in the region has included qualitative and quantitative survey data, and collecting large archives of banked human sera and other biological samples from high zoonotic-risk populations. For example, under the USAID-PREDICT project, EHA has collected 9,933 and 9,269 specimens in Malaysia and Thailand respectively from people living in zoonotic disease interfaces, all of which will be available for retrospective serological testing by EID-SEARCH. Our core group has collected and tested many thousand additional specimens from other important community cohorts (Table 2), and some of these will continue under EID-SEARCH (See section 2.4). Of particular interest is the access to indigenous communities in Peninsular Malaysia (Orang Asli) and Sarawak (Bidayuh, Iban people), and the bat guano harvesters in Thailand. These communities hunt, butcher and eat wildlife daily, and work in supremely high-risk zoonotic interfaces (e.g. bat caves). One of our indigenous community sites is experiencing an ongoing outbreak of unknown etiology that we are investigating currently (See section 3.2.a).

**Table 2:** Current or recent biological sample collection from healthy populations conducted by members of our consortium in EID-SEARCH hub countries

**2.2.b Human Contact Risk Factors:** EHA is the lead organization across all 27 USAID-PREDICT project countries for collecting data on, and analyzing the human aspects of, zoonotic spillover risk (147, 148). We conducted exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities, using these data to assess local social and cultural norms underlying wildlife contact (148). We then developed a risk factor survey to accompany human biological sampling to evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in 27 countries, and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). For example, survey and biological samples were collected from: 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, China; 1,400 participants from 4 sites in Malaysia; and 678 participants from 4 sites in

**Commented [KJO62]:** Check these numbers, don't think we have 9000 people sampled, if this represents individuals! Per below, we say we have 9000 specimens, not people, so need to adjust.

**Commented [KJO63]:** Emily: Will we be sampling participants more than once?

**Commented [PD64]:** I think that would be good, depending on the sample size

**Commented [KJO65]:** Need to decide if we do PCR on community samples, we can add in the questionnaire if you've been sick in the last 10 days and if so, then maybe test only this subset.

**Commented [PD66]:** Kevin's comment makes sense to me

**Commented [KJO67]:** Don't match table numbers, need to change table header to # specimens, not # enrolled.

Thailand. Samples were tested with novel serological assays and results analyzed against risk factors from survey data (12). In China, CoV-seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), that are male (6/9). Although these results are preliminary and don't provide detailed information on routes of exposure, they identify key subpopulations to target that would likely increase the opportunity for identifying evidence of spillover for other CoVs, paramyxoviruses and filoviruses. Data from PREDICT surveys will be used to help identify target populations in Aim 2, identify strategies to better target at-risk people, and conduct focused **human animal contact surveys and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.** In Aim 2, we will use combined biological sampling and risk factor surveillance in targeted populations within the community to 1) identify risk factors correlated with seropositivity to henipaviruses, filoviruses and CoVs; 2) assess possible health effects of infection in people; and 3) where recent illness is reported, obtain clinical samples for PCR testing and potential viral isolation and characterization. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**2.2.c. Risk factors for illness:** Our preliminary data from PREDICT in Thailand, Malaysia and China revealed that frequent contact with wild (e.g. bats, rodents, non-human primates) and domestic animals (e.g. poultry, swine) among local communities was associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms. In addition, people involved in crop production, hunting and butchering of wildlife reported statistically significantly higher SARI and ILI symptoms (Li *et al.*, in prep.). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with further refining serological tools, we will be able to identify the likely routes of exposure to known or novel coronaviruses, henipaviruses, and filoviruses in the study region, as well as build data on the illnesses they cause in people.

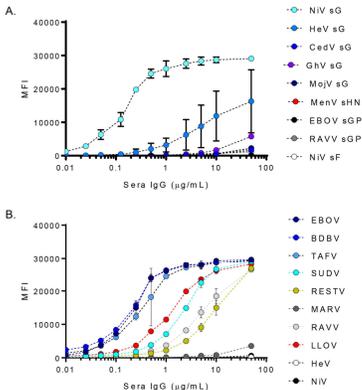

**2.2.d. Serological platform for community surveillance:** One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. By contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes (149). However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. Henipaviruses, filovirus and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filoviruses/henipaviruses=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (150)?, developing monoclonal antibodies (151, 152) and as subunit vaccines (153, 154), is presently developing a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, filoviruses and coronaviruses. This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (150). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

Commented [KJO68]: Peter, sent over LASSO figure for ILI from Thailand and Malaysia for you to consider.

Commented [PD69]: Chris/Eric Is this the right ref?

Commented [KJO70]: See my comment in Aim 1 that some of that serology platform stuff can be moved here.

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay. The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (Fig. XXX). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-related African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (76, 77). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus

henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (155-157). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity. The majority of ebolaviruses are endemic to Africa, however the discovery of Měnglà virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown pathogenicity and zoonotic potential exists. Our past work in collaboration with Duke-NUS demonstrated that three under-sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (41).

Fig. XXX: Validation of multiplex microsphere immunoassay

(MMIA) specificity and identification of immunologically cross-reactive viruses for NiVpah (A) and EBOVbola (B).

**2.3 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (Fig. XX). In Aim 2 we will conduct community-based surveillance using a brief, focused questionnaire to identify the prevalence and frequency of risk-factors for viral spillover in tandem with collection of high quality biological samples to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the communities sampled in Aim 2. Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and PCR prevalence in symptomatic patients.

**2.4 Target population & sample sizes:** We will target populations in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, that are EID hotspots, and that are well-connected through regional travel and trade hubs to the global travel network (Fig X). We will target specific communities based on our analysis of previously-collected PREDICT behavioral questionnaire data, to assess key at-risk populations and occupations with high exposure to wildlife, as well as using other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will identify populations at two sites in each of the following regions, building on our preliminary data (Table 2): Thailand (Co-I Wacharapluesadee): We will continue surveillance in bat guano harvesters and their villages in Ratchaburi province where we have identified MERS-related CoV in bat guano and rectal swabs (48, 158) and serological evidence of α-CoVs, HKU1-CoV in people (Wacharapluesadee in prep.). Our second site will be in Chonburi province where we have found NiVpah virus (99% identity of whole genome sequence to NiV from a Bangladesh patient) in flying foxes but no outbreaks have yet been reported (REFThai MOPH, unpublished), and have found several novel paramyxoviruses and CoVs have been found in bat feces roosting there ((159, 160), Wacharapluesadee in prep.).

Commented [PD71]: Hongying -Need a new figure that lays out the community/clinical approach – small one with pretty images.

Commented [PD72]: Supaporn/Kevin/ -Need sample sizes for both populations and power calculations for serology for a typical virus from one of the three families we're targeting

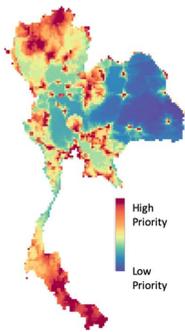

Commented [KJ073]: I pasted in info from Supaporn below.

Commented [PD74]: Supaporn – please insert a reference into this comment box

Commented [KJ075]: Added in a couple more of her refs.

Sample size: Serological exposure likely low due to low risk of onward transmission. High risk occupational groups vs. community sample at each site. Need to stratify sampling in villages based on

Thailand: 100 subjects of healthy high-risk community from 2 study sites (Chonburi and Ratchaburi) will be enrolled on Year 2 and tested for antibody, and specimen from ill subject will be collected and tested by PCR and serology assays. Specimens from same subject will be collected on Y3 and Y4 for serology re-testing.

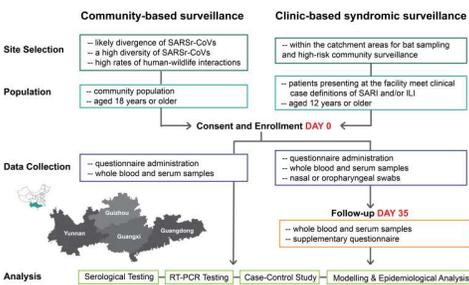

**Fig. X:** Geographic analysis to target high-risk sites for human zoonotic disease surveillance in Thailand. Our spatial analysis from Aim 1 will be extended to optimize sites for human community surveillance in Thailand and Malaysia by ranking areas with high numbers of expected viruses in wildlife, greater spillover probability based on EID risk factors, and higher levels of connectivity (measured by road density data) that may facilitate person-person spread.

**Peninsular Malaysia (Co-I Hughes, CM Ltd.):** We will expand our sampling of the Orang Asli indigenous communities to include additional communities in the 3 Districts we have already sampled, and additional Districts in the States of Kelantan Perak, Pahang, and Kelantan. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled. Human samples will include serum, whole blood, throat swabs, nasal swabs, urine, and fecal sample or rectal swab. Samples will be collected in duplicate in VTM and Trizol. Samples will be stored and tested at NPHL. Participants who hunt, butcher or consume wildlife, or who rear animals will be considered suitable

for enrolment. Participants will complete a consent form and questionnaire in addition to having samples collected. During these community trips the field team will conduct community meetings to help inform the Orang Asli about the public health risk of zoonoses. **Sarawak (Co-I Tan, UNIMAS):** We will expand our sampling of the Bidayuh and Iban indigenous people to include the Dayak and Orang Ulu ("people of the interior") because this group has a more intimate connection to remote wildlife-rich areas than the other two, albeit all are hunters. Human sampling will be led by UniMAS in collaboration with CM Ltd / EHA. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled, following the same protocols as for Peninsular Malaysia. **Sabah:** We will conduct sampling at the Madai bat and bird cave that has 200 permanent residents who harvest bird's nests for soup, and >1,000 during the harvesting season and at Gomantong cave – one of the largest bat and cave swiftlet nesting sites in the world. Protocols follow those for Peninsular Malaysia. **Singapore:** Active human surveillance will not be conducted in Singapore, but archived human specimens e.g. from our Melaka virus serosurvey (4), will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

**Sample sizes:** From our previous work we anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so

that they make up  $\geq 30\%$  of the sampled population in each community. We will stratify sampling to ensure appropriate representation of sex, demographic, and socio-economic factors at each community site. Estimating 5% overall seroprevalence in these high-exposure populations, these sample sizes are sufficient to estimate effect sizes of risk factors of 2X or greater with 80% power. For community-based surveillance, we will enroll xxx individuals per county/province, pooled across two sites for each, allowing us to make county/province-level comparisons of differing effects.

**Commented [S76]:** I think the animal and human specimen collection should be in a same format for Thailand and Malaysia.

**Commented [PD77]:** Need this figure for Singapore, Pen. Malaysia, Sarawak, Sabah as well – all together is best

**Commented [KJ078]:** Sam is going to send a combined figure tomorrow AM.

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**2.5 Data & sample collection:** Following enrollment of eligible participants and completion of the consent procedure, biological specimens (5ml will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 2.5ml whole blood; two 500 µL serum samples) will be collected and a questionnaire will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent considerations for participants enrolled from clinical settings we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

**2.6: Laboratory analysis: 2.6.a Serological testing:**

In a previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity detected (12). **This suggests that if we can expand our serology tests to cover other bat CoVs, and that doing so may identify many more seropositive individuals.** We will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 bat SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoVs SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (12), and HKU10 is known to jump from one host bat species to another (161) so is likely to have infected people more widely. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV, at a phylogenetic distance where therapeutic or vaccine efficacy may falter. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or S1 (n-terminal domain); 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (13). Additionally, in Thailand, as an initial project on our EIDRC, we will develop serology assays to the novel CoVs found in bats at the bat guano site using LIPS assays and viral genomic data, and will screen archived specimens from 230 participants (2 years' collection in 2017-2018, a subset of the subjects have been sampled at multiple time points to allow us to assess seroconversion).

**2.6.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b.4.c for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein genes. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E, NiV, HeV, Ebola (WHO PCR protocol) based on the symptom as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

**2.6.c Biological characterization of viruses identified:** Novel viruses identified in humans will be recovered by cultivation or from full length genome sequences using reverse genetic approaches. Viruses will be characterized for growth in primary human cell lines and in mouse models, including the Collaborative Cross

**Commented [PD79]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipas, filoviruses and CoVs.

**Commented [PD80]:** Emily/Hongying Please check

**Commented [PD81]:** Chris, Eric, Linfa, Dani etc. please draft some language here...

**Commented [DA82]:** Can we cut out some of the very specific CoV details? Especially the recombination (which filovirus and paramyxovirus don't do).

**Commented [PD83]:** HELP – please add text for Henipavirus, filovirus

**Commented [DA84]:** RdRp and glycoproteins applies to all

**Commented [MOU85]:** Supaporn: These should be depending on the viruses found in wildlife animal from the studied countries.

Mice or humanized mice expressing human receptors from related strains. The approaches are discussed in more detail under Aim 1.

**2.7 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for Henipavirus, Filoviruses, and CoVs spillover. "Cases" are defined as participants whose samples tested positive for Henipavirus, Filoviruses, or CoVs by serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative for Henipavirus, Filoviruses, or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between Henipavirus, Filoviruses, or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, paramyxoviruses, and influenza viruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may not match known viruses due to recombination events, particularly for CoVs.** We will use the three-tiered serological testing system outline in 2.6.a to try to identify these 'novel' viruses, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

### **Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research (Table 1) and other data suggests that there are substantial numbers of outbreaks or clinical cases for which the etiologic agent is not diagnosed, e.g. (162, 163). To investigate this in SE. Asia, we will work directly with clinics and outbreak control organizations to identify the causes of some 'cryptic' outbreaks or cases in the region. Specifically, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and who present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We conduct novel viral discovery assays on patients who present with symptoms indicative of a high-risk zoonotic virus. If novel pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the pathogen, using the *in vitro* and *in vivo* strategy laid out in Aim 1.

**3.2 Preliminary data clinical surveillance: 3.2.a. Clinical surveys and outbreak investigations:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes: ***Peninsular Malaysia: At the time of writing, there is an outbreak of suspected viral undiagnosed illness in the indigenous Batek Orang Asli ("people of the forest") community living at Gua Musang ("civet cat cave") district, in Kelantan, Malaysia, close to Taman Negara – a National Park containing the oldest known rainforest. This community is one where we have conducted prior routine surveillance and biological***

**Commented [KJ086]:** Make this more general. There's a greater challenge of interpretation of serological data, esp. if we're using many platforms (each will have its own problems that our lab colleagues are probably more familiar with). Noam may be able to generally comment on a solution here from a statistical perspective.

**Commented [PD87]:** Kevin – please modify according to your comment

**Commented [KJ088]:** Noam is working on this section, so can review after/tomorrow.

sampling, demonstrating proof-of-concept that our two-pronged high-risk community/clinic approach will work. Dozens of people are affected and the outbreak is currently being investigated by our collaborators at the Malaysian NPHL. The Orang Asli live in remote villages in the rainforest of Malaysia, with limited access to modern health care and extensive contact hunting, butchering, and eating wildlife as their primary source of protein. This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC - to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia. **Investigating this outbreak be a key priority if EID-SEARCH is funded.** *Sabah:* Co-I Kamruddin (BMHRC) is leading an asymptomatic leptospirosis study on sanitation workers, an ILI study in a Kota Kinabalu clinic and diarrheal study in children under 5 yrs. Co-Is William, Tan and others have conducted clinical observational studies to determine the etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah. Co-Is Tan, William have collaborated with Co-I Wang to enroll 90 adult and over 100 pediatric participants with central nervous system infections, negative tests for malaria and dengue from 3 district hospitals in Sabah to determine the various etiologies. While a high proportion tested positive for rickettsial agents, the majority had no clear diagnosis. *Sarawak:* Dr Tan (UNIMAS) is conducting a survey of high-risk female Kelabit indigenous people and has found 8% with HPV52 as the dominant strain. He is working on clinical cohorts of hand, foot and mouth disease and will recruit patients from that study in the current proposed work. Finally, he is conducting a longterm study of rotavirus and other viral etiologies of acute gastroenteritis in Kuching, Sarawak that will include swine herders and farmers. These are an important group in Malaysia because pig farms are shunned by the government and local villagers to they are placed far away from town centers, deep in the forest, and it is this scenario that led to the emergence of Nipah virus in 1998-9 (18, 164). *Thailand:* The Chulalongkorn Univ. TRC-EID laboratory works in coordination with the Thailand Ministry of Health to investigate outbreak etiology, including the first case of imported MERS-CoV in Thailand, **for which we produced sequence confirmation within 24 hours from acquiring the specimen** ~~(Fig. X)~~. Three imported MERS cases have been detected in Thailand since 2015, and all cases were confirmed at the TRC-EID. We worked during the Zika outbreak to identify > 500 PCR-positive Zika patients with sequence confirmation. We have also worked on returning and suspected Ebola travelers, syndromic surveillance for SARI, Encephalitis, Hand Foot and Mouth disease in children and Viral diarrhea. Working with the US CDC (Thailand), between 1998 and 2002 we enrolled a large cohort of children from Kamphaeng Phet Province to examine Dengue virus and JE epidemiology (165, 166). Among the 784/2,574 convalescent sera Henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence), suggesting prior exposure to endemic henipaviruses or a related paramyxovirus in rural Thailand. *Singapore:* Duke-NUS has worked with the Ministry of Health to investigate Zika cases (167), and with EcoHealth and others, Duke-NUS has developed novel CoV assays for clinical surveillance, and for expedited analysis during outbreaks. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing is as rapid as several months, with the development of novel serological assays from sequence data in 7 days (13). **For example, with the discovery of SADS-CoV, we identified and fully sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (*Rhinolophus* spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (13).**

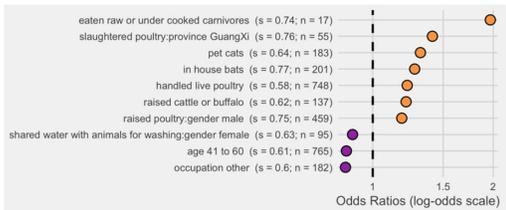

**3.2.b Analysis of self-reported illness:** In addition to biological outcomes we have developed a standardized approach in PREDICT for analyzing data on self-reported symptoms related to targeted illnesses; of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), fever with muscle aches (fevers of unknown origin (FUO) and, cough or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI and/or SARI symptoms and demographics, occupation, and contact with animals in the last year. Results have clear biological relevance. In Yunnan, China, salient associated variables or combination of variables were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (Fig. 11). We will expand this approach for all syndromes in Aim 3, and use more granular targeted questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country.

Formatted: Underline

Commented [KJO89]: Deleted sentence below, because reality is, not likely an issue in ~4-6 months when we get funded and seems to be measles. Should play up as an example, but not an actual item for follow up..

Commented [MOU90]: Replace w Malaysia or Thailand LASSO

**Fig. 11:** Associated variables of self-reported ILI and/or SARI in prior 12 months ( $s$  = bootstrap support;  $n$  = number +ve out of 1,585 respondents). **Orange circles** = odds ratios > 1 (positively associated with the outcome); **purple** = odds ratios <1 (negatively associated with the outcome).

**3.3 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms

typical of high-impact emerging viruses. We will collect survey data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.4 Clinical cohorts. 3.4.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at 2 town-level level clinics and 2 provincial-level hospitals in Thailand, Peninsular Malaysia, Sabah and Sarawak. These all serve as the catchment healthcare facility for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients  $\geq 12$  years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, fevers of unknown origin, or hemorrhagic fever will be recruited into the study. We will enroll a total of xxxx individuals for clinical syndromic surveillance, which accounts for up to 40% loss from follow-up. Study data will be pooled across country sites, as clinical patients are limited by the number of individuals presenting at hospitals. Sites: Thailand: Two new district hospitals at the same site of high-risk community will be included to the study to collect specimens (PREDICT sample protocol) from patients with respiratory and/or encephalitis symptom during 3 years of the study (Year 2 to Year 4), at least 100 patients from each hospital will be enrolled and laboratory tested by PCR and serology assays. The second blood after 21 days of fever will be collected for serology testing. -XXXXX Peninsular Malaysia: Focusing immediately on the current outbreak in Orang Asli, we will work closely with the Malaysian Ministry of Health to support their investigation. We will also work with 6 Orang Asli clinics which focus solely on this indigenous community. Sarawak: XXXXXX Sabah: XXXXXXXXXX, Singapore: XXXXX Given budget constraints we will not deperform clinical cohorts, however in the event of a suspected outbreak we have close relationships with xxxxx xxxxx all hospitals nationwide, and the central infectious disease reference lab.

**3.4.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever of unknown etiology; or 6) severe diarrhea. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance of PCR detection of viruses (168). We will follow up 35 days after enrollment to collect an additional two 500  $\mu$ L serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period, and allow 35 days gives adequate time for development of IgG, which occurs <28 days after onset of symptoms for SARS patients (169). These samples may prove valuable to collaborators in that the PBMC could be used in production of therapeutic antibodies.

**3.4.c Sampling:**

Commented [KJO91]: Pasted in from Supaporn.

Commented [KJO92]: Make sure this matches our timeline and target numbers. Noam to calculate minimum samples size for detection assuming 1-3% ?? viral prev. Need some refs or data on detection rate for "novel" etiological agents.

Commented [PD93]: Tom, Kevin – we need information.

Commented [KJO94]: Linfa/Dani?

Commented [DA95]: Technically this is true, it is a small country and Linfa knows everyone in the field.

Commented [PD96]: Hongying Emily

Commented [PD97]: Need data for Nipah and filovirus patients

Commented [PD98]: Ralph: PBMC could be valuable for making therapeutic antibodies through collaborations?

Commented [DA99]: EBOV review PMID: 28820067 NIV PMID: 30869046

Following enrollment with signed consent form, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples) including two nasal or oropharyngeal swabs will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

**Commented [KJO100]:** Blood just during 35 day follow up, or both? I guess both ideally, but weigh against IRB.

### 3.5 Sample testing: PCR, Serol to link symptoms to etiologic agents

The standard syndromic diagnostic PCR assays for the common pathogens will be conducted and the results will be shared te-with the hospital with 48 hours. Specimens will be further tested for 3 viral families; CoV, PmV and filovirus by consensus PCR. Appropriate specimen from dead/Necropsy samples from deceased patients case will be further conducted-characterized by NGS if the previous PCR tests are negative and unable to identify the/ied cause of infection. A VirScan/The serology panel assay will be conducted from-using paired serum samples. This serological assay

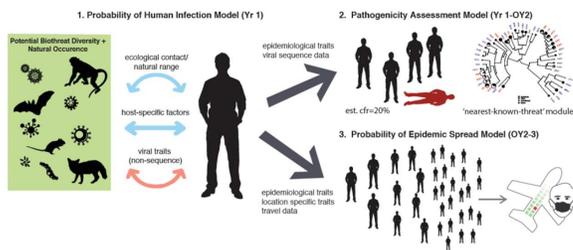

**Commented [PD101]:** This is v. weak – can someone strengthen it please!

**Commented [KJO102]:** Text from Supaporn

Serology: Panel serology assay will be performed from paired serum to determine identifies antibodies with a the four-fold rise in titer in the convalescent sample as compared with the acute sample, thereby indicating a possible etiologic agent, raising antibody. A The-specific-primer PCR for the identified virus antibody positive-case will be further tested fromin the acute specimens to confirm-for infection.

**Commented [PD103]:** This is v. weak – can someone strengthen it please!

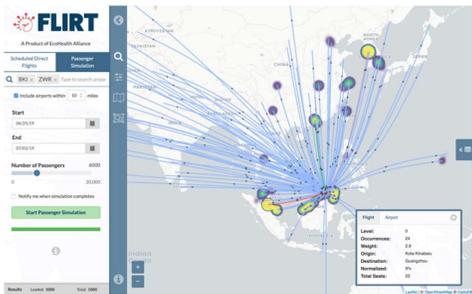

**3.5 Assessing potential for pandemic spread:** Building off our spillover risk characterization in Aim 1, wWe will use statistical models built from collated biological, ecological, and genetic data to predict-further assess the likelihood of human infection (or-spillover) and also pathogenicity for a-the range of diverse viruses we will characterize. The aim is to quickly identify and assess which viruses pose the most significant risk to human health and thus prioritize additional resources to more fully characterize, better understand pathogenicity, and invest in therapeutic development for those pathogens. We will combine two independent but related statistical models to predict pathogen spillover risk and pathogenicity. First, we will expand a simple generalized additive modeling approach (90) to assess spillover risk probability to a new virus that is currently not known to infect people, when we have only limited genetic data from initial PCR screening and sequencing. Additional data from receptor binding protein homology and cell line infection experiments can-will be incorporated into the model framework as available. Second, given high likelihood to spillover and infect humans, or direct evidence of human infection from our clinical surveillance, we will then predict pathogenicity using nearest neighbor phylogenetic analyses as a first approximation and by incorporating more detailed data from genomic characterization and animal model experiments (Aim 1). For-the pathogenicity model, hEuman-epidemiological trait data for ~300 viral species known to infect people (e.g. case fatality rate, global estimates of number of human cases per year or decade,  $R_0$ , infectious period, and primary symptoms) will be aggregated including fromhave been collated by recent studies-previous and will be used as reviews [Woolhouse ref] to use as predictor variables. Thirdly, we will build-offapply tools already developed, and being refined by EHA under's previous DTRA and DHS supported research, to predict pandemic spread for viursesviruses we identify by integrating surveillance site data,using global flight models (170), as well as additional datasets (road networks, shipping-routes, cell phone data) to measure-on human movement and connectivity across Southeast Asia.

**Fig. XXXX:** Conceptual framework highlighting 3 underlying models to estimate: 1) probability of human infection, or spillover, the first necessary step to understand pathogenicity when status of human infection is unknown; 2) pathogenicity, i.e. probability of causing clinical signs, case fatality rate estimates, and other metrics relevant to humans; and 3) probability of pathogen spread based on ecological, epidemiological, and airline connectivity and human migration data.

**Commented [PD104]:** Hongying – please work with Kevin to come up with something of relevance here. Also, make the text brief, bold and large so it's readable

**Commented [KJO105]:** See also FLIRT flight simulator figure below. Peter, let's decide if I should rework this figure to combine both, or how to proceed with this section.

**3.7 Potential problems/alternative approaches:** Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases. Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development *was* ~28 days (168). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the

**Commented [PD106]:** Add data for Nipah and filio infections

**Commented [DA107]:** Add the same references I listed above

potential public health importance of discovering active spillover of a new henipavirus, filovirus or CoV infection.

**Additional Instructions – Specific to the EIDRC FOA:**

**4. Administrative Plan**

In a clearly labeled section entitled “Administrative Plan”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.

Chula TRC-EID is National reference laboratory for diagnostic and confirmation of EIDs pathogen along with the National public health laboratory at the Department of Medical Science and the WHO Collaborating Centre for Research and Training on Viral Zoonoses. We have built a EID laboratory network in-country among three Ministry including Ministry of Public Health (Department of Medical Science and Department of Disease Control), Department of Livestock and Development, and Department of National Parks, Wildlife and Plant Conservation and Universities and among SEARO countries. Our clinicians provide case consultation for Thailand and SEARO countries. The laboratory and clinic training are regularly conducted.

**Commented [PD108]:** All – I've started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**Commented [PD109]:** From Supaporn

**For Malaysia –**

**NPHL** – Molecular and serological screening (BioPlex) of PM Orang Asli samples, serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval)

**PERHILITAN molecular zoonosis laboratory, at the National Wildlife Forensic Laboratory** - Molecular and serological screening (BioPlex) of PM wildlife samples

**UPM Faculty of Veterinary Medicine** - Molecular and serological screening (BioPlex) of PM livestock samples

**KKPHL** - Molecular of syndromic samples from Sabah (already done) and Sarawak (would need approval)

**SWD WHGFL** - Molecular screening of Sabah wildlife samples

**BMHRC** - Molecular and serological screening (BioPlex) of Sabah livestock samples, serological screening (BioPlex) of Sabah wildlife samples, Molecular and serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval). BMHRC will need renovations and BioPlex to do this work – Menzies team might have funds for BioPlex that they would base here as part of DTRA project.

- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

List out all of our involvement with outbreak investigations, ministries of health surveillance etc.

If possible the clean or summarized answers from the questionnaire should be shared to the hospital Infectious Control team and Bureau of Epidemiology for their information for controlling the outbreak.

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

CM/EHA helped establish and manages with SWD the Wildlife Health, Genetic and Forensic Laboratory (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications) that has all the equipment necessary to store samples, run extractions, PCR and analysis on biological samples for wildlife disease surveillance. The lab is used to conduct health checks on rescued and relocated wildlife before being released into new areas or sanctuaries, to screen samples for the PREDICT and Deep Forest Project and for genetic research and forensic investigations. CM/EHA also helped establish the new molecular zoonosis laboratories (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications), at DWNP's National Wildlife Forensic Laboratory. The lab is used to screen samples for the PREDICT & DTRA projects. In addition CM/EHA also has access to NPHL and KKPHL for screening human samples and the Virology lab at FVMUPM for screening Livestock samples.

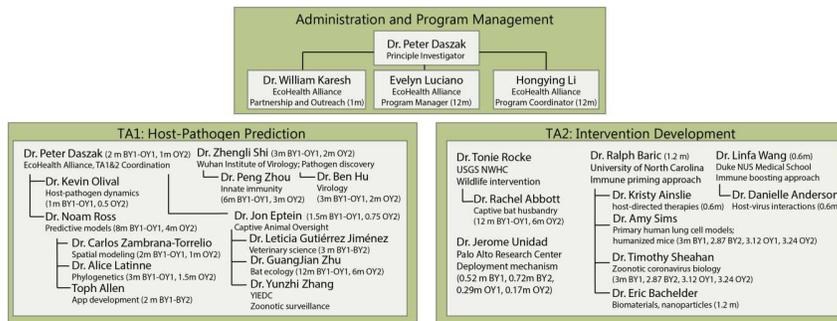

The Borneo Medical and Health Research Centre (BMHRC) is a centre of excellence that conducts teaching and scientific researches on communicable diseases, outbreak investigations, and ethnomedicine. BMHRC has offices space including a meeting room and seven laboratories which including preparation lab, parasitology lab, cell culture lab, bacteriology lab, natural product lab, virology lab, and molecular biology lab.

Commented [PD110]: From Supaporn – do same for all countries

BMHRC is supported by an administration staff, medical lab technologist, and research assistants who are available to work on projects. Through this project we will help to establish a certified BSL-2 lab at the BMHRC. This lab can then be used for human testing to elevate pressure at KKP HL and QEHL labs. It would also be an ideal location for a Luminex platform as human, wildlife and livestock samples could all be screened here. Co-Is Hughes and Kamruddin will be starting outbreak response training in August 2019 with a team from Sabah CDC, KKP HL and BMHRC. (Dr. Maria Suleiman now in PM But still collaborating with us, Dr. Muhammad Jikal current Director CDC working with us and Dato' Dr Cristina Rundi Director Sabah state health Dept is supportive) this collaborative group is working to develop a Sabah outbreak response team that will help support SSSH/ CDC outbreak team and also conduct sampling for disease surveillance to be based at BMHRC and we will develop this as part of this proposal. In addition the UMS hospital will come in line in 2021 providing additional opportunities for cohort studies and capacity building.

FROM DARPA grant:

**Section 1.03 MANAGEMENT PLAN**

Project DEFUSE lead institution is EcoHealth Alliance, New York, an international research organization focused on emerging zoonotic diseases. The PI, Dr. Daszak, has 25+ years' experience

Commented [KJO111]: Figure like this would be good, but instead of breaking down by TA, maybe by country or Specific Aim. Per FOA, Need to also show how we'll link in with the Coordinating Center and other EIDRCs.

managing lab, field and modeling research projects on emerging zoonoses. Dr. Daszak will commit 2 months annually (one funded by DEFUSE, one funded by core EHA funds) to oversee and coordinate all project activities, with emphasis on modeling and fieldwork in TA1. Dr. Karesh has 40+ years' experience leading zoonotic and wildlife disease projects, and will commit 1 month annually to manage partnership activities and outreach. Dr. Epstein, with 20 years' experience working emerging bat zoonoses will coordinate animal trials across partners. Drs. Olival and Ross will manage modeling approaches for this project. Support staff includes a field surveillance team, modeling analysts, developers, data managers, and field consultants in Yunnan Province, China. The EHA team has worked extensively with other collaborators: Prof. Wang (15+ yrs); Dr. Shi (15+ yrs); Prof. Baric (5+ yrs) and Dr. Roche (15+ yrs).

**Subcontracts: #1** to Prof. Baric, UNC, to oversee reverse engineering of SARSr-CoVs, BSL-3 humanized mouse experimental infections, design and testing of targeted immune boosting treatments; **#2** to Prof. Wang, Duke-NUS, to oversee broadscale immune boosting, captive bat experiments, and analyze immunological and virological responses to immune modulators; **#3** to Dr. Shi, Wuhan Inst. Virol., to conduct PCR testing, viral discovery and isolation from bat samples collected in China, spike protein binding assays, humanized mouse work, and experimental trials on *Rhinolophus* bats; **#4** to Dr. Roche, USGS NWHC, to refine delivery mechanisms for immune boosting treatments. Dr. Roche will use a captive colony of bats at NWHC for initial trials, and oversee cave experiments in the US and China. **#5** to Dr. Unidat, PARC, to develop innovative aerosol platform into a field-deployable device for large-scale inoculation of the bats. Dr. Unidat will collaborate closely with Dr. Roche in developing a field deployable prototype for both initial trails and cave experiments in China.

**Collaborator Coordination:** All key personnel will join regularly-scheduled web conferencing and conference calls in addition to frequent ad hoc email and telephone interactions between individuals and groups of investigators. Regular calls will include:

- Weekly meetings between the PI and Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.
- Monthly web conferences between key personnel (research presentations/coordination)
- Four in-person partner meetings annually with key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

Evaluation metrics will include the generation of high-quality data, successful achievement of milestones and timelines, scientific interaction and collaboration, the generation of high quality publications, and effective budget management. The PI and subawardee PIs will attend a kickoff meeting and the PI will meet regularly with DAPRA at headquarters and at site visits.

**Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by Dr. Daszak and the Project Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation. Should a resolution not be forthcoming, consultation with our technical advisors and DARPA Program staff may be warranted.

**Risk management:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. A project of this nature requires a different mindset from that typically associated with basic research activities that move at an incremental pace with investigators gradually optimizing experimental systems, refining data, or waiting for additional data before moving ahead with an analysis approach. To maintain our timeline, we will continually evaluate these trade-offs to make decisions about when iteration is appropriate and when necessary to move forward with current information.

**Biographies:**

**Dr. Peter Daszak** is President and Chief Scientist of EcoHealth Alliance, Chair of the NASEM Forum on Microbial Threats, member of the Executive Committee and the EHA institutional lead for the \$130 million USAID-EPT-PREDICT. His >300 scientific papers include the first global map of EID hotspots, estimates of unknown viral diversity, predictive models of virus-host relationships, and evidence of the bat origin of SARS-CoV and other emerging viruses.

**Prof. Ralph Baric** is a Professor in the UNC-Chapel Hill Dept. of Epidemiology and Dept. of Microbiology & Immunology. His work focuses on coronaviruses as models to study RNA virus transcription, replication, persistence, cross species transmission and pathogenesis. His group has developed a platform strategy to assess and evaluate countermeasures of the potential “pre-epidemic” risk associated with zoonotic virus cross species transmission.

**Prof. Linfa Wang** is the Emerging Infectious Diseases Programme Director at Duke-NUS Medical School. His research focuses on emerging bat viruses, including SARS-CoV, SADS-CoV, henipaviruses, and others and genetic work linking bat immunology, flight, and viral tolerance. A 2014 recipient of the Eureka Prize for Research in Infectious Diseases, he currently heads a Singapore National Research Foundation grant “Learning from bats” (\$9.7M SGD).

Thailand – **CM Ltd**: Department of Disease Control, Ministry of Public Health (Rome Buathong, Pawinee Doungngern, Pongtorn Chartpituck ), Department of National Park, Wildlife and Plant Conservation (Pattarapol Manee-On), Faculty of Forestry, Kasetsart University (Prateep Duengkae), Mahidol-Oxford Tropical Medicine Research Unit, (Stuart Blacksell, Richard Maude), Chulalongkorn University (Supaporn Wacharapluesadee).

Chulalongkorn lab is a WHO Collaborating Centre for Research and Training on Viral Zoonoses, we work closely with WHO SEARO and SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste. We had conducted the PREDICT lab training for Veterinary lab in the Southeast Asia region for FAO. We conducted (transferred?) the bat sampling technique for scientists from Malaysia, Myanmar, the Philippines, and China.

## 5. Data Management Plan

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe

how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.

- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system

#### Language from NIH CoV grant:

**Data Sharing Plan:** Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited for in long-term public scientific repositories – all sequence data will be made publicly available via GenBank, species location data via the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestrictive MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Viral isolates will remain at the Wuhan Institute of Virology initially. Isolates, reagents and any other products, should they be developed, will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Sharing Model Organisms:** We do not anticipate the development of any model organisms from this study. Should any be developed, they will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Genomic Data Sharing:** We anticipate obtaining genetic sequence data for 100s of novel coronavirus genotypes, including RNA-dependent RNA polymerase (RdRp) and Spike genes for all strains/genotypes. In addition, we will generate full viral genomes for a subset of the bat SARSr-CoVs that we identify. All sequence data will be deposited in the NIH genetic sequence database, GenBank. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also be submitted. The genotype data will be made publicly available no later than the date of initial publication or six months after the receipt of final sequencing data, whichever comes first. We anticipate sequence generation will occur over the 5 year proposed project period.

**Genome Wide Association Studies (GWAS):** Not applicable.

Commented [KJO113]: From CoV NIH grant

Thailand TRC-EID Chulalongkorn lab: Specimen management and BioBank: The software called PACS (Pathogen Asset Control System) supported by BTRP DTRA, is now used for managing the specimen from specimen registration (barcoding, and may move to use QR code system soon), aliquoting, tracking, short patient history record, data summary, searching, test reporting and etc. Our biobank system contains 28 freezers (-80C) and liquid N2 system. Its size is around 120 sq meters. There is a separate electric generator for our lab and biobank. There are CC TV cameras at the biobank and laboratory.

Chula TRC-EID has our own server for data management and analysis. We have the necessary software including Bioinformatic tools (Blast Standalone, SAMTOOL, GATK, AliVIEW, RaxML, FigTREE, MAFFT, Guppy, Megan, PoreChop, MEGA), Database (MySQL, MongoDB) Web, jQuery, Node.js, Express.js React,

API, PHP, Ruby, Python, Java, C#, HTML5, Bootstrap, CSS, Responsive, Cloud, Linux Command, PACS (sample management system), Virtualbox virtual machines, R programming languages, Perl scripts, Bash shell scripts, Open source software, Microsoft Office running on both Apple Mac OS X, Ubuntu, Linux, and Windows Operating Systems. Chula TRC-EID has a dedicated 16-core Ram 64GB Linux server with 4TB hard drives, dual quad-core Mac Pro Server with 2TB hard drives and another dedicated iMac Pro (Retina 4K, 21.5-inch, 2017) Processor 3.6GHz quad-core Intel Core i7 (Turbo Boost up to 4.2GHz) Ra, 16GB with 512GB hard drives. TRC-EID also has HPC Linux server CPU: 4 x 26cores Intel Xeon = 104 cores 2.1GHz with 52 TB HDD and 2x3.84TB SSD with GPU 2x Tesla v100 (CUDA core = 5120 cores/GPU, Tensor core = 640 cores/GPU). TRC-EID has a dedicated 10/100/1000 of LAN (Local Area Network), 2.4G / 5G Gigabit Wi-Fi 802.11ac.

Commented [KJO114]: From Supaporn for their lab, some may go in Facilities doc?

From DARPA:

**Data Management and Sharing:** EcoHealth Alliance will maintain a central database of data collected and generated via all project field, laboratory, and modeling work. The database will use secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations, and enable compliance with DARPA data requests and disclosure requirements. All archived human sample data will be de-identified. Partners will provide raw and processed data to the central database throughout the course of the project. Project partners will have access to the data they generate in the database at all times, and maintain control over local copies. Release of any data from the database to non-DARPA outside parties or for public release or publication will occur only after consultations with all project partners. EHA has extensive experience in managing data for multi-partner partner projects (PREDICT, USAID IDEEAL, the Global Ranavirus Reporting System).

Commented [KJO115]: Text from DARPA Preempt

## 6. Clinical Management Plan

### Clinical site selection

Our consortium partners have been conducting lab and human surveillance research, inclusive of human surveillance during outbreaks, for over the past two decades and in that time have developed strong relationships with local clinical facilities and processes. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1. These are regions where we will sample wildlife due to the high potential of zoonotic viral diversity. Additionally, these will be clinical sites that serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. In PREDICT we developed successful working relationships with the major healthcare facilities the hotspot areas in 6 different countries, including Thailand and Malaysia and we will continue to work with these sites going forward. Continuing to work with these hospitals means we will begin this project with successfully established partners and we can begin data collection quickly. This also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites for this study is limited. All that is required of sites will be the ability to enroll patients that meet the clinical case definitions of interest, capacity to collect and temporarily store biological samples, and follow standards for data management and protection. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently site staff. These will be persons who are locally trained and certified to collect biological specimen from participants including blood draw technique, e.g. doctor or nurse. Last, the clinical site will need the capacity to securely store all personal health information and personally identifiable research data, this will include locked offices with locked filing cabinets to store all paper records and an encrypted computer. Training on project procedures will be provided for all local project staff by local country project management staff and partners from headquarters. The study at clinical sites will begin by developing relationships with local stakeholders at the hospitals and clinics in our geographic areas of interest that serve as catchment facilities for people of within the community surveillance study. We will recruit hospital staff that will be extensively trained for project procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data

Commented [EH116]: Is that true

management plans. During the Development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data (e.g. locked filing cabinet, dry shipper, secure laptop). [Did not specifically address CONDUCT]. Oversight for clinical sites will be managed by the country coordinator for each country. This will be done with regular site visits to the clinical sites and annual visits by headquarter research staff. Site visits will include monitoring and evaluating the process for patient enrollment, collecting and storage of samples, administration of the questionnaire, and secure and data management procedures for secure personal health information and research data. During these visits any additional training will also be provided.

### **Standardized approach oversight and implementation**

Management and oversight for all study sites will be managed by the local country coordinator who is supported by staff at headquarters. Implementation of a standardized approach across all study sites, community and clinical, will begin by extensive training of staff on procedures on requirements of the project, this includes: enrollment, data collection, and data management. Our research team has over 5 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research. This includes SOPs for screening, enrollment, and retention of participants. In addition to yearly monitoring reports the country coordinator will regularly visit each clinical site to ensure quality standards and compliance of procedures are being met. Through our work with clinical sites in PREDICT we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical research staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll, allowing for minimal disruption and prevents potential enrollees from being overlooked if the research staff is not on duty. At clinical sites that do scheduled outpatient days we may have a trained member of the research staff with the intake nurse to monitor the patients coming to the clinic more rapidly to no delay screening or enrollment in such a fast pace environment. Using the screening tools, we will recruit and enroll patients who present with symptoms that meet the clinical case definitions of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology within the past 10 days. These patients will be enrolled, samples collected and survey conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; 3) environment biosecurity. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either coronaviruses, henipavirus, or filoviruses, serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between coronaviruses, henipavirus, or filoviruses in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. [How do these cohorts be leveraged for new emerging pathogens] Achieving the adequate numbers will be attained through duration of the as clinical participant enrollment. While patient's enrollment is limited by the number of individuals presenting at hospitals, during the PREDICT project we had an average of 105 patients enrolled per year, ranging from 77-244. The country coordinator will be continually monitoring the project database to be sure that we are on track to reach our target.

### Clinical cohort setup, recruitment, enrollment

We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology for symptoms reported onset of illness to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 2\* 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples and two nasal or oropharyngeal swabs will be collected. The cases are defined as participants whose samples tested positive for Henipaviruses, Filoviruses, or CoVs by PCR or serological tests. The controls will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500 µL serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms for coronaviruses, henipavirus, or filoviruses infected patients to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

**Commented [EH117]:** Will these cohort fulfill the goals of the EIDRC.

**Commented [EH118]:** PREDICT we also make the stipulation that we will collective relative samples if available from treatment collection, eg CSF if the MD is doing a spinal tap we will request an aliquot if possible

### Utilization of collected data

Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses the are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire allows us to assess relative measures of human-wildlife contact from our survey work that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk.

**Commented [EH119]:** Please add any information that might address: types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

The biological specimens to be collected (2\*5mL whole blood for whole blood and serum analysis and nasal or oropharyngeal swabs) from all eligible participants and follow up specimen 35 days (3mL of whole blood for serum) after enrollment with the standardized questionnaire. Capacity for specimen is collection is not more than standard phlebotomy skills and we will collected by locally trained and certified personnel that are part of the research team in country. Staff we will trainline on ethical guidelines for conducting human subjects research and survey data collection methods. Collection of whole blood, serum, and nasal or oropharyngeal swabs allows us to test the samples for PCR to detect viruses in our priority viral families, serologically test for immunological response and historical exposure to zoonotic diseases of relevance, and the questionnaire will assess individuals evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

**Commented [EH120]:** Please add any information that might address: Describe methods that might be applied to elucidate a zoonotic source

### Potential expansion

Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research or an outbreak in the region. If expansion is required we could rapidly implement research activities in additional clinical or community sites through the same process we on-boarded the initial locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital

settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transpiration, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provided necessary information for granular understand of disease spread.

In a clearly labeled section entitled "**Clinical Management Plan**":

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment. including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics

2. Tekada Sanofi Pasteur dengue

3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

## 7. Statistical Analysis Plan

In a clearly labeled section within the Research Strategy entitled "**Statistical Analysis Plan**":

- Describe the overall plan for statistical analysis of preliminary research data, including observational

cohort data.

- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

### 8. Project Milestones and Timelines

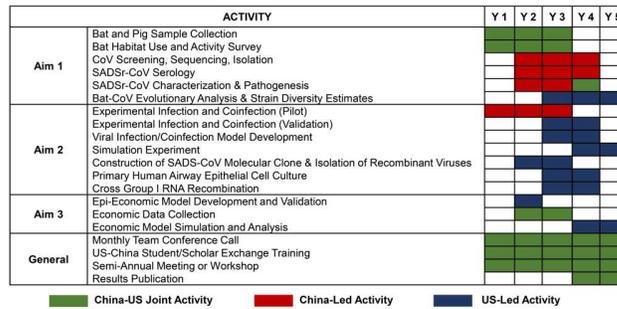

In a clearly labeled section entitled “Project Milestones and Timelines”:

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

#### Project Management & Timeline

PI Daszak will oversee all aspects of the project. Dr. Daszak has two decades of experience managing international, multidisciplinary research in disease ecology, including successful multi-year projects funded by NSF, NIH and USAID. He will conduct monthly conference calls with all co-PIs, including the China team (see Activity schedule below). He will be assisted by EHA Sr. Personnel Li, who is a US-based Chinese national with fluent

Mandarin. Co-PI Olival will oversee Aim 1 working closely with China PI Tong, who will test samples. Co-PI Ma (China team) will coordinate and lead all Chinese experimental infections, with guidance from co-PI Saif, who will coordinate and lead all US experiments with co-PI Qihong Wang. Sr. Personnel Ross will conduct all modeling activities in Aim 2, working closely with co-PI Saif to parameterize the models. Co-PI Baric and Sr. Personnel Sims will lead infectious clone, recombinant viral and culture experiments. Consultant Linfa Wang will advise on serology, PCR and other assays. China team co-PIs Shi and Zhou will oversee viral characterization in Aim 1. Sr. Personnel Feferholtz will oversee the economic modeling in close collaboration with Ross.

Commented [KJO121]: Text and figure From NSF-NIH SADS grant. Peter will adapt

Another Example of Milestones and specific tasks from a prev DHS (unfunded) proposal:

#### Expand existing databases to include predictor variables for pathogenicity risk model

Task 1: Collate available human clinical information from the literature for ~300 viral pathogens known to infect humans (Contract Award Date to 6 month)

**Task 2:** Update EHA host-viral association database to include new data for mammalian and avian species from literature 2015-present (Contract Award Date to 3 month)

**Task 3:** Extract and curate full and partial genomic data from Genbank for 5-6 viral families with a high proportion of human-infectious pathogens for phylogenetic analyses – e.g. 'nearest-known-threat module'. (Month 2 to 6 month)

#### **Develop underlying pathogenicity and spillover risk assessment models**

**Task 4:** Fit generalized linear models in Stan for multiple response variables to measure pathogen impact (Month 7 to 10 month)

**Task 5:** Fit generalized linear models to estimate risk of human infection (spillover) based on host, ecological, and location specific traits (Month 4 to 8 month)

**Task 6:** Validate model effectiveness by simulating early-outbreak, limited-information scenarios from known pandemics to confirm model behavior (Month 8 to 10 month)

**Commented [KJO122]:** Just example, but probably just want to use a Gantt chart format per most of our grants, depending on space.

Dear All,

Here's version 4. Apologies for the delay. It's in better shape now, but there are still lots of areas that need your attention. Please put in time today, and tomorrow to edit and firm up the text. I've put your names in some of the comment boxes where I need specific help but I also need you to read this critically now and edit and tighten it up. We have 30 pages of space, and our research plan is now 21 pages, so we need to lose maybe 3 or 4 pages. There are also some weak points, specifically on Filoviruses, on the details of where we'll do our clinical work, and on what we'll do with the animal models for henipias and filoviruses.

Please get comments back with me before Wednesday 26<sup>th</sup> 4pm New York time, so that I have Wednesday evening and all day Thursday to incorporate them. In the meantime, I'll be working with folks here on better figures, and all the extra sections that come after the research plan. I'll need you all to help with those on Thursday while I'm finishing off the draft.

Thanks to all of you in advance and look forward to the next round.

Cheers,

Peter

**Subject:** EIDRC-SEA v.3

**Importance:** High

Dear all,

Thanks to everyone for comments and text for the earlier draft at the beginning of the week. Kevin's spent the last couple of days pulling all the comments together into one draft and inserting his changes, and I've now attached a v3 of the draft. It's still rough, and now too long, but it's getting there. I wanted you to look at this rough version because I'm stuck in Liberia in meetings Friday, then flying back home Saturday. I'll continue editing this draft on the plane and will be working solely on this grant from home on Sunday, Monday, Tues, Wed, Thurs.

Please work on this rapidly if possible. If you can all push your comments through, using track changes, and get them back to me **by Sunday evening New York Time**, I will turn round a polished draft by Tuesday, giving us time for significant last go-over on Wed, Thurs. It's tight, but unfortunately, it is what it is, so please commit the time if you can!! As well as general edits (using track changes, with references in comment boxes), please do the following...

Linfa/Danielle – We especially need your input in section 1.1, 1.3, 1.4 and 2.5

Ralph/Amy - Please work your magic on this draft, inserting text, editing and reducing text, and making sure the technical details of the characterization are correct and fit the proposed work on CoVs, PMVs and Henipaviruses

Chris/Eric – Eric – congratulations on your (b) (6) and thanks for working on it at this time! Chris – please help and edit/finesse the language in the relevant sections for you

Tom – Your edits crossed over with Kevin's changes, so please insert all the bits that were new in the last version you sent to me, into this version. I think these are mainly the sections and comments from the other Malaysian colleagues, but please check and re-insert all key text. We especially need to be specific about which partner in Malaysia is doing what cohorts, and where, and about who's doing the testing

Thanks again all, and I'm looking forward to non-stop work on this as soon as I get on my flight in 24 hours...

Cheers,

Peter

## II. Research Strategy:

### 1. Significance:

Southeast Asia is a critical hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of key ecological and socioeconomic drivers of emergence (**Fig. 1**) (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is also undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread.

**Fig. 1:** Southeast Asia, and in particular, parts of Thailand and Malaysia are hotspots of risk for disease emergence (**left**), and predicted high diversity of 'missing' or as-yet undiscovered viruses, yellow = highest diversity (**left**). From (1, 2).

Not surprisingly a number of novel viruses, including near-neighbors of known agents, have emerged in the region leading to sometimes

unusual clinical presentations (**Table 1**). These factors are also behind a significant background burden of repeated Dengue virus outbreaks in the region (16), and over 30 known *Flavivirus* species circulating throughout S. and SE Asia (17). The events in Table 1 are dominated by three viral families: coronaviruses, henipaviruses and filoviruses, which serve as initial examples of team research focus and capabilities. These viral groups have led to globally important emerging zoonoses (18-29). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (30-32). Furthermore, relatives and near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium: henipaviruses in bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (33-39); a novel henipavirus, Mojiang virus, in wild rats in Yunnan (10); serological evidence of filoviruses in bats in Bangladesh (40) and Singapore (41); Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (Hughes *et al.*, in prep.); evidence of novel filoviruses in bats in China (42-44), including Mēnglà virus that appears capable of infecting human cells (45); novel paramyxoviruses in bats and rodents consumed as bushmeat/bush meat in Vietnam (46); a

Viral agent	Site, date	Impact	Novelty of event	Ref.	lineage C $\beta$ -CoV in bats in China that uses the same cell receptor as MERS-CoV and can infect human cells <i>in vitro</i> (47); MERSr-CoVs in dry bat guano being harvested as fertilizer in Thailand (48), and directly in bats (Wacharapluesadee <i>et al.</i> , in prep.);

emergence, or unusual presentations for known or close relatives of known viruses.

172 novel  $\beta$ -CoVs (52 novel SARSr-CoVs) and a new  $\beta$ -CoV clade ("lineage E") in bat species in S. China that are also found throughout the region (20, 47, 49, 50); and 9 and 27 novel wildlife-origin CoVs and

paramyxoviruses in Thailand (respectively) and 9 novel CoVs in Malaysia identified as part our work under USAID-PREDICT funding (49, 51). These discoveries underscore the clear and present danger of future zoonotic events in the region. Furthermore, the wide diversity of potentially pathogenic viral strains has significant potential to help in the development of broadly active vaccines, immunotherapeutics and drugs (47).

Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 2). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (29, 52). However, these regions tend to be in the developing world, where nations often lack the resources to investigate novel zoonotic events, or wildlife reservoirs of zoonoses, and prioritize more immediate public health concerns such as Dengue virus or NTDs (16). Zoonotic disease surveillance and control is also hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (53). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in x/xx (x%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (12, 54). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (3) as well as 12/856 (1.4%) people screened in Singapore (4). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (7), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (55). Preliminary screening in Malaysia with funding from DTRA for serological surveillance of Henipaviruses henipaviruses and Filoviruses filoviruses spillover found serological evidence of past exposure to Nipah (NiV) and Ebola antigenically-related viruses in non-human primates (NHPs) and people humans (Hughes, in prep.). Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70% (56). NiV pah-virus has been reported in people in West Bengal, India, which borders Bangladesh (26), in bats in Central North India (57), and now in people in Kerala, South India in 2018 and 2019, raising the specter of future spillover at other sites in the region (14, 58).

**Fig. 2: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (52).

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (59), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (20, 47, 49, 50, 60-62). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-concept for an early warning approach that we will expand in this EIDRC to target key viral groups in**

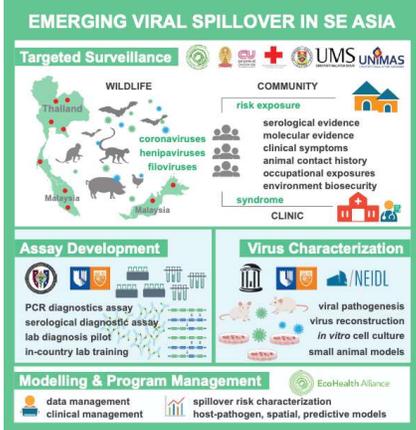

Commented [PD1]: Peter will correct

Commented [PD2]: Peter to do

**one of the world's most high-risk EID hotspots.**

The overall premise for of this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. To scale-up this approach, we propose to launch **EID-SEARCH** (the **E**merging **I**nfectious **D**iseases - **S**outh **E**ast **A**sia **R**esearch **C**ollaboration **H**ub), to better understand the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and novel CoVs, henipaviruses, and filoviruses in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development, and cross-training in surveillance and novel diagnostic platforms. We will develop and transfer technology to test these viruses' capacity to infect human cells and **mouse models**, develop new specific and sensitive serological and molecular diagnostic tools, conduct surveillance of human communities with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover of viruses causing previously 'cryptic' clinical syndromes in people. We will test the capacity of novel viruses ~~we isolate, or genetically characterize,~~ to infect human cells and/or mouse models, and thus assess potential for spillover and spread which will feed into our risk models. Our group also has extensive experience in other viruses, including vector-borne flaviviruses, and alphaviruses, and will use this experience to provide robust long-term surveillance, diagnostics, human and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EID-SEARCH is poised to rapidly respond to any **new emerging** outbreak. Thus, filoviruses, henipaviruses and coronaviruses are examples of sentinel surveillance systems in place that can capture, identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.

**2. Innovation:** Previous work by our consortium has developed strategies to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses. In the EID-SEARCH we scale up this approach in a central research "hub" made up of leading laboratories, clinics and surveillance sites in three critically high-risk EID hotspot countries in SE Asia. EID-SEARCH's reach is expanded through its regional network of collaborators that covers nearly all of the greater SE Asia region. The innovation of the EID-SEARCH is in: 1) Its multidisciplinary approach that combines modeling to target geographic and taxonomic sampling targets with on-the-ground zoonotic disease surveillance in human and wildlife populations; 2) the biological characterization approach that identifies how likely viruses are to be able

to spillover into people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARS-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (Fig. 2). In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to ~~people~~ humans. We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. We will use *in silico* methods (inovel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into

**Fig. 2:** EID-SEARCH approach, core members, and roles.

**Commented [BRS3]:** Statement should be in the aims. ...Our center covers the worlds most high risk EID hotspot?

**Commented [PD4]:** Hongying – Figure needs edits to text: top panel, 'wildlife' should read "Aim 1: WILDLIFE", "AIM 2: COMMUNITY", "AIM 3: CLINIC". Right hand side: "Clinical symptoms" should be "Clinical history", "Occupational exposures" should be "Occupational exposure", "environment biosecurity" should be "environmental risk factors"

Middle panel: "Assay Development" and "Virus Characterization" should have "(Aim 1)" after them. Left hand side: should read "PCR diagnostics", "serology", "piloting diagnostics" and the last one is ok. Right hand side bullets should be "receptor binding characterization" "in vitro characterization" and "mouse models"

Bottom panel: all good

high-risk human populations. **In Aim 2, we will conduct focused, targeted surveys and sampling of human communities with high exposure to wildlife and other animals.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. Serological findings will be analyzed together with clinical metadata (including a simple animal-contact survey, location data, viral sequence/isolates etc.) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise 'cryptic' outbreaks.** We will enroll and collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs. Our US partner BSL-4 laboratory, ~~NEIDL~~, ~~will attempt isolation and characterize any~~ viruses requiring high levels of containment (e.g. any novel filoviruses discovered).

### 3. Approach

**Research team:** The EID-SEARCH builds on long-term collaboration among world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (**Fig. 2**). Over the past two decades, our consortium partners have conducted high profile research on EIDs within the region and globally, including identifying the wildlife reservoirs for ~~NiV~~~~pah~~ and Hendra virus, MERS- and SARS-CoVs (20, 25, 59, 63-66), discovering SADS-CoV (13), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (60-62, 67-80). Our team has substantial experience conducting human surveillance in the community and during outbreaks (See sections 2.x.x, 3.x.x), including: USAID-PREDICT, and DTRA-funded viral surveillance of indigenous communities in Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah (Co-I Hughes); collection of >2,000 serum samples from healthy blood donors and sanitation workers, febrile and influenza like illness (ILI), and diarrheal stool samples from children under 5 years of age (Co-I Kamruddin); collaboration on the MONKEYBAR project with the London School of Hygiene and Tropical Medicine to analyze risk and prevalence of the zoonotic malaria *Plasmodium knowlesi* (Co-Is William, Tock Hing); case control and cross-sectional studies in Sabah villages (~800, 10,000 participants resp.) (Co-Is GR, TYW). As a proof-of-concept of how our team can rapidly scale up resources for diagnostics and surveillance in the face of a new EID, in 2016, we discovered a novel bat-origin HKU-2 CoV (81, 82) killing >20,000 pigs in S. China, designed PCR and LIPS-~~serology~~ tests, ~~then~~-surveyed pig farmers for evidence of exposure, and conducted experimental infections, pathogenesis and molecular studies, **all in the span of 3 months** (13, 83).

The administration of this center (**See section X**) will be led by PI Daszak, who has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5- 20 ~~yrs-years~~ on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival and Zambrana are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesdee, Hughes and collaborators have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from NIH, DoD, USAID, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to our EIDRC.

**Geographical focus:** The three core (hub) countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and ~~people-humans~~ in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh,

**Commented [PD5]:** PD will get stronger letter from Jerry Keusch: opportunity for visiting scholars to be certified for BSL-4 research, strong Ebola person at NEIDL to conduct characterization if we find filoviruses.

Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH, DTRA, and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our core member's extensive network of collaborators in clinics, research institutes and public health laboratories in almost every other Southeast Asian country. We will conduct regular meetings with key research, public

health and community leaders, including >50 leading laboratories/institutions in XX countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

Fig.3 : Map of Southeast Asia indicating three hub countries for this proposed EIDRC (Red: Thailand, Singapore, Malaysia) and countries in

which Key Personnel have collaborating partners (Green), indicating that EID-SEARCH provides access to key collaborators throughout the region.

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and non-human primates (84). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (Fig. 1) (2). In Aim 1, we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and apply novel predictive models to estimate viral diversity and host range to identify wildlife species that have been ignored or under-sampled by previous zoonotic disease surveillance efforts. We will strategically collect specimens from these species and screen them, together with some of the tens of thousands of recently collected samples we have archived in freezers in our labs, for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel viruses in high risk RNA viral families, *Coronaviridae*, *Paramyxoviridae*, and *Filoviridae*. We will expand to other groups of pathogens, pending available resources and priorities established with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation. On this subset of viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, gene edited humanized transgenic mice and the collaborative cross genetic reference mouse population) previously developed and widely used by our team to predict capacity of novel viruses to infect people and spillover (61, 85-88). These high-risk viruses and their close relatives will be targets for human community and clinical sampling in Aim 2 and 3, respectively.

**1.2 Preliminary data: 1.2.a. Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a major high risk location for pathogen emergence (1, 2). For Southeast Asia, these EID hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (Fig 1). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (2). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals

Commented [PD6]: Hongying – “EIDRC Program Countries” should be “EID-SEARCH core countries” and “External Partner Countries” should be “Collaborating Partners”

Commented [PD7]: PD to Remember to correct specific aims with same titles

Commented [KJ08]: Will we? If so, make sure we mention primates more and include in vert animal sections.

Commented [DA9R8]: We have banked NHP sera in SG

Commented [PD10]: PD will discuss both of these comments with Kevin

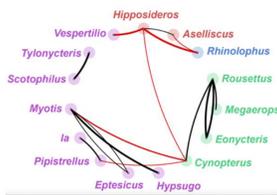

Commented [KJ011]: Do you think we need to add in or mention vectors (arthropods)? We don't have big banks of these as far as I know, so maybe best not too?

Commented [DA12R11]: I would not add this

Commented [PD13]: From Kevin - we need to specify in the methods below how many viruses (number of) we will have resources to do this on

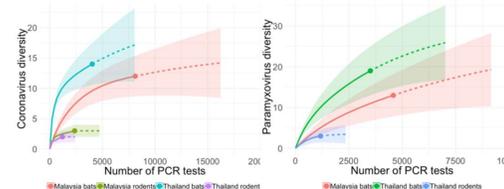

across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 1). In a ~~Separately paper on risk of viruses emerging from bat hosts~~, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bush meat hunting, livestock production) (89). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data and flight model software we have produced with Dept Homeland Security funds (90). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

**1.2.b. Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primates represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential (91). Thus, the bulk of our proposed wildlife sampling and testing will consist of these three taxa with a focus on bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses (48, 92-94). Bats ~~also~~ have the highest proportion of predicted zoonotic viruses in any mammalian group (2), and are exceedingly diverse in Southeast Asia (~500 species). To further prioritize taxonomic sampling targets within these diverse geographic hotspots, we have used a novel, Bayesian phylogeographic analysis to identify host taxa that are the most important centers of evolutionary diversity for a given viral group, e.g. bat genera for  $\beta$ -CoVs using an extensive CoV sequence dataset from our NIH-funded research (Fig. 5) (49). This approach will be extended to other mammal taxa and viral families of interest, allowing us to identify the ancestral wildlife hosts of specific zoonotic viral groups, where their diversity is likely highest.

**Fig 5:** Preliminary analysis to identify the most important bat genera in Southeast Asia as hosts for beta-CoVs using our previously-collected CoV sequence data. Line thickness is proportional to the probability of virus sharing between two genera. Inter-family switches are highlighted in red. We will apply this Bayesian discrete phylogeographic model to identify taxonomic and geographic centers of viral diversification and sharing for relevant paramyxovirus, coronavirus, and other virus clades.

Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (95, 96) (Fig. 6). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. **In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively identify new strains to support experimental infection studies and risk assessment.**

**Fig. 6:** Estimated coronavirus (left) and paramyxovirus (right) putative viral 'species' diversity in bats and rodents for Thailand and Malaysia, using RdRp gene sequence preliminary data from >13,000 PCR tests in bats and 4,500 in rodents. Bats in Thailand and Malaysia have 4X the number of viruses than rodent species, controlling for sampling effort. CoV and paramyxovirus diversity estimates are comparable, but discovery has not yet saturated in any taxonomic group or location. We estimate that additional sampling of ~5,000 bats and testing of our archived rodents specimens alone will identify >80% of remaining CoV and paramyxovirus viral species in these key reservoirs. We will use this approach to define sampling targets for other wildlife taxa, and for viral strain diversity.

**1.2.c. Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. Under the 10-year PREDICT program globally, we identified 912 novel and 210 known viruses, more than the total number of viruses previously recognized in mammals by the ~~International Committee on Taxonomy of Viruses-CTV~~. This work included collecting nearly 300,000 individual mammal samples from 14 EHA-led PREDICT countries and PCR-screening more than 60,000 individual specimens (51). In southern China alone, this sampling lead to the identification of 178  $\beta$ -CoVs, of which 172 were novel

**Commented [BRS14]:** I would say we focus on these three species (plus vectors?). To demonstrate the capability of the team, this proposal will focus on bat surveillance (for a variety of reasons), noting that this approach will also be applied to other zoonotic vectors during the 5 year program throughout the region.

**Commented [PD15]:** Ralph – have we done this well enough now? If not, please add text/edit

**Commented [PD16]:** Kevin - Can you get rid of the shading on the background to this figure and change the colors so the circles and genus names are more visible (esp. the green). Colors should be darker and more contrasty

**Commented [KJO17]:** We can show just a single curve per country (aggregating all wildlife species) for simplicity, and could fit CoVs and PMVs on one graph.

**Commented [PD18]:** Evan/Hongying/Kevin, please send that also and I'll choose one

**Commented [PD19]:** Kevin – please get someone to check EIDITH – I think I just gestimated these numbers...

(52 novel SARSr-CoVs). Included were members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus, SADS-CoV, responsible for killing >20,000 pigs in Guangdong Province (13). Many of the identified bat species are found across the region. We have collected 28,957 samples from bats, rodents and primates in Thailand and 51,373 in Malaysia, conducting 146,527 PCR tests on a large proportion of these specimens. We have **archived duplicate samples which are now available for use in this project**, including fecal, oral, urogenital and serum samples from bats, rodents, and non-human primates, and primate biopsies. In Thailand this screening has identified 100 novel viruses and 37 known viruses in wildlife reservoirs. In Malaysia this screening has identified 77 novel viruses and 23 known viruses in wildlife reservoirs (66 novel and 19 known in Sabah and 11 novel and 9 known from Peninsular Malaysia). We used family level primers for henipaviruses, filoviruses and CoVs and have already discovered 9 novel and 7 known CoVs and 26 novel and 2 known paramyxoviruses in Thailand. This is in addition to 13 novel and 5 known CoVs and 15 novel and 1 known paramyxovirus in Malaysia from wildlife. In the current proposed work, we will attempt to sequence, isolate and characterize those viruses that our analyses below suggest are most likely to be able to infect humans.

Our collaborative group has worked together on these projects, as well as other DTRA funded projects in Singapore/Thailand (Co-Is Broder, Wacharapleusadee, Wang) to design, cross-train, and use novel serological and molecular platforms to investigate virus infection dynamics in bats and examine potential spillover events with or without human disease. For serology, Co-Is Wang and Anderson (Duke-NUS) will develop a phage-display method to screen antibodies for all known and related bat-borne viruses, focusing on henipaviruses, filoviruses and coronaviruses. Once various "trends" are discovered, additional platforms (including Luminex and LIPS) will be used for verification and expanded surveillance. For molecular investigation, we will combine a targeted PCR approach with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified. In Malaysia (Co-Is Hughes, Broder, Laing) we have transferred the Luminex serology platform to partner laboratories for screening of wildlife, livestock and human samples to investigate the spillover of henipaviruses and filoviruses at high risk interfaces. These interfaces include farms near the forest and indigenous communities with lots of subsistence hunting in Peninsular Malaysia, and preliminary screening has found serological evidence of past exposure to viruses antigenically-related to Nipah and Ebola in humans, bats and ~~non-human primates (NHPS)~~. In Thailand, Co-Is Broder, Laing and Wacharapleusadee have transferred a Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses and known henipaviruses in wildlife and human samples, with testing underway and currently being validated in our Chulalongkorn University laboratory (**See also section 2.2.d**).

**1.2.d. In vitro & in vivo characterization of viral potential for human infection:** Using *Coronaviridae* as an example, we have conducted *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3-7% (20, 59, 97). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (59). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of two different variants. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in those without ACE2 (20, 59, 97). We used the SARS-CoV reverse genetics system (71) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (60). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry**. The Baric lab has a well-established hACE2 and DPP4 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect (85, 98). We used this chimera approach to demonstrate that pathogenicity of bat SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the value of this model in assessing novel SARSr-CoV pathogenicity**. Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals-antibodies that attenuate SARS-CoV pathogenicity, nor**

Commented [DA20]: I am removing the text if the abbreviations have been used.

Formatted: Font: Italic

after challenge following vaccination against SARS-CoV (60). We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, and found that they are unable to use the ACE2 receptor. Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines.

A similar approach to the above pipeline for CoVs will be applied to novel henipaviruses and filoviruses we discover during our research. The broad mammalian tropism of HeV and NiV is likely mediated by their usage of highly conserved ephrin ligands for cell entry (15, 99). A third isolated henipavirus, Cedar virus (CedV), does not cause pathogenesis in animal models. Recently, Co-Is Broder and Laing have developed a reverse genetics system and rescued a recombinant CedV to test ephrin receptor usage/tropism and pathogenicity during henipavirus infections (76). CedV is unable to use the Ephrin-B3 receptor (76, 100) which is found in the spinal cord and may underlie NiV encephalitis (101) and that pathogenesis also involves virulence factors V and W proteins. The putative henipaviruses, Ghana virus and Mojiang virus, predict V and W protein expression, with GhV able to bind to ephrin-B2, but not -B2-B3 (102), and the receptor for MoJV remaining unknown (103) but is likely ephrin-B2 (104). Primary human lung endothelial cells are highly susceptible to Ebolavirus-EBOV infection (105). Huh7 cells are good candidates for ebola-EBOV infection in the liver, oftentimes used to isolate virus from clinical samples (106) Huh7 cells also offer advantages for reverse genetic recovery of novel filoviruses (107). The three filovirus genera, Ebolavirus, Marburgvirus and Cuevavirus, use Niemann-Pick type C1 (NPC1) protein as cell entry receptor. Co-Is Wang and Anderson used cells originating from various mammalian species to determine spillover and/or zoonotic potential of MLAV, a newly discovered filovirus (REF). Despite the low amino acid sequence identity (22–39%) of the glycoprotein with other filoviruses, MLAV is capable of using NPC1 as entry receptor. Cells from humans, monkeys, dogs, hamsters and bats were able to be infected with a MLAV pseudovirus, implying a broad species cell tropism with a high risk of interspecies spillover transmission. Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G).

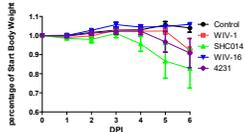

Fig. 7: Body weight change in hACE2 transgenic mice after SARSr-CoV infection, demonstrating that bat-origin SARSr-CoVs cause similar clinical presentation to outbreak strain (4231). From (60, 61).

**Models of Outbred Populations.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments (108). We have used this model for CoV, filovirus (Ebola), flaviviruses, and alphaviruses infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection (86-88, 109-112). **Bat Models.** Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (113).

Commented [PD21]: Ralph/Danielle/Eric/Chris – need something substantial here on filovirus binding that shows we have a valid approach for novel filoviruses

Commented [DA22]: PMID: 31021739

Formatted: Font: Bold

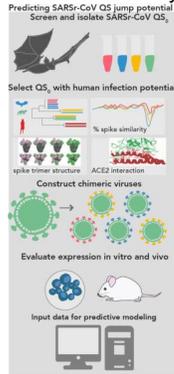

Commented [DA23]: PMID: 30617348  
Mengla paper

Commented [PD24]: Ralph – I think I mis-spoke in this fig. description – please correct.

Commented [PD25]: Ralph – please add data from the CC mouse re. filoviruses, to beef up the image of us as a filovirus group

Commented [PD26]: Linfa/Danielle – please draft a brief para explaining how we'll use these two models

**1.3. General Approach:** We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new sampling of wildlife in high risk locales. We will use viral family level PCR screening to identify and partially characterize viruses, then follow up

sequencing of relevant receptor binding proteins to assess homology and predict binding affinity, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will follow this with *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease (Fig. 8). EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses, as well as cross-training and tech transfer to the hub labs in Thailand and Malaysia. This will include via support of one Malaysian Ph.D student, Mei-Ho Lee (CM Ltd.) who has worked with the EID-SEARCH collaborators for 9 years. The focus of her study will be infection potential of novel CoVs and paramyxoviruses already found in bats in Malaysia under preliminary data for this proposal.

**Fig. 8:** Schematic showing EID-SEARCH approach to selection of sampling, viral testing, prioritization and characterization to identify novel, high zoonotic-risk viruses in wildlife.

**1.4 Wildlife samples: 1.4.a. Geographic and taxonomic targeting for newly collected wildlife samples:**

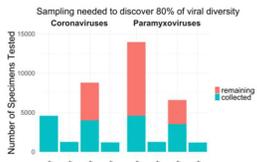

We will prioritize sites within each country that rank highest for both the risk of zoonotic disease emergence (114) and the predicted number of 'missing' zoonotic viruses (91). Our preliminary analysis (Fig. 1) suggests priority areas include: the Isthmus of Kra (S. Thailand and N. Peninsular Malaysia), NW Thailand (near the Myanmar-Laos border), and the lowland rainforests of Sarawak and Sabah. In each of these 'hottest of the hotspots' regions, we will identify 2-4 distinct sampling sites based on the geographic distribution of key hosts we prioritize for intensive wildlife sampling. We will priority rank bat, rodent, and primate species using analysis of host trait data for the highest predicted number of viruses based (91). We will also identify species predicted to be centers of evolutionary diversity for Corona-, Paramyxo-, and Filoviridae using ancestral host reconstruction of available sequence data and Bayesian discrete phylogeographic models (115-117). We will ensure wildlife sampling is complimentary to specimens archived in our extensive freezer banks. We will collect only the additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes given predicted levels of viral richness and rates of discovery (see 1.4.b). We will leverage our strong collaborations with wildlife experts in Malaysia and Thailand to ground-truth geographic and taxonomic model outputs with local expert knowledge to ensure the sampling plan is realistic based on current species distributions, population size estimates, seasonality, and accessibility to sites.

Recognizing that most zoonotic viruses are multi-host, i.e. naturally harbored by multiple wildlife species, and that the phylogenetic relatedness of those hosts is predictable and varies across viral families (91) – we will also apply a generalizable phylogenetic and spatial modeling approach to rapidly predict new (unsampled) hosts for novel viruses we discover during our research. We will use a combined network analysis and a phylogeographic model to estimate a viruses' host range and to prioritize additional wildlife species for sampling and testing for viruses we discover. Our recently developed model of viral sharing uses just two phylogeographic traits (wildlife species range overlap and phylogenetic similarity between host species) to successfully predict host species in the top 2% of all 4,200 possible mammal species (118).

**Commented [PD27]:** Hongying – this is a placeholder from DARPA proposal. We need a new one with Stages: 1) Geographic and taxonomic modeling to maximize discovery of potential zoonotic viruses; 2) PCR screening and partial RNA sequencing; 3) Full genome or RBD and Glycoprotein sequencing to model receptor binding based on sequence similarity; 4) Cell line infections (for prioritized viruses); 5) animal model infections (for prioritized); 6) High priority viruses ranked based on data (red, yellow, green) schematic.

**Commented [PD28]:** Kevin - That doesn't make clear sense straight away – please re-word better without increasing length

**1.4.b. Sample size justifications for testing new and archived wildlife specimens:** We will use our preliminary data on average PCR prevalence from screening tens of thousands of bat, rodent and primate specimens for CoV and Paramyxoviruses under the USAID-PREDICT project in Malaysia and Thailand. We will refine these sample size targets, in real-time, over the course of our project using viral discovery curve analyses (Fig. 6) to either scale-up or scale-back sampling and testing of archived specimens for each species depending on their viral diversity. For example, given 5-12% prevalence of CoVs in the most common bat species we previously-sampled in Thailand and Malaysia, a target of XXX individuals per species would yield XX (± x) PCR positive individual bats, and an estimated ~xx novel strains. Similarly, for paramyxoviruses with an average PCR detection rate of X%, we would need XX individuals per species to detect 80% of predicted viral strain diversity with 80% power. Preliminary analysis indicates we will require XX,000 samples to identify 80% of remaining viral diversity (Fig. 9). All wildlife sampling will be nondestructive. In the event that an animal is found dead or needs to be euthanized due to injury we will collect biopsy samples for screening.

**Fig. 9.** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMVs from high-risk bat and rodent taxa in Malaysia and Thailand

**We estimate the following sampling effort, broken down for each region:** *Peninsular Malaysia:* Wildlife sampling will be led by CM Ltd / EHA in collaboration with PERHILITAN. Archive bat, rodent and NHP samples will be screened serologically using the BioPlex and other serology techniques identified through this project. New wildlife sampling will focus on bats but it is expected that rodents and NHPs will be sample as well. Wildlife sampling will be conducted around Orang Asli communities sampled as part of aim 2. Three new communities will be identified in the districts we have already sampled in. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at PERHILITAN's NWFL. *Sarawak, Malaysia:* Wildlife sampling will be led by CM Ltd / EHA in collaboration with UniMAS. Wildlife sampling will be conducted around Dyak communities sampled as part of aim 2. One community will be identified. Concurrent sampling trip will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife mainly bats will be sampled. Wildlife and domestic animal samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at UniMAS or BMHRC. *Sabah, Malaysia:* Bat sampling will be led by CM Ltd / EHA in collaboration with SWD and WHU. Bat sampling will initially focus on 3 caves. Batu Supu Sabah low disturbance cave and surrounding area, Madai medium disturbance cave and surrounding area, Gomantong cave high disturbance cave and surrounding area. Each cave will be sampled twice once in wet season and once in dry season targeting 500 bats at each cave on each trip for a total of 3000 bats. Wildlife samples will include serum, whole blood, throat swabs, urine sample of urogenital swab and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored at WHGFL, molecular testing will be conducted at WHGFL and serology screening at BMHRC. In addition at Madi cave the community that lives in the mouth of the cave will also be sampled targeting 150 people, while at Gomantong cave 25 workers involved in the bird next farming will be enrolled into the study. *Thailand:* XXXXXXXXXXXX

**1.4.c. Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C. PCR will be performed with pan-coronavirus, filovirus and paramyxovirus primers. PCR products will be gel purified and sequenced. We will attempt isolation on samples that contain viruses of interest (determined in 1.4, below), using Vero cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). This includes the over 30 bat cell lines maintained at Duke-NUS from four different bat species.

**1.4.d. Moving beyond RNA viruses:** To detect pathogens from other families, such as non-RNA viruses we will combine conserved PCR assays with NGS. We will perform either unbiased NGS, or use a pan-viral

**Commented [MOU29]:** Kevin will work with Noam and Evan to fill in these numbers.

**Commented [PD30]:** Hongying/KEvin Need less text on the figure, but larger font size, or crisper text to make it all visible at this size.

**Commented [T31]:** Will dig into budget tomorrow to confirm numbers.

**Commented [T32]:** With Dr Tan and possibly Dr Faisal – still waiting for Dr Faisal paper work and details of samples he has in storage will discuss with Dr Tan tomorrow.

**Commented [T33]:** Will dig into budget tomorrow to confirm numbers.

**Commented [T34]:** Discussing with Tam tomorrow.

**Commented [T35]:** Will dig into budget tomorrow to confirm numbers.

**Commented [PD36]:** Kevin – who can write this bits?

**Commented [PD37]:** Linfa – can you give a v. brief description of these please, e.g.: "This includes 13 primary lung, 5 primary gut epithelial, and 1 primary liver cell line. In addition we have 12 immortalized cell lines, 7 of which are intestinal, and therefore suitable for CoVs. Cell lines are derived from insectivorous and frugivorous bats (genera.....)"

enrichment library to sequence full-length genomes. We will conduct this work via EID-CC research projects or as part of outbreak detection/investigation in the region from DNA viruses or other agents.

**1.4.e. Sequencing Spike Glycoproteins:** Based on earlier studies, our working hypothesis is that zoonotic coronaviruses, filoviruses and henipaviruses encode receptor binding glycoproteins that elicit efficient infection of primary human cells (e.g., lung, liver, etc.) (12, 59, 60). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (Fig. 4) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are undersampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (20, 60, 119), suggesting that existing vaccines and immunotherapeutics could easily fail against future emerging SARS-like CoV. Moreover, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic receptor binding protein genes of MERS-related, Ebola-related and Nipah/Hendra-related viruses will also program efficient entry via human ortholog receptors. For all novel virus strains, we will sequence the complete entry spike genes by amplifying overlapping fragments using degenerate primers as shown previously (20, 59). Full-length genomes of selected CoV strains (representative across subclades) will be sequenced using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR or MinIon sequencing will be performed to fill gaps in the genome. The full length spike gene sequences, including the amount of variation in the receptor binding residues that bind the appropriate human receptor will be used to select strains for Aim 3 experiments.

**1.5. Assessing risk for spillover. 1.5.a. Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, filoviruses and henipaviruses, we will use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (60, 61, 120). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs or other test filoviruses or henipaviruses to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other viruses (62, 70). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (61, 121) or monoclonal antibodies targeting the Ebola or Marburg E glycoprotein (Available through BEI), or Nipah or Hendra viruses (122). As controls or if antisera is not available, the S genes of novel SARSr-CoV or spike entry genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (123). Polyclonal sera against SARS-related viruses will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (61, 124, 125). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (126) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (127-129). Similar approaches will be applied to novel MERS-related viruses, other CoV, filoviruses or henipaviruses. While most wildlife-origin viruses with unknown transmission potential or pathogenicity in people are BSL-2 or -3, cell culture for potentially BSL-4 pathogens will be undertaken at collaborating institute NEIDL. To facilitate this, duplicate samples in culture medium from animals PCR +ve for filoviruses will be

**Commented [BRS38]:** Any antibodies available? If not we can synthesize them from published co-crystals.

**Commented [PD39]:** Can someone answer Ralph's question please?

shipped to NEIDL (**See letter of support**) for culture, characterization and sharing with other approved agencies including NIH RML. When appropriate of feasible, training opportunities at NEIDL for in-country staff will be given.

**1.5.b. Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the intraspecific scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (69). A lot of variation in the NPC1 receptor alters EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains (130). Signatures of positive selection in bat NPC1 were concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in *Eidolon helvum* cells. Thus NPC1 is a genetic determinant of filovirus susceptibility in bats, and some NPC1 variations likely reflect host adaptations to reduce filovirus replication and virulence (131). Nipah and Hendra use ephrin B2 or ephrin B3 as a receptor, and variation affects its ability to use human vs bat receptor molecules (102, 132).

**1.5.c. Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RdRp (or L genes), receptor binding glycoproteins, and full genome sequence (when available) data to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, filoviruses and henipaviruses that we identify. We will rerun MCC analyses (**Fig. 3**) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR-positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (**Fig. 4**) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) or other virus families within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (96, 133).

**1.5.d. Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (121, 134-136). For novel henipaviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize strains that are predicted to interact with ephrin-B2 and expression V/W proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models. We will assess ability to infect human cells using a continuous lung epithelial cell line, Calu3, that our group has previously used to generate data on NiV and HeV growth curves and a variety of host expression changes after infection (137). We will also use primary human airway cultures to assess human infection for Henipavirus and MERS- and SARS-related CoV (138) (139). There is some evidence for Nipah and Hendra virus replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (140, 141). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted Ebola infections (86-88).

**1.5.e. Animal models:** We will use transgenic mouse models and the UNC Collaborative Cross model to assess spillover potential of viruses. For work on CoVs, we will follow the protocols in the transgenic mouse model used by the Baric lab previously. Briefly, in the BSL3 lab, n=8 10- to 20-week old hACE2 or hDPP4

**Commented [PD40]:** Kevin/Alice – please edit this section to include relevance for filoviruses and henipaviruses as well (and other hosts)

transgenic mice will be intranasally inoculated with  $5 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins or MERS-CoV and MERS-related CoV, respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV or MERS-CoV mAbs (142, 143) will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (120, 144). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (61, 120). For the Collaborative Cross model, we will....

Finally, for more detailed pathogenesis studies in the natural reservoir, we will use the bat models (natural and transgenic mouse model) at Duke-NUS. Both animal systems can be used to test susceptibility, pathogenesis and immune responses of any newly discovered viruses.

**1.6. Potential problems/alternative approaches:** **to sample bats in sites or provinces we select.** We have a >20-year track record of successful field work in Malaysia, Thailand and >10 years in Singapore, and have worked with local authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based on a range of PCR data and are fairly conservative in our approach. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses. The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (145), do not suggest a strong pattern of seasonality in CoV shedding, although there are studies that suggest this occurs in henipavirus and filovirus (MARV?) shedding (REFS?). Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province.

**Aim 2: Test evidence of viral spillover in high-risk communities using novel serological assays.**

**Commented [PD41]:** Ralph – please insert a couple of sentences on how we'll use the cc mouse and what we'd expect

**Commented [PD42]:** Linfa/Danielle – could you put a couple of sentences in on what we might do with the models. Remember – this could be an additional short project from the EIDCC extra funding.

**Commented [PD43]:** Kevin – please edit/check

**Commented [PD44]:** Kevin – please check the veracity of these comments

**2.1 Rationale/Innovation:** Rapid response requires early detection. Thus, assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that interface frequently with wildlife that harbor high risk emerging viral strains. To enhance the low statistical probability of identifying these rare events, we will target rural human communities inhabiting regions of high wildlife biodiversity, that also engage in practices that increase the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will build and expand on our preliminary biological sampling and enroll large cross-sectional samples in human populations with high behavioral risk of exposure to wildlife-origin viruses and that live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will initially identify 2 sites in each of Thailand, Peninsular Malaysia, Sarawak, and Sabah for repeated biological sampling. We will design and deploy behavioral risk factor questionnaires, and specific and sensitive serological assays to identify the baseline frequency, and causes of, spillover of known and related novel viral pathogens in these populations. In participants where symptoms are reported in the last 10 days, paired serum specimens (acute and 21 days after fever) will be collected to determine titer of positive antibody. Samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, and for isolation and biological characterization of potential pathogens, using the approach laid out in Aim 1.

Country, site	Lead	# enrolled, focus	Findings
Peninsular Malaysia	Hughes	1,390 Orang Asli indigenous population, PCR/serol.	25+ novel CoVs, influenza, Nipah ab+ve, filovirus ab+ve
Malaysia Sabah	Kamruddin	1,283 serology	40% JE, 5% ZIKV ab+ve
Malaysia Sabah	William	10,800 zoonotic malaria	High burden of macaque-origin malaria
Malaysia Sabah	Hughes	150 bat cave workers	Ongoing
Malaysia Sarawak	Tan	500 Bidayuh and Iban people	8% PCR prevalence HPV in women
Malaysia PREDICT	Hughes	9,933 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Thailand	Wacharapluesadee	1,000 bat guano harvesters/villagers	Novel HKU1-CoV assoc. clinical findings
Thailand PREDICT	Wacharapluesadee	9,269 high zoonotic-risk communities, viral PCR, serology	Ongoing. Multiple known and novel CoVs, paramyxoviruses, others.
Singapore	Wang	856, Melaka virus	7-11% ab+ve

serological testing by EID-SEARCH. Our core group has collected and tested many thousand additional specimens from other important community cohorts (**Table 2**), and some of these will continue under EID-SEARCH (**See section 2.4**). Of particular interest is the access to indigenous communities in Peninsular Malaysia (Orang Asli) and Sarawak (Bidayuh, Iban people), and the bat guano harvesters in Thailand. These communities hunt, butcher and eat wildlife daily, and work in supremely high-risk zoonotic interfaces (e.g. bat caves). One of our indigenous community sites is experiencing an ongoing outbreak of unknown etiology that we are investigating currently (See section 3.2.a).

**Table 2:** Current or recent biological sample collection from healthy populations conducted by members of our consortium in EID-SEARCH hub countries

**2.2.b Human Contact Risk Factors:** EHA is the lead organization across all 27 USAID-PREDICT project countries for collecting data on, and analyzing the human aspects of, zoonotic spillover risk (146, 147). We conducted exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities, using these data to assess local social and cultural norms underlying wildlife contact (147). We then developed a risk factor survey to accompany human biological sampling to evaluate the type and frequency of animal contact, wildlife

**2.2 Preliminary data on high-zoonotic risk human community surveillance: 2.2.a Biological sample collection in SE Asia:** Our longterm collaboration in the region has included qualitative and quantitative survey data, and collecting large archives of banked human sera and other biological samples from high zoonotic-risk populations. For example, under the USAID-PREDICT project, EHA has collected 9,933 and 9,269 specimens in Malaysia and Thailand respectively from people living in zoonotic disease interfaces, all of which will be available for retrospective

**Commented [KJO45]:** Emily: Will we be sampling participants more than once?

**Commented [PD46]:** I think that would be good, depending on the sample size

**Commented [KJO47]:** Need to decide if we do PCR on community samples, we can add in the questionnaire if you've been sick in the last 10 days and if so, then maybe test only this subset.

**Commented [PD48]:** Kevin's comment makes sense to me

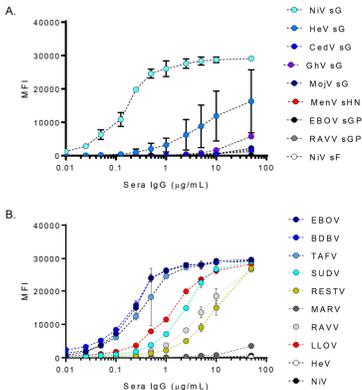

exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in 27 countries, and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). For example, survey and biological samples were collected from: 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, China; 1,400 participants from 4 sites in Malaysia; and 678 participants from 4 sites in Thailand. Samples were tested with novel serological assays and results analyzed against risk factors from survey data (12). In China, CoV-seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), that are male (6/9). Although these results are preliminary and don't provide detailed information on routes of exposure, they identify key subpopulations to target that would likely increase the opportunity for identifying evidence of spillover for other CoVs, paramyxoviruses and filoviruses. Data from PREDICT surveys will be used to help identify target populations in Aim 2, identify strategies to better target at-risk people, and conduct focused **human animal contact surveys and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.** In Aim 2, we will use combined biological sampling and risk factor surveillance in targeted populations within the community to 1) identify risk factors correlated with seropositivity to henipaviruses, filoviruses and CoVs; 2) assess possible health effects of infection in people; and 3) where recent illness is reported, obtain clinical samples for PCR testing and potential viral isolation and characterization. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**2.2.c. Risk factors for illness:** Our preliminary data from PREDICT in Thailand, Malaysia and China revealed that frequent contact with wild (e.g. bats, rodents, non-human primates) and domestic animals (e.g. poultry, swine) among local communities was associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms. In addition, people involved in crop production, hunting and butchering of wildlife reported statistically significantly higher SARI and ILI symptoms (Li *et al.*, in prep.). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with further refining serological tools, we will be able to identify the likely routes of exposure to known or novel coronaviruses, henipaviruses, and filoviruses in the study region, as well as build data on the illnesses they cause in people.

**2.2.d. Serological platform for community surveillance:** One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. By contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes (148). However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. Henipaviruses, filovirus and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filoviruses/henipaviruses=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (149)?, developing monoclonal antibodies (150, 151) and as subunit vaccines (152, 153), is presently developing a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, filoviruses and coronaviruses. This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (149). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

Commented [PD49]: Chris/Eric Is this the right ref?

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay. The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (Fig. XXX). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-related African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (77, 78). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus

henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (154-156). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity. The majority of ebolaviruses are endemic to Africa, however the discovery of Měnglà virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown pathogenicity and zoonotic potential exists. Our past work in collaboration with Duke-NUS demonstrated that three under-sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (41).

**Fig. XXX:** Validation of multiplex microsphere immunoassay

(MMIA) specificity and identification of immunologically cross-reactive viruses for Nipah (A) and Ebola (B).

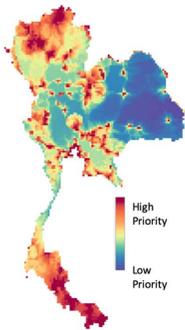

**2.3 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (Fig. XX). In Aim 2 we will conduct community-based surveillance using a brief, focused questionnaire to identify the prevalence and frequency of risk-factors for viral spillover in tandem with collection of high quality biological samples to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the communities sampled in Aim 2. Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and PCR prevalence in symptomatic patients.

**2.4 Target population & sample sizes:** We will target populations in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, that are EID hotspots, and that are well-connected through regional travel and trade hubs to the global travel network (Fig X). We will target specific communities based on our analysis of previously-collected PREDICT behavioral questionnaire data, to assess key at-risk populations and occupations with high exposure to wildlife, as well as using other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will identify populations at two sites in each of the following regions, building on our preliminary data (Table 2): *Thailand (Co-I Wacharapluesadee)*: We will continue surveillance in bat guano harvesters and their villages in Ratchaburi province where we have identified MERS-related CoV in bat guano and rectal swabs (48, 157) and serological evidence of  $\alpha$ -CoV, HKU1-CoV in people (Wacharapluesadee in prep.). Our second site will be in Chonburi province where we have found Nipah virus (99% identity of whole genome sequence to NiV from a Bangladesh patient) in flying foxes but no outbreaks have yet been reported (REF), and have found several novel paramyxoviruses and CoVs have been found in bat feces roosting there (Wacharapluesadee in prep.).

**Commented [PD50]:** Hongying -Need a new figure that lays out the community/clinical approach – small one with pretty images.

**Commented [PD51]:** Supaporn/Kevin/ -Need sample sizes for both populations and power calculations for serology for a typical virus from one of the three families we're targeting

**Commented [PD52]:** Supaporn – please insert a reference into this comment box

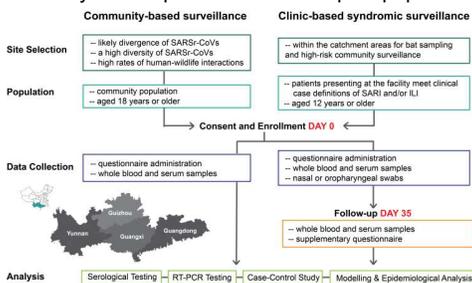

**Fig. X:** Geographic analysis to target high-risk sites for human zoonotic disease surveillance in Thailand. Our spatial analysis from Aim 1 will be extended to optimize sites for human community surveillance in Thailand and Malaysia by ranking areas with high numbers of expected viruses in wildlife, greater spillover probability based on EID risk factors, and higher levels of connectivity (measured by road density data) that may facilitate person-person spread.

**Commented [PD53]:** Need this figure for Singapore, Pen. Malaysia, Sarawak, Sabah as well – all together is best

**Peninsular Malaysia (Co-I Hughes, CM Ltd.):** We will expand our sampling of the Orang Asli indigenous communities to include additional communities in the 3 Districts we have already sampled, and additional Districts in the States of Kelantan Perak, Pahang, and Kelantan. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled. Human samples will include serum, whole blood, throat swabs, nasal swabs, urine, and fecal sample or rectal swab. Samples will be collect in duplicate in VTM and Trizol. Samples will be stored and tested at NPHL. Participants who hunt, butcher or consume wildlife, or who rear animals will be considered suitable

for enrolment. Participants will complete a consent form and questionnaire in addition to having samples collected. During these community trips the field team will conduct community meetings to help inform the Orang Asli about the public health risk of zoonoses. **Sarawak (Co-I Tan, UNIMAS):** We will expand our sampling of the Bidayuh and Iban indigenous people to include the Dayak and Orang Ulu (“people of the interior”) because this group has a more intimate connection to remote wildlife-rich areas than the other two, albeit all are hunters. Human sampling will be led by UniMAS in collaboration with CM Ltd / EHA. Concurrent sampling trips will be conducted during which 150 members of the community, 30 hunting dogs or other domestic animals and 60 wildlife (mainly bats) will be sampled, following the same protocols as for Peninsular Malaysia. **Sabah:** We will conduct sampling at the Madai bat and bird cave that has 200 permanent residents who harvest bird’s nests for soup, and >1,000 during the harvesting season and at Gomantong cave – one of the largest bat and cave swiftlet nesting sites in the world. Protocols follow those for Peninsular Malaysia. **Singapore:** Active human surveillance will be not be conducted in Singapore, but archived human specimens e.g. from our Melaka virus serosurvey (4), will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

**Sample sizes:** From our previous work we anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so that they make up  $\geq 30\%$  of the sampled population in each community. We will stratify sampling to ensure appropriate representation of sex, demographic, and socio-economic factors at each community site. Estimating 5% overall seroprevalence in these high-exposure populations, these sample sizes are sufficient to estimate effect sizes of 2X or greater with 80% power. For community-based surveillance, we will enroll xxx individuals per county/province, pooled across two sites for each, allowing us to make county/province-level comparisons of differing effects.

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**Commented [PD54]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipaviruses, filoviruses and coronaviruses.

**Commented [PD55]:** Emily/Hongying Please check

**2.5 Data & sample collection:** Following enrollment of eligible participants and completion of the consent procedure, **biological specimens** (5ml will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 2.5ml whole blood; two 500  $\mu$ L serum samples) will be collected and a **questionnaire** will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported

interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent considerations for participants enrolled from clinical settings we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

#### **2.6: Laboratory analysis: 2.6.a Serological testing:**

In a previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity detected (12). **This suggests that if we can expand our serology tests to cover other bat CoVs, and that doing so may identify many more seropositive individuals.** We will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 bat SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoVs SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (12), and HKU10 is known to jump from one host bat species to another (158) so is likely to have infected people more widely. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV, at a phylogenetic distance where therapeutic or vaccine efficacy may falter. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or S1 (n-terminal domain); 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (13). Additionally, in Thailand, as an initial project on our EIDRC, we will develop serology assays to the novel CoVs found in bats at the bat guano site using LIPS assays and viral genomic data, and will screen archived specimens from 230 participants (2 years' collection in 2017-2018, a subset of the subjects have been sampled at multiple timepoints to allow us to assess seroconversion).

**2.6.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

**2.6.c Biological characterization of viruses identified:** Novel viruses identified in humans will be recovered by cultivation or from full length genome sequences using reverse genetic approaches. Viruses will be characterized for growth in primary human cell lines and in mouse models, including the Collaborative Cross Mice or humanized mice expressing human receptors from related strains. The approaches are discussed in more detail under Aim 1.

**2.7 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for Henipavirus, Filoviruses, and CoVs spillover. "Cases" are defined as participants whose samples tested positive for Henipavirus, Filoviruses, or CoVs by serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative for Henipavirus, Filoviruses, or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation

Commented [PD56]: Chris, Eric, Linfa, Dani etc. please draft some language here...

Commented [PD57]: HELP – please add text for Henipas, filov

and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between Henipavirus, Filoviruses, or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, paramyxoviruses, and influenza viruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may not match known viruses due to recombination events, particularly for CoVs.** We will use the three-tiered serological testing system outline in 2.6.a to try to identify these 'novel' viruses, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

### **Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research (Table 1) and other data suggests that there are substantial numbers of outbreaks or clinical cases for which the etiologic agent is not diagnosed, e.g. (159, 160). To investigate this in SE. Asia, we will work directly with clinics and outbreak control organizations to identify the causes of some 'cryptic' outbreaks or cases in the region. Specifically, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and who present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We conduct novel viral discovery assays on patients who present with symptoms indicative of a high-risk zoonotic virus. If novel pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the pathogen, using the *in vitro* and *in vivo* strategy laid out in Aim 1.

**3.2 Preliminary data clinical surveillance: 3.2.a. Clinical surveys and outbreak investigations:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes: **Peninsular Malaysia: At the time of writing, there is an outbreak of suspected viral undiagnosed illness in the indigenous Batek Orang Asli ("people of the forest") community living at Gua Musang ("civet cat cave") district, in Kelantan, Malaysia, close to Taman Negara – a National Park containing the oldest known rainforest. This community is one where we have conducted prior routine surveillance and biological sampling, demonstrating proof-of-concept that our two-pronged high-risk community/clinic approach will work.** Dozens of people are affected and the outbreak is currently being investigated by our collaborators at the Malaysian NPHL. The Orang Asli live in remote villages in the rainforest of Malaysia, with limited access to modern health care and extensive contact hunting, butchering, and eating wildlife as their primary source of protein. This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC - to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia. **Investigating this outbreak be a key priority if EID-SEARCH is funded.** *Sabah:* Co-I Kamruddin (BMHRC) is leading an asymptomatic leptospirosis study on sanitation workers, an ILI study in a Kota Kinabalu clinic and diarrheal study in children under 5 yrs. Co-Is William, Tan and others have conducted clinical observational studies to determine the

**Commented [KJ058]:** Make this more general. There's a greater challenge of interpretation of serological data, esp. if we're using many platforms (each will have its own problems that our lab colleagues are probably more familiar with). Noam may be able to generally comment on a solution here from a statistical perspective.

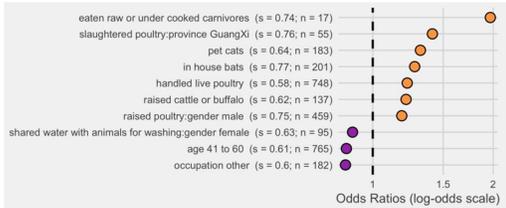

**Commented [PD59]:** Kevin – please modify according to your comment

etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah. Co-Is Tan, William have collaborated with Co-I Wang to enroll 90 adult and over 100 pediatric participants with central nervous system infections, negative tests for malaria and dengue from 3 district hospitals in Sabah to determine the various etiologies. While a high proportion tested positive for rickettsial agents, the majority had no clear diagnosis. **Sarawak:** Dr Tan (UNIMAS) is conducting a survey of high-risk female Kelabit indigenous people and has found 8% with HPV52 as the dominant strain. He is working on clinical cohorts of hand, foot and mouth disease and will recruit patients from that study in the current proposed work. Finally, he is conducting a longterm study of rotavirus and other viral etiologies of acute gastroenteritis in Kuching, Sarawak that will include swine herders and farmers. These are an important group in Malaysia because pig farms are shunned by the government and local villagers to they are placed far away from town centers, deep in the forest, and it is this scenario that led to the emergence of Nipah virus in 1998-9 (18, 161). **Thailand:** The Chulalongkorn Univ. TRC-EID laboratory works in coordination with the Thailand Ministry of Health to investigate outbreak etiology, including the first case of imported MERS-CoV in Thailand, **for which we produced sequence confirmation within 24 hours from acquiring the specimen (Fig. X)**. Three imported MERS cases have been detected in Thailand since 2015, and all cases were confirmed at the TRC-EID. We worked during the Zika outbreak to identify > 500 PCR-positive Zika patients with sequence confirmation. We have also worked on returning and suspected Ebola travelers, syndromic surveillance for SARI, Encephalitis, Hand Foot and Mouth disease in children and Viral diarrhea. Working with the US CDC (Thailand), between 1998 and 2002 we enrolled a large cohort of children from Kamphaeng Phet Province to examine Dengue virus and JE epidemiology (162, 163). Among the 784/2,574 convalescent sera Henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence), suggesting prior exposure to endemic henipaviruses or a related paramyxovirus in rural Thailand. **Singapore:** Duke-NUS has worked with the Ministry of Health to investigate Zika cases (164), and with EcoHealth and others, Duke-NUS has developed novel CoV assays for clinical surveillance, and for expedited analysis during outbreaks. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing is as rapid as several months, with the development of novel serological assays from sequence data in 7 days (13). **For example, with the discovery of SADS-CoV, we identified and fully sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (*Rhinolophus* spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (13).**

Commented [PD60]: Fig coming from Hongying

**3.2.b Analysis of self-reported illness:** In addition to biological outcomes we have developed a standardized approach in PREDICT for analyzing data on self-reported symptoms related to targeted illnesses; of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), fever with muscle aches (fevers of unknown origin (FUO) and, cough or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI and/or SARI symptoms and demographics, occupation, and contact with animals in the last year. Results have clear biological relevance. In Yunnan, China, salient associated variables or combination of variables were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (Fig. 11). We will expand this approach for all syndromes in Aim 3, and use more granular targeted questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country.

**Fig. 11:** Associated variables of self-reported ILI and/or SARI in prior 12 months (s = bootstrap support; n = number +ve out of 1,585 respondents). **Orange circles** = odds ratios > 1 (positively associated with the outcome); **purple** = odds ratios <1 (negatively associated with the outcome).

**3.3 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms

typical of high-impact emerging viruses. We will collect survey data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.4 Clinical cohorts. 3.4.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at 2 town-level clinics and 2 provincial-level hospitals in Thailand, Peninsular Malaysia, Sabah and Sarawak. These all serve as the catchment healthcare facility for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients  $\geq 12$  years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, fevers of unknown origin, or hemorrhagic fever will be recruited into the study. We will enroll a total of xxxx individuals for clinical syndromic surveillance, which accounts for up to 40% loss from follow-up. Study data will be pooled across country sites, as clinical patients are limited by the number of individuals presenting at hospitals. Sites: *Thailand:* XXXXX | *Peninsular Malaysia:* Focusing immediately on the current outbreak in Orang Asli, we will work closely with the Malaysian Ministry of Health to support their investigation. We will also work with 6 Orang Asli clinics which focus solely on this indigenous community. *Sarawak:* XXXXXX *Sabah:* XXXXXXXXXX | *Singapore:* XXXXX

**3.4.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever of unknown etiology; or 6) severe diarrhea. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance of PCR detection of viruses (165). We will follow up 35 days after enrollment to collect an additional two 500  $\mu$ L serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs  $<28$  days after onset of symptoms for SARS patients (166). These samples may prove valuable to collaborators in that the PBMC could be used in production of therapeutic antibodies.

### 3.4.c Sampling:

Following enrollment with signed consent form, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500  $\mu$ L whole blood; two 500  $\mu$ L serum samples) including two nasal or oropharyngeal swabs will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

**3.5 Sample testing:** PCR, Serol to link symptoms to etiologic agents

**Commented [PD61]:** Supaporn, Kevin – we need information!

**Commented [PD62]:** Tom, Kevin – we need information.

**Commented [PD63]:** Hongying Emily

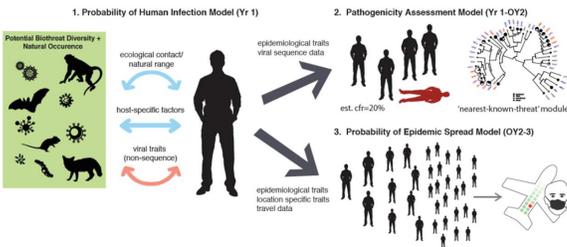

**Commented [PD64]:** Need data for Nipah and filovirus patients

**Commented [PD65]:** Ralph: PBMC could be valuable for making therapeutic antibodies through collaborations?

The standard syndromic diagnostic PCR assay for the common pathogens will be conducted and the results will be shared to the hospital with 48 hours. Specimens will be further tested for 3 viral families; CoV, PmV and filovirus by consensus PCR. Appropriate specimen from dead case will be further conducted by NGS if the previous PCR tests are negative to identified cause of infection. The serology panel assay will be conducted from paired serum.

Commented [PD66]: This is v. weak – can someone strengthen it please!

**3.5 Assessing potential for pandemic spread:** We will use statistical models built from collated biological, ecological, and genetic data to predict the likelihood of human infection (or spillover) and pathogenicity for a the range of diverse viruses we will characterize. The aim is to quickly identify and assess which viruses pose the most significant risk to human health and thus prioritize additional resources to more fully characterize, better understand pathogenicity, and invest in therapeutic development for those pathogens. We will combine two independent but related statistical models to predict pathogen spillover risk and pathogenicity. First, we will expand a simple generalized additive modeling approach (91) to assess spillover risk probability to a new virus that is currently not known to infect people, when we have only limited genetic data from initial PCR screening and sequencing. Additional data from receptor binding protein homology and cell line infection experiments can be incorporated into the model framework as available. Second, given high likelihood to spillover and infect humans, or direct evidence of human infection from our clinical surveillance, we will then predict pathogenicity using nearest neighbor phylogenetic analyses as a first approximation and by incorporating more detailed data from genomic characterization and animal model experiments. For the pathogenicity model, human epidemiological data for ~300 viral species known to infect people (case fatality rate, global estimates of number of human cases per year or decade,  $R_0$ , infectious period, and primary symptoms) will be aggregated including from previous reviews [Woolhouse ref] to use as predictor variables. Thirdly, we will build off EHA's previous DTRA and DHS supported research to predict pandemic spread for viruses we identify by integrating surveillance site data, global flight models (167), as well as additional datasets (road networks, shipping routes, cell phone data) to measure human movement and connectivity across Southeast Asia.

**Fig. XXXXX:** Conceptual framework highlighting 3 underlying models to estimate: 1) probability of human infection, or spillover, the first necessary step to understand pathogenicity when status of human infection is unknown; 2) pathogenicity, i.e. probability of causing clinical signs, case fatality rate estimates, and other metrics relevant to humans; and 3) probability of pathogen spread based on ecological, epidemiological, and airline connectivity and human migration data.

Commented [PD67]: Hongying – please work with Kevin to come up with something of relevance here. Also, make the text brief, bold and large so it's readable

### 3.7 Potential problems/alternative

**approaches: Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases.** Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (165). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the potential public health importance of discovering active spillover of a new henipavirus, filovirus or CoV infection.

Commented [PD68]: Add data for Nipah and filo infections

**Additional Instructions – Specific to the EIDRC FOA:**

**4. Administrative Plan**

In a clearly labeled section entitled “**Administrative Plan**”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.

Chula TRC-EID is National reference laboratory for diagnostic and confirmation of EIDs pathogen along with the National public health laboratory at the Department of Medical Science and the WHO Collaborating Centre for Research and Training on Viral Zoonoses. We have built a EID laboratory network in-country among three Ministry including Ministry of Public Health (Department of Medical Science and Department of Disease Control), Department of Livestock and Development, and Department of National Parks, Wildlife and Plant Conservation and Universities and among SEARO countries. Our clinicians provide case consultation for Thailand and SEARO countries. The laboratory and clinic training are regularly conducted.

**For Malaysia –**

**NPHL –** Molecular and serological screening (BioPlex) of PM Orang Asli samples, serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval)

**PERHILITAN molecular zoonosis laboratory, at the National Wildlife Forensic Laboratory -** Molecular and serological screening (BioPlex) of PM wildlife samples

**UPM Faculty of Veterinary Medicine -** Molecular and serological screening (BioPlex) of PM livestock samples

**KKPHL -** Molecular of syndromic samples from Sabah (already done) and Sarawak (would need approval)

**SWD WHGFL -** Molecular screening of Sabah wildlife samples

**BMHRC -** Molecular and serological screening (BioPlex) of Sabah livestock samples, serological screening (BioPlex) of Sabah wildlife samples, Molecular and serological screening of syndromic samples from Sabah (already approved) and Sarawak (would need approval). BMHRC will need renovations and BioPlex to do this work – Menzies team might have funds for BioPlex that they would base here as part of DTRA project.

- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

**List out all of our involvement with outbreak investigations, ministries of health surveillance etc.**

If possible the clean or summarized answers from the questionnaire should be shared to the hospital Infectious Control team and Bureau of Epidemiology for their information for controlling the outbreak.

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging

**Commented [PD69]:** All – I’ve started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**Commented [PD70]:** From Supaporn

**Commented [PD71]:** From Supaporn – do same for all countries

infectious diseases in an international setting.

CM/EHA helped establish and manages with SWD the Wildlife Health, Genetic and Forensic Laboratory (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications) that has all the equipment necessary to store samples, run extractions, PCR and analysis on biological samples for wildlife disease surveillance. The lab is used to conduct health checks on rescued and relocated wildlife before being released into new areas or sanctuaries, to screen samples for the PREDICT and Deep Forest Project and for genetic research and forensic investigations. CM/EHA also helped establish the new molecular zoonosis laboratories (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications), at DWNP's National Wildlife Forensic Laboratory. The lab is used to screen samples for the PREDICT & DTRA projects. In addition CM/EHA also has access to NPHL and KKPFL for screening human samples and the Virology lab at FVMUPM for screening Livestock samples.

The Borneo Medical and Health Research Centre (BMHRC) is a centre of excellence that conducts teaching and scientific researches on communicable diseases, outbreak investigations, and ethnomedicine. BMHRC has offices space including a meeting room and seven laboratories which including preparation lab, parasitology lab, cell culture lab, bacteriology lab, natural product lab, virology lab, and molecular biology lab. BMHRC is supported by an administration staff, medical lab technologist, and research assistants who are available to work on projects. Through this project we will help to establish a certified BSL-2 lab at the BMHRC. This lab can then be used for human testing to elevate pressure at KKPFL and QEH labs. It would also be an ideal location for a Luminex platform as human, wildlife and livestock samples could all be screened here. Co-Is Hughes and Kamruddin will be starting outbreak response training in August 2019 with a team from Sabah CDC, KKPFL and BMHRC. (Dr. Maria Suleiman now in PM But still collaborating with us, Dr. Muhammad Jikal current Director CDC working with us and Dato' Dr Cristina Rundi Director Sabah state health Dept is supportive) this collaborative group is working to develop a Sabah outbreak response team that will help support SSHD/ CDC outbreak team and also conduct sampling for disease surveillance to be based at BMHRC and we will develop this as part of this proposal. In addition the UMS hospital will come in line in 2021 providing additional opportunities for cohort studies and capacity building.

FROM DARPA grant:

**Section 1.03 MANAGEMENT PLAN**

Project DEFUSE lead institution is EcoHealth Alliance, New York, an international research organization focused on emerging zoonotic diseases. The PI, Dr. Daszak, has 25+ years' experience

Commented [KJ072]: Figure like this would be good, but instead of breaking down by TA, maybe by country or Specific Aim. Per FOA, Need to also show how we'll link in with the Coordinating Center and other EIDRCs.

managing lab, field and modeling research projects on emerging zoonoses. Dr. Daszak will commit 2 months annually (one funded by DEFUSE, one funded by core EHA funds) to oversee and coordinate all project activities, with emphasis on modeling and fieldwork in TA1. Dr. Karesh has 40+ years' experience leading zoonotic and wildlife disease projects, and will commit 1 month annually to manage partnership activities and outreach. Dr. Epstein, with 20 years' experience working emerging bat zoonoses will coordinate animal trials across partners. Drs. Olival and Ross will manage modeling approaches for this project. Support staff includes

a field surveillance team, modeling analysts, developers, data managers, and field consultants in Yunnan Province, China. The EHA team has worked extensively with other collaborators: Prof. Wang (15+ yrs); Dr. Shi (15+ yrs); Prof. Baric (5+ yrs) and Dr. Rocke (15+ yrs).

**Subcontracts:** #1 to Prof. Baric, UNC, to oversee reverse engineering of SARS-CoVs, BSL-3 humanized mouse experimental infections, design and testing of targeted immune boosting treatments; #2 to Prof. Wang, Duke-NUS, to oversee broadscale immune boosting, captive bat experiments, and analyze immunological and virological responses to immune modulators; #3 to Dr. Shi, Wuhan Inst. Virol., to conduct PCR testing, viral discovery and isolation from bat samples collected in China, spike protein binding assays, humanized mouse work, and experimental trials on *Rhinolophus* bats; #4 to Dr. Rocke, USGS NWHC, to refine delivery mechanisms for immune boosting treatments. Dr. Rocke will use a captive colony of bats at NWHC for initial trials, and oversee cave experiments in the US and China. #5 to Dr. Unidad, PARC, to develop innovative aerosol platform into a field-deployable device for large-scale inoculation of the bats. Dr. Unidad will collaborate closely with Dr. Rocke in developing a field deployable prototype for both initial trials and cave experiments in China.

**Collaborator Coordination:** All key personnel will join regularly-scheduled web conferencing and conference calls in addition to frequent ad hoc email and telephone interactions between individuals and groups of investigators. Regular calls will include:

- Weekly meetings between the PI and Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.
- Monthly web conferences between key personnel (research presentations/coordination)
- Four in-person partner meetings annually with key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

Evaluation metrics will include the generation of high-quality data, successful achievement of milestones and timelines, scientific interaction and collaboration, the generation of high quality publications, and effective budget management. The PI and subawardee PIs will attend a kickoff meeting and the PI will meet regularly with DAPRA at headquarters and at site visits.

**Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by Dr. Daszak and the Project Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation. Should a resolution not be forthcoming, consultation with our technical advisors and DARPA Program staff may be warranted.

**Risk management:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. A project of this nature requires a different mindset from that typically associated with basic research activities that move at an incremental pace with investigators gradually optimizing experimental systems, refining data, or waiting for additional data before moving ahead with an analysis approach. To maintain our timeline, we will continually evaluate these trade-offs to make decisions about when iteration is appropriate and when necessary to move forward with current information.

#### **Biographies:**

**Dr. Peter Daszak** is President and Chief Scientist of EcoHealth Alliance, Chair of the NASEM Forum on Microbial Threats, member of the Executive Committee and the EHA institutional lead for the \$130 million USAID-EPT-PREDICT. His >300 scientific papers include the first global map of EID hotspots, estimates of unknown viral diversity, predictive models of virus-host relationships, and evidence of the bat origin of SARS-CoV and other emerging viruses.

**Prof. Ralph Baric** is a Professor in the UNC-Chapel Hill Dept. of Epidemiology and Dept. of Microbiology & Immunology. His work focuses on coronaviruses as models to study RNA virus transcription, replication,

**Commented [PD73]:** Some of references in this section are duplicates

persistence, cross species transmission and pathogenesis. His group has developed a platform strategy to assess and evaluate countermeasures of the potential “pre-epidemic” risk associated with zoonotic virus cross species transmission.

**Prof. Linfa Wang** is the Emerging Infectious Diseases Programme Director at Duke-NUS Medical School. His research focuses on emerging bat viruses, including SARS-CoV, SADS-CoV, henipaviruses, and others and genetic work linking bat immunology, flight, and viral tolerance. A 2014 recipient of the Eureka Prize for Research in Infectious Diseases, he currently heads a Singapore National Research Foundation grant “Learning from bats” (\$9.7M SGD).

**Current list of contacts at key human (especially) and wildlife orgs in every SE Asian country from map above – please add to this if we’ve missed any**

Indonesia – EHA: Eijkman (Dodi Safari), IPB (Imung Joko Pamungkas); **CM Ltd**: IPB (Imung Joko Pamungkas), Bogor Agricultural University (Diah Iskandriati)

SE China – EHA: Yunnan CDC (XX), Wuhan Inst. Virol. (Zhengli Shi);

Myanmar – Chulalongkorn (Thiravat and Supaporn) have collaborated extensively with Win Min Thit, MD (Yangon General Hospital, Myanmar); Khin Yi Oo (National Health Laboratory, Myanmar) and also in training PREDICT Myanmar veterinarians in bat sampling under PREDICT.

Japan – **BMHRC**: Oita University (Hidekatsu Iha, Kiyoshi Aoyagi), Nagasaki University (Koichi Morita, Kazuhiko Moji)

Cambodia -

Laos - **CM Ltd**: Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (Matthew Robinson)

Bangladesh – EHA: IEDCR (Meerjady Sabrina Flora, Ariful Islam), icddr,b (Mohammed Ziaur)

Malaysia – **CM Ltd**: Borneo Medical and Health Research Center (Ahmed Kamruddin), Department of Wildlife and National Parks Peninsular Malaysia (Frankie Sitam, Jeffrine Japning, Rahmat Topani, Kadir Hashim, Hatta Musa), Hospital Universiti Malaysia Sabah (Helen Lasimbang), Faculty of Medicine, Universiti of Malaya (Sazaly Abu Bakar), Kota Kinabalu Public Health Laboratory (Jiloris Dony, Joel Jaimin), Ministry of Health (Chong Chee Kheong, Khebir Verasahib, Maria Suleiman), National Public Health Laboratory (Hani Mat Hussin, Noorliza Noordin, Yu Kie Chem), Queen Elizabeth Hospital (Giri Rajahram, Heng Gee Lee), Sabah State Health Department (Christina Rundi, Mohammad Jikal), Sabah Wildlife Department (Rosa Sipangkui, Senthilvel Nathan, Augustine Tuuga, Jumrafiah Sukor), Gleneagles Hospital Kota Kinabalu (Timothy William); **BMHRC**: **CM Ltd** (Tom Hughes), HQEII (Shahnaz Sabri), Kota Kinabalu Public Health Laboratory (Jiloris Dony), Sabah State Health Department (Mohammad Jikal)

Thailand – **CM Ltd**: Department of Disease Control, Ministry of Public Health (Rome Buathong, Pawinee Doungngern, Pongtorn Chartpituck), Department of National Park, Wildlife and Plant Conservation (Pattarapol Manee-On), Faculty of Forestry, Kasetsart University (Prateep Duengkae), Mahidol-Oxford Tropical Medicine Research Unit, (Stuart Blacksell, Richard Maude), Chulalongkorn University (Supaporn Wacharapluesadee).

Chulalongkorn lab is a WHO Collaborating Centre for Research and Training on Viral Zoonoses, we work closely with WHO SEARO and SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste. We had conducted the PREDICT lab training for Veterinary lab in the Southeast Asia region for FAO. We conducted (transferred?) the bat sampling technique for scientists from Malaysia, Myanmar, the Philippines, and China.

## 5. Data Management Plan

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system

### Language from NIH CoV grant:

**Data Sharing Plan:** Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited in long-term public scientific repositories – all sequence data will be made publicly available via GenBank, species location data via the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestrictive MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Viral isolates will remain at the Wuhan Institute of Virology initially. Isolates, reagents and any other products, should they be developed, will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Sharing Model Organisms:** We do not anticipate the development of any model organisms from this study. Should any be developed, they will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Genomic Data Sharing:** We anticipate obtaining genetic sequence data for 100s of novel coronavirus genotypes, including RNA-dependent RNA polymerase (RdRp) and Spike genes for all strains/genotypes. In addition, we will generate full viral genomes for a subset of the bat SARSr-CoVs that we identify. All sequence data will be deposited in the NIH genetic sequence database, GenBank. We will ensure that all meta-data

associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also submitted. The genotype data will be made publicly available no later than the date of initial publication or six months after the receipt of final sequencing data, whichever comes first. We anticipate sequence generation will occur over the 5 year proposed project period.

Genome Wide Association Studies (GWAS): Not applicable.

Commented [KJ074]: From CoV NIH grant

Thailand TRC-EID Chulalongkorn lab: Specimen management and BioBank: The software called PACS (Pathogen Asset Control System) supported by BTRP DTRA, is now used for managing the specimen from specimen registration (barcoding, and may move to use QR code system soon), aliquoting, tracking, short patient history record, data summary, searching, test reporting and etc. Our biobank system contains 28 freezers (-80C) and liquid N2 system. Its size is around 120 sq meters. There is a separate electric generator for our lab and biobank. There are CC TV cameras at the biobank and laboratory.

Chula TRC-EID has our own server for data management and analysis. We have the necessary software including Bioinformatic tools (Blast Standalone, SAMTOOL, GATK, AliVIEW, RaxML, FigTREE, MAFFT, Guppy, Megan, PoreChop, MEGA), Database (MySQL, MongoDB) Web, jQuery, Node.js, Express.js React, API, PHP, Ruby, Python, Java, C#, HTML5, Bootstrap, CSS, Responsive, Cloud, Linux Command, PACS (sample management system), Virtualbox virtual machines, R programming languages, Perl scripts, Bash shell scripts, Open source software, Microsoft Office running on both Apple Mac OS X, Ubuntu, Linux, and Windows Operating Systems. Chula TRC-EID has a dedicated 16-core Ram 64GB Linux server with 4TB hard drives, dual quad-core Mac Pro Server with 2TB hard drives and another dedicated iMac Pro (Retina 4K, 21.5-inch, 2017) Processor 3.6GHz quad-core Intel Core i7 (Turbo Boost up to 4.2GHz) Ra, 16GB with 512GB hard drives. TRC-EID also has HPC Linux server CPU: 4 x 26cores Intel Xeon = 104 cores 2.1GHz with 52 TB HDD and 2x3.84TB SSD with GPU 2x Tesla v100 (CUDA core = 5120 cores/GPU, Tensor core = 640 cores/GPU). TRC-EID has a dedicated 10/100/1000 of LAN (Local Area Network), 2.4G / 5G Gigabit Wi-Fi 802.11ac.

Commented [KJ075]: From Supaporn for their lab, some may go in Facilities doc?

From DARPA:

**Data Management and Sharing:** EcoHealth Alliance will maintain a central database of data collected and generated via all project field, laboratory, and modeling work. The database will use secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations, and enable compliance with DARPA data requests and disclosure requirements. All archived human sample data will be de-identified. Partners will provide raw and processed data to the central database throughout the course of the project. Project partners will have access to the data they generate in the database at all times, and maintain control over local copies. Release of any data from the database to non-DARPA outside parties or for public release or publication will occur only after consultations with all project partners. EHA has extensive experience in managing data for multi-partner partner projects (PREDICT, USAID IDEEAL, the Global Ranavirus Reporting System).

Commented [KJ076]: Text from DARPA Preempt

## 6. Clinical Management Plan

### Clinical site selection

Our consortium partners have been conducting lab and human surveillance research, inclusive of human surveillance during outbreaks, for over the past two decades and in that time have developed strong relationships with local clinical facilities and processes. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1. These are regions where we will sample wildlife due to the high potential of zoonotic viral diversity. Additionally, these will be clinical sites that serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. In PREDICT we developed successful working relationships with the major healthcare facilities the hotspot areas in 6 different countries, including Thailand and Malaysia and we will continue to work with these sites going forward. Continuing to

Commented [EH77]: Is that true

work with these hospitals means we will begin this project with successfully established partners and we can begin data collection quickly. This also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites for this study is limited. All that is required of sites will be the ability to enroll patients that meet the clinical case definitions of interest, capacity to collect and temporarily store biological samples, and follow standards for data management and protection. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently site staff. These will be persons who are locally trained and certified to collect biological specimen from participants including blood draw technique, e.g. doctor or nurse. Last, the clinical site will need the capacity to securely store all personal health information and personally identifiable research data, this will include locked offices with locked filing cabinets to store all paper records and an encrypted computer. Training on project procedures will be provided for all local project staff by local country project management staff and partners from headquarters. The study at clinical sites will begin by developing relationships with local stakeholders at the hospitals and clinics in our geographic areas of interest that serve as catchment facilities for people of within the community surveillance study. We will recruit hospital staff that will be extensively trained for project procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data management plans. During the Development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data (e.g. locked filing cabinet, dry shipper, secure laptop). [Did not specifically address CONDUCT]. Oversight for clinical sites will be managed by the country coordinator for each country. This will be done with regular site visits to the clinical sites and annual visits by headquarter research staff. Site visits will include monitoring and evaluating the process for patient enrollment, collecting and storage of samples, administration of the questionnaire, and secure and data management procedures for secure personal health information and research data. During these visits any additional training will also be provided.

#### **Standardized approach oversight and implementation**

Management and oversight for all study sites will be managed by the local country coordinator who is supported by staff at headquarters. Implementation of a standardized approach across all study sites, community and clinical, will begin by extensive training of staff on procedures on requirements of the project, this includes: enrollment, data collection, and data management. Our research team has over 5 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research. This includes SOPs for screening, enrollment, and retention of participants. In addition to yearly monitoring reports the country coordinator will regularly visit each clinical site to ensure quality standards and compliance of procedures are being met. Through our work with clinical sites in PREDICT we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical research staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll, allowing for minimal disruption and prevents potential enrollees from being overlooked if the research staff is not on duty. At clinical sites that do scheduled outpatient days we may have a trained member of the research staff with the intake nurse to monitor the patients coming to the clinic more rapidly to no delay screening or enrollment in such a fast pace environment. Using the screening tools, we will recruit and enroll patients who present with symptoms that meet the clinical case definitions of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology within the past 10 days. These patients will be enrolled, samples collected and survey conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; 3) environment biosecurity. With permission from each clinic, and consent from participants, we will review clinical records to

collect data on medical history, clinical syndromes, and patient etiology. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either coronaviruses, henipavirus, or filoviruses, serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between coronaviruses, henipavirus, or filoviruses in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. [How do these cohorts be leveraged for new emerging pathogens] Achieving the adequate numbers will be attained through duration of the as clinical participant enrollment. While patient's enrollment is limited by the number of individuals presenting at hospitals, during the PREDICT project we had an average of 105 patients enrolled per year, ranging from 77-244. The country coordinator will be continually monitoring the project database to be sure that we are on track to reach our target.

#### Clinical cohort setup, recruitment, enrollment

We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology for symptoms reported onset of illness to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 2\* 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples and two nasal or oropharyngeal swabs will be collected. The cases are defined as participants whose samples tested positive for Henipaviruses, Filoviruses, or CoVs by PCR or serological tests. The controls will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500 µL serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms for coronaviruses, henipavirus, or filoviruses infected patients to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

#### Utilization of collected data

Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses the are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire allows us to assess relative measures of human-wildlife contact from our survey work that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk.

The biological specimens to be collected (2\*5mL whole blood for whole blood and serum analysis and nasal or oropharyngeal swabs) from all eligible participants and follow up specimen 35 days (3mL of whole blood for serum) after enrollment with the standardized questionnaire. Capacity for specimen is collection is not more than standard phlebotomy skills and we will collected by locally trained and certified personnel that are part of the research team in country. Staff we will trainline on ethical guidelines for conducting human subjects

**Commented [EH78]:** Will these cohort fulfill the goals of the EIDRC.

**Commented [EH79]:** PREDICT we also make the stipulation that we will collective relative samples if avialble from treatmean collection, eg CSF if the MD is doing a spinal tap we will request an aliquot if possible

**Commented [EH80]:** Please add any information that might address: types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

**Commented [EH81]:** Please add any information that might address: Describe methods that might be applied to elucidate a zoonotic source

research and survey data collection methods. Collection of whole blood, serum, and nasal or oropharyngeal swabs allows us to test the samples for PCR to detect viruses in our priority viral families, serologically test for immunological response and historical exposure to zoonotic diseases of relevance, and the questionnaire will assess individuals evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

#### **Potential expansion**

Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research or an outbreak in the region. If expansion is required we could rapidly implement research activities in additional clinical or community sites through the same process we on-boarded the initial locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transportation, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provided necessary information for granular understand of disease spread.

In a clearly labeled section entitled "**Clinical Management Plan**":

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment. including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen

collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

#### Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics
2. Tekada Sanofi Pasteur dengue
3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

### 7. Statistical Analysis Plan

In a clearly labeled section within the Research Strategy entitled "**Statistical Analysis Plan**":

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

### 8. Project Milestones and Timelines

In a clearly labeled section entitled "**Project Milestones and Timelines**":

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

**Project Management & Timeline**

PI Daszak will oversee all aspects of the project. Dr. Daszak has two decades of experience managing international, multidisciplinary research in disease ecology, including successful multi-year projects funded by NSF, NIH and USAID. He will conduct monthly conference calls with all co-PIs, including the China team (see Activity schedule below). He will be assisted by EHA Sr. Personnel Li, who is a US-based Chinese national with fluent

Mandarin. Co-PI Olival will oversee Aim 1 working closely with China PI Tong, who will test samples. Co-PI Ma (China team) will coordinate and lead all Chinese experimental infections, with guidance from co-PI Saif, who will coordinate and lead all US experiments with co-PI Qihong Wang. Sr. Personnel Ross will conduct all modeling activities in Aim 2, working closely with co-PI Saif to parameterize the models. Co-PI Baric and Sr. Personnel Sims will lead infectious clone, recombinant viral and culture experiments. Consultant Linfa Wang will advise on serology, PCR and other assays. China team co-PIs Shi and Zhou will oversee viral characterization in Aim 1. Sr. Personnel Feferholtz will oversee the economic modeling in close collaboration with Ross.

Commented [KJ082]: Text and figure From NSF-NIH SADS grant. Peter will adapt

Another Example of Milestones and specific tasks from a prev DHS (unfunded) proposal:

**Expand existing databases to include predictor variables for pathogenicity risk model**

**Task 1:** Collate available human clinical information from the literature for ~300 viral pathogens known to infect humans (Contract Award Date to 6 month)

**Task 2:** Update EHA host-viral association database to include new data for mammalian and avian species from literature 2015-present (Contract Award Date to 3 month)

**Task 3:** Extract and curate full and partial genomic data from Genbank for 5-6 viral families with a high proportion of human-infectious pathogens for phylogenetic analyses – e.g. ‘nearest-known-threat module’. (Month 2 to 6 month)

**Develop underlying pathogenicity and spillover risk assessment models**

**Task 4:** Fit generalized linear models in Stan for multiple response variables to measure pathogen impact (Month 7 to 10 month)

**Task 5:** Fit generalized linear models to estimate risk of human infection (spillover) based on host, ecological, and location specific traits (Month 4 to 8 month)

**Task 6:** Validate model effectiveness by simulating early-outbreak, limited-information scenarios from known pandemics to confirm model behavior (Month 8 to 10 month)

Commented [KJ083]: Just example, but probably just want to use a Gantt chart format per most of our grants, depending on space.

Dear All,

Here's version 4. Apologies for the delay. It's in better shape now, but there are still lots of areas that need your attention. Please put in time today, and tomorrow to edit and firm up the text. I've put your names in some of the comment boxes where I need specific help but I also need you to read this critically now and edit and tighten it up. We have 30 pages of space, and our research plan is now 21 pages, so we need to lose maybe 3 or 4 pages. There are also some weak points, specifically on Filoviruses, on the details of where we'll do our clinical work, and on what we'll do with the animal models for henipias and filoviruses.

Please get comments back with me before Wednesday 26<sup>th</sup> 4pm New York time, so that I have Wednesday evening and all day Thursday to incorporate them. In the meantime, I'll be working with folks here on better figures, and all the extra sections that come after the research plan. I'll need you all to help with those on Thursday while I'm finishing off the draft.

Thanks to all of you in advance and look forward to the next round.

Cheers,

Peter

**Subject:** EIDRC-SEA v.3  
**Importance:** High

Dear all,

Thanks to everyone for comments and text for the earlier draft at the beginning of the week. Kevin's spent the last couple of days pulling all the comments together into one draft and inserting his changes, and I've now attached a v3 of the draft. It's still rough, and now too long, but it's getting there. I wanted you to look at this rough version because I'm stuck in Liberia in meetings Friday, then flying back home Saturday. I'll continue editing this draft on the plane and will be working solely on this grant from home on Sunday, Monday, Tues, Wed, Thurs.

Please work on this rapidly if possible. If you can all push your comments through, using track changes, and get them back to me **by Sunday evening New York Time**, I will turn round a polished draft by Tuesday, giving us time for significant last go-over on Wed, Thurs. It's tight, but unfortunately, it is what it is, so please commit the time if you can!! As well as general edits (using track changes, with references in comment boxes), please do the following...

Linfa/Danielle – We especially need your input in section 1.1, 1.3, 1.4 and 2.5

Ralph/Amy - Please work your magic on this draft, inserting text, editing and reducing text, and making sure the technical details of the characterization are correct and fit the proposed work on CoVs, PMVs and Henipaviruses

Chris/Eric – Eric – congratulations on your (b) (6) and thanks for working on it at this time! Chris – please help and edit/finesse the language in the relevant sections for you

Tom – Your edits crossed over with Kevin's changes, so please insert all the bits that were new in the last version you sent to me, into this version. I think these are mainly the sections and comments from the other Malaysian colleagues, but please check and re-insert all key text. We especially need to be specific about which partner in Malaysia is doing what cohorts, and where, and about who's doing the testing

Thanks again all, and I'm looking forward to non-stop work on this as soon as I get on my flight in 24 hours...

Cheers,

Peter

## Understanding risk of zoonotic virus emergence in EID hotspots of Southeast Asia

### II. Research Strategy:

#### 1. Significance:

Southeast Asia is a well-defined hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of critical ecological and socioeconomic drivers of disease emergence (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is also undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread. It is therefore not surprising that a number of recent discoveries have identified novel viruses, including near-neighbors of known agents spilling over to livestock and people through often novel pathways, leading to sometimes unusual clinical presentations (Table 1). These factors are also behind a significant background burden of repeated Dengue virus outbreaks in the region (3), and over 30 known *Flavivirus* species in South and Southeast Asia (4).

Viral agent	Site, date	Impact	Novelty of event	Ref.	
Melaka virus & Kampar virus	Malaysia, 2006	Caused SARI in family group, individual	1 <sup>st</sup> disease due to bat-origin reoviruses (other reports Singapore, Vietnam etc.)	(5-8)	<b>Table 1:</b> Recent reports from SE Asia indicating potential for novel pathways of emergence, or unusual presentations for known or close relatives of known viruses.  These events are dominated by three viral families: coronaviruses, henipaviruses and filoviruses, which will act as the key research viral groups in this proposal. These viral groups have led to some of the most
Reston filovirus	Philippines 2008	Seropositive people killed pigs,	No prior findings of filoviruses in pigs	(9)	
Thrombocytopenia Syndrome virus	China 2009	Domestic animals, illness in people	Novel syndrome with large caseload	(10)	
Reston filovirus	Shanghai 2011	PCR positive pigs	Further evidence of pig RESTV infection	(11)	
Mojiang virus	Yunnan 2012	Implicated in death of 3 mineworkers exposed to rats	1 <sup>st</sup> evidence of rodent origin henipavirus in people	(12)	
Nipah-like virus	Philippines 2015	Killed horses	No prior horse infection for NiV, known for HeV	(13)	
SADS-CoV (HKU2)	China 2017	>25,000 pig deaths seronegative people	Novel emergence of bat-origin CoV	(14)	
SARSr-CoV & HKU10-CoV	Yunnan, Guangxi 2015	Seropositive people	1 <sup>st</sup> evidence human infection HKU10 & SARSr-CoV	(15)	
Nipah virus	Kerala, 2018, 2019	19 people infected/ 17 dead 2018, 1 infected 2019	1 <sup>st</sup> outbreak of NiV outside Bangladesh, W. Bengal focus	(16, 17)	

important recent emerging zoonoses (18-29). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (30-32). In addition to the events in Table 1, relatives and near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium including: henipaviruses in frugivorous bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (33-39); a novel henipavirus, Mojiang virus, in wild rats in Yunnan (12); serological evidence of filoviruses in bats in Bangladesh (40) and Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (EHA, unpublished data); evidence of novel filoviruses in bats in Singapore (41) and China (42-44), including Mēnglā virus that appears capable of infecting human cells (45); novel paramyxoviruses in bats and rodents consumed as bushmeat in Vietnam (46), a lineage C β-CoV in bats in China that uses the same cell receptor as MERS-CoV and can infect human cells *in vitro* (47); MERSr-CoVs found in dry bat guano being harvested as fertilizer in Khao Chong Pran cave, Ratchaburi, Thailand (48) and later directly in bats (CU, unpublished); 52 novel SARSr-CoVs in 9 bat species in southern China (172 novel β-CoVs from >16,000 sampled bats) that are also found throughout the region (20, 47, 49, 50), a new β-CoV clade ("lineage E") in bats (50); and 9 and 27 novel wildlife-origin CoVs and paramyxoviruses in Thailand (respectively) and 9 novel CoVs in Malaysia identified as part our work under USAID-PREDICT funding (49, 51). These discoveries underscore the genetic diversity of potentially

Commented [KJO1]: Double check w EIDITH

pathogenic viral strains in wildlife in the region, and their potential to help in the development of broadly active vaccines, immunotherapeutics and drugs (52).

Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 1). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (29, 53). However, surveillance and control is hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (54). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in x/xx (x%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (15, 55). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (5) as well as 12/856 (1.4%) people screened in Singapore (6). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (9), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (56). Preliminary screening in Malaysia with funding from DTRA for serological surveillance of Henipaviruses and Filoviruses spillover found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in non-human primates (NHPs) and people (Hughes, unpublished data). Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed

or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70%, and that it is also present in bats in India (REF). Nipah virus was originally misdiagnosed as 'aberrant measles' in West Bengal, India (REF), has now emerged repeatedly in North India, and in Kerala, South India in 2018 and 2019 (ongoing), raising the specter of future spillover at other sites across the region (16, 57).

**Fig. 1: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (53).

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (58), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (20, 47, 49, 50, 59-61). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-concept for an early warning approach that we will expand in this EIDRC to target key viral groups in one of the world's most high-risk EID hotspots.**

The overall rationale for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and

Formatted: Highlight

Commented [BRS2]: Statement should be in the aims. ...Our center covers the worlds most high risk EID hotspot?

their clinical manifestations and potential to cause pandemics are unknown and underestimated; and **3)** our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. The overarching goal of this proposal is to launch the **EIDRC-SEA (SouthEast Asia)** to better understand the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and closely related CoVs, henipaviruses, and filoviruses in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development and such. We will test these viruses' capacity to infect human cells and mouse models, develop new specific and sensitive serological and molecular diagnostic tools, and conduct surveillance of human populations with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover and pandemic potential, and of viruses causing previously 'cryptic' clinical syndromes in people. Our group also has extensive experience in other viral pathogens, including vector-borne flaviviruses, and will use this experience to provide robust long-term surveillancesurveillance, diagnostics, human and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EIDRC-SEA is poised to rapidly respond to any new emerging outbreak. Thus, filoviruses, henipaviruses and coronaviruses are examples of sentinel surveillancesurveillance systems in place that can capture, identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.

**2. Innovation:** Previous work by our consortium has developed a system to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses (REF). The EIDRC-SEA we take this approach and scale it up to cover three critically high-risk EID hotspot countries in Southeast Asia, within a regional network of collaborators. The innovation of the EIDRC-SEA is in:

1) its multidisciplinary approach that combines modeling to target the geography for wildlife and human sampling, novel phylogenetic and *in vitro* and animal model approaches to obtain precise biological risk assessments of viral spillover potential into people, the development and transfer of novel serological and molecular diagnostics capabilities throughout the region, and use of parallel large scale cohorts to identify spillover and illness due to known and novel viruses; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people, the evaluation of existing countermeasure technologies; technologies that are grounded on our successful work on SARS-CoVs; and 3) the combination of geographically targeted human populations with high risk of animal contact and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach. **In Aim 1, we will target viruses in new and archived wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, as well as further characterize viruses we have recently discovered. We will use *in silico* methods (i.e. novel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into high-risk human populations. **In Aim 2, we will conduct focused, targeted surveys and sampling of human communities with high exposure to wildlife and other animals.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. Serological findings will be analyzed together with clinical meta-data (including a simple animal-contact survey, location data, etc) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise 'cryptic' outbreaks.** We will enroll and collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs. Our **US partner BSL-4 laboratory, NEIDL,** will attempt isolation and characterize any viruses requiringrequiring high levels of containment (e.g. any novel Filoviruses-filoviruses discovered).

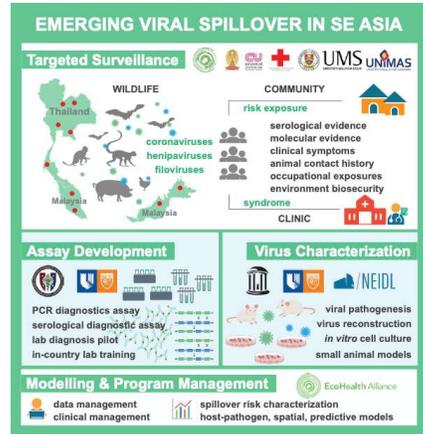

**Commented [BRS3]:** Number one innovation is the nuclear core sites that make up the EIDRC and its expanded network of long-term collaborators that saturation the most biodiverse EID host spot in the world, 2) extensive sample collections from wildlife, people in close proximity to EID hotspots, and samples from cohorts in individuals seeking medical care at our participating centers? (major goal of proposal if I remember correctly is to set up surveillance network for rapid response and interface wit health care facilities to collect large sample sets and/or develop clinical cohorts for testing intervention technologies ( in the future).

**Commented [KJO4]:** From MeiHo: Another innovation from EIDRC is the quick response if an outbreak happens in the region when the team has been developed and trained under this initiative.

**Commented [KJO5]:** List out what other labs will do too? Or just rely on our Org chart figure for all of this?

### 3. Approach

**Research team:** The EIDRC-SEA builds on long-term collaboration among world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (Fig. 2). Over the past two decades, our consortium partners have collaborated together within the region and globally to conduct high profile research on EIDs. This work includes identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (20, 25, 58, 62-65), discovering SADS-CoV (14), and developing

an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (59-61, 66-79). Our team has substantial experience conducting human surveillance during outbreaks (e.g– The ongoing viral surveillance using molecular and serological techniques with the indigenous communities of Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah with undiagnosed syndromes through the USAID-PREDICT program and the DTRA funded serological surveillance of Henipaviruses and Filoviruses spillover. - Please insert examples that you've been involved in and REFS), and as part of longitudinal efforts to pre-empt pandemics (80, 81).

In 2016, our collaborative team, together with partners in China, discovered an HKU2-clade  $\alpha$ -CoV(82, 83) in 5 pig farms in Guangdong Province affected by fatal diarrheal disease. We used PCR, serology, pathology, phylogenetic analysis, and infection experiments to show that this novel virus, SADS-CoV, originated in *Rhinolophus* spp. bats and killed > 20,000 pigs at

these farms – all in the span of three months (14, 84)

Fig. 2: Interdisciplinary team & roles in the proposed EIDRC-SEA.

PI Daszak has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5- 20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival, Zambrana, and Ross are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesedee, Hughes and collaborators have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from DoD, USAID, NIH, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to the EIDRC (See Section XX).

Fig.3 : Map of Southeast Asia indicating the three core countries for this proposed EIDRC (White: Thai, Sing, Mal) and those that Key Personnel are actively collaborating with (Green: field sites and collaborating labs indicated with asterisk).

**Geographical focus:** The three core countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses

Please add any other examples you have.

diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our consortium's extensive network of collaborators in clinics, research institutes and public health laboratories in every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in XX countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Current list of contacts at key human (especially) and wildlife orgs in every SE Asian country from map above – please add to this if we've missed any**

Indonesia – EHA: Eijkman (Dodi Safari), IPB (Imung Joko Pamungkas);

SE China – EHA: Yunnan CDC (XX), Wuhan Inst. Virol. (Zhengli Shi);

Myanmar – Chulalongkorn (Thiravat and Supaporn) have collaborated extensively with Win Min Thit, MD (Yangon General Hospital, Myanmar); Khin Yi Oo (National Health Laboratory, Myanmar) and also in training PREDICT Myanmar veterinarians in bat sampling under PREDICT.

Cambodia -

Laos - **CM Ltd:** Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (Matthew Robinson)

Bangladesh – EHA: IEDCR (Meerjady Sabrina Flora, Ariful Islam), icddr,b (Mohammed Ziaur)

India – EHA: Jon's collaborators;

Vietnam – Wellcome CRU ? Liaison with Zhengli Shi for Serol assays etc.?

Philippines – EHA, **CM Ltd:** Biodiversity Management Bureau, Department of Environment and Natural Resources (Anson Tagtag),

Malaysia – **CM Ltd:** Borneo Medical and Health Research Center (Ahmed Kamruddin), Department of Wildlife and National Parks Peninsular Malaysia (Frankie Sitam, Jeffrine Japning, Rahmat Topani, Kadir Hashim, Hatta Musa), Hospital Universiti Malaysia Sabah (Helen Lasimbang), Faculty of Medicine, Universiti of Malaya (Sazaly Abu Bakar), Kota Kinabalu Public Health Laboratory (Jiloris Dony, Joel Jaimin), Ministry of Health (Chong Chee Kheong, Khebir Verasahib, Maria Suleiman), National Public Health Laboratory (Hani Mat Hussin, Noorliza Noordin, Yu Kie Chem), Queen Elizabeth Hospital (Giri Rajahram, Heng Gee Lee), Sabah State Health Department (Christina Rundi), Sabah Wildlife Department (Rosa Sipangkui, Senthilvel Nathan, Augustine Tuuga, Jumrafiah Sukor),

Thailand – **CM Ltd:** Mahidol-Oxford Tropical Medicine Research Unit, (Stuart Blacksell, Richard Maude), Ministry of Public Health (Prayuth Sudathip, Hinjoy Soawapak), Faculty of Forestry, Kasetsart University (Prateep Duengkae), Chulalongkorn University (Supaporn Wacharapluesadee).

Chulalongkorn lab is a WHO Collaborating Centre for Research and Training on Viral Zoonoses, we work closely with WHO SEARO and SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste.

We had conducted the PREDICT lab training for Veterinary lab in the Southeast Asia region for FAO.

We conducted (transferred?) the bat sampling technique for scientists from Malaysia, Myanmar, the Philippines, and China.

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**

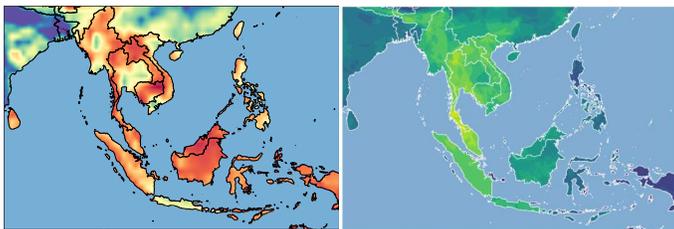

**Commented [BR57]:** Show this somehow in the picture. Primary sites, collaborative linkages that extend the breadth of the EIDRC.

**Commented [KJ08]:** From Supaporn

**Commented [PD9]:** Remember to correct specific aims with same title

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and non-human primates (2). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (Fig 4) (2). In Aim 1, we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and apply novel predictive models to estimate viral host range and identify new host species that have been previously ignored by EID surveillance systems. We will strategically collect specimens from under- or not-yet-sampled species of wildlife and screen these together with some of the tens of thousands of recently collected samples we have archived in freezers in our labs for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel virus in high risk RNA viral families, *Coronaviridae*, *Paramyxoviridae*, and *Filoviridae*. We will expand to other groups of pathogens, pending available resources, after priority setting with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation attempts. For the subset of highly-ranked and genetically characterized viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, and mouse models) previously developed and widely use by our team [REFS?] to predict capacity of novel viruses to infect people and spillover. These high-risk-high-risk viruses will be targets for human community and clinical sampling in Aim 2 and 3, respectively fully. This approach is built on substantial previous proof-of-concept preliminary data:

**Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a particular high risk location for pathogen emergence (1, 2). For Southeast Asia, these EID hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (Fig 4a). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (2). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 4b). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (85). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data and flight model software we have produced with Dept Homeland Security funds (86). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

**Fig. 4:** Our previous work has shown proof-of-concept in geographically targeting sampling in 'hotspot' areas of highest risk for wildlife-to-human spillover and disease emergence (Fig. 4a), and regions with high diversity of predicted 'missing' or as-yet undiscovered viruses, yellow = highest diversity (Fig 4b). From (1, 2).

**Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primates represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential (2). The bulk of our sampling and sample testing will consist of bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses (48, 87-89) (ADD REFS). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (2). We have used a novel phylogeographic analysis,

**Commented [KJO10]:** Will we? If so, make sure we mention primates more and include in vert animal sections.

**Commented [KJO11]:** Do you think we need to add in or mention vectors (arthropods)? We don't have big banks of these as far as I know, so maybe best not too?

**Commented [DA12R11]:** We are not focusing on arboviruses, so I would leave it out

**Formatted:** Font: Italic

**Formatted:** Font: Italic

**Formatted:** Font: Italic

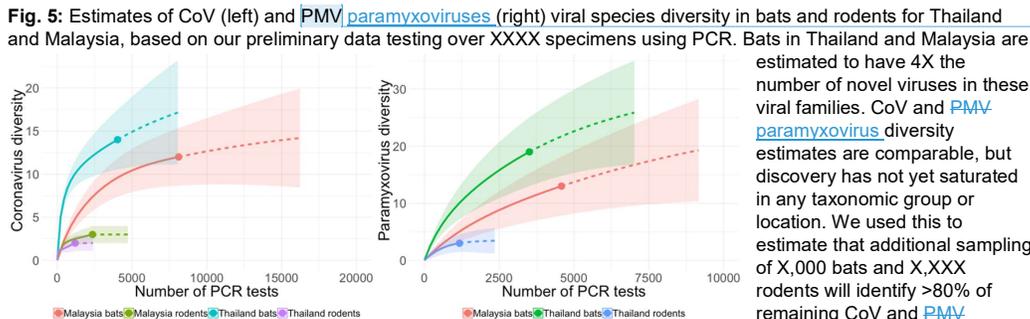

**Commented [PD13]:** Kevin – please edit

**Commented [KJO14]:** Peter, consider showing this figure earlier on considering Ralph's point about highlighting the EID rich geography of SE Asia first.

**Commented [PD15]:** Kevin to edit

**Commented [BRS16]:** I would say we focus on these three species (plus vectors?). To demonstrate the capability of the team, this proposal will focus on bat surveillance (for a variety of reasons), noting that this approach will also be applied to other zoonotic vectors during the 5 year program throughout the region.

Maximum Clade Credibility (MCC) tree, to reconstruct the geographic areas of evolutionary origin for  $\beta$ -CoVs that we sequenced in bats (49). This approach allows us to identify the ancestral home of specific zoonotic viral groups in wildlife, where their diversity is likely highest. Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (90, 91) (Fig. 5). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. **In the current proposal**, we will use these analyses to estimate geographic and species-specific sampling targets **to more effectively identify new strains to support experimental infection studies and risk assessment.**

paramyxovirus viral species from key wildlife species in these regions. We will apply this approach to our target host and viral taxa, for Thailand and Malaysia to calculate sampling targets to capture maximal viral species diversity (shown), but also for estimating targets for capturing viral strain diversity.

**Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. In the first 5 years of the PREDICT program globally (2009-2014), we found more viruses (815 novel, 169 known) than the total number of viruses previously recognized in mammals by the International Committee on Taxonomy of Viruses. This work includes collecting samples from nearly 300,000 individual mammal specimens from 14 EHA-led PREDICT countries and PCR-screening more than 60,000 individual specimens (51). In southern China alone, this sampling led to the identification of 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARS-CoVs). This included members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus (SADS-CoV, responsible for) killing >20,000 pigs in Guangdong Province (14). Many of the identified bat species are found across the region. We have collected 28,760 samples from bats, rodents and primates in Thailand and 62,012 in Malaysia under PREDICT, conducting 146,503 PCR tests on a large proportion of these specimens, and archiving duplicates which are now available for use in this project (92). In Thailand this screening has identified XX. In Malaysia this screening has identified 77 novel viruses and 23 known viruses in wildlife reservoirs (66 novel and 19 known in Sabah and 11 novel and 9 known from Peninsular Malaysia). We used family level primers for henipaviruses, filoviruses and CoVs and have already discovered XX in Thailand and 13 novel and 5 known CoVs and 15 novel and 1 known PMV-paramyxovirus in Malaysia from wildlife. In the current proposed work, we will attempt to sequence, isolate and characterize the full genomes for those viruses that our analyses below suggest are most likely to be able to infect humans.

Our collaborative group has worked together on these projects, as well as under other DTRA funded projects in Singapore/Thailand (Co-Is Wacharapleusadee, Wang) to design, cross-train, and use novel serological and molecular platforms to investigate virus infection dynamics in bats and examine potential spillover events with or without human disease. For serology, our lab at Duke-NUS will be developing a phage-display method to screen antibodies for all known and related bat-borne viruses, focusing on henipaviruses, filoviruses and coronaviruses. Once various "trends" are discovered, additional platforms (including Luminox

**Commented [KJO17]:** We can show just a single curve per country (aggregating all wildlife species) for simplicity, and could fit CoVs and PMVs on one graph.

**Commented [DA18]:** PMV is not a common abbreviation for paramyxovirus (I have not seen this in a paper apart from here). I will remove the abbreviations.

**Commented [PD19]:** All to edit

**Commented [KJO20]:** More?

**Commented [KJO21]:** Latest numbers from EIDITH for P1 and P2

**Commented [PD22]:** Kevin – need the PREDICT numbers here please

**Commented [T23]:** Do we want to mention other viruses we found of public health concern that are not part of the 3 viral families we are focusing on in this proposal?

and LIPS) will be used for verification and expanded surveillance. For molecular investigation, we will combine targeted PCR approach with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified. In Malaysia (Co-Is Hughes, Broder, Laing) ~~the we have transfer~~transferred-of the Luminex serology platform to partner laboratories for screening of wildlife, livestock and human samples screening to investigate the spillover of ~~Henipaviruses-henipaviruses~~ and ~~Filoviruses-filoviruses~~ at high risk interfaces. These interfaces including farms near the forest and indigenous communities with lots of subsistence hunting in Peninsular Malaysia, and preliminary screening has found serological evidence of past exposure to ~~Nipah and Ebolaviruses~~ antigenically-related ~~viruses to Nipah and Ebola~~ in humans, bats and NHPs-non-human primates (NHPs)and people. In Thailand (Co-Is Broder, Laing and Wacharapluesadee) tech transfer of Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses and known henipaviruses in wildlife and human samples is underway and currently being validated in our Chulalongkorn University laboratory. This is part of a planned DoD regional center of excellence for training in Thailand (details please?).

We have found 13 novel CoVs and 15 novel PMVs-paramyxoviruses and have begun using Illumina sequencing and virome capture sequencing to further characterize 6 of these novel CoVs and 10 of these novel paramyxovirusesPMVs. To date, we have completed the full genome sequencing for two novel CoVs that were part of the PREDICT Deep Forest project in Sabah – PREDICT CoV-51 found in *Hipposideros cervinus* and PREDICT-CoV-52 (HKU10-like) found in *Hipposideros diadema*. As part of our PREDICT further characterization work, we will investigate the zoonotic potential of these viruses (i.e., their ability to infect human cells). We will reverse engineer the viral RNA from the genome sequence we obtained, recover the infectious virus, and test its ability to infect a range of human cells. This involves generating a very large synthetic construct of the viral genome, which is extremely difficult and time consuming. Therefore, we use two strategies to investigate the risk of PREDICT CoVs and PMV-paramyxoviruses: 1) We use surrogate experimental systems to evaluate just the important parts/components of the virus. In this case, we focus only on the CoV receptor binding domain (RBD) in the spike protein and glycoproteins of paramyxoviruses and filoviruses, rather than the whole virus, and test whether it is able to determine if these regions can mediate entry into human cells. The advantage of this approach is that it can be done quickly and give us provide a good (but preliminary) assessment of the zoonotic risk. This work is-will be done with our partners at the NIH Rocky Mountain. 2) While this work is ongoingConcurrently, we willstart to reverse engineer the full-complete virus to, so we can investigate cell-entry in the context of authentic virus. This work is-will be done at the Center for Infection and Immunity, Mailman School of Public Health, Columbia University. This can take 6-12 months to generate a construct and test it which is why we use both approaches.

For Peninsular Malaysia we have 1438 serum samples from Orang Asli (1390 from current study and 48 archived samples), 560 serum samples from bats, 167 serum samples from rodents and 1022 serum samples from NHPs, 301 bat biopsy samples, 123 rodent biopsy samples and 3845 NHPs biopsy samples. For Sabah we have 10 serum samples from syndromic surveillance patients, 1179 serum samples from bats, 485 serum samples from rodents and 83 serum samples from NHPs, 294 bat biopsy samples, 114 rodent biopsy samples and 62 NHPs biopsy samples. Biopsy samples include brain, heart, lungs, liver, kidney, spleen, large and small intestine.

Commented [KJO24]: From Supaporn: I do not have this information yet, but it is possible.

Commented [L25]: Not me as I am not involved

Commented [PD26]: I think this is something that Linfa, Supaporn or Chris mentioned?

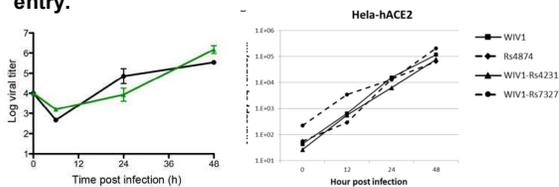

Formatted: Font: Italic

Formatted: Font: Italic

Commented [T27]: Waiting to hear from Simon that same technique for Cov and PMV

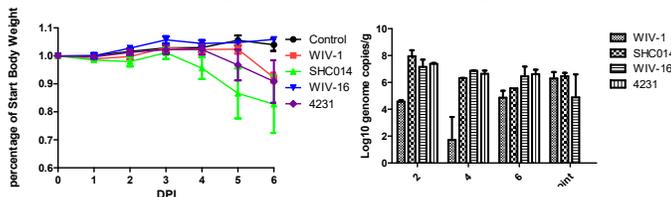

Commented [KJO28]: More from Tom. With this comment: Malaysian colleagues please can you add details here of any archived samples you have that could potentially be included in this proposal using similar level of detail to the above.

**In vitro & in vivo characterization viral potential for human infection for Coronaviruses:** We have used *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3-7% (20, 58, 93). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs from a specific cave site in Yunnan China, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (58). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of different variants, including WIV1-Rs4231S and WIV1-Rs7327S. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in HeLa cells that don't express ACE2 (20, 58, 93) (**Fig. 5a**). We used the SARS-CoV reverse genetics system (70) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (59) (**Fig. 5b**). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry.**

**Fig. 5a (left):** RT-PCR shows that bat SARSr-CoVs WIV1, Rs4874, and chimeras WIV1-Rs4231S, WIV1-Rs7327S grow in HeLa cells expressing human ACE2. **Fig. 5b (right):** Viral replication of SARS-CoV Urbani (black) and SARS-SHC014S (green) primary air-liquid interface human airway epithelial cell cultures at an MOI of 0.01.

We infected transgenic mice expressing hACE2 with  $10^5$  pfu of full-length recombinant WIV1 and three chimeric viruses (WIV1 backbone with SHC014S, WIV16S and Rs4231S). hACE2 transgenic mice challenged with rWIV1-SHC014S experienced ~20% body weight loss by 6dpi; rWIV1 and rWIV1-4231S produced less body weight loss, and rWIV1-WIV16S led to no body weight loss (**Fig. 6a**). At 2 and 4 dpi, viral loads in lung tissues of mice challenged with all three chimeras reached  $> 10^6$  genome copies/g, significantly higher than rWIV1 infection (**Fig. 6b**). This demonstrates that pathogenicity of SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the value of this model in assessing novel SARSr-CoV pathogenicity.**

**Fig. 6:** *In vivo* infection of SARSr-CoVs in hACE2 transgenic mice. **6a (left)** Body weight change after infection; **6b (right)** Viral load in lung tissues.

Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity/pathogenicity.** Vaccination against SARS-CoV did not reduce severity of clinical signs in mice subsequently infected with rSARS-SHC014S (59). We found 2/4 broad human mAbs against SARS-CoV RBD cross-neutralized WIV1, but none could efficiently neutralize SHC014 which is less similar to SARS-CoV in the RBD (94). We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they are unable to use the ACE2 receptor.** Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines. **The ability of HKU3r-CoVs to infect people, and their receptor binding target, remain unknown.**

**All – what can we say about Nipah and filoviruses in this section – what is the rationale for a similar approach (e.g. we're looking for viruses somewhere between Cedar and Nipah in the Henipaviruses, and trying to assess the likelihood of some of the novel filoviruses infecting human cells).**

**Commented [KJO29]:** Think we need to shorten the CoV part of this from the previous NIH. I've added in some basic info and refs on Henipas and Filos in a separate section below (for now), but Ralph/Linfa/Dani/Chris/Eric should check and ideally we integrate into one section. WE need to specify what labs are doing what!

**Commented [PD30]:** Ralph, Amy – this is directly from our CoV R01 renewal – **please reduce the length of this section** and adapt for this proposal. We prob don't need all these figures – just one or two would do.

**Commented [PD31]:** Ralph, Amy, Linfa, Danielle, Chris, Eric – need details for what approach we'll use for henipas and filoviruses

## Are we just going to use cell culture for henipav and filov, or can we look at spike protein diversity?

### What about using bat cell lines and batized mice from Linfa?

In vitro & in vivo characterization viral potential for human infection for Henipaviruses and Filoviruses

A similar approach to the above pipeline for CoVs will be applied to novel [Henipaviruses](#) and [Filoviruses](#) we discover during our research.

#### Henipaviruses

Hendra virus and Nipah virus have a broad mammalian tropism with natural infection recorded in bats, horses, pigs, humans, cattle, goats and dogs. This broad species tropism is likely mediated by henipavirus receptor usage of highly conserved ephrins ligands (e.g. ephrin-B2 and -B3) for cell entry. Ephrins are critical in evolutionary developmental process such as cell migration, axonal guidance and angiogenesis (REF), and ephrin tissue distribution correlates with the multi-systemic cellular pathology, vasculitis and encephalitis disease presentation during HeV and NiV infection. The third isolated henipavirus is Cedar virus, yet unlike NiV/HeV, CedV does not cause pathogenesis in animal models. Recently, Dr. Broder and Laing have developed a reverse genetics system for Cedar henipavirus and have rescued a recombinant Cedar virus that is used as a model henipavirus tool to understand how ephrin receptor usage/tropism contributes to pathogenicity during henipavirus infections. Ephrin-B3 is distributed in the spinal cord, and usage of ephrin-B3 has been postulated to underlie the enhanced encephalitis seen during NiV infection. Further dissimilar from HeV/NiV, CedV is unable to utilize ephrin-B3 as a receptor (Marsh 2012; Laing 2018) nor does it express the interferon antagonizing virus factors: V and W proteins (Marsh 2012). However, Dr. Broder and Laing have discovered that CedV has a promiscuous/broad ephrin receptor usage and in addition to ephrin-B2 is able to utilize ephrins-B1, -A2 and -A5 for cell entry (Can include microscopy image/column graph for unpublished figure). Additionally, it was discovered that CedV can utilize mouse ephrin-A1, which differs from human ephrin-A1 by one amino acid residue in the key binding pocket, demonstrating the first evidence of henipavirus species-specific receptor use (Can include unpublished figure). Like ephrin-B3, ephrin-B1 is widely distributed throughout spinal cord tissues, however, CedV is non-pathogenic. Pathogenicity of henipaviruses is likely mediated by a contribution of both utility of ephrin receptors and expression of virulence factors V and W proteins. The full genome assembles of putative henipaviruses, Ghana virus and Mojiang virus, predict expression of V and W proteins. GhV is able to bind to ephrin-B2, but not -B2 (Lee – African emergent henipavirus B2 crystal) and the receptor for MoJV remains unknown (Lee, idiosyncratic 2017), but is unlikely an ephrin. Thus, when we identify novel henipaviruses or paramyxoviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize molecular experimentation with novel henipaviruses that are predicted to interact with ephrin-B2 and expression V/W proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models.

For novel Henipaviruses we will assess ability to infect human cells using a continuous lung epithelial cell line, Calu3, that our group has previously used to generate data on NiV and HeV growth curves (95). We will also use primary human airway cultures to assess human infection for Henipavirus and MERS- and SARS-related CoV (96) (97). There is some evidence for Nipah and Hendra virus replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (98, 99). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted ebola infections.

[Am J Pathol](#). 2003 Dec;163(6):2371-82 Primary human lung endothelial cells are highly susceptible to EBOLA virus infection, so we can use these cells. Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (Viruses. 2019 Feb 16;11(2). pii: E161. ) Huh7 cells also offers advantages for reverse genetic recovery of novel filoviruses ([J Infect Dis](#). 2015 Oct 1;212 Suppl 2:S129-37. )

**Commented [KJ032]:** Think we need to shorten the CoV part above and still incorporate more for Henipav and Filos. For now some info below, but Ralph/Linfa/Dani/Chris/Eric should check and try to integrate into one section with additional info on the Cedar virus work, Mojiang, etc.. WE also need to specify what labs are doing what!

**Commented [KJ033]:** General question, do we want to limit to Henipav, or keep more general to Paramyxoviruses? Do we care about Rubulaviruses, etc.

**Commented [KJ034]:** Ralph: [Am J Pathol](#). 2003 Dec;163(6):2371-82 Primary human lung endothelial cells are highly susceptible to EBOLA virus infection, so we can use these cells. Attachment Glycoprotein has greater genetic diversity

Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G)

pon mapping sequence conservation between GhV-G and MojPV-G onto the GhV-G-ephrinB2 co-crystal structure, it becomes apparent that MojPV is unlikely to utilize ephrinB2 receptor (100)

Cedar uses Ephrin B, but doesn't cause disease. reverse genetics of Henipap - would need to be done in BSL4, pseudovirus can do in BSL 2, but no pathogenesis. Benhur Lee has done similar work to what Ralph has done, structural comparison w diff receptors for Cedar, Henipap, and ferret model. Doesn't express G protein and is therefore less pathogenic.

Mojiang diff cell binding: <https://www.nature.com/articles/ncomms16060>

" Furthermore, we find that MojV-G is antigenically distinct, indicating that MojV would less likely be detected in existing large-scale serological screening studies focused on well-established HNVs. "

## 1.2 General Approach:

We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new collection from wildlife in high risk locales. We will use serological & PCR testing, to identify viruses, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will then conduct *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease. EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses.

A key goal of this work will be technology transfer to the region, including cell culture, animal models, serological and PCR diagnostics, as well as knowledge transfer by embedding staff in partner labs and by regular meetings. This will leverage substantially from the other funding available to consortium partners.

A key goal of this work will be technology transfer to the region, including cell culture, animal models, serological and PCR diagnostics, as well as knowledge transfer by maintaining our current team members and embedding additional staff in partner labs, supporting one Malaysian PhD student and by regular meetings. This will leverage substantially from the other funding available to consortium partners. The PhD student Mei Ho Lee is part of the CM Ltd team and has worked with the collaborators on this project for 9 years. Mei Ho will enroll at the Faculty of Tropical Medicine at Mahidol University in Bangkok. The focus of her study will be to further investigate the infection potential of some of novel [Cov-CoVs](#) and [PMVs-viruses](#) found in Malaysia through PREDICT.

CM/EHA helped establish and manages with SWD the Wildlife Health, Genetic and Forensic Laboratory (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications) that has all the equipment necessary to store samples, run extractions, PCR and analysis on biological samples for wildlife disease surveillance. The lab is used to conduct health checks on rescued and relocated wildlife before being released into new areas or sanctuaries, to screen samples for the PREDICT and Deep Forest Project and for genetic research and forensic investigations. CM/EHA also helped establish the new molecular zoonosis laboratories (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications), at DWNP's National Wildlife Forensic Laboratory. The lab is used to screen samples for the PREDICT & DTRA

**Commented [DA41]:** This is not correct. Cedar expresses G. The gene responsible for the difference in pathogenesis is P. If we were using the assays described above, we would assume cedar was most likely pathogenic. I don't know how to incorporate more details until we delete some of the SARS stuff- or just leave that general paragraph above that says "the same will be don't for filo/paramyxo"

projects. In addition CM/EHA also has access to NPHL and KKPHL for screening human samples and the Virology lab at FVMUPM for screening Livestock samples.

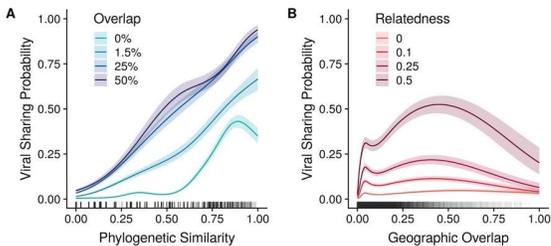

Through this project we will help to establish a certified BSL-2 lab at the BMHRC. This lab can then be used for human testing to elevate pressure at KKPHL and QEH labs. It would also be an ideal location for a Luminex platform as human, wildlife and livestock samples could all be screened here. Co-Is Hughes and Kamruddin will be starting outbreak response training in August 2019 with a team from Sabah CDC, KKPHL and BMHRC. (Dr. Maria Suleiman now in PM But still collaborating with us, Dr. Muhammad Jikal current Director CDC working with us and Dato' Dr Cristina Rundi Director Sabah state health Dept is supportive) this collaborative group is working to develop a Sabah outbreak response team that will help support SSHD/ CDC outbreak team and also conduct sampling for disease surveillance to be based at BMHRC and we will develop this as part of this proposal. In addition the UMS hospital will come in line in 2021 providing additional opportunities for cohort studies and capacity building.

### 1.3 Wildlife samples: 1.3.a Geographic and taxonomic targeting for newly collected wildlife samples

Adapt text from the rationale/innovation above and make brief statements about the work we'll do:

- Geographic targeting: we will use refined hotspot, 'missing viruses', and FLIRT analyses
- Targeting of host species/viral discovery targets: We will use phylogenetic MCC analyses and viral discovery curves
- Additional approaches: mapping of cave sites,

Using network analyses and a phylogeographic model of host range we recently developed [REF- Greg], we will prioritize additional wildlife species to be sampled and tested for the known and novel viruses we discover. Applying a generalizable model that includes just two phylogeographic traits (wildlife species range overlap and phylogenetic similarity between host species, Fig X.), we are able model the viral sharing network for 4200 mammal species and successfully predicted known hosts above 98% of other mammal species.

### 1.3.b Sample size justifications for testing new and archived wildlife specimens

To calculate sample sizes, we will use our preliminary data on average prevalence from screening bat, rodent and primate specimens for CoVs, PMVs, and FVs under PREDICT in Malaysia and Thailand, previously published data, and our viral discovery curve analyses (Fig 5) to determine the required samples sizes to maximize discovery of wildlife viruses with zoonotic potential.

Commented [KJO42]: From Tom.

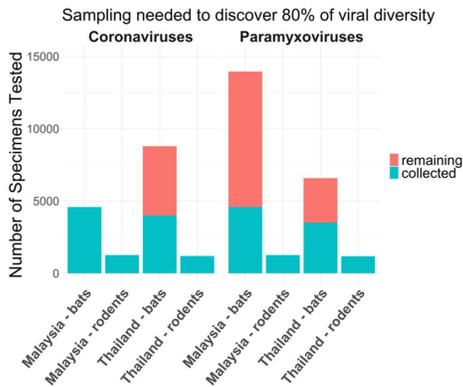

Commented [DA43R42]: Delete the duplicate text

Commented [KJO44]: Peter, I'll clean ups this section a little more and flesh it out while you are working on this draft.

Commented [KJO45]: From Tom: We should consider wildlife sampling at –

- Danum Valley, Sabah
- Tabin Forest Reserve, Sabah
- Around Orang Asli settlements PM (focus on Kedah, Kelantan, Pahang and Perlis),
- Around Dayak settlements in Sarawak
- Kubah National Park, Sarawak
- Batu Supu Sabah low disturbance cave and surrounding area
- Madai medium disturbance cave and surrounding area
- Gomantong high disturbance cave and surrounding area
- Caves in Peninsular Malaysia

Commented [PD46]: Please check section 1.4.b and see if parts of that should be here..

**Figure X.** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMVs from high-risk bat and rodent taxa in Malaysia and Thailand. Estimates of predicted viral richness calculated from viral discover curve analysis (Fig 5) using data from thousands of wildlife specimens that we have previously tested and sequenced.

In Y1 we will use our bat host and viral trait modeling, phylogeographic analyses of [RdRp and Spolymerase and receptor binding Protein-protein](#) sequences, and geographic and host species-based viral discovery curve analyses to identify [SARSr-CoVvirus](#) diversity hotspot regions for bat sampling. We will sample at 8 new sites in four provinces. We will use cave site data (101), and demographic information to identify two sites in each of

Yunnan, Guangxi, Guangdong, and Guizhou where humans likely have contact with bats. In Yunnan, we will identify two unsampled caves close to, but distinct from, the Jinning cave (58). [This will provide adequate coverage of lineage 1 and 2 SARSr-CoVs, including a rich source of new HKU3r-CoVs, which have unknown potential for zoonotic spillover. Sampling will begin towards the end of Y1.](#) We will use survey data from our previous R01 and host-specific viral accumulation curve data to target an additional 10 under-sampled *Rhinolophus* spp., 5 that were SARSr-CoV negative in our study, and a small number of related bat genera (including *Hipposideros* spp. and *Aselliscus* spp.) we previously found PCR positive for SARSr-CoVs (Table 1). We will sample at least 5,000 bats from these 4 provinces (~1250 per province). Given ~5-12% prevalence of SARSr-CoVs in *Rhinolophus* spp. at our previous sites, **this sample size would give us 425 (±175) positive individual bats, and ~125 novel strains.**

**1.3c Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C. [One-step hemi-nested RT-PCR will be performed with pan-coronavirus, filovirus and paramyxovirus primers \(Invitrogen\) will be used to detect the presence of CoV sequences using primers that target a 440 nt fragment in the RNA dependent RNA polymerase gene \(RdRp\) of all known α- and β-CoVs \(102\).](#) PCR products will be gel purified and sequenced with an ABI Prism 3730 DNA analyzer.

We will attempt isolation on samples that contain viruses of interest (determined in 1.4, below), using Vero-E6 cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). This includes the over-XX 30 bat cell lines maintained at Duke-NUS from four different bat species.

**1.3d Moving beyond RNA viruses:** [Show how our platform is generalizable to other To detect pathogens from other families, such as groups and non-RNA viruses we will combine i.e. using conserved PCR assays with NGS. We will perform either unbiased NGS, or use a pan-viral enrichment library to sequence full-length genomes. sy and vircapseq.](#) If and when depending necessary on EID-CC research projects and outbreaks detected in the region from DNA viruses or other agents]

**1.3.e Sequencing S-receptor binding proteins:** [Our working hypothesis is that many zoonotic SARS-like, MERS-like, coronaviruses, filoviruses and henipaviruses encode spike-receptor binding glycoproteins that program elicit efficient infection of primary human cells \(e.g., lung, liver, etc.\).](#) For example, our previous R01 work identified diverse SARSr-CoVs with high propensity for human infection (15, 58, 59). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains

**Commented [BR547]:** CoV specific, ebola and nipha/Hendra have different spike glycoprotein designations and polymerase designations.

**Commented [L48]:** More generic terms to use: "Viral polymerase and receptor binding protein sequences"

**Commented [BR549]:** Chinese locations? Do we have equivalent cool bat caves in Malaysia, Thailand, etc? to chase bat viruses in?

**Commented [BR550]:** Don't forget about the eovl mers-like cov discovered in the region (PMC6002729) and that can use the human receptor (don't be so SARS centric).

**Commented [DA51R50]:** This section and the numbers make it too CoV specific.

**Commented [KJ052]:** I still need to rework this.

**Commented [PD53]:** Ralph, Amy, Linfa, Danielle, Chris, Eric - This is from our CoV R01. Please insert details that apply also to henipa and filoviruses.

**Commented [KJ054]:** Should we just rely on PREDICT PCR protocols for PMVs and Filos? We can add in methods from PREDICT protocols. Unless there are better screening assays to use?

**Commented [PD55]:** Brief description of these please

**Commented [KJ056]:** Added this b/c noted on call w Linfa.

**Commented [PD57]:** Ralph et al. - I'm assuming this will still be of value for the CoVs, so a reduced version of this could be in here, but what about spike proteins of filoviruses and henipaviruses - is that not of any use for assessing their capacity to infect human cells. Can we do similar work with filovirus pseudotypes from sequencing the spike proteins, for example, to assess binding to human receptors? If so, please draft some text and point to some references

lose human ACE2 receptor usage. Our viral discovery curves (**Fig. 4**) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are undersampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (20, 59, 103), suggesting that-. However, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic [spike-receptor binding protein](#) genes of MERS-[relatedlike](#), Ebola-[relatedlike](#) and Nipha/Hendra-[relatedlike](#) viruses will also program efficient entry via human ortholog receptors.

For all novel SARSr-CoV strains, we will sequence the complete S gene by amplifying overlapping fragments using degenerate primers as shown previously (20, 58). Full-length genomes of selected SARSr-CoV strains (representative across subclades) will be sequenced via high throughput sequencing method followed by genome walking. The sequencing libraries will be constructed using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR will be performed to fill gaps in the genome. The full length S gene sequences, including the amount of variation in the S receptor binding residues that bind the ACE2 receptor, will be used to select strains for Aim 3 experiments.

**1.4. Assessing risk for spillover. 1.4.a Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, [Filoviruses](#)~~filoviruses~~ and [Henipaviruses](#)~~henipaviruses~~, we will use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (59, 60, 104). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other virus strains (61, 69). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (60, 92). As controls or if antisera is not available, the S genes of novel SARSr-CoV or structural genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (105). Polyclonal sera against SARS-like viruses will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (60, 106, 107). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (108) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (109-111). Similar approaches will be applied to MERS-like viruses, other CoV, filoviruses or henipaviruses

Filoviruses (primary endothelial cells – ralph has primary lung endos – see if anyone has liver primary hepatocytes. Other option are monocytes) – where will we do this? BSL4? (NEIDL). Duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (See letter of support) for culture and sharing with other agencies. Check on this re. wildlife filoviruses... See if can do training opportunities so they can work with the NEIDL – visiting scholar appointments

**1.4.xx Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the [intraspecific](#) scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human

**Commented [L58]:** Please use XXX-related instead of XXX-like as the field does like the XXX-like term anymore although it was used ten years ago!

**Commented [BRS59]:** Way too specific. We should do spike genes of all novel CoV, including searching for elusive group 1 or group 2 CoV (group 2d, 2e, etc.) that have the potential to replicate in human cells (intestinal CaCO2 or lung HAE...noting that bat cov are enteric pathogens so human caco2 may be likely target). Same with filoviruses and nipha/Hendra like strains.

**Commented [L60]:** No live Mengla virus yet. The WIV team is trying to rescue now

**Commented [BRS61]:** Can we get our hands on the live Chinese ebola like strains? We could try to use reverse genetics to recover, although I personally have no documented success with filovirus reverse genetics. Am familiar with approach and the bsl4 in boston should allow recovery.

**Formatted:** Font: Not Italic

**Commented [PD62]:** Ralph, Linfa, Chris – please expand and draft – I think this could be a good role for NEIDL, but don't know what the rules are...

**Commented [BRS63]:** Check my comments above, I covered this completely and the situation is good.

orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (68).

**1.4.b Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RdRp (or L genes), [Spike-receptor binding](#) glycoproteins, and full genome sequence (when available) data to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, filoviruses and henipaviruses that we identify. We will rerun MCC analyses (**Fig. 3**) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR-positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (**Fig. 4**) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) or other virus families within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (91, 112).

**1.4.c Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSr-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (92, 113-115).

**1.4.d Animal models:** Transgenic Mice. We will use a series of mouse models to assess spillover potential of viruses. First, the Baric lab has a well-established hACE2 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect. This group also has transgenic mice expressing hDPP4 receptors ([PMC5578707](#), [PMC5165197](#)). Briefly, in BSL3, n=5 10- to 20-week old hACE2 or hDPP4 transgenic mice will be intranasally inoculated with  $1 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins or MERS-CoV and MERS-like CoV, respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV or MERS-CoV mAbs ([PMC4769911](#), [PMC4547275](#)) will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (104, 116). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (60, 104).

**Models of Outbred Populations.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments. We have used this model for CoV, filo (Ebola), Flaviviruses, and alphaviruses infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection ( ).

Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (117). Both animal systems can be used to test susceptibility, pathogenesis and immune responses of any

**Commented [BRS64]:** A lot of variation in the NPC1 receptor alters EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains ([J Infect Dis](#). 2018 Nov 22;218(suppl\_5):S397-S402.) [PMC4709267](#)  
Second paper says: *We found signatures of positive selection in bat NPC1 concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in Eidolon helvum cells. Our work identifies NPC1 as a genetic determinant of filovirus susceptibility in bats, and suggests that some NPC1 variations reflect host adaptations to reduce filovirus replication and virulence.*

*Nipha and Hendra use ephrin B2 or ephrin B3 as a receptor, and variation effects its ability to use human vs bat receptor molecules*  
([PMC4418902](#), [PMC2045465](#))

**Commented [PD65]:** Kevin/Ralph – I don't think this is relevant for our EIDRC – please let me know and delete if correct.

**Commented [PD66]:** KevIn/Alice – please modify this section for filoviruses and henipaviruses as well (and other hosts) - or does it belong in 1.3.a above?

**Commented [BRS67]:** Way to sars centric

**Commented [PD68]:** Ralph – can you reduce this section to a feasible amount of work for this project, and remove a bunch of text

**Commented [BRS69]:** We need to do this with novel Nipha/Hendra and EboV as well.

**Commented [PD70]:** Ralph – please draft a brief para explaining what we'll do with this mouse model

**Commented [BRS71]:** Trends Genet. 2018 Oct;34(10):777-789.

**Commented [BRS72]:** G3 (Bethesda). 2018 Feb 2;8(2):427-445.

**Commented [PD73]:** Linfa/Danielle – please draft a brief para explaining how we'll use either or both...

newly discovered viruses.

**1.5 Potential problems/alternative approaches: Permission to sample bats in sites or provinces we select.** We have a >20-year track record of successful field work in Malaysia, Thailand and >10 years in Singapore, and have worked with local authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based on a range of PCR data and are fairly conservative in our approach. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses. The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (118), do not suggest a strong pattern of seasonality in CoV shedding, although there are studies that suggest this occurs in henipavirus and filovirus (MARV?) shedding (REFS?). Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province.

Commented [PD74]: Kevin – please edit/check

Commented [PD75]: Kevin – please check the veracity of these comments

**Aim 2: Test evidence of viral spillover in high-risk communities using novel serological assays.**

Commented [KJ076]: We can make this aim all about human serology, and 3<sup>rd</sup> aim more about molecular characterization of human pathogens and outbreak etiologies.

**2.1 Rationale/Innovation:** Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that are the first to get infected. To enhance low statistical probability of identifying these rare events, populations will be targeted that both live in rural locations close to high wildlife biodiversity, and also engage in practices that enhance the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will expand from our current work in the region to identify and enroll large cross-sectional samples from human populations that have a high behavioral risk of exposure to wildlife origin viruses and live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will initially identify X-X sites in each Thailand, Peninsular Malaysia, Sarawak, and Sabah for repeated biological sampling of high-risk human communities, design and deploy specific and sensitive serological assays to identify the baseline spillover of known or novel viral pathogens in these populations. In participants where symptoms are reported samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, attempt to isolate and biologically characterize the pathogen, using the collaborative cross mouse (Aim 1) to identify an appropriate animal model to conduct preliminary pathogenesis work.

Commented [KJ077]: Emily: Will we be sampling participants more than once?

Commented [KJ078]: Need to decide if we do PCR on community samples, we can add in the questionnaire if you've been sick in the last 10 days and if so, then maybe test only this subset.

At the time of writing, a currently undiagnosed outbreak in the Batek Orang Asli (indigenous) population living in Gua Musang ("civet cat cave") district, in Kelantan, Malaysia has infected dozens of people and is currently being investigated by our colleagues at NPHL. The Orang Asli live in remote villages in the rainforest of Malaysia, with limited access to modern health care and extensive contact hunting, butchering, and eating wildlife as their primary source of protein. This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC -- to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia.

Commented [KJ079]: [https://en.wikipedia.org/wiki/Gua\\_Musang\\_District](https://en.wikipedia.org/wiki/Gua_Musang_District)

Commented [KJ080]: From Tom email.

**Preliminary data human biological sampling:** Our longterm collaboration in the region has included identification of key at-risk human populations using previously collected qualitative and quantitative survey data, and developing and gaining access to large archives of banked human sera and other biological samples. In the last 5 years under the USAID-PREDICT project, EHA has collected 9933 and 9269 human specimens in Malaysia and Thailand, respectively, which will be available for retrospective serological testing under our proposed work. Other studies from our research team have included the collection and testing of many thousand more specimens from community cohorts. Preliminary findings and details from these data and other research from are listed below:

Commented [PD81]: All – please read and share with collaborators to flesh out and correct details here.

*Peninsular Malaysia:* Data from 1390 Orang Asli samples, screened by PCR for 5 viral families found: 4 known CoVs in 16 people and one known Influenza virus in one person. Serology screening is ongoing but preliminary screening as part of training government partner to use the Luminex serology platform found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in people.

Commented [T82]: Unpublished

*Sabah:* Data from 10 Syndromic Surveillance samples, screened by PCR for 5 viral families found: 1 known virus - Human Parainfluenzavirus 2 (GenBank Accession No.AF533011) in the family Paramyxoviruses. Serology screening is yet to start.

Commented [KJ083]: Previous text from PD: We have ~25 new CoVs in Sabah. Simon is using HTS to further characterize and Tom will get the data for this proposal from Simon

Kamruddin (UMS Borneo Medical Health Research Center) has identified some high risk communities.

Commented [T84]: Malaysian colleagues please can you add details here of any human sampling and findings from those studies that are relevant to this proposal

Tim, Giri, Tsin Wen has archived samples from Kudat Monkey bar project – 2,000 human sera already screened for bacteria and parasites, we've been reached out to about this. Data on macaque tracking data/human tracking data also. Encephalitis study etc Dr. Yeo Tsin Wen, DUKE-NUS, Singapore – Has worked with Giri and tim on knowlesi work with communities – 2000 selected villagers 500micros looking for asymptomatic parasitemias – led by King Fonese from LSTMH – 10,000 people – archived serum samples (prob 2-3,000 – in London, KK)

Commented [T85]: These are from wildlife so I have moved to "Identify Known and novel" section above

Commented [KJ086]: From PD: Kamruddin (UMS Borneo Medical Health Research Center) has identified some high risk communities. We can help with them and build out the BSL-2 lab, as well as work on outbreak response within DHRU (in collab with Sabah CDC?).

*Sarawak:* Dr Tan (Cheng Sieng) Center for Tropical and Emerging Diseases, Faculty of Medicine at UNIMAS – high risk Dayak communities that he's identified. We will do further sampling, questionnaires etc. Has Prelim data on HPV work in Dayak communities in remote Sarawak – we can work with those communities and can reach many by car, others by 4WD or boats. Has also Enterovirus 71 paper and is interested in CoVs. Has access to caves and guano. Will look into what other archived samples he has. Will give us access to Sarawak Forestry and Health Depts.

Commented [KJ087]: From Tom

*Thailand:* We have conducted longitudinal community-based surveillance for the last 5 years in two villages (Chonburi and Ratchaburi provinces) at high risk of infection from bats. In Chonburi province we sampled and tested over 300 villagers living around the largest population of flying foxes (*Pteropus lylei*), at a temple (Wat) roosting site where we have seasonal detections of Nipah virus from bat urine each year (with viral shedding peaking in May-July. Serological screening of monks and We also have sampled and tested over 300 villagers from Ratchaburi province, including a population of bat guano miners, and workers from Department of National Parks – both of whom have extensive contact with wildlife in the area. We previously detected a MERS-like CoV in the bat guano being harvested (48). Molecular screening of guano miners identified human CoV, HKU1 strain, with high viral load in one healthy bat guano miner and our team was able to obtain the whole genome sequence from a clinical specimen from this individual (119). No evidence of novel bat CoVs have yet been detected in these populations.

*US CDC (Thailand):* A large cohort of children from the Kamphaeng Phet Province, Thailand were enrolled as part of a multi-year study (1998-2002) to examine the epidemiology of dengue virus (DENV) and Japanese encephalitis virus (JEV) (120, 121). From 2,574 paired serum samples, 784 (30%) convalescent sera were selected at random among samples drawn between 1998-2002. Among the 784 samples tested, subjects ranged in age from 6 to 16 years (mean 9 years) and 51% were male. Henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence) by Enzyme-linked Immunosorbent Assay (ELISA) using a soluble highly-native recombinant G glycoprotein (sG<sub>NiV</sub> and sG<sub>HeV</sub>) capture antigens. The ELISA endpoint titers for sG<sub>NiV</sub> reactive samples ranged from 1:20 to 1:1280, with six of the thirteen samples exhibiting a titer of 1:640 or greater. Although none of the samples inhibited NiV or HeV infection *in vitro*, 3 of the 13 ELISA sero-positive patient serum samples reacted with denatured G antigen in Western blot. The presence of henipavirus-specific antibody responses suggests prior exposure to endemic henipaviruses or a henipa-like virus in rural Thailand. The

Formatted: Font: Not Bold

presence of pre-existing henipavirus antibodies among these children in Thailand suggest that ["background"](#) henipavirus infections do occur and were self-limited illness without serious health impacts.

**Singapore:** ~~No active~~ Active human surveillance will be **not be** conducted in Singapore, but archived human specimens ([REFS](#), e.g. Melaka virus serosurvey) will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

**Human Contact Risk Factors:** EHA is the lead global organization in the USAID-PREDICT project for characterizing the human aspects of zoonotic spillover risk. The approach began by conducting exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities (e.g. we interviewed 88 people involved in trading wild bats in China – REF). This allowed us to assess the local social and cultural norms and individual attitudes underlying wildlife contact. We used these study findings to develop a risk survey to accompany human biological samples to evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in >15 countries during the last 5 years, and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). Survey and biological samples were collected from 1,585 participants from 7 sites in China in Yunnan, Guangxi, and Guangdong provinces, 1,400 participants from 4 sites in Malaysia and 678 participants from 4 sites in Thailand. During this study serological assays were developed for implementation in China, and survey responses and demographic data suggest specific risk factors included type of occupation, keeping of pets and visiting wet markets. Seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), and are male (6/9). However, these characteristics were common and occurred in ~40% of survey respondents. Although these results are preliminary and don't provide detailed information on routes of exposure, they suggest that further refining of tools for serological tests coupled with survey data will identify likely routes of exposure to CoVs, novel CoVs, Henipavirus, and Filoviruses in our expanded study. The results of these surveys will be used in Aim 2 of this EIDRC proposal to better identify target populations and in Aim 2, we identify strategies to better target at-risk people, and conduct focused **human animal contact surveys and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.**

**Behavioral risk: Clinical meta-data to assess human-animal contact:** EHA is the global lead organization in the USAID-PREDICT project for assessing the risk of zoonotic spillover, including extensive behavioral surveys in high-risk populations under this award. Our general approach has been to conduct qualitative exploratory studies using standardized one-on-one semi-structured ethnographic interviews and observational data in among people engaged in clearly high-zoonotic risk activities (e.g. we interviewed 88 people involved in trading wild bats in China – REF). This allows us to assess local social and cultural norms and individual attitudes underlying wildlife contact. We used qualitative study findings to develop a human behavioral risk questionnaire on the type and frequency of animal contact, wildlife observed in daily life, and unusual illnesses reported over the past 12 months. Under our USAID-PREDICT project, we conducted cross-sectional studies in high risk populations in >15 countries during the last 5 years. In total, we have enrolled XX,XXX participants who have provided serum, nasopharyngeal, oral, and fecal samples and each completed behavioral risk questionnaires to assess animal contact. Questionnaires and biological samples were collected from 1390 participants from 9 sites in the Districts of Gua Musang, Kuala Lipis and Kuala Kangsar Malaysia, 10 syndromic surveillance patients at the Queen Elizabeth Hospital in Sabah, and 673 people from 3 sites in Thailand. The results of these surveys will be used in Aim 2 to better identify target populations.

**Serological Evidence of Exposure:** In China, we developed serological assays for HKU9 CoVs ( $\beta$ ), SARSr-CoV Rp3 ( $\beta$ ), HKU10 CoV ( $\alpha$ ), and MERS-CoV ( $\beta$ ) and used ELISA and Western blot to test serum samples collected in 2016/17. **We found 7 individuals (7/733, 0.95%) living within a 6 km radius of the Jinning Cave, and 6/209 people (2.87%) at one site, with evidence of exposure to bat SARSr-CoVs.** We found

**Commented [PD88]:** Linfa, Danielle – are we going to do human sampling in high risk communities in Singapore? If so, what would you propose and do you already have some prelim work you've done. Note these are high risk populations, i.e. high exposure to wildlife. Clinical cohorts are in Aim 3

**Commented [DA89]:** PMID: 30411364

**Commented [PD90]:** Hongying/Emily to edit

**Commented [EH91]:** For the survey and biological data collection we worked with 27 countries and managed 11

For Qualitative work we oversaw 13 countries

**Commented [PD92]:** Hongying/Emily – any information from Thailand or Malaysian surveys?

**Commented [KJ093]:** Edits from Emily.

**Commented [PD94]:** Hongying/Emily to edit

**Commented [KJ095]:** Make sure to delete most reference to "Behavioral" research throughout, but okay to do some surveys to collect "clinical meta-data".

**Commented [KJ096]:** Sum up for ALL countries?

**Commented [KJ097]:** Same as paragraph above, but including my and Tom's edits.

evidence among human populations in Guangxi Province of people with prior exposure to the bat  $\alpha$ -CoV HKU10 (2/412, 0.48%). This is of potential public health interest because HKU10 is known to be able to jump host species within bats, and therefore may have high propensity for emergence (122). However, the low seroprevalence (0.6%-2.7% at positive sites) suggests we need a larger sample size, and a focused, targeted study to maximize the likelihood of identifying seropositive cases. In Aim 2, we will use combined biological-behavioral risk surveillance in targeted populations within the community and clinical settings to 1) identify risk factors correlated with seropositivity (exposure to) and PCR positive status (infection with) henipaviruses, filoviruses and CoVs; and 2) assess possible health effects of infection in people. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**Risk Factors:** In China, questionnaire response and demographic data suggest specific risk factors included type of occupation, keeping of pets and visiting wet markets. Seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), and are male (6/9). However, these characteristics were common and occurred in ~40% of survey respondents. Although these results are preliminary and don't provide detailed information on routes of exposure, they suggest that further refining use serological tests coupled with qualitative and questionnaire data will identify likely routes of exposure to novel CoVs in China. In Aim 2 of this EIDRC proposal, we identify strategies to better target at-risk people, and conduct focused **questionnaires and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.**

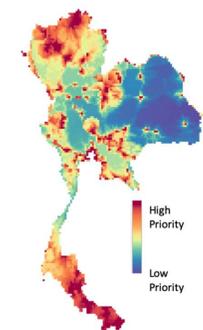

Commented [PD98]: Hongying/Emily – any information from Thailand or Malaysian surveys?

**2.2 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (**Fig. XX**). In Aim 2 we will conduct community-based surveillance with a focused questionnaire to identify the prevalence and frequency of risk-factors for viral spillover in these communities in tandem with biological sampling to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the community-based surveillance sites of Aim 2 (details in Aim 3). Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological/PCR status and symptoms.

Commented [KJO99]: ?

**2.3 Target population & sample sizes:** We will target sites in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, in regions that are EID hotspots, and are well-connected to regional travel and trade hubs and the global travel network (Fig X). We will target specific communities based on our analysis of the previously collected PREDICT behavioral questionnaire data to assess key at-risk populations and occupations with high exposure to wildlife, as well as using other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will also expand on work currently underway in the following particularly high exposure populations:

Commented [PD100]: Hongying/Emily to edit

**Fig X.** Preliminary analysis of geographic sites to target for human zoonotic disease surveillance in Thailand. Novel spatial analysis optimizes site selection by ranking areas with high numbers of expected viruses in wildlife and greater human access to these sites using road density data.

Commented [KJO101]: Think we need to be strategic and just pick a couple sites per country, so it doesn't look too ambitious given budget.

**Thailand:** In 2018 We have conducted behavioral risk surveys and biological sampling in 117 guano miners and the communities in Ratchaburi province where MERS like CoV has been found from dry bat guano and bat rectal swab during the PREDICT study. These workers visit bat caves and dig fecal material to use as fertilizer, and are therefore highly exposed to bats and rodents in particular. At Khao Chong Pran cave in Ratchaburi we have detected and characterized novel Alpha CoVs, HKU1, and MERS like CoV (short sequence)

((48, 119) and Chulalongkorn, unpublished). As an initial project on our EIDRC, we will develop serology assays to the novel CoVs found in bats at this site using LIPS assays and viral genomic data, and screen archived specimens from 230 participants (2 years' collection in 2017-2018, a subset of the subjects have been sampled at multiple timepoints to allow us to assess seroconversion). Clinical syndromic surveillance at the district hospital will be conducted from the patient with respiratory symptom, the known viral and bacterial pathogens will be tested by real-time PCR commercial kit (the test result will be provided to the hospital within 48 hours for treatment), along with PCR for 3 viral family and serology for CoV found from bat in this area.

Commented [KJO102]: LIPS?

The second site is at Chonburi province where Nipah virus (99% identity of whole genome sequence to NiV from Bangladesh patient) has been found from Lyley flying foxes but no infected patient been reported. Several novel Paramyxovirus and CoV have been found from bat feces roosting here. Screening using serology assays for a panel of Henipaviruses is ongoing via our existing collaborations with USUS's Luminex platform, and will be expanded under our EIDRC. The clinical syndromic surveillance at the district hospital will be conducted from the patient with encephalitis and respiratory symptom, the known viral and bacterial pathogens will be tested by real-time PCR commercial kit (the test result will be provided to the hospital within 48 hours for treatment), along with PCR for 3 viral family and serology for NiV, novel CoV, novel PmV found from bat in this area.

Commented [S103]: planned clinical surveillance work at 2 sites

Commented [KJO104]: From Supaporn, should this be moved to Aim 3?

The serology platform based on the sequence from bat need to be develop and used as an antigen for serology testing. HKU1 full genome sequence from guano miner (119)

Commented [KJO105]: Same thing. From Supaporn in this section, but maybe move to Aim 3.

Commented [KJO106]: From Supaporn

**Peninsular Malaysia:** We have sampled Orang Asli populations during 2016 – 2018 in 3 districts, enrolling 1390 people. We will expand this to include additional communities in the Districts we have already sampled, additional Districts in the States of Kelantan Perak and Pahang and also Districts in the State of Kelantan. The Ministry of Health, Department of Wildlife and National Parks Peninsular Malaysia and Department of Veterinary Services are all supportive of this expansion and the continued surveillance and capacity building that this will entail.

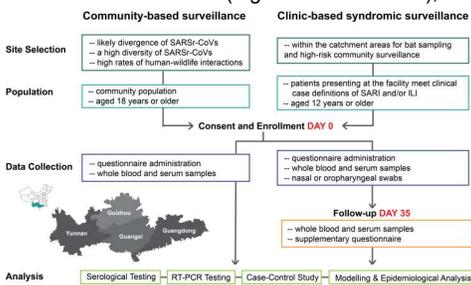

**Sarawak:** Dr Tan (Cheng Sieng) Center for Tropical and Emerging Diseases, Faculty of Medicine at UNIMAS – high risk Dayak communities that he's identified. We will do further sampling, questionnaires etc. Has Prelim data on HPV work in Dayak communities in remote Sarawak – we can work with those communities and can reach many by car, others by 4WD or boats. Has also Enterovirus 71 paper and is interested in CoVs. Has access to caves and guano. Will look into what other archived samples he has. Will give us access to Sarawak Forestry and Health Depts.

**Sabah:** Queen Elizabeth hospital syndromic surveillance, UMS Hospital syndromic surveillance, BMHRC human sampling outbreak response

Commented [PD107]: Tom – please start writing some plans for what we could do.

**Singapore:** No human sampling

**Community-based surveillance** will be conducted at XX sites in each country, a total of xx sites. From our previous work we anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so that they make up ≥30% of the sampled population in each community. We will stratify sampling to ensure appropriate representation of sex, demographic, and socio-economic factors at each community site. Estimating 5% overall seroprevalence in these high-exposure populations, these sample sizes are sufficient to estimate effect sizes of risk factors of 2X or greater with 80% power. For community-based surveillance, we will enroll xxx individuals per

county/province, pooled across two sites for each, allowing us to make county/province-level comparisons of differing effects.

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**2.4 Data & sample collection:** Following enrollment of eligible participants and completion of the consent procedure, **biological specimens** (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples) will be collected and a **questionnaire** will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent considerations for participants enrolled from clinical settings we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

**2.5: Laboratory analysis: 2.5.a Serological testing:**

One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. In contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes. However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. Henipaviruses, filovirus and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filoviruses/henipaviruses=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (Bossart 2008), developing monoclonal antibodies (Zhu 2008, Bossart 2009) and as subunit vaccines (Bossart 2012, Mire 2014), is presently developing a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, filoviruses and coronaviruses (Table XX).

This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (Bossart 2008, Chan YP 2009). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay. The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (Preliminary Figure A). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-like African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (Peel 2012, Chowdury 2014). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (Shuh 2019, MacNeill 2011, Natesan 2016). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity (Preliminary Figure B). The majority of ebolaviruses are endemic to Africa, however the discovery of Mengla virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown

**Commented [PD108]:** All – not sure if we should have one figure for community and clinical cohort surveillance (aim 2 and 3 respectively) or if we should have two separate ones?

**Commented [PD109]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipas, filov and CoVs.

**Commented [PD110]:** Emily/hongying

**Commented [EH111]:** We will need to take more than this from people as there are not vacutainers that small. Also do we want to use a serum separator tube specifically?

For 1mL of serum we will need 2.5mL of blood plus whole blood.

**Commented [PD112]:** Chris, Eric, Linfa, Dani etc. please draft some language here...

**Commented [EL113]:** Nations, F. a. A. O. o. t. U. in *FAO Animal Production and Health Manual* Vol. No. 12 (ed H.E. Field S.H. Newman, C.E. de Jong and J.H. Epstein.) (Rome, 2011).

pathogenicity and zoonotic potential exists. Our past work in collaboration with Dr. Smith and Mendenhall at Duke-NUS demonstrated that three under sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (Laing 2018).

The below is from our previous CoV proposal:

In our previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity was detected (15). **While this shows it is a specific test for Rp3, it suggests that if we can expand our serology tests to cover other bat CoVs, we may identify many more seropositive individuals.** In this renewal, we will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoVs SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (15), but HKU10 is known to jump from one host bat species to another (122) and is therefore likely to have infected people more widely. Incorporating serological testing for SHC014 is also likely to yield higher seroprevalence because it is readily divergent from SARS-CoV wildtype and therefore unlikely to have been picked up in our earlier testing. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, we recognize that CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or RBD; 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (14).

**2.5.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

**2.6 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for Henipavirus, Filoviruses, and CoVs spillover. "Cases" are defined as participants whose samples tested positive for Henipavirus, Filoviruses, or CoVs by serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative for Henipavirus, Filoviruses, or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between Henipavirus, Filoviruses, or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.2.2 Behavioral risks among population:** Qualitative and quantitative human study have conducted among

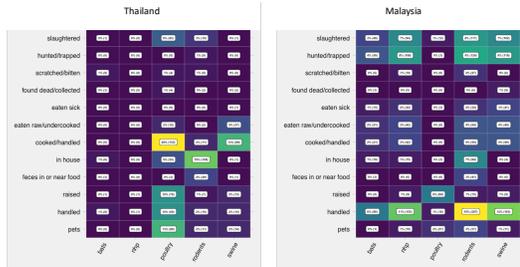

Commented [EL114]: PMID:

29260678

Commented [PD115]: Please modify for Henipas, filoviruses and CoVs

Commented [PD116]: Hongying/Emily

xxxx residents at xxxx community sites in Thailand and Malaysia, revealing the frequent contact with both wild (e.g., bats, rodents, non-human primates) and domestic animals (e.g., poultry, swine) among local communities (**Figure X**), which are associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms.

Figures of LASSO ILI/SARI analysis

Figure X High-risk human animal contact among community residents in Thailand and Malaysia

In addition, people making a living on crops production, engage in practices that enhance the risk of spillover (e.g. hunting and butchering wildlife) are at the risk of exposure and reported SARI and ILI symptoms (**Figure X – need a figure for this**). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with further refining serological tools, we will identify the likely routes of exposure to known or novel coronaviruses, henipaviruses, and filoviruses in the study region.

**2.7 Biological characterization of viruses identified: XXX**

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, paramyxoviruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may not match known CoVs due to recombination events.** We will use the three-tiered serological testing system outline in 2.6.a to try to identify these 'novel' CoVs, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

**Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not diagnosed. By working directly with individuals reporting to clinics with symptoms similar to known high-impact viral agents, we may be able to capture novel emerging diseases in at-risk communities before they spread into the general population and risk becoming pandemic. This will have clear value for public health in the region, and potentially wider. To do this, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in

**Commented [KJO117]:** From Hongying and Emily, may go in diff section for prelim behavioral data. Showing freq and type of animal contact based on Thailand and Malaysia P2 survey data.

**Commented [PD118]:** All –Not sure if we should weigh too heavily on this for the community survey – or should it just be serology for Aim 2. If you want include this section, please modify and insert language from Aim 1 here.

**Commented [KJO119]:** I think Aim 2 should just be serology, esp. since developing new LIPS assays or applying some of the serochip stuff from Linfa and Luminex from USU is already a lot.

**Commented [KJO120]:** Make this more general. There's a greater challenge of interpretation of serological data, esp. if we're using many platforms (each will have its own problems that our lab colleagues are probably more familiar with). Noam may be able to generally comment on a solution here from a statistical perspective.

rural communities linked to Aim 2 and present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We will enroll and conduct novel viral discovery assays on patients who present with unique clinical signs or relevant symptomatic cases. If novel pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the pathogen, using the collaborative **cross** to identify an appropriate animal model to conduct preliminary pathogenesis work.

Commented [KJO121]: ?

**Preliminary data clinical surveillance:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes:

Commented [PD122]: All – please read and share with collaborators to flesh out and correct details here.

**Singapore:** In collaboration with EcoHealth Alliance and colleagues from the Wuhan **Virological Institute of Virology** in China, we have **been** develop**ing** novel CoV assays for clinical surveillance. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing has been optimized and streamlined to be as rapid as several months, with the development of novel serological assays from sequence data in 7 days [REF]. For example, with the discovery of SARS-CoV, we identified **and and** fully-**genome** sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (Rhinolophus spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (14). [Maybe a timeline figure too?]

Commented [KJO123]: Per Linfa's comments, we should highlight the work from SARS-COV from new virus detection, to assay development, to serological testing in X months.

Commented [KJO124]: From Linfa and Dani, ref – SARS?

Commented [DA125R124]: PMID: 29618817 (same as ref 14 below)

**ADD Lancet ID paper on Zika sequencing by Dani and Duke-NUS team.**

Commented [KJO126]: Hongying? Similar to the revised Thailand one?

Following the detection of Zika virus in Singapore in 2016, we reported the first comprehensive analysis of the outbreak. Clinical and epidemiological data were collected from patients with confirmed Zika virus infection and mosquitoes were captured from areas with Zika disease clusters to assess which species were present, their breeding numbers, and to test for Zika virus. Mosquito virus strains were compared with human strains through phylogenetic analysis after full genome sequencing using our enrichment NGS protocol. We extended our studies into non-human primate models to assess the impact of flavivirus cross-reactivity in assays utilized to detect Zika virus, an important factor during outbreak of surveillance.

Commented [DA127]: PMID: 28527892

Commented [DA128]: PMID: 28527892  
PMID: 31022183

Commented [DA129]: PMID: 30155852

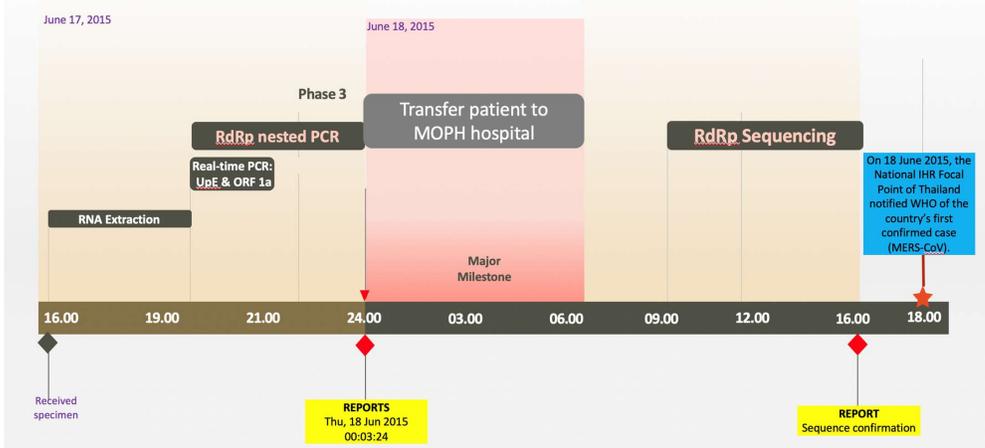

**Thailand:** The TRC-EID laboratory is a leader in rapid detection of human clinical specimens using broadly reactive and specific assays and in-house sequencing technology. For example, in coordination with the Thailand Ministry of Health, we identified the first case of imported MERS-CoV in Thailand using sequence confirmation within 24 hours from acquiring the specimen (Fig X).

Commented [KJO130]: Hongying was going to work on a very narrow, horizontal version of this if we want to include it.

Three imported MERS cases **were have been** detected in Thailand since 2015, **and** all cases were confirmed at Chula lab. More than **500** Zika patients were tested positive by PCR and sequence confirmation. The specimens from suspected Ebola travelers were tested negative, PREDICT filovirus protocol has been used as an additional protocol further investigation. The syndromic surveillance has been conducted and tested at Chula lab including SARI, Encephalitis, Hand Foot and Mouth disease in children and Viral diarrhea. These are research studies supported by PREDICT, US DoD and Thai government grant and the routine surveillance by the Thai Bureau of Epidemiology.

Commented [DA131]: This part isn't clear. Is it a list of the different assays?

## 24 Hours Laboratory Confirmation

### Peninsular Malaysia:

**Sabah:** Linfa has worked with Timothy Williams on an encephalitis cohort from Queen Elizabeth Hospital 1 & 2 (poss has worked with Linfa on these) and this is another possibility. He's doing outbreak response training in August with team from Sabah CDC (Dr. Maria now in Pen. But still collaborating with us, Jikal current director working with us and Dato Cristina dir. Sabah state health Dept and is supportive) this collaborative group is working to develop a Sabah outbreak response team – we will support that – to be based at BMHRC and we will develop this as part of this proposal. Prof. Kamruddin will summarize the serum samples he has. POCs: Sabah State Health Dept (e.g. Dr. Giri Shan Rajahram), Queen Elizabeth Hospital (Dr. LEE Heng-Gee)

**Sarawak:** From Linfa – Dr. Ooi used to work with Jayne Cardosa at UNIMAS and has access to samples of patients with unusual presentation

**Strategy for analysis of self-reported illness:** In addition to biological outcomes we have developed a standardized approach in PREDICT for analyzing data on self-reported symptoms related to targeted illnesses; of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), fever with muscle aches (fevers of unknown origin (FUO) and, cough or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI-like and/or SARI symptoms and demographics, occupation, and contact with animals in the last year. Results have clear biological relevance. In Yunnan, China, salient associated variables or combination of variables were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (Fig. 11). We will expand this approach for all syndromes in Aim 3, and use more granular targeted questions

Commented [PD132]: Tom to add – Queen Elizabeth Hospital?

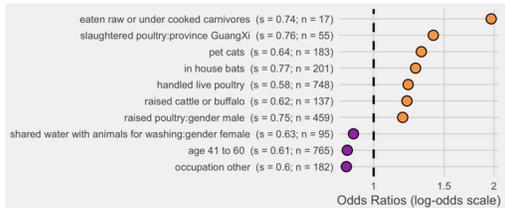

Commented [KJO133]: Comment from Tom: Sabah team please add details of any cohort work you have done

Commented [PD134]: Tom

Commented [KJO135]: Comment from Tom: Dr Tan have you done any clinical cohort work in Sarawak?

Commented [PD136]: Emily/Hongying

Commented [KJO137]: Emily: Will we do this in the community as well. We could also add animal contact as the outcome. We have data and figures for that as well

designed to assess patient's exposure to wildlife in terms that are relevant to the specific country. **Fig. 11:** Associated variables of self-reported ILI and/or SARI in prior 12 months (s = bootstrap support; n = number +ve out of 1,585 respondents). Orange circles = odds ratios > 1 (positively associated with the outcome); purple = odds ratios < 1 (negatively associated with the outcome).

### 3.2 General Approach:

Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms typical of high-impact emerging viruses. We will collect survey data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.3 Clinical cohorts. 3.3.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at XX town-level level clinics and xx provincial-level hospitals in each country, in total xx clinical/hospital sites, that all serve as the catchment healthcare facility for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients ≥ 12 years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, fevers of unknown origin, or hemorrhagic fever will be recruited into the study. We will enroll a total of xxxx individuals for clinical syndromic surveillance, which accounts for up to 40% loss from follow-up. Study data will be pooled across country sites, as clinical patients are limited by the number of individuals presenting at hospitals.

**3.3.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever of unknown etiology. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance of PCR detection of viruses (123). We will follow up 35 days after enrollment to collect an additional two 500 µL serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs <28 days after onset of symptoms for SARS patients (124).

### 3.3.c Sampling:

Following enrollment with signed consent form, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples) including two nasal or oropharyngeal swabs will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

**3.4 Sample testing:** PCR, Serol to link symptoms to etiologic agents

Commented [PD138]: Hongying/Emily

Commented [KJO139]: MeiHo: Just QEL in Sabah

Commented [PD140]: Hongying Emily

Commented [EH141]: Both inpatient and outpatient

Commented [PD142]: Need data for Nipah and filovirus patients

**3.5 Assessing potential for pandemic spread:** We will...leverage EHA's work with DHS to develop FLIRT (Flight Risk Tracker) that tracks the probable pathways for spread for viruses that are able to be transmitted among people...

Commented [PD143]: KEvin to draft

Commented [KJO144]: Pasted in a bunch of stuff, but still need to clean this up.

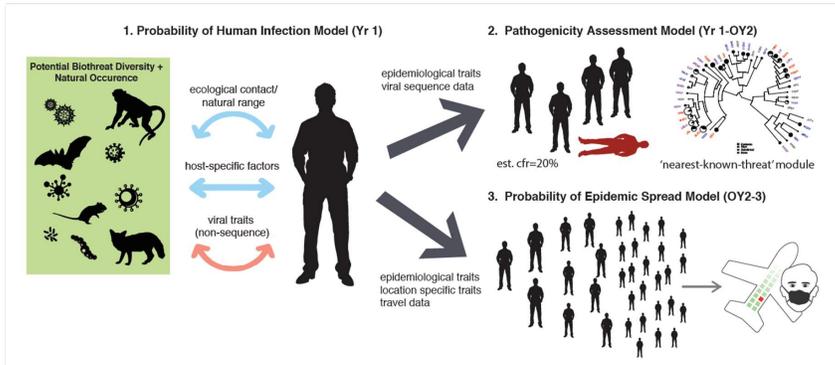

IBIS mines and collates data regarding on-going bioevents from biosurveillance networks and uses data on commercial air traffic to assess their risk of and likely routes of ingress into the United States. In contrast, BAT can use relatively rudimentary, high-level data, such as might be available for a newly discovered biothreat that has not yet caused a bioevent or is not subject to intense biosurveillance, in order to assess the agent's inherent pathogenicity. Thus, BAT and IBIS address distinct, but highly complementary, use cases.

Traditional approaches to pathogen assessment focus only on internal functional components of pathogens and often fail to account for the broader characteristics of host-pathogen interactions now recognized as critical for risk determination. Initial development will focus on characterization of viral pathogens, which constitute the majority of emerging diseases, especially those with pandemic potential. will use statistical models built from collated biological, ecological, and genetic data to predict the likelihood of human infection (or spillover) and pathogenicity for a diverse range of biothreats. The overarching aim of the proposed technology is to improve overall situational awareness of existing and novel infectious agents around the world, allowing DHS to more quickly identify and assess which threats pose the most significant risk to human health and thus either more rapidly deploy resources to respond to and mitigate their impact when necessary.

**Lab-based virology and bacteriology studies are necessary but not sufficient** because they are narrowly-focused and do not consider the broader suite of ecological, evolutionary, and host-specific factors that may affect an infectious agent's pathogenicity and transmissibility.

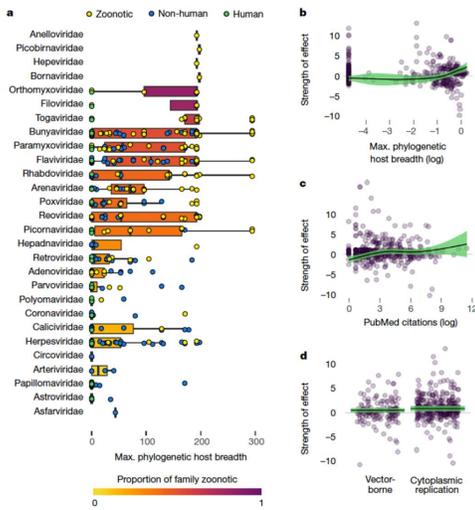

The initial phase of our work will build upon the existing, curated global-level pathogen and host databases currently housed at EHA. Specifically, we will employ systematic, targeted literature reviews to extend and customize these databases to include viral ecological, epidemiological, and biochemical traits to fit our statistical models and target pathogenicity predictions for the BAT. Predictor variables will span a range of data granularity, and vary according to the four information levels. For example for Level 1, variables may include location of detection (to integrate underlying EID hotspot models based on demographic and geographic factors), and non-human host range and taxonomy. For level 2, coarse-grained viral traits that are independent of sequence data may include: viral family, nucleic acid type, mode of transmission, and phylogenetic host breadth for virus (see Figure 2). For levels 3 and 4 viral sequence data will be integrated by including viral phylogenetic distance and 'nearest-known-threat' analyses (see Figure 3). For the pathogenicity model, human epidemiological data for ~300 viral species known to infect people (case fatality rate, global estimates of number of human cases per year or decade,  $R_0$ , infectious period, and primary symptoms) will be aggregated to use as predictor variables.

For ease of interpretation and for applicability across a broad range of pathogens, we propose to use two independent but related statistical models that will be used to predict pathogen spillover risk and pathogenicity, respectively. First, a model will be developed using spillover as the relevant outcome. In this case, spillover will be defined as either a binary variable, with "0" indicating a virus that is not known to spillover into human populations and establish infection whereas "1" will indicate a virus that is capable of spillover (or is solely a human pathogen). This model will enable us to assign a spillover risk probability to a new biothreat agent that is currently not known to infect people. Given the capacity to spillover and infect humans, we would then use a second model to predict pathogenicity of the novel pathogen. We will model pathogenicity in human hosts on a discrete scale from 1 to 10, with 1 representing a pathogen having no discernible negative effect on human health (i.e., asymptomatic infection) and 10 representing the most severely pathogenic bioagents with high case fatality rates. Additional functionality for the BAT (i.e., Option Years 2-3) may include integration of models to assess pathogen spread via travel and travel networks.

Commented [KJO145]: From our unfunded DHS proposal a couple of years ago, to modify if we want to include this.

**Figure 1.** Conceptual framework highlighting 3 underlying models of the Biothreat Assessment Tool (BAT) to estimate: 1) probability of human infection, or spillover, the first necessary step to understand pathogenicity when status of human infection is unknown (Year 1); 2) pathogenicity, i.e. probability of causing clinical signs, case fatality rate estimates, and other metrics relevant to humans (or domestic animal species) (Year 1 – Option Year 2); 3) probability of pathogen spread based on ecological, epidemiological, and trade data (Option Years 2-3).

**Figure 2.** Example of analysis using Level 2 information (limited pathogen characterization) to assess likelihood of human infection (zoonotic potential) for a virus. Figure from Olival et al. 2017, analysis of ~500 unique mammalian viruses. Similar analyses will be developed to assess level of pathogenicity.

From CoV renewal: use data from 3.3 to identify rank SARSr-CoV strains most likely to infect people and evade therapeutic and vaccine modalities. We will use bat survey and zoological data (101) to build species distribution models (125) and predict the distribution of bat species that harbor low, medium and high risk viral strains. Stacking these modeled distributions for the ~20-30 *Rhinolophus* and related species that occur in the

region will allow estimates of SARSr-CoV diversity for a given locality. We will use machine learning models (boosted regression trees) and spatial 'hotspot' mapping approaches to identify the ecological, socio-economic and other correlates of SARSr-CoV diversity and spillover (from serosurveys) (1, 2, 85). We will include data from our human behavioral surveys and sampling to give a direct measure of where risk of spillover to people is likely to be highest in the region.

**Potential problems/alternative approaches: Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases.** Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (123). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the potential public health importance of discovering active spillover of a new henipavirus, filovirus or CoV infection.

**ALL – the sections below are going to be critical to demonstrate our capacity to do this work. I've not yet started drafting, but please don't hesitate to insert whole sections from other proposals you've done if they're relevant here – we'll need to be creative and get all the language we can from others...**

#### Additional Instructions – Specific to the EIDRC FOA:

##### **Administrative Plan**

In a clearly labeled section entitled “**Administrative Plan**”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.
- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

**List out all of our involvement with outbreak investigations, ministries of health surveillance etc.**

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

FROM DARPA grant:

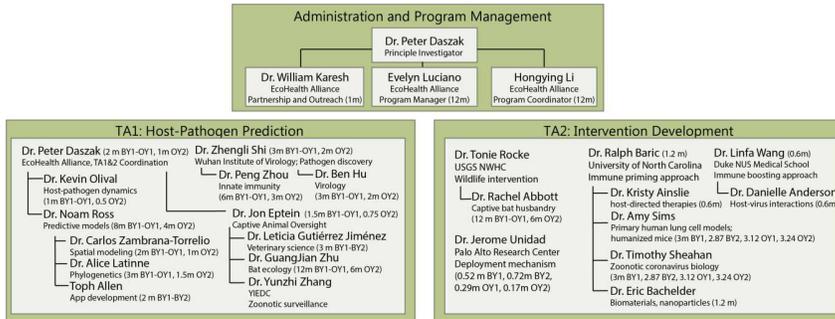

**Commented [PD146]:** Add data for Nipah and filo infections

**Commented [PD147]:** All – I've started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**Commented [KJO148]:** Peter, I've added in some examples from other grants

Section 1.03

MANAGEMENT PLAN

Project DEFUSE lead institution is EcoHealth Alliance, New York, an international research organization focused on emerging zoonotic diseases. The PI, Dr. Daszak, has 25+ years' experience

Commented [KJO149]: Figure like this would be good, but instead of breaking down by TA, maybe by country or Specific Aim. Per FOA, Need to also show how we'll link in with the Coordinating Center and other EIDRCs.

managing lab, field and modeling research projects on emerging zoonoses. Dr. Daszak will commit 2 months annually (one funded by DEFUSE, one funded by core EHA funds) to oversee and coordinate all project activities, with emphasis on modeling and fieldwork in TA1. Dr. Karesh has 40+ years' experience leading zoonotic and wildlife disease projects, and will commit 1 month annually to manage partnership activities and outreach. Dr. Epstein, with 20 years' experience working emerging bat zoonoses will coordinate animal trials across partners. Drs. Olival and Ross will manage modeling approaches for this project. Support staff includes a field surveillance team, modeling analysts, developers, data managers, and field consultants in Yunnan Province, China. The EHA team has worked extensively with other collaborators: Prof. Wang (15+ yrs); Dr. Shi (15+ yrs); Prof. Baric (5+ yrs) and Dr. Rocke (15+ yrs).

**Subcontracts: #1** to Prof. Baric, UNC, to oversee reverse engineering of SARSr-CoVs, BSL-3 humanized mouse experimental infections, design and testing of targeted immune boosting treatments; **#2** to Prof. Wang, Duke-NUS, to oversee broadscale immune boosting, captive bat experiments, and analyze immunological and virological responses to immune modulators; **#3** to Dr. Shi, Wuhan Inst. Virol., to conduct PCR testing, viral discovery and isolation from bat samples collected in China, spike protein binding assays, humanized mouse work, and experimental trials on *Rhinolophus* bats; **#4** to Dr. Rocke, USGS NWHC, to refine delivery mechanisms for immune boosting treatments. Dr. Rocke will use a captive colony of bats at NWHC for initial trials, and oversee cave experiments in the US and China. **#5** to Dr. Unidat, PARC, to develop innovative aerosol platform into a field-deployable device for large-scale inoculation of the bats. Dr. Unidat will collaborate closely with Dr. Rocke in developing a field deployable prototype for both initial trails and cave experiments in China.

**Collaborator Coordination:** All key personnel will join regularly-scheduled web conferencing and conference calls in addition to frequent ad hoc email and telephone interactions between individuals and groups of investigators. Regular calls will include:

- Weekly meetings between the PI and Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.
- Monthly web conferences between key personnel (research presentations/coordination)
- Four in-person partner meetings annually with key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

Evaluation metrics will include the generation of high-quality data, successful achievement of milestones and timelines, scientific interaction and collaboration, the generation of high quality publications, and effective budget management. The PI and subawardee PIs will attend a kickoff meeting and the PI will meet regularly with DAPRA at headquarters and at site visits.

**Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by Dr. Daszak and the Project Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation. Should a resolution not be forthcoming, consultation with our technical advisors and DARPA Program staff may be warranted.

**Risk management:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. A project of this nature requires a different mindset from that typically associated with basic research activities that move at an incremental pace with investigators gradually optimizing experimental systems, refining data, or waiting for additional data before moving ahead with an analysis approach. To maintain our timeline, we will continually evaluate these trade-offs to make decisions about when iteration is appropriate and when necessary to move forward with current information.

#### **Biographies:**

**Dr. Peter Daszak** is President and Chief Scientist of EcoHealth Alliance, Chair of the NASEM Forum on Microbial Threats, member of the Executive Committee and the EHA institutional lead for the \$130 million USAID-EPT-PREDICT. His >300 scientific papers include the first global map of EID hotspots(1, 126), estimates of unknown viral diversity(127), predictive models of virus-host relationships(2), and evidence of the bat origin of SARS-CoV(20) and other emerging viruses (40, 128-130).

**Prof. Ralph Baric** is a Professor in the UNC-Chapel Hill Dept. of Epidemiology and Dept. of Microbiology & Immunology. His work focuses on coronaviruses as models to study RNA virus transcription, replication, persistence, cross species transmission and pathogenesis. His group has developed a platform strategy to assess and evaluate countermeasures of the potential "pre-epidemic" risk associated with zoonotic virus cross species transmission(60, 70, 131-134).

**Prof. Linfa Wang** is the Emerging Infectious Diseases Programme Director at Duke-NUS Medical School. His research focuses on emerging bat viruses, including SARS-CoV, SADS-CoV, henipaviruses, and others (20, 135-138) and genetic work linking bat immunology, flight, and viral tolerance (139-142). A 2014 recipient of the Eureka Prize for Research in Infectious Diseases, he currently heads a Singapore National Research Foundation grant "Learning from bats" (\$9.7M SGD).

#### **Data Management Plan**

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system

Language from NIH CoV grant:

Data Sharing Plan: Data will be available to the public and researchers without cost or registration, and be released under a CCO license, as soon as related publications are in press. Data will be deposited for in long-

term public scientific repositories – all sequence data will be made publicly available via GenBank, species location data via the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestrictive MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Viral isolates will remain at the Wuhan Institute of Virology initially. Isolates, reagents and any other products, should they be developed, will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

Sharing Model Organisms: We do not anticipate the development of any model organisms from this study. Should any be developed, they will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

Genomic Data Sharing: We anticipate obtaining genetic sequence data for 100s of novel coronavirus genotypes, including RNA-dependent RNA polymerase (RdRp) and Spike genes for all strains/genotypes. In addition, we will generate full viral genomes for a subset of the bat SARSr-CoVs that we identify. All sequence data will be deposited in the NIH genetic sequence database, GenBank. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also be submitted. The genotype data will be made publicly available no later than the date of initial publication or six months after the receipt of final sequencing data, whichever comes first. We anticipate sequence generation will occur over the 5 year proposed project period.

Genome Wide Association Studies (GWAS): Not applicable.

Commented [KJO150]: From CoV NIH grant

Thailand TRC-EID Chulalongkorn lab: Specimen management and BioBank: The software called PACS (Pathogen Asset Control System) supported by BTRP DTRA, is now used for managing the specimen from specimen registration (barcoding, and may move to use QR code system soon), aliquoting, tracking, short patient history record, data summary, searching, test reporting and etc. Our biobank system contains 28 freezers (-80C) and liquid N2 system. Its size is around 120 sq meters. There is a separate electric generator for our lab and biobank. There are CC TV cameras at the biobank and laboratory.

Chula TRC-EID has our own server for data management and analysis. We have the necessary software including Bioinformatic tools (Blast Standalone, SAMTOOL, GATK, AliVIEW, RaxML, FigTREE, MAFFT, Guppy, Megan, PoreChop, MEGA), Database (MySQL, MongoDB) Web, jQuery, Node.js, Express.js React, API, PHP, Ruby, Python, Java, C#, HTML5, Bootstrap, CSS, Responsive, Cloud, Linux Command, PACS (sample management system), Virtualbox virtual machines, R programming languages, Perl scripts, Bash shell scripts, Open source software, Microsoft Office running on both Apple Mac OS X, Ubuntu, Linux, and Windows Operating Systems. Chula TRC-EID has a dedicated 16-core Ram 64GB Linux server with 4TB hard drives, dual quad-core Mac Pro Server with 2TB hard drives and another dedicated iMac Pro (Retina 4K, 21.5-inch, 2017) Processor 3.6GHz quad-core Intel Core i7 (Turbo Boost up to 4.2GHz) Ra, 16GB with 512GB hard drives. TRC-EID also has HPC Linux server CPU: 4 x 26cores Intel Xeon = 104 cores 2.1GHz with 52 TB HDD and 2x3.84TB SSD with GPU 2x Tesla v100 (CUDA core = 5120 cores/GPU, Tensor core = 640 cores/GPU). TRC-EID has a dedicated 10/100/1000 of LAN (Local Area Network), 2.4G / 5G Gigabit Wi-Fi 802.11ac.

Commented [KJO151]: From Supaporn for their lab, some may go in Facilities doc?

From DARPA:

**Data Management and Sharing:** EcoHealth Alliance will maintain a central database of data collected and generated via all project field, laboratory, and modeling work. The database will use secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations, and enable compliance with DARPA data requests and disclosure requirements. All archived human sample data will be de-identified. Partners will provide raw and processed data to the central database throughout the course of the project. Project partners will have access to the data they generate in the database at all times, and maintain control over local copies. Release of any data from the database to non-DARPA outside parties or for public release or publication will occur only after consultations with all project partners. EHA has extensive experience in managing data for multi-partner partner projects (PREDICT, USAID IDEEAL, the Global Ranavirus Reporting System).

Commented [KJO152]: Text from DARPA Preempt

## Clinical Management Plan

### Clinical site selection

Our consortium partners have been conducting lab and human surveillance research, inclusive of human surveillance during outbreaks, for over the past two decades and in that time have developed strong relationships with local clinical facilities and processes. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1. These are regions where we will sample wildlife due to the high potential of zoonotic viral diversity. Additionally, these will be clinical sites that serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. In PREDICT we developed successful working relationships with the major healthcare facilities the hotspot areas in 6 different countries, including Thailand and Malaysia and we will continue to work with these sites going forward. Continuing to work with these hospitals means we will begin this project with successfully established partners and we can begin data collection quickly. This also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites for this study is limited. All that is required of sites will be the ability to enroll patients that meet the clinical case definitions of interest, capacity to collect and temporarily store biological samples, and follow standards for data management and protection. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently site staff. These will be persons who are locally trained and certified to collect biological specimen from participants including blood draw technique, e.g. doctor or nurse. Last, the clinical site will need the capacity to securely store all personal health information and personally identifiable research data, this will include locked offices with locked filing cabinets to store all paper records and an encrypted computer. Training on project procedures will be provided for all local project staff by local country project management staff and partners from headquarters. The study at clinical sites will begin by developing relationships with local stakeholders at the hospitals and clinics in our geographic areas of interest that serve as catchment facilities for people of within the community surveillance study. We will recruit hospital staff that will be extensively trained for project procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data management plans. During the Development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data (e.g. locked filing cabinet, dry shipper, secure laptop). [Did not specifically address CONDUCT]. Oversight for clinical sites will be managed by the country coordinator for each country. This will be done with regular site visits to the clinical sites and annual visits by headquarter research staff. Site visits will include monitoring and evaluating the process for patient enrollment, collecting and storage of samples, administration of the questionnaire, and secure and data management procedures for secure personal health information and research data. During these visits any additional training will also be provided.

Commented [EH153]: Is that true

### Standardized approach oversight and implementation

Management and oversight for all study sites will be managed by the local country coordinator who is supported by staff at headquarters. Implementation of a standardized approach across all study sites, community and clinical, will begin by extensive training of staff on procedures on requirements of the project, this includes: enrollment, data collection, and data management. Our research team has over 5 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research. This includes SOPs for screening, enrollment, and retention of participants. In addition to yearly monitoring reports the country coordinator will regularly visit each clinical site to ensure quality standards and compliance of procedures are being met. Through our work with clinical sites in PREDICT we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical research staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll, allowing for minimal disruption and prevents potential enrollees from being overlooked if the research staff is not on duty. At clinical sites that do scheduled outpatient days we may have a trained member of the research staff with the intake nurse to monitor the patients coming to the clinic more rapidly to no delay screening or enrollment in such a fast pace environment. Using the screening tools, we will recruit and enroll patients who present with symptoms that meet the clinical case definitions of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology within the past 10 days. These patients will be enrolled, samples collected and survey conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; 3) environment biosecurity. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either coronaviruses, henipavirus, or filoviruses, serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between coronaviruses, henipavirus, or filoviruses in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. [How do these cohorts be leveraged for new emerging pathogens] Achieving the adequate numbers will be attained through duration of the as clinical participant enrollment. While patient's enrollment is limited by the number of individuals presenting at hospitals, during the PREDICT project we had an average of 105 patients enrolled per year, ranging from 77-244. The country coordinator will be continually monitoring the project database to be sure that we are on track to reach our target.

### Clinical cohort setup, recruitment, enrollment

We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology for symptoms reported onset of illness to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 2\* 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL

Commented [EH154]: Will these cohort fulfill the goals of the EIDRC.

serum samples and two nasal or oropharyngeal swabs will be collected. The cases are defined as participants whose samples tested positive for Henipaviruses, Filoviruses, or CoVs by PCR or serological tests. The controls will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500 µL serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms for coronaviruses, henipavirus, or filoviruses infected patients to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

#### Utilization of collected data

Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses that are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire allows us to assess relative measures of human-wildlife contact from our survey work that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk.

The biological specimens to be collected (2\*5mL whole blood for whole blood and serum analysis and nasal or oropharyngeal swabs) from all eligible participants and follow up specimen 35 days (3mL of whole blood for serum) after enrollment with the standardized questionnaire. Capacity for specimen collection is not more than standard phlebotomy skills and we will collect by locally trained and certified personnel that are part of the research team in country. Staff we will trainline on ethical guidelines for conducting human subjects research and survey data collection methods. Collection of whole blood, serum, and nasal or oropharyngeal swabs allows us to test the samples for PCR to detect viruses in our priority viral families, serologically test for immunological response and historical exposure to zoonotic diseases of relevance, and the questionnaire will assess individuals evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

#### Potential expansion

Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research or an outbreak in the region. If expansion is required we could rapidly implement research activities in additional clinical or community sites through the same process we on-boarded the initial locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transpiration, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provided necessary information for granular understand of disease spread.

**Commented [EH155]:** PREDICT we also make the stipulation that we will collective relative samples if avialble from treatmean collection, eg CSF if the MD is doing a spinal tap we will request an aliquot if possible

**Commented [EH156]:** Please add any information that might address: types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

**Commented [EH157]:** Please add any information that might address: Describe methods that might be applied to elucidate a zoonotic source

In a clearly labeled section entitled **"Clinical Management Plan"**:

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment, including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics

2. Tekada Sanofi Pasteur dengue

3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

### Statistical Analysis Plan

In a clearly labeled section within the Research Strategy entitled **"Statistical Analysis Plan"**:

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

**Project Milestones and Timelines**

In a clearly labeled section entitled “**Project Milestones and Timelines**”:

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

**Project Management & Timeline**

PI Daszak will oversee all aspects of the project. Dr. Daszak and has two decades of experience managing international, multidisciplinary research in disease ecology, including successful multi-year projects funded by NSF, NIH and USAID. He will conduct monthly conference calls with all co-PIs, including the China team (see Activity schedule below). He will be assisted by EHA Sr. Personnel Li, who is a US-based Chinese national with fluent

■ China-US Joint Activity ■ China-Led Activity ■ US-Led Activity

Mandarin. Co-PI Olival will oversee Aim 1 working closely with China PI Tong, who will test samples. Co-PI Ma (China team) will coordinate and lead all Chinese experimental infections, with guidance from co-PI Saif, who will coordinate and lead all US experiments with co-PI Qihong Wang. Sr. Personnel Ross will conduct all modeling activities in Aim 2, working closely with co-PI Saif to parameterize the models. Co-PI Baric and Sr. Personnel Sims will lead infectious clone, recombinant viral and culture experiments. Consultant Linfa Wang will advise on serology, PCR and other assays. China team co-PIs Shi and Zhou will oversee viral characterization in Aim 1. Sr. Personnel Feferholtz will oversee the economic modeling in close collaboration with Ross.

Commented [KJO158]: Text and figure From NSF-NIH SADS grant. Peter will adapt

Another Example of Milestones and specific tasks from a prev DHS (unfunded) proposal:

**Expand existing databases to include predictor variables for pathogenicity risk model**

**Task 1:** Collate available human clinical information from the literature for ~300 viral pathogens known to infect humans (Contract Award Date to 6 month)

**Task 2:** Update EHA host-viral association database to include new data for mammalian and avian species from literature 2015-present (Contract Award Date to 3 month)

**Task 3:** Extract and curate full and partial genomic data from Genbank for 5-6 viral families with a high proportion of human-infectious pathogens for phylogenetic analyses – e.g. ‘nearest-known-threat module’. (Month 2 to 6 month)

**Develop underlying pathogenicity and spillover risk assessment models**

**Task 4:** Fit generalized linear models in Stan for multiple response variables to measure pathogen impact (Month 7 to 10 month)

**Task 5:** Fit generalized linear models to estimate risk of human infection (spillover) based on host, ecological, and location specific traits (Month 4 to 8 month)

**Task 6:** Validate model effectiveness by simulating early-outbreak, limited-information scenarios from known pandemics to confirm model behavior (Month 8 to 10 month)

**Commented [KJO159]:** Just example, but probably just want to use a Gantt chart format per most of our grants, depending on space.

Ralph: [Am J Pathol](#). 2003 Dec;163(6):2371-82 Primary human lung endothelial cells are highly susceptible to EBOLA virus infection, so we can use these cells. Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (*Viruses*. 2019 Feb 16;11(2). pii: E161. ) Huh7 cells also offers advantages for reverse genetic recovery of novel filoviruses ([J Infect Dis](#). 2015 Oct 1;212 Suppl 2:S129-37. )

We have growth curves of Nipha and Hendra in Calu3 cells, a continuous lung epithelial cell, including a variety of host expression changes after infection. Likely grow in primary human airway cultures as well as they infect ciliated and secretory cells ([J Gen Virol](#). 2016 May;97(5):1077-86. ). Nipha and hendra also infect primary human microvascular endothelial cells, like mers and ebola ([PMC3477106](#), [PMC3791741](#)). I'm less sure what kind of neural cell should be used for Nipha and Hendra.

Some evidence for nipha and Hendra replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (PMC4057804, PMC3393746). Thus it is likely these models could be improved in the collaborative cross mouse resource here at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted ebola infections.

---

## Understanding risk of zoonotic virus emergence in EID hotspots of Southeast Asia

### II. Research Strategy:

#### 1. Significance:

Southeast Asia is a well-defined hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of critical ecological and socioeconomic drivers of disease emergence (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is also undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread. It is therefore not surprising that a number of recent discoveries have identified novel viruses, including near-neighbors of known agents spilling over to livestock and people through often novel pathways, leading to sometimes unusual clinical presentations (**Table 1**). These factors are also behind a significant background burden of repeated Dengue virus outbreaks in the region (3), and over 30 known *Flavivirus* species in South and Southeast Asia (4).

Viral agent	Site, date	Impact	Novelty of event	Ref.
Melaka virus & Kampar virus	Malaysia, 2006	Caused SARI in family group, individual	1 <sup>st</sup> disease due to bat-origin reoviruses (other reports Singapore, Vietnam etc.)	(5-8)
Reston filovirus	Philippines 2008	Seropositive people killed pigs,	No prior findings of filoviruses in pigs	(9)
Thrombocytopenia Syndrome virus	China 2009	Domestic animals, illness in people	Novel syndrome with large caseload	(10)
Reston filovirus	Shanghai 2011	PCR positive pigs	Further evidence of pig RESTV infection	(11)
Mojiang virus	Yunnan 2012	Implicated in death of 3 mineworkers exposed to rats	1 <sup>st</sup> evidence of rodent origin henipavirus in people	(12)
Nipah-like virus	Philippines 2015	Killed horses	No prior horse infection for NiV, known for HeV	(13)
SADS-CoV (HKU2)	China 2017	>25,000 pig deaths	Novel emergence of bat-origin CoV	(14)
SARSr-CoV & HKU10-CoV	Yunnan, Guangxi 2015	Seronegative people	1 <sup>st</sup> evidence human infection	(15)
Nipah virus	Kerala, 2018, 2019	19 people infected/ 17 dead 2018, 1 infected 2019	1 <sup>st</sup> outbreak of NiV outside Bangladesh, W. Bengal focus	(16), (17)

**Table 1:** Recent reports from SE Asia indicating potential for novel pathways of emergence, or unusual presentations for known or close relatives of known viruses.

These events are dominated by three viral families: coronaviruses, henipaviruses and filoviruses, which will act as the key research viral groups in this proposal. These viral groups have led to some of the most important recent emerging zoonoses (18-29). Their outbreaks

have caused tens of thousands of deaths, and billions of dollars in economic damages (30-32). In addition to the events in **Table 1**, relatives and near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium including: henipaviruses in frugivorous bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (33-39); a novel henipavirus, Mojiang virus, in wild rats in Yunnan (12); serological evidence of filoviruses in bats in Bangladesh (40) and Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (EHA, unpublished data); evidence of novel filoviruses in bats in Singapore (41) and China (42-44), including Mênglà virus that appears capable of infecting human cells (45); novel paramyxoviruses in bats and rodents consumed as bushmeat in Vietnam (46), a lineage C  $\beta$ -CoV in bats in China that uses the same cell receptor as MERS-CoV and can infect human cells *in vitro* (47); MERSr-CoVs found in dry bat guano being harvested as fertilizer in Khao Chong Pran cave, Ratchaburi, Thailand (48) and later directly in bats (CU, unpublished); 52 novel SARSr-CoVs in 9 bat species in southern China (172 novel  $\beta$ -CoVs from >16,000 sampled bats) that are also found throughout the region (20, 47, 49, 50), a new  $\beta$ -CoV clade ("lineage E") in bats (50); and 9 and 27 novel wildlife-origin CoVs and paramyxoviruses in Thailand (respectively) and 9 novel CoVs in Malaysia identified as part our work under USAID-PREDICT funding (49, 51). These discoveries underscore the genetic diversity of potentially pathogenic viral strains in wildlife in the region, and their potential to help in the development of broadly active vaccines, immunotherapeutics and drugs (52).

Commented [KJO1]: Double check w EIDITH

Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 1). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (29, 53). However, surveillance and control is hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (54). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in x/xx (x%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (15, 55). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (5) as well as 12/856 (1.4%) people screened in Singapore (6). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (9), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (56). Preliminary screening in Malaysia with funding from DTRA for serological surveillance of Henipaviruses and Filoviruses spillover found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in non-human primates (NHPs) and people (Hughes, unpublished data). Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed

or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70%, and that it is also present in bats in India (REF). Nipah virus was originally misdiagnosed as 'aberrant measles' in West Bengal, India (REF), has now emerged repeatedly in North India, and in Kerala, South India in 2018 and 2019 (ongoing), raising the specter of future spillover at other sites across the region (16, 57).

**Fig. 1: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (53).

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (58), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (20, 47, 49, 50, 59-61). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-concept for an early warning approach that we will expand in this EIDRC to target key viral groups in one of the world's most high-risk EID hotspots.**

The overall rationale for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be

Commented [BRS2]: Statement should be in the aims. ...Our center covers the worlds most high risk EID hotspot?

used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. The overarching goal of this proposal is to launch the **EIDRC-SEA (SouthEast Asia)** to better understand the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and closely related CoVs, henipaviruses, and filoviruses in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development and such. We will test these viruses' capacity to infect human cells and mouse models, develop new specific and sensitive serological and molecular diagnostic tools, and conduct surveillance of human populations with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover and pandemic potential, and of viruses causing previously 'cryptic' clinical syndromes in people. Our group also has extensive experience in other viral pathogens, including vector-borne flaviviruses, and will use this experience to provide robust long-term surveillance, diagnostics, human and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EIDRC-SEA is poised to rapidly respond to any new emerging outbreak. Thus, filoviruses, henipaviruses and coronaviruses are examples of sentinel surveillance systems in place that can capture, identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.

**2. Innovation:** Previous work by our consortium has developed a system to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses (REF). The EIDRC-SEA we take this approach and scale it up to cover three critically high-risk EID hotspot countries in Southeast Asia, within a regional network of collaborators. The innovation of the EIDRC-SEA is in:

1) its multidisciplinary approach that combines modeling to target the geography for wildlife and human sampling, novel phylogenetic and *in vitro* and animal model approaches to obtain precise biological risk assessments of viral spillover potential into people, the development and transfer of novel serological and molecular diagnostics capabilities throughout the region, and use of parallel large scale cohorts to identify spillover and illness due to known and novel viruses; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people, the evaluation of existing countermeasure technologies; technologies that are grounded on our successful work on SARS-CoVs; and 3) the combination of geographically targeted human populations with high risk of animal contact and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an **early warning system** approach. **In Aim 1, we will target viruses in new and archived wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, as well as further characterize viruses we have recently discovered. We will use *in silico* methods (i.e. novel ecological-phylogenetic risk ranking and antigenic mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into high-risk human populations. **In Aim 2, we will conduct focused, targeted surveys and sampling of human communities with high exposure to wildlife and other animals.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. Serological findings will be analyzed together with clinical meta-data (including a simple animal-contact survey, location data, etc) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise 'cryptic' outbreaks.** We will enroll and collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs. Our **US partner BSL-4 laboratory, NEIDL,** will attempt isolation and characterize any viruses requiring high levels of containment (e.g. any novel Filoviruses discovered).

### 3. Approach

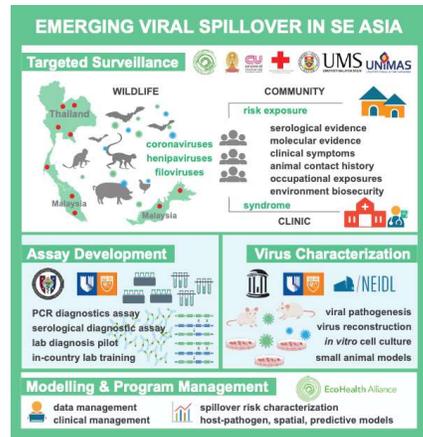

**Research team:** The EIDRC-SEA builds on long-term collaboration among world leaders in emerging virus

**Commented [BRS3]:** Number one innovation is the nuclear core sites that make up the EIDRC and its expanded network of long-term collaborators that saturation the most biodiverse EID host spot in the world, 2) extensive sample collections from wildlife, people in close proximity to EID hotspots, and samples from cohorts in individuals seeking medical care at our participating centers? (major goal of proposal if I remember correctly is to set up surveillance network for rapid response and interface wit health care facilities to collect large sample sets and/or develop clinical cohorts for testing intervention technologies ( in the future).

**Commented [KJO4]:** From MeiHo: Another innovation from EIDRC is the quick response if an outbreak happens in the region when the team has been developed and trained under this initiative.

**Commented [KJO5]:** List out what other labs will do too? Or just rely on our Org chart figure for all of this?

research with proven experience collaborating internationally on field, lab and human surveillance research (Fig. 2). Over the past two decades, our consortium partners have collaborated together within the region and globally to conduct high profile research on EIDs. This work includes identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (20, 25, 58, 62-65), discovering SADS-CoV (14), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (59-61, 66-79). Our team has substantial experience conducting human

surveillance during outbreaks (e.g– The ongoing viral surveillance using molecular and serological techniques with the indigenous communities of Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah with undiagnosed syndromes through the USAID-PREDICT program and the DTRA funded serological surveillance of Henipaviruses and Filoviruses spillover. - Please insert examples that you've been involved in and REFS), and as part of longitudinal efforts to pre-empt pandemics (80, 81).

In 2016, our collaborative team, together with partners in China, discovered an HKU2-clade  $\alpha$ -CoV(82, 83) in 5 pig farms in Guangdong Province affected by fatal diarrheal disease. We used PCR, serology, pathology, phylogenetic analysis, and infection experiments to show that this novel virus, SADS-CoV, originated in *Rhinolophus* spp. bats and killed > 20,000 pigs at these farms – all in the span of three months (14, 84)

Fig. 2: Interdisciplinary team & roles in the proposed EIDRC-SEA.

PI Daszak has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5- 20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival, Zambrana, and Ross are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesedee, Hughes and collaborators have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from DoD, USAID, NIH, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to the EIDRC (See Section XX).

Fig.3 : Map of Southeast Asia indicating the three core countries for this proposed EIDRC (White: Thai, Sing, Mal) and those that Key Personnel are actively collaborating with (Green: field sites and collaborating labs indicated with asterisk).

**Geographical focus:** The three core countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses

diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife

Commented [KJ06]: From Tom: Tim, Giri, Tsin Wen – Please can you add in details for MonkeyBar

Tsin Wen – Please can you add details here on your Univ N. Sumatra malaria/fever patients to find malaria

Tim and Tsin Wen – Please can you add in details of your encephalitis study

Dr Tan – Please can you add in details of your work with Dayak and other human studies you have done

Dr Lee – Please can you add in details of any hospital based or other human surveillance you have been involved with.

Prof Kamruddin – Please can you add in details of your blood donor, Garbage collector, Febrile and diarrhea

Please add any other examples you have.

species, people otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our consortium's extensive network of collaborators in clinics, research institutes and public health laboratories in every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in XX countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Current list of contacts at key human (especially) and wildlife orgs in every SE Asian country from map above – please add to this if we've missed any**

Indonesia – EHA: Eijkman (Dodi Safari), IPB (Imung Joko Pamungkas);  
SE China – EHA: Yunnan CDC (XX), Wuhan Inst. Virol. (Zhengli Shi);

Myanmar – Chulalongkorn (Thiravat and Supaporn) have collaborated extensively with Win Min Thit, MD (Yangon General Hospital, Myanmar); Khin Yi Oo (National Health Laboratory, Myanmar) and also in training PREDICT Myanmar veterinarians in bat sampling under PREDICT.

Cambodia -

Laos - **CM Ltd**: Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (Matthew Robinson)  
Bangladesh – EHA: IEDCR (Meerjady Sabrina Flora, Ariful Islam), icddr,b (Mohammed Ziaur)

India – EHA: Jon's collaborators;

Vietnam – Wellcome CRU ? Liaison with Zhengli Shi for Serol assays etc.?

Philippines – EHA, **CM Ltd**: Biodiversity Management Bureau, Department of Environment and Natural Resources (Anson Tagtag),

Malaysia – **CM Ltd**: Borneo Medical and Health Research Center (Ahmed Kamruddin), Department of Wildlife and National Parks Peninsular Malaysia (Frankie Sitam, Jeffrine Japning, Rahmat Topani, Kadir Hashim, Hatta Musa), Hospital Universiti Malaysia Sabah (Helen Lasimbang), Faculty of Medicine, Universiti of Malaya (Sazaly Abu Bakar), Kota Kinabalu Public Health Laboratory (Jiloris Dony, Joel Jaimin), Ministry of Health (Chong Chee Kheong, Khebir Verasahib, Maria Suleiman), National Public Health Laboratory (Hani Mat Hussin, Noorliza Noordin, Yu Kie Chem), Queen Elizabeth Hospital (Giri Rajahram, Heng Gee Lee), Sabah State Health Department (Christina Rundi), Sabah Wildlife Department (Rosa Sipangkui, Senthilvel Nathan, Augustine Tuuga, Jumrafiah Sukor),

Thailand – **CM Ltd**: Mahidol-Oxford Tropical Medicine Research Unit, (Stuart Blacksell, Richard Maude), Ministry of Public Health (Prayuth Sudathip, Hinjoy Soawapak), Faculty of Forestry, Kasetsart University (Prateep Duengkae), Chulalongkorn University (Supaporn Wacharapluesadee).

Chulalongkorn lab is a WHO Collaborating Centre for Research and Training on Viral Zoonoses, we work closely with WHO SEARO and SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste.

We had conducted the PREDICT lab training for Veterinary lab in the Southeast Asia region for FAO.

We conducted the bat sampling technique for scientists from Malaysia, Myanmar, the Philippines, and China.

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and non-human primates (2). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have

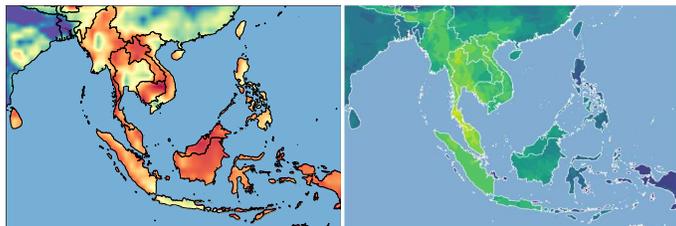

**Commented [BR57]:** Show this somehow in the picture. Primary sites, collaborative linkages that extend the breadth of the EIDRC.

**Commented [KJ08]:** From Supaporn

**Commented [PD9]:** Remember to correct specific aims with same title

close contact to these wildlife (Fig 4) (2). In Aim 1, we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and apply novel predictive models to estimate viral host range and identify new host species that have been previously ignored by EID surveillance systems. We will strategically collect specimens from under- or not-yet-sampled species of wildlife and screen these together with some of the tens of thousands of recently collected samples we have archived in freezers in our labs for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel virus in high risk RNA viral families, Coronaviridae, Paramyxoviridae, and Filoviridae. We will expand to other groups of pathogens, pending available resources, after priority setting with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation attempts. For the subset of highly-ranked and genetically characterized viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, and mouse models) previously developed and widely use by our team [REFS?] to predict capacity of novel viruses to ] infect people and spillover. These high risk viruses will be targets for human community and clinical sampling in Aim 2 and 3, respectfully. This approach is built on substantial previous proof-of concept preliminary data:

**Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a particular high risk location for pathogen emergence (1, 2). For Southeast Asia, these EID hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (Fig 4a). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (2). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 4b). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (85). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data and flight model software we have produced with Dept Homeland Security funds (86). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

**Fig. 4:** Our previous work has shown proof-of-concept in geographically targeting sampling in 'hotspot' areas of highest risk for wildlife-to-human spillover and disease emergence (Fig. 4a), and regions with high diversity of predicted 'missing' or as-yet undiscovered viruses, yellow = highest diversity (Fig 4b). From (1, 2).

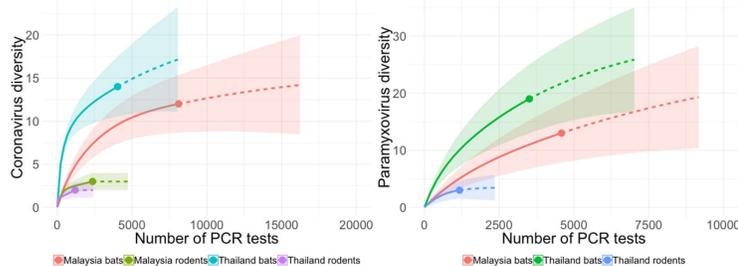

**Commented [KJO10]:** Will we? If so, make sure we mention primates more and include in vert animal sections.

**Commented [KJO11]:** Do you think we need to add in or mention vectors (arthropods)? We don't have big banks of these as far as I know, so maybe best not too?

**Commented [PD12]:** Kevin – please edit

**Commented [KJO13]:** Peter, consider showing this figure earlier on considering Ralph's point about highlighting the EID rich geography of SE Asia first.

**Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primate represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential (2). The bulk of our sampling and sample testing will consist of bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses (48, 87-89) (ADD REFS). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (2). We have used a novel phylogeographic analysis, Maximum Clade Credibility (MCC) tree, to reconstruct the geographic areas of evolutionary origin for  $\beta$ -CoVs that we sequenced in bats (49). This approach allows us to identify the ancestral home of specific zoonotic viral groups in wildlife, where their diversity is likely highest. Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (90, 91) (Fig. 5). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we

**identify new strains to support experimental infection studies and risk assessment.**

**Fig. 5:** Estimates of CoV (left) and PMV (right) viral species diversity in bats and rodents for Thailand and Malaysia, based on our preliminary data testing over XXXX specimens using PCR. Bats in Thailand and Malaysia are estimated to have 4X the number of novel viruses in these viral families. CoV and PMV diversity estimates are comparable, but discovery has not yet saturated in any taxonomic group or location. We used this to estimate that additional sampling of X,000 bats and X,XXX rodents will identify >80% of remaining CoV and PMV viral species from key wildlife species in these regions. We will apply this approach to our target host and viral taxa, for Thailand and Malaysia to calculate sampling targets to capture maximal viral species diversity (shown), but also for estimating targets for capturing viral strain diversity.

**Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. In the first 5 years of the PREDICT program globally (2009-2014), we found more viruses (815 novel, 169 known) than the total number of viruses previously recognized in mammals by the International Committee on Taxonomy of Viruses. This includes collecting nearly 300,000 individual mammal specimens from 14 EHA-led PREDICT countries and PCR-screening more than 60,000 individual specimens(51). In southern China alone, this led to the identification of 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARSr-CoVs). This includes members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus (SADS-CoV) killing >20,000 pigs in Guangdong Province (14). Many of these bat species are found across the region. We have collected 28,760 samples from bats, rodents and primates in Thailand and 62,012 in Malaysia under PREDICT, conducting 146,503 PCR tests on a large proportion of these specimens, and archiving duplicates which are now available for use in this project(92). In Thailand this screening has identified XX. In Malaysia this screening has identified 77 novel viruses and 23 known viruses in wildlife reservoirs (66 novel and 19 known in Sabah and 11 novel and 9 known from Peninsular Malaysia). We used family level primers for henipaviruses, filoviruses and CoVs and have already discovered XX in Thailand and 13 novel and 5 known CoVs and 15 novel and 1 known PMV in Malaysia from wildlife. In the current proposed work, we will attempt to isolate and characterize the full genomes for those that our analyses below suggest are most likely to be able to infect humans.

Commented [PD14]: Kevin to edit

Commented [BRS15]: I would say we focus on these three species (plus vectors?). To demonstrate the capability of the team, this proposal will focus on bat surveillance (for a variety of reasons), noting that this approach will also be applied to other zoonotic vectors during the 5 year program throughout the region.

Commented [KJO16]: We can show just a single curve per country (aggregating all wildlife species) for simplicity, and could fit CoVs and PMVs on one graph.

we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively

Commented [PD17]: All to edit

Commented [KJO18]: More?

Commented [KJO19]: Latest numbers from EIDITH for P1 and P2

Commented [PD20]: Kevin – need the PREDICT numbers here please

Commented [T21]: Do we want to mention other viruses we found of public health concern that are not part of the 3 viral families we are focusing on in this proposal?

Our collaborative group has worked together on these projects, as well as under DTRA funding in Singapore/Thailand (Co-Is Wacharapleusadee, Wang) to design, cross-train, and use novel serological and molecular platforms to investigate virus infection dynamics in bats and examine potential spillover events with or without human disease. For serology, our lab at Duke-NUS will be developing a phage-display method to screen antibodies for all known and related bat-borne viruses, focusing on henipaviruses, filoviruses and coronaviruses. Once various “trends” are discovered, additional platforms (including Luminex and LIPS) will be used for verification and expanded surveillance. For molecular investigation, we will combine targeted PCR approach with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified. In Malaysia (Co-Is Hughes, Broder, Laing) the transfer of the Luminex serology platform to partner laboratories for wildlife, livestock and human samples screening to investigate the spillover of Henipaviruses and Filoviruses at high risk interfaces including farms near the forest and indigenous communities with lots of subsistence hunting in Peninsular Malaysia, preliminary screening has found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in bats, NHPs and people. In Thailand (Co-Is Broder, Laing and Wacharapleusadee) tech transfer of Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses and known henipaviruses in wildlife and human samples is underway and currently being validated in our Chulalongkorn University laboratory. This is part of a planned DoD regional center of excellence for training in Thailand (details please?).

**Commented [KJO22]:** From Supaporn: I do not have this information yet, but it is possible.

**Commented [PD23]:** I think this is something that Linfa, Supaporn or Chris mentioned?

We have found 13 novel CoVs and 15 novel PMV and have begun using Illumina sequencing and virome capture sequencing to further characterize 6 of these novel CoVs and 10 of these novel PMV. To date have completed the full genome sequencing for two novel CoVs that were part of the PREDICT Deep Forest project in Sabah – PREDICT CoV-51 found in *Hipposideros cervinus* and PREDICT-CoV-52 (HKU10-like) found in *Hipposideros diadema*. As part of our PREDICT further characterization work, we will investigate the zoonotic potential of these viruses (i.e., their ability to infect human cells). We will reverse engineer the viral RNA from the genome sequence we obtained, recover the infectious virus, and test its ability to infect a range of human cells. This involves generating a very large synthetic construct of the viral genome, which is extremely difficult and time consuming. Therefore, we use two strategies to investigate the risk of PREDICT CoVs and PMV: 1) We use surrogate experimental systems to evaluate just the important parts of the virus. In this case, we focus only on the receptor binding domain (RBD) in the spike protein, rather than the whole virus, and test whether it is able to mediate entry into human cells. The advantage of this approach is that it can be done quickly and give us a good (but preliminary) assessment of the zoonotic risk. This work is done with our partners at the NIH Rocky Mountain. 2) While this work is ongoing, we start to reverse engineer the full virus, so we can investigate cell-entry in the context of authentic virus. This work is done at the Center for Infection and Immunity, Mailman School of Public Health, Columbia University. This can take 6-12 months to generate a construct and test it which is why we use both approaches.

**Commented [TD24]:** Waiting to hear from Simon that same technique for Cov and PMV

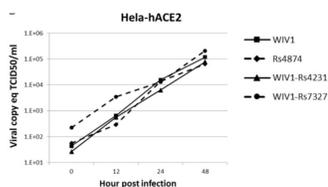

For Peninsular Malaysia we have 1438 serum samples from Orang Asli (1390 from current study and 48 archived samples), 560 serum samples from bats, 167 serum samples from rodents and 1022 serum samples from NHPs, 301 bat biopsy samples, 123 rodent biopsy samples and 3845 NHPs biopsy samples. For Sabah we have 10 serum samples from syndromic surveillance patients, 1179 serum samples from bats, 485 serum samples from rodents and 83 serum samples from NHPs, 294 bat biopsy samples, 114 rodent biopsy samples and 62 NHPs biopsy samples. Biopsy samples include brain, heart, lungs, liver, kidney, spleen, large and small intestine.

**Commented [KJO25]:** More from Tom. With this comment: **Malaysian colleagues please can you add details here of any archived samples you have that could potentially be included in this proposal using similar level of detail to the above.**

**Commented [KJO26]:** Think we need to shorten the CoV part of this from the previous NIH. I’ve added in some basic info and refs on Henipas and Filos in a separate section below (for now), but Ralph/Linfa/Dani/Chris/Eric should check and ideally we integrate into one section. WE need to specify what labs are doing what!

*In vitro & in vivo characterization viral potential for human infection for Coronaviruses:* We have used *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs protein sequences from bat feces: WIV1, WIV16 and Rs4874, with S that diverged from SARS-CoV by 3% to 7% (20,

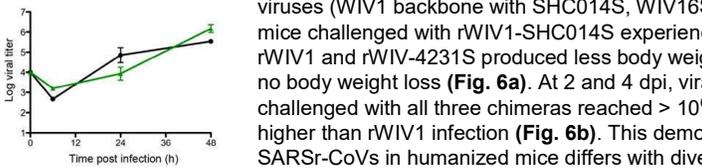

**Commented [PD27]:** Ralph, Amy – this is directly from our CoV R01 renewal – **please reduce the length of this section** and adapt for this proposal. We prob don’t need all these figures – just one or two would do.

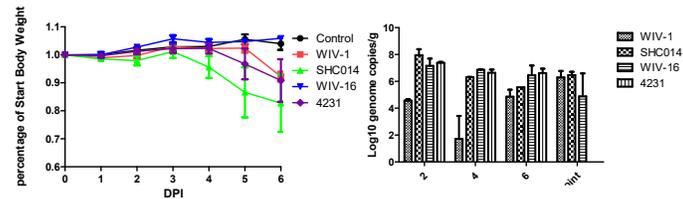

58, 93). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs from a specific cave site in Yunnan China, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (58). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of different variants, including WIV1-Rs4231S and WIV1-Rs7327S. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in HeLa cells that don't express ACE2 (20, 58, 93) (**Fig. 5a**). We used the SARS-CoV reverse genetics system (70) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (59) (**Fig. 5b**). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry.**

**Fig. 5a (left):** RT-PCR shows that bat SARSr-CoVs WIV1, Rs4874, and chimeras WIV1-Rs4231S, WIV1-Rs7327S grow in HeLa cells expressing human ACE2. **Fig. 5b (right):** Viral replication of SARS-CoV Urbani (black) and SARS-SHC014S (green) primary air-liquid interface human airway epithelial cell cultures at an MOI of 0.01.

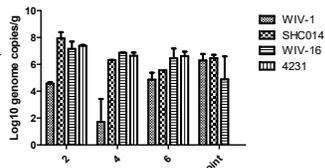

We infected transgenic mice expressing hACE2 with  $10^5$  pfu of full-length recombinant WIV1 and three chimeric viruses (WIV1 backbone with SHC014S, WIV16S and Rs4231S), hACE2 transgenic mice challenged with rWIV1-SHC014S experienced ~20% body weight loss by 6dpi; rWIV1 and rWIV1-4231S produced less body weight loss, and rWIV1-WIV16S led to no body weight loss (**Fig. 6a**). At 2 and 4 dpi, viral loads in lung tissues of mice challenged with all three chimeras reached  $> 10^6$  genome copies/g, significantly higher than rWIV1 infection (**Fig. 6b**). This demonstrates that pathogenicity of SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the**

**value of this model in assessing novel SARSr-CoV pathogenicity.**

**Fig. 6:** *In vivo* infection of SARSr-CoVs in hACE2 transgenic mice. **6a (left)** Body weight change after infection; **6b (right)** Viral load in lung tissues.

Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity.**

Vaccination against SARS-CoV did not reduce severity of clinical signs in mice subsequently infected with rSARS-SHC014S (59). We found 2/4 broad human mAbs against SARS-CoV RBD cross-neutralized WIV1, but none could efficiently neutralize SHC014 which is less similar to SARS-CoV in the RBD (94). We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they are unable to use the ACE2 receptor.** Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines. **The ability of HKU3r-CoVs to infect people, and their receptor binding target, remain unknown.**

**All – what can we say about Nipah and filoviruses in this section – what is the rationale for a similar approach (e.g. we're looking for viruses somewhere between Cedar and Nipah in the Henipaviruses, and trying to assess the likelihood of some of the novel filoviruses infecting human cells).**

**Are we just going to use cell culture for henipavas and filovs, or can we look at spike protein diversity?**

**What about using bat cell lines and batized mice from Linfa?**

**In vitro & in vivo characterization viral potential for human infection for Henipaviruses and Filoviruses**

A similar approach to the above pipeline for CoVs will be applied to novel Henipaviruses and Filoviruses we discover during our research.

*Henipaviruses*

**Commented [PD28]:** Ralph, Amy, Linfa, Danielle, Chris, Eric – need details for what approach we'll use for henipavas and filovs

**Commented [KJO29]:** Think we need to shorten the CoV part above and still incorporate more for Henipavas and Filovs. For now some info below, but Ralph/Linfa/Dani/Chris/Eric should check and try to integrate into one section with additional info on the Cedar virus work, Mojiang, etc.. WE also need to specify what labs are doing what!

**Commented [KJO30]:** General question, do we want to limit to Henipavas, or keep more general to Paramyxoviruses? Do we care about Rubulaviruses, etc.

**Commented [KJO31]:** Ralph: [Am J Pathol.](#) 2003 Dec;163(6):2371-82 Primary human lung endothelial cells are highly susceptible to EBOLA virus infection, so we can use these cells. Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (Viruses. 2019 Feb 16;11(2). pii: E161. ) Huh7 cells also offers advantages for reverse genetic recovery of novel filoviruses ([J Infect Dis.](#) 2015 Oct 1;212 Suppl 2:S129-37. )

We have growth curves of Nipha and Hendra in Calu3 cells, a continuous lung epithelial cell, including a variety of host expression changes after infection. Likely grow in primary human airway cultures as well as they infect ciliated and secretory cells ([J Gen Virol.](#) 2016 May;97(5):1077-86. ). Nipha and hendra also infect primary human microvascular endothelial cells, like mers and ebola ([PMC3477106](#), [PMC3791741](#)). I'm less sure what kind of neural cell should be used for Nipha and Hendra.

Some evidence for nipha and Hendra replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (PMC4057804, PMC3393746). Thus it is likely these models could be improved in the collaborative cross mouse resource here at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted ebola infections.

Hendra virus and Nipah virus have a broad mammalian tropism with natural infection recorded in bats, horses, pigs, humans, cattle, goats and dogs. This broad-species tropism is likely mediated by henipavirus receptor usage of highly conserved ephrins ligands (e.g. ephrin-B2 and -B3) for cell entry. Ephrins are critical in evolutionary developmental process such as cell migration, axonal guidance and angiogenesis (REF), and ephrin tissue distribution correlates with the multi-systematic cellular pathology, vasculitis and encephalitis disease presentation during HeV and NiV infection. The third isolated henipavirus is Cedar virus, yet unlike NiV/HeV, CedV does not cause pathogenesis in animal models. Recently, Dr. Broder and Laing have developed a reverse genetics system for Cedar henipavirus and have rescued a recombinant Cedar virus that is used as a model henipavirus tool to understand how ephrin receptor usage/tropism contributes to pathogenicity during henipavirus infections. Ephrin-B3 is distributed in the spinal cord, and usage of ephrin-B3 has been postulated to underlie the enhanced encephalitis seen during NiV infection. Further dissimilar from HeV/NiV, CedV is unable to utilize ephrin-B3 as a receptor (Marsh 2012; Laing 2018) nor does it express the interferon antagonizing virus factors: V and W proteins (Marsh 2012). However, Dr. Broder and Laing have discovered that CedV has a promiscuous/broad ephrin receptor usage and in addition to ephrin-B2 is able to utilize ephrins-B1, -A2 and -A5 for cell entry (Can include microscopy image/column graph for unpublished figure). Additionally, it was discovered that CedV can utilize mouse ephrin-A1, which differs from human ephrin-A1 by one amino acid residue in the key binding pocket, demonstrating the first evidence of henipavirus species-specific receptor use (Can include unpublished figure). Like ephrin-B3, ephrin-B1 is widely distributed throughout spinal cord tissues, however, CedV is non-pathogenic. Pathogenicity of henipaviruses is likely mediated by a contribution of both utility of ephrin receptors and expression of virulence factors V and W proteins. The full genome assemblies of putative henipaviruses, Ghana virus and Mojiang virus, predict expression of V and W proteins. GhV is able to bind to ephrin-B2, but not -B2 (Lee – African emergent henipavirus B2 crystal) and the receptor for MoJV remains unknown (Lee, idiosyncratic 2017), but is unlikely an ephrin. Thus, when we identify novel henipaviruses or paramyxoviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize molecular experimentation with novel henipaviruses that are predicted to interact with ephrin-B2 and expression V/W proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models.

For novel Henipaviruses we will assess ability to infect human cells using a continuous lung epithelial cell line, Calu3, that our group has previously used to generate data on NiV and HeV growth curves (95). We will also use primary human airway cultures to assess human infection for Henipavirus and MERS- and SARS-related CoV (96) (97). There is some evidence for Nipah and Hendra virus replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (98, 99). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted ebola infections.

[Am J Pathol](#). 2003 Dec;163(6):2371-82 Primary human lung endothelial cells are highly susceptible to EBOLA virus infection, so we can use these cells. Huh7 cells are good candidates for ebola in the liver, oftentimes used to isolate virus from clinical samples (Viruses. 2019 Feb 16;11(2). pii: E161. ) Huh7 cells also offers advantages for reverse genetic recovery of novel filoviruses ([J Infect Dis](#). 2015 Oct 1;212 Suppl 2:S129-37. )

#### Attachment Glycoprotein has greater genetic diversity

Thus far, paramyxovirus attachment glycoproteins have been divided into three major groups: hemagglutinin (H), hemagglutinin-neuraminidase (HN), and attachment glycoproteins (G)

pon mapping sequence conservation between GhV-G and MojPV-G onto the GhV-G-ephrinB2 co-crystal structure, it becomes apparent that MojPV is unlikely to utilize ephrinB2 receptor (100)

Cedar uses Ephrin B, but doesn't cause disease. reverse genetics of Henipap - would need to be done in BSL4, pseudovirus can do in BSL 2, but no pathogenesis. Benhur Lee has done similar work to what Ralph has done, structural comparison w diff receptors for Cedar, Henipap, and ferret model. Doesn't express G protein and is therefore less pathogenic.

Mojiang diff cell binding: <https://www.nature.com/articles/ncomms16060>

" Furthermore, we find that MojV-G is antigenically distinct, indicating that MojV would less likely be detected in existing large-scale serological screening studies focused on well-established HNVs. "

### 1.2 General Approach:

We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new collection from wildlife in high risk locales. We will use serological & PCR testing, to identify viruses, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will then conduct *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease. EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses.

A key goal of this work will be technology transfer to the region, including cell culture, animal models, serological and PCR diagnostics, as well as knowledge transfer by embedding staff in partner labs and by regular meetings. This will leverage substantially from the other funding available to consortium partners.

A key goal of this work will be technology transfer to the region, including cell culture, animal models, serological and PCR diagnostics, as well as knowledge transfer by maintaining our current team members and embedding additional staff in partner labs, supporting one Malaysian PhD student and by regular meetings. This will leverage substantially from the other funding available to consortium partners. The PhD student Mei Ho Lee is part of the CM Ltd team and has worked with the collaborators on this project for 9 years. Mei Ho will enroll at the Faculty of Tropical Medicine at Mahidol University in Bangkok. The focus of her study will be to further investigate the infection potential of some of novel Cov and PMV viruses found in Malaysia through PREDICT.

CM/EHA helped establish and manages with SWD the Wildlife Health, Genetic and Forensic Laboratory (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications) that has all the equipment necessary to store samples, run extractions, PCR and analysis on biological samples for wildlife disease surveillance. The lab is used to conduct health checks on rescued and relocated wildlife before being released into new areas or sanctuaries, to screen samples for the PREDICT and Deep Forest Project and for genetic research and forensic investigations. CM/EHA also helped establish the new molecular zoonosis laboratories (certified as a BSL- 2 laboratory according to the US standard for laboratory specifications), at DWNP's National Wildlife Forensic Laboratory. The lab is used to screen samples for the PREDICT & DTRA projects. In addition CM/EHA also has access to NPHL and KKPHL for screening human samples and the Virology lab at FVMUPM for screening Livestock samples.

Through this project we will help to establish a certified BSL-2 lab at the BMHRC. This lab can then be used for human testing to alleviate pressure at KKPHL and QEH labs. It would also be an ideal location for a Luminex platform as human, wildlife and livestock samples could all be screened here. Co-Is Hughes and Kamruddin will be starting outbreak response training in August 2019 with a team from Sabah CDC, KKPHL and BMHRC. (Dr. Maria Suleiman now in PM But still collaborating with us, Dr. Muhammad Jikal current Director CDC

working with us and Dato' Dr Cristina Rundi Director Sabah state health Dept is supportive) this collaborative group is working to develop a Sabah outbreak response team that will help support SSHD/ CDC outbreak team and also conduct sampling for disease surveillance to be based at BMHRC and we will develop this as part of this proposal. In addition the UMS hospital will come in line in 2021 providing additional opportunities for cohort studies and capacity building.

Commented [KJO38]: From Tom.

**1.3 Wildlife samples: 1.3.a Geographic and taxonomic targeting for newly collected wildlife samples**

Adapt text from the rationale/innovation above and make brief statements about the work we'll do:

Commented [KJO39]: Peter, I'll clean ups this section a little more and flesh it out while you are working on this draft.

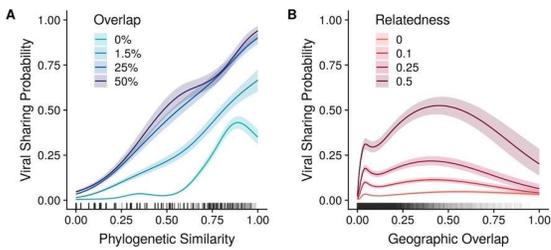

- Geographic targeting: we will use refined hotspot, 'missing viruses', and FLIRT analyses
- Targeting of host species/viral discovery targets: We will use phylogenetic MCC analyses and viral discovery curves
- Additional approaches: mapping of cave sites,

Commented [KJO40]: From Tom: We should consider wildlife sampling at –

- Danum Valley, Sabah
- Tabin Forest Reserve, Sabah
- Around Orang Asli settlements PM (focus on Kedah, Kelantan, Pahang and Perlis),
- Around Dayak settlements in Sarawak
- Kubah National Park, Sarawak
- Batu Supu Sabah low disturbance cave and surrounding area
- Madai medium disturbance cave and surrounding area
- Gomantong high disturbance cave and surrounding area
- Caves in Peninsular Malaysia

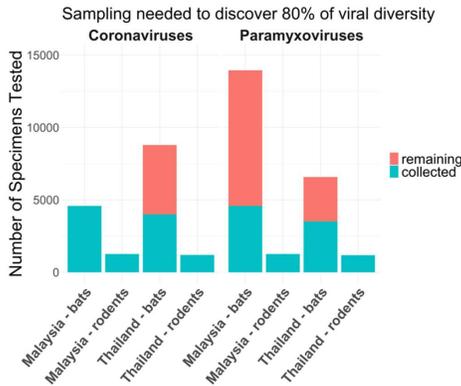

Using network analyses and a phylogeographic model of host range we recently developed [REF- Greg], we will prioritize additional wildlife species to be sampled and tested for the known and novel viruses we discover. Applying a generalizable model that includes just two phylogeographic traits (wildlife species range overlap and phylogenetic similarity between host species, Fig X.), we are able model the viral sharing network for 4200 mammal species and successfully predicted known hosts above 98% of other mammal species.

Commented [PD41]: Please check section 1.4.b and see if parts of that should be here..

**1.3.b Sample size justifications for testing new and archived wildlife specimens**

To calculate sample sizes, we will use our preliminary data on average prevalence from screening bat, rodent and primate specimens for CoVs, PMVs, and FVs under PREDICT in Malaysia and Thailand, previously published data, and our viral discovery curve analyses (Fig 5) to determine the required samples sizes to maximize discovery of wildlife viruses with zoonotic potential.

**Figure X.** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMVs from high-risk bat and rodent taxa in Malaysia and Thailand. Estimates of predicted viral richness calculated from viral discover curve analysis (Fig 5) using data from thousands of wildlife specimens that we have previously tested and sequenced.

In Y1 we will use our bat host and viral trait modeling, phylogeographic analyses of RdRp and S Protein sequences, and geographic and host species-based viral discovery curve analyses to identify SARSr-CoV diversity hotspot regions for bat sampling. We will sample at 8 new sites in four provinces. We will use cave site data (101), and demographic information to identify two sites in each

Commented [BRS42]: CoV specific, ebola and nipa/Hendra have different spike glycoprotein designations and polymerase designations.

of Yunnan, Guangxi, Guangdong, and Guizhou where humans likely have contact with bats. In Yunnan, we will identify two unsampled caves close to, but distinct from, the Jinning cave (58). This will provide adequate coverage of lineage 1 and 2 SARSr-CoVs, including a rich source of new HKU3r-CoVs, which have unknown potential for zoonotic spillover. Sampling will begin towards the end of Y1. We will use survey data from our previous R01 and host-specific viral accumulation curve data to target an additional 10 under-sampled *Rhinolophus* spp., 5 that were SARSr-CoV negative in our study, and a small number of related bat genera (including *Hipposideros* spp. and *Aselliscus* spp.) we previously found PCR positive for SARSr-CoVs (Table 1). We will sample at least 5,000 bats from these 4 provinces (~1250 per province). Given ~5-12% prevalence of SARSr-CoVs in *Rhinolophus* spp. at our previous sites, **this sample size would give us 425 (±175) positive individual bats, and ~125 novel strains.**

**1.3c Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C. One-step hemi-nested RT-PCR (Invitrogen) will be used to detect the presence of CoV sequences using primers that target a 440-nt fragment in the RNA-dependent RNA polymerase gene (RdRp) of all known  $\alpha$ - and  $\beta$ -CoV (102). PCR products will be gel purified and sequenced with an ABI Prism 3730 DNA analyzer.

We will attempt isolation on samples that contain viruses of interest (determined in 1.4, below), using Vero E6 cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). This includes the over XX cell lines maintained at Duke-NUS.

**1.3d Moving beyond RNA viruses:** [Show how our platform is generalizable to other pathogen groups and non-RNA viruses i.e. using conserved PCR assays and vircapseq. If and when depending necessary on EID-CC research projects and outbreaks detected in the region from DNA viruses or other agents]

**1.3.e Sequencing S proteins:** *Our working hypothesis is that many zoonotic SARS-like, MERS-like, filoviruses and henipaviruses encode spike glycoproteins that program efficient infection of primary human cells (e.g., lung, liver, etc.).* For example, our previous R01 work identified diverse SARSr-CoVs with high propensity for human infection (15, 58, 59). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (Fig. 4) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are undersampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (20, 59, 103), suggesting that. However, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic spike genes of MERS-like, Ebola-like and Nipha/Hendra like viruses will also program efficient entry via human ortholog receptors.

For all novel SARSr-CoV strains, we will sequence the complete S gene by amplifying overlapping fragments using degenerate primers as shown previously (20, 58). Full-length genomes of selected SARSr-CoV strains (representative across subclades) will be sequenced via high throughput sequencing method followed by genome walking. The sequencing libraries will be constructed using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR will be performed to fill gaps in the genome. The full length S gene sequences, including the amount of variation in the S receptor binding residues that bind the ACE2 receptor, will be used to select strains for Aim 3 experiments.

**Commented [BRS43]:** Chinese locations? Do we have equivalent cool bat caves in Malaysia, Thailand, etc? to chase bat viruses in?

**Commented [BRS44]:** Don't forget about the novel MERS-like CoV discovered in the region (PMC6002729) and that can use the human receptor (don't be so SARS centric).

**Commented [KJO45]:** I still need to rework this.

**Commented [PD46]:** Ralph, Amy, Linfa, Danielle, Chris, Eric - This is from our CoV R01. Please insert details that apply also to henipa and filoviruses.

**Commented [KJO47]:** Should we just rely on PREDICT PCR protocols for PMVs and Filos? We can add in methods from PREDICT protocols. Unless there are better screening assays to use?

**Commented [PD48]:** Linfa, Supaporn, Danielle - is this correct?

**Commented [PD49]:** Brief description of these please

**Commented [KJO50]:** Added this b/c noted on call w Linfa.

**Commented [PD51]:** Ralph et al. - I'm assuming this will still be of value for the CoVs, so a reduced version of this could be in here, but what about spike proteins of filoviruses and henipaviruses - is that not of any use for assessing their capacity to infect human cells. Can we do similar work with filovirus pseudotypes from sequencing the spike proteins, for example, to assess binding to human receptors? If so, please draft some text and point to some references

**Commented [KJO52]:** Not sure these are "Spike" genes for PMVs and Filos?

**Commented [BRS53]:** Way too specific. We should do spike genes of all novel CoV, including searching for elusive group 1 or group 2 CoV (group 2d, 2e, etc.) that have the potential to replicate in human cells (intestinal CaCO2 or lung HAE....noting that bat CoV are enteric pathogens so human CaCO2 may be likely target). Same with filoviruses and nipha/Hendra like strains.

**1.4. Assessing risk for spillover. 1.4.a Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, Filoviruses and *Henipaviruses*, we will use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (59, 60, 104). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other virus strains (61, 69). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (60, 92). As controls or if antisera is not available, the S genes of novel SARSr-CoV or structural genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (105). Polyclonal sera against SARS-like viruses will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (60, 106, 107). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (108) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (109-111). Similar approaches will be applied to MERS-like viruses, other CoV, filoviruses or henipaviruses

Filoviruses (primary endothelial cells – ralph has primary lung endos – see if anyone has liver primary hepatocytes. Other option are monocytes) – where will we do this? BSL4? (NEIDL). Duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (See letter of support) for culture and sharing with other agencies. Check on this re. wildlife filoviruses... See if can do training opportunities so they can work with the NEIDL – visiting scholar appointments

**1.4.xx Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the *intraspecific* scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (68).

**1.4.b Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RdRp (or L genes), Spike glycoproteins, and full genome sequence (when available) data to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, filoviruses and henipaviruses that we identify. We will rerun MCC analyses (Fig. 3) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR-positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (Fig. 4) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) or other virus families within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (91, 112).

**1.4.c Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of

**Commented [BR554]:** Can we get our hands on the live Chinese ebola like strains? We could try to use reverse genetics to recover, although I personally have no documented success with filovirus reverse genetics. Am familiar with approach and the bsl4 in boston should allow recovery.

**Commented [PD55]:** Ralph, Linfa, Chris – please expand and draft – I think this could be a good role for NEIDL, but don't know what the rules are...

**Commented [BR556]:** Check my comments above, I covered this completely and the situation is good.

**Commented [BR557]:** A lot of variation in the NPC1 receptor alters EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains ([J Infect Dis](#), 2018 Nov 22;218(suppl\_5):S397-S402.) [PMC4709267](#)  
Second paper says: *We found signatures of positive selection in bat NPC1 concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in Eidolon helvum cells. Our work identifies NPC1 as a genetic determinant of filovirus susceptibility in bats, and suggests that some NPC1 variations reflect host adaptations to reduce filovirus replication and virulence.*

*Nipha and Hendra use ephrin B2 or ephrin B3 as a receptor, and variation effects its ability to use human vs bat receptor molecules*  
([PMC4418902](#), [PMC2045465](#))

**Commented [PD58]:** Kevin/Ralph – I don't think this is relevant for our EIDRC – please let me know and delete if correct.

**Commented [PD59]:** KKevin/Alice – please modify this section for filoviruses and henipaviruses as well (and other hosts) – or does it belong in 1.3.a above?

**Commented [BR560]:** Way to sars centric

antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (92, 113-115).

**1.4.d Animal models: Transgenic Mice.** We will use a series of mouse models to assess spillover potential of viruses. First, the Baric lab has a well-established hACE2 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect. This group also has transgenic mice expressing hDPP4 receptors (PMC5578707, PMC5165197). Briefly, in BSL3, n=5 10- to 20-week old hACE2 or hDPP4 transgenic mice will be intranasally inoculated with  $1 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins or MERS-CoV and MERS-like CoV, respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV or MERS-CoV mAbs (PMC4769911, PMC4547275) will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (104, 116). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (60, 104).

**Models of Outbred Populations.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments. We have used this model for CoV, filo (Ebola), Flaviviruses, and alphaviruses infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection ( ).

Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (117). Both animal systems can be used to test susceptibility, pathogenesis and immune responses of any newly discovered viruses.

**1.5 Potential problems/alternative approaches: Permission to sample bats in sites or provinces we select.** We have a >20-year track record of successful field work in Malaysia, Thailand and >10 years in Singapore, and have worked with local authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based on a range of PCR data and are fairly conservative in our approach. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses. The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (118), do not suggest a strong pattern of seasonality in CoV shedding, although there are studies that suggest this occurs in henipavirus and filovirus (MARV?) shedding (REFS?). Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province.

**Commented [PD61]:** Ralph – can you reduce this section to a feasible amount of work for this project, and remove a bunch of text

**Commented [BRS62]:** We need to do this with novel Nipha/Hendra and EBoV as well.

**Commented [PD63]:** Ralph – please draft a brief para explaining what we'll do with this mouse model

**Commented [BRS64]:** Trends Genet. 2018 Oct;34(10):777-789.

**Commented [PD66]:** Linfa/Danielle – please draft a brief para explaining how we'll use either or both...

**Commented [PD67]:** Kevin – please edit/check

**Commented [PD68]:** Kevin – please check the veracity of these comments

**Aim 2: Test evidence of viral spillover in high-risk communities using novel serological assays.**

**2.1 Rationale/Innovation:** Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that are the first to get infected. To enhance low statistical probability of identifying these rare events, populations will be targeted that both live in rural locations close to high wildlife biodiversity, and also engage in practices that enhance the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will expand from our current work in the region to identify and enroll large cross-sectional samples from human populations that have a high behavioral risk of exposure to wildlife origin viruses and live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will initially identify X-X sites in each Thailand, Peninsular Malaysia, Sarawak, and Sabah for repeated biological sampling of high-risk human communities, design and deploy specific and sensitive serological assays to identify the baseline spillover of known or novel viral pathogens in these populations. In participants where symptoms are reported samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, attempt to isolate and biologically characterize the pathogen, using the collaborative cross mouse (Aim 1) to identify an appropriate animal model to conduct preliminary pathogenesis work.

At the time of writing, a currently undiagnosed outbreak in the Batek Orang Asli (indigenous) population living in Gua Musang (“civet cat cave”) district, in Kelantan, Malaysia has infected dozens of people and is currently being investigated by our colleagues at NPHL. The Orang Asli live in remote villages in the rainforest of Malaysia, with limited access to modern health care and extensive contact hunting, butchering, and eating wildlife as their primary source of protein. This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC -- to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia.

**Preliminary data human biological sampling:** Our longterm collaboration in the region has included identification of key at-risk human populations using previously collected qualitative and quantitative survey data, and developing and gaining access to large archives of banked human sera and other biological samples. In the last 5 years under the USAID-PREDICT project, EHA has collected 9933 and 9269 human specimens in Malaysia and Thailand, respectively, which will be available for retrospective serological testing under our proposed work. Other studies from our research team have included the collection and testing of many thousand more specimens from community cohorts. Preliminary findings and details from these data and other research from are listed below:

**Peninsular Malaysia:** Data from 1390 Orang Asli samples, screened by PCR for 5 viral families found: 4 known CoVs in 16 people and one known Influenza virus in one person. Serology screening is ongoing but preliminary screening as part of training government partner to use the Luminex serology platform found serological evidence of past exposure to Nipah and Ebola antigenically-related viruses in people.

**Sabah:** Data from 10 Syndromic Surveillance samples, screened by PCR for 5 viral families found: 1 known virus - Human Parainfluenzavirus 2 (GenBank Accession No.AF533011) in the family Paramyxoviruses. Serology screening is yet to start.

**Kamruddin (UMS Borneo Medical Health Research Center)** has identified some high risk communities.

Tim, Giri, Tsin Wen has archived samples from Kudat Monkey bar project – 2,000 human sera already screened for bacteria and parasites, we’ve been reached out to about this. Data on macaque tracking data/human tracking data also. Encephalitis study etc Dr. Yeo Tsin Wen, DUKE-NUS, Singapore – Has worked with Giri and tim on knowlesi work with communities – 2000 selected villagers 500micros looking for

**Commented [KJO69]:** We can make this aim all about human serology, and 3<sup>rd</sup> aim more about molecular characterization of human pathogens and outbreak etiologies.

**Commented [KJO70]:** Emily: Will we be sampling participants more than once?

**Commented [KJO71]:** Need to decide if we do PCR on community samples, we can add in the questionnaire if you’ve been sick in the last 10 days and if so, then maybe test only this subset.

**Commented [KJO72]:** [https://en.wikipedia.org/wiki/Gua\\_Musang\\_District](https://en.wikipedia.org/wiki/Gua_Musang_District)

**Commented [KJO73]:** From Tom email.

**Commented [PD74]:** All – please read and share with collaborators to flesh out and correct details here.

**Commented [T75]:** Unpublished

**Commented [KJO76]:** Previous text from PD: We have ~25 new CoVs in Sabah. Simon is using HTS to further characterize and Tom will get the data for this proposal from Simon

**Commented [T77]:** Malaysian colleagues please can you add details here of any human sampling and findings from those studies that are relevant to this proposal

**Commented [T78]:** These are from wildlife so I have moved to “Identify Known and novel” section above

**Commented [KJO79]:** From PD: Kamruddin (UMS Borneo Medical Health Research Center) has identified some high risk communities. We can help with them and build out the BSL-2 lab, as well as work on outbreak response within DHRU (in collab with Sabah CDC?).

asymptomatic parasitemias – led by King Fonese from LSTMH – 10,000 people – archived serum samples (prob 2-3,000 – in London, KK)

Commented [KJO80]: From Tom

*Sarawak:* Dr Tan (Cheng Sieng) Center for Tropical and Emerging Diseases, Faculty of Medicine at UNIMAS – high risk Dayak communities that he’s identified. We will do further sampling, questionnaires etc. Has Prelim data on HPV work in Dayak communities in remote Sarawak – we can work with those communities and can reach many by car, others by 4WD or boats. Has also Enterovirus 71 paper and is interested in CoVs. Has access to caves and guano. Will look into what other archived samples he has. Will give us access to Sarawak Forestry and Health Depts.

*Thailand:* We have conducted longitudinal community-based surveillance for the last 5 years in two villages (Chonburi and Ratchaburi provinces) at high risk of infection from bats. In Chonburi province we sampled and tested over 300 villagers living around the largest population of flying foxes (*Pteropus lylei*), at a temple (Wat) roosting site where we have seasonal detections of Nipah virus from bat urine each year (with viral shedding peaking in May-July. Serological screening of monks and We also have sampled and tested over 300 villages from Ratchaburi province, including a population of bat guano miners, and workers from Department of National Parks – both of whom have extensive contact with wildlife in the area. We previously detected a MERS-like CoV in the bat guano being harvested (48). Molecular screening of guano miners identified human CoV, HKU1 strain, with high viral load in one healthy bat guano miner and our team was able to obtain the whole genome sequence from a clinical specimen from this individual (119). No evidence of novel bat CoVs have yet been detected in these populations.

*US CDC (Thailand):* A large cohort of children from the Kamphaeng Phet Province, Thailand were enrolled as part of a multi-year study (1998-2002) to examine the epidemiology of dengue virus (DENV) and Japanese encephalitis virus (JEV) (120, 121). From 2,574 paired serum samples, 784 (30%) convalescent sera were selected at random among samples drawn between 1998-2002. Among the 784 samples tested, subjects ranged in age from 6 to 16 years (mean 9 years) and 51% were male. Henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence) by Enzyme-linked Immunosorbent Assay (ELISA) using a soluble highly-native recombinant G glycoprotein (sG<sub>NiV</sub> and sG<sub>HeV</sub>) capture antigens. The ELISA endpoint titers for sG<sub>NiV</sub> reactive samples ranged from 1:20 to 1:1280, with six of the thirteen samples exhibiting a titer of 1:640 or greater. Although none of the samples inhibited NiV or HeV infection *in vitro*, 3 of the **13 ELISA sero-positive patient serum samples** reacted with denatured G antigen in Western blot. **The presence of henipavirus-specific antibody responses suggests prior exposure to endemic henipaviruses or a henipa-like virus in rural Thailand.** The presence of pre-existing henipavirus antibodies among these children in Thailand suggest that “background” henipavirus infections do occur and were self-limited illness without serious health impacts.

*Singapore:* No active human surveillance will be conducted in Singapore, but archived human specimens (REFS, e.g. Melaka virus serosurvey) will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

Commented [PD81]: Linfa, Danielle – are we going to do human sampling in high risk communities in Singapore? If so, what would you propose and do you already have some prelim work you’ve done. Note these are high risk populations, i.e. high exposure to wildlife. Clinical cohorts are in Aim 3

*Human Contact Risk Factors:* EHA is the lead global organization in the USAID-PREDICT project for characterizing the human aspects of zoonotic spillover risk. The approach began by conducting exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities (e.g. we interviewed 88 people involved in trading wild bats in China – REF). This allowed us to assess the local social and cultural norms and individual attitudes underlying wildlife contact. We used these study findings to develop a risk survey to accompany human biological samples to evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in >15 countries during the last 5 years,

Commented [PD82]: Hongying/Emily to edit

Commented [EH83]: For the survey and biological data collection we worked with 27 countries an managed 11

For Qualitative work we oversaw 13 countries

and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). Survey and biological samples were collected from 1,585 participants from 7 sites in China in Yunnan, Guangxi, and Guangdong provinces, 1,400 participants from 4 sites in Malaysia and 678 participants from 4 sites in Thailand. During this study serological assays were developed for implementation in China, and survey responses and demographic data suggest specific risk factors included type of occupation, keeping of pets and visiting wet markets. Seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), and are male (6/9). However, these characteristics were common and occurred in ~40% of survey respondents. Although these results are preliminary and don't provide detailed information on routes of exposure, they suggest that further refining of tools for serological tests coupled with survey data will identify likely routes of exposure to CoVs, novel CoVs, Henipavirus, and Filoviruses in our expanded study. The results of these surveys will be used in Aim 2 of this EIDRC proposal to better identify target populations and in Aim 2, we identify strategies to better target at-risk people, and conduct focused **human animal contact surveys and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.**

Commented [PD84]: Hongying/Emily – any information from Thailand or Malaysian surveys?

Commented [KJ085]: Edits from Emily.

**Behavioral-risk: Clinical meta-data to assess human-animal contact:** EHA is the global lead organization in the USAID-PREDICT project for assessing the risk of zoonotic spillover, including extensive behavioral surveys in high-risk populations under this award. Our general approach has been to conduct qualitative exploratory studies using standardized one-on-one semi-structured ethnographic interviews and observational data in among people engaged in clearly high-zoonotic risk activities (e.g. we interviewed 88 people involved in trading wild bats in China – REF). This allows us to assess local social and cultural norms and individual attitudes underlying wildlife contact. We used qualitative study findings to develop a human behavioral risk questionnaire on the type and frequency of animal contact, wildlife observed in daily life, and unusual illnesses reported over the past 12 months. Under our USAID-PREDICT project, we conducted cross-sectional studies in high risk populations in >15 countries during the last 5 years. In total, we have enrolled ~~XX,XXX~~ participants who have provided serum, nasopharyngeal, oral, and fecal samples and each completed behavioral risk questionnaires to assess animal contact. Questionnaires and biological samples were collected from 1390 participants from 9 sites in the Districts of Gua Musang, Kuala Lipis and Kuala Kangsar Malaysia, 10 syndromic surveillance patients at the Queen Elizabeth Hospital in Sabah, and 673 people from 3 sites in Thailand. The results of these surveys will be used in Aim 2 to better identify target populations.

Commented [PD86]: Hongying/Emily to edit

Commented [KJ087]: Make sure to delete most reference to “Behavioral” research throughout, but okay to do some surveys to collect “clinical meta-data”.

Commented [KJ088]: Sum up for ALL countries?

Commented [KJ089]: Same as paragraph above, but including my and Tom's edits.

**Serological Evidence of Exposure:** In China, we developed serological assays for HKU9 CoVs ( $\beta$ ), SARSr-CoV Rp3 ( $\beta$ ), HKU10 CoV ( $\alpha$ ), and MERS-CoV ( $\beta$ ) and used ELISA and Western blot to test serum samples collected in 2016/17. **We found 7 individuals (7/733, 0.95%) living within a 6 km radius of the Jinning Cave, and 6/209 people (2.87%) at one site, with evidence of exposure to bat SARSr-CoVs.** We found evidence among human populations in Guangxi Province of people with prior exposure to the bat  $\alpha$ -CoV HKU10 (2/412, 0.48%). This is of potential public health interest because HKU10 is known to be able to jump host species within bats, and therefore may have high propensity for emergence (122). However, the low seroprevalence (0.6%-2.7% at positive sites) suggests we need a larger sample size, and a focused, targeted study to maximize the likelihood of identifying seropositive cases. In Aim 2, we will use combined biological-behavioral risk surveillance in targeted populations within the community and clinical settings to 1) identify risk factors correlated with seropositivity (exposure to) and PCR positive status (infection with) henipaviruses, filoviruses and CoVs; and 2) assess possible health effects of infection in people. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

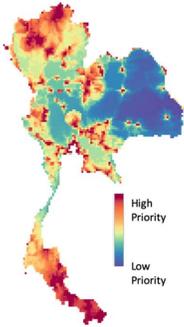

**Risk Factors:** In China, questionnaire response and demographic data suggest specific risk factors included type of occupation, keeping of pets and visiting wet markets. Seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), and are male (6/9). However, these characteristics were common and occurred in ~40% of survey respondents. Although these results are preliminary and don't provide detailed information on routes of

Commented [PD90]: Hongying/Emily – any information from Thailand or Malaysian surveys?

exposure, they suggest that further refining use serological tests coupled with qualitative and questionnaire data will identify likely routes of exposure to novel CoVs in China. In Aim 2 of this EIDRC proposal, we identify strategies to better target at-risk people, and conduct focused **questionnaires and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.**

**2.2 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (**Fig. XX**). In Aim 2 we will conduct community-based surveillance with a focused questionnaire to identify the prevalence and frequency of risk-factors for viral spillover in these communities in tandem with biological sampling to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the community-based surveillance sites of Aim 2 (details in Aim 3). Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological/PCR status and symptoms.

**2.3 Target population & sample sizes:** We will target sites in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, in regions that are EID hotspots, and are well-connected to regional travel and trade hubs and the global travel network (Fig X). We will target specific communities based on our analysis of the previously collected PREDICT behavioral questionnaire data to assess key at-risk populations and occupations with high exposure to wildlife, as well as using other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will also expand on work currently underway in the following particularly high exposure populations:

**Fig X.** Preliminary analysis of geographic sites to target for human zoonotic disease surveillance in Thailand. Novel spatial analysis optimizes site selection by ranking areas with high numbers of expected viruses in wildlife and greater human access to these sites using road density data.

**Thailand:** In 2018 We have conducted behavioral risk surveys and biological sampling in 117 guano miners and the communities in Ratchaburi province where MERS like CoV has been found from dry bat guano and bat rectal swab during the PREDICT study. These workers visit bat caves and dig fecal material to use as fertilizer, and are therefore highly exposed to bats and rodents in particular. At Khao Chong Pran cave in Ratchaburi we have detected and characterized novel Alpha CoVs, HKU1, and MERS like CoV (short sequence) ((48, 119) and Chulalongkorn, unpublished). As an initial project on our EIDRC, we will develop serology assays to the novel CoVs found in bats at this site using LIPS assays and viral genomic data, and screen archived specimens from 230 participants (2 years' collection in 2017-2018, a subset of the subjects have been sampled at multiple timepoints to allow us to assess seroconversion). Clinical syndromic surveillance at the district hospital will be conducted from the patient with respiratory symptom, the known viral and bacterial pathogens will be tested by real-time PCR commercial kit (the test result will be provided to the hospital within 48 hours for treatment), along with PCR for 3 viral family and serology for CoV found from bat in this area.

The second site is at Chonburi province where Nipah virus (99% identity of whole genome sequence to NiV from Bangladesh patient) has been found from Lylei flying foxes but no infected patient been reported. Several novel Paramyxovirus and CoV have been found from bat feces roosting here. Screening using serology assays for a panel of Henipaviruses is ongoing via our existing collaborations with USUS's Luminex platform, and will be expanded under our EIDRC. The clinical syndromic surveillance at the district hospital will be conducted from the patient with encephalitis and respiratory symptom, the known viral and bacterial pathogens will be tested by real-time PCR commercial kit (the test result will be provided to the hospital within 48 hours for

**Sabah:** Queen Elizabeth hospital syndromic surveillance, UMS Hospital syndromic surveillance, BMHRC human sampling outbreak response

Commented [PD99]: Tom – please start writing some plans for what we could do.

**Singapore:** No human sampling

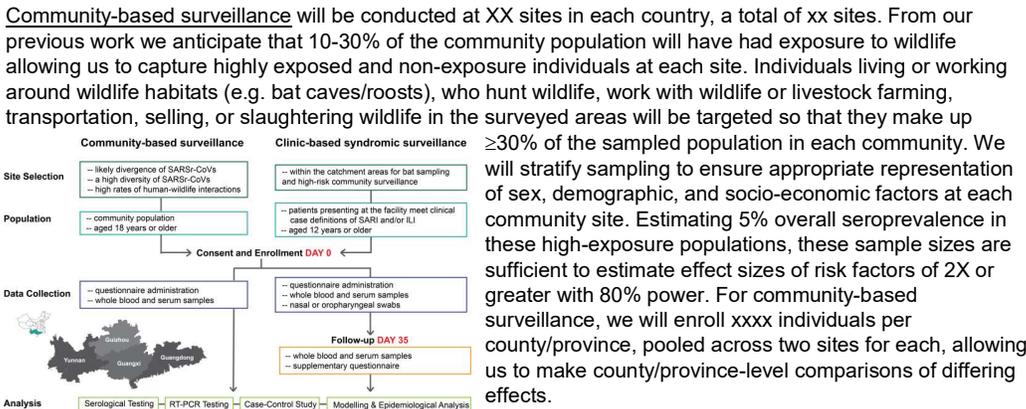

Fig. XX: Human survey and sampling study design overview (Aim 2 and 3)

**2.4 Data & sample collection:** Following enrollment of eligible participants and completion of the consent procedure, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples) will be collected and a questionnaire will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent

Commented [PD100]: All – not sure if we should have one figure for community and clinical cohort surveillance (aim 2 and 3 respectively) or if we should have two separate ones?

Commented [PD101]: Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipap, filop and CoVs.

Commented [PD102]: Emily/hongying

Commented [EH103]: We will need to take more than this from people as there are not vacutainers that small. Also do we want to use a serum separator tube specifically?

For 1mL of serum we will need 2.5mL of blood plus whole blood.

considerations for participants enrolled from clinical settings we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

### 2.5: Laboratory analysis: 2.5.a Serological testing:

One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. In contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes. However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. Henipaviruses, filovirus and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filoviruses/henipaviruses=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (Bossart 2008), developing monoclonal antibodies (Zhu 2008, Bossart 2009) and as subunit vaccines (Bossart 2012, Mire 2014), is presently developing a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, filoviruses and coronaviruses (Table XX).

This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (Bossart 2008, Chan YP 2009). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay. The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (Preliminary Figure A). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-like African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (Peel 2012, Chowdury 2014). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (Shuh 2019, MacNeill 2011, Natesan 2016). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity (Preliminary Figure B). The majority of ebolaviruses are endemic to Africa, however the discovery of Mengla virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown pathogenicity and zoonotic potential exists. Our past work in collaboration with Dr. Smith and Mendenhall at Duke-NUS demonstrated that three under sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (Laing 2018).

#### The below is from our previous CoV proposal:

In our previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity was detected (15). **While this shows it is a specific test for Rp3, it suggests that if we can expand our serology tests to cover other bat CoVs, we may identify many more seropositive individuals.** In this renewal, we will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoVs SADS-CoV and HKU10. We previously found

Commented [PD104]: Chris, Eric, Linfa, Dani etc. please draft some language here...

Commented [EL105]: Nations, F. a. A. O. o. t. U. in *FAO Animal Production and Health Manual* Vol. No. 12 (ed H.E. Field S.H. Newman, C.E. de Jong and J.H. Epstein.) (Rome, 2011).

Commented [EL106]: PMID:

29260678

serological evidence of human exposure to HKU10 (15), but HKU10 is known to jump from one host bat species to another (122) and is therefore likely to have infected people more widely. Incorporating serological testing for SHC014 is also likely to yield higher seroprevalence because it is readily divergent from SARS-CoV wildtype and therefore unlikely to have been picked up in our earlier testing. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, we recognize that CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or RBD; 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (14).

**2.5.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

**2.6 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for Henipavirus, Filoviruses, and CoVs spillover. "Cases" are defined as participants whose samples tested positive for Henipavirus, Filoviruses, or CoVs by serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative for Henipavirus, Filoviruses, or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between Henipavirus, Filoviruses, or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.2.2 Behavioral risks among population:** Qualitative and quantitative human study have conducted among xxxx residents at xxxx community sites in Thailand and Malaysia, revealing the frequent contact with both wild (e.g., bats, rodents, non-human primates) and domestic animals (e.g., poultry, swine) among local communities (Figure X), which are associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms.

Commented [PD107]: Please modify for Henipavirus, filoviruses, and CoVs

Commented [PD108]: Hongying/Emily

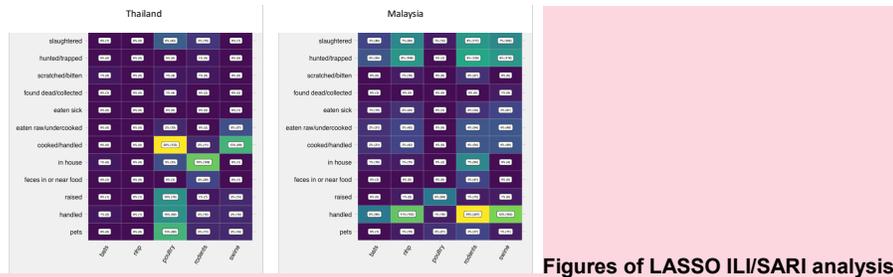

Figure X High-risk human animal contact among community residents in Thailand and Malaysia

In addition, people making a living on crops production, engage in practices that enhance the risk of spillover (e.g. hunting and butchering wildlife) are at the risk of exposure and reported SARI and ILI symptoms (**Figure X – needed a figure for this**). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with further refining serological tools, we will identify the likely routes of exposure to known or novel coronaviruses, henipaviruses, and filoviruses in the study region.

**2.7 Biological characterization of viruses identified:** XXXX

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, paramyxoviruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may not match known CoVs due to recombination events.** We will use the three-tiered serological testing system outline in 2.6.a to try to identify these 'novel' CoVs, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

**Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not diagnosed. By working directly with individuals reporting to clinics with symptoms similar to known high-impact viral agents, we may be able to capture novel emerging diseases in at-risk communities before they spread into the general population and risk becoming pandemic. This will have clear value for public health in the region, and potentially wider. To do this, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We will enroll and conduct novel viral discovery assays on patients who present with unique clinical signs or relevant symptomatic cases. If novel

**Commented [KJO109]:** From Hongying and Emily, may go in diff section for prelim behavioral data. Showing freq and type of animal contact based on Thailand and Malaysia P2 survey data.

**Commented [PD110]:** All –Not sure if we should weigh too heavily on this for the community survey – or should it just be serology for Aim 2. If you want include this section, please modify and insert language from Aim 1 here.

**Commented [KJO111]:** I think Aim 2 should just be serology, esp. since developing new LIPS assays or applying some of the serochip stuff from Linfa and Luminex from USU is already a lot.

**Commented [KJO112]:** Make this more general. There's a greater challenge of interpretation of serological data, esp. if we're using many platforms (each will have its own problems that our lab colleagues are probably more familiar with). Noam may be able to generally comment on a solution here from a statistical perspective.

pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the pathogen, using the collaborative **cross** to identify an appropriate animal model to conduct preliminary pathogenesis work.

Commented [KJO113]: ?

**Preliminary data clinical surveillance:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes:

Commented [PD114]: All – please read and share with collaborators to flesh out and correct details here.

**Singapore:** In collaboration with EcoHealth Alliance and colleagues from the Wuhan Virological Institute in China, we have been developing novel CoV assays for clinical surveillance. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing has been optimized and streamlined to be as rapid as several months, with the development of novel serological assays from sequence data in 7 days [REF]. For example, with the discovery of SADS-CoV, we identified and full-genome sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (*Rhinolophus* spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (14). [Maybe a timeline figure too?]

Commented [KJO115]: Per Linfa's comments, we should highlight the work from SADS-CoV from new virus detection, to assay development, to serological testing in X months.

Commented [KJO116]: From Linfa and Dani, ref – SADS?

Commented [KJO117]: Hongying? Similar to the revised Thailand one?

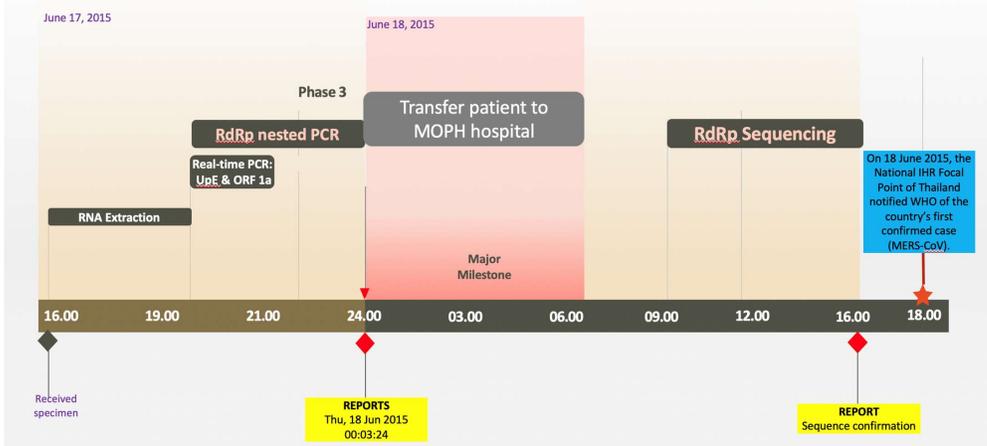

**ADD Lancet ID paper on Zika sequencing by Dani and Duke-NUS team.**

**Thailand:** The TRC-EID laboratory is a leader in rapid detection of human clinical specimens using broadly reactive and specific assays and in-house sequencing technology. For example, in coordination with the Thailand Ministry of Health, we identified the first case of imported MERS-CoV in Thailand using sequence confirmation within 24 hours from acquiring the specimen (Fig X).

Commented [KJO118]: Hongying was going to work on a very narrow, horizontal version of this if we want to include it.

Three imported MERS cases were detected in Thailand since 2015, all cases were confirmed at Chula lab. More than 500 Zika patients were tested positive by PCR and sequence confirmation. The specimens from suspected Ebola travelers were tested negative, PREDICT filovirus protocol has been used as an additional protocol further investigation. The syndromic surveillance has been conducted and tested at Chula lab including SARI, Encephalitis, Hand Foot and Mouth disease in children and Viral diarrhea. These are research studies supported by PREDICT, US DoD and Thai government grant and the routine surveillance by the Thai Bureau of Epidemiology.

## 24 Hours Laboratory Confirmation

### Peninsular Malaysia:

**Sabah:** Linfa has worked with Timothy Williams on an encephalitis cohort from Queen Elizabeth Hospital 1 & 2 (poss has worked with Linfa on these) and this is another possibility. He's doing outbreak response training in August with team from Sabah CDC (Dr. Maria now in Pen. But still collaborating with us, Jikal current director working with us and Dato Cristina dir. Sabah state health Dept and is supportive) this collaborative group is working to develop a Sabah outbreak response team – we will support that – to be based at BMHRC and we will develop this as part of this proposal. Prof. Kamruddin will summarize the serum samples he has.  
POCs: Sabah State Health Dept (e.g. Dr. Giri Shan Rajahram), Queen Elizabeth Hospital (Dr. LEE Heng-Gee)

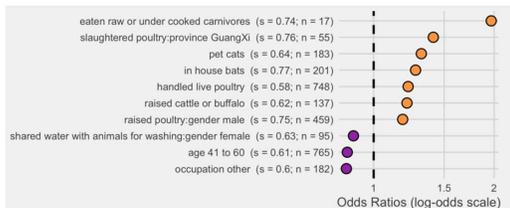

**Sarawak:** From Linfa – Dr. Ooi used to work with Jayne Cardosa at UNIMAS and has access to samples of patients with unusual presentation

Commented [PD119]: Tom to add – Queen Elizabeth Hospital?

Commented [KJO120]: Comment from Tom: Sabah team please add details of any cohort work you have done

Commented [PD121]: Tom

Commented [KJO122]: Comment from Tom: Dr Tan have you done any clinical cohort work in Sarawak?

**Strategy for analysis of self-reported illness:** In addition to biological outcomes we have developed a standardized approach in PREDICT for analyzing data on self-reported symptoms related to targeted illnesses; of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), fever with muscle aches (fevers of unknown origin (FUO) and, cough or sore throat (influenza-like illness - ILI) from study participants. We used a least

Commented [PD123]: Emily/Hongying

Commented [KJO124]: Emily: Will we do this in the community as well. We could also add animal contact as the outcome. We have data and figures for that as well

absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI-like and/or SARI symptoms and demographics, occupation, and contact with animals in the last year. Results have clear biological relevance. In Yunnan, China, salient associated variables or combination of variables were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (Fig. 11). We will expand this approach for all syndromes in Aim 3, and use more granular targeted questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country. Fig. 11: Associated variables of self-reported ILI and/or SARI in prior 12 months (s = bootstrap support; n = number +ve out of 1,585 respondents). Orange circles = odds ratios > 1 (positively associated with the outcome); purple = odds ratios < 1 (negatively associated with the outcome).

**3.2 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms typical of high-impact emerging viruses. We will collect survey data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.3 Clinical cohorts. 3.3.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at XX town-level level clinics and xx provincial-level hospitals in each country, in total xx clinical/hospital sites, that all serve as the catchment healthcare facility for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients ≥ 12 years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, fevers of unknown origin, or hemorrhagic fever will be recruited into the study. We will enroll a total of xxx individuals for clinical syndromic surveillance, which accounts for up to 40% loss from follow-up. Study data will be pooled across country sites, as clinical patients are limited by the number of individuals presenting at hospitals.

Commented [PD125]: Hongying/Emily

Commented [KJO126]: MeiHo: Just QEL in Sabah

**3.3.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever of unknown etiology. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance of PCR detection of viruses (123). We will follow up 35 days after enrollment to collect an additional two 500 µL serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs <28 days after onset of symptoms for SARS patients (124).

Commented [PD127]: Hongying Emily

Commented [EH128]: Both inpatient and outpatient

Commented [PD129]: Need data for Nipah and filovirus patients

**3.3.c Sampling:**

Following enrollment with signed consent form, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500  $\mu$ L whole blood; two 500  $\mu$ L serum samples) including two nasal or oropharyngeal swabs will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

**3.4 Sample testing:** PCR, Serol to link symptoms to etiologic agents

**3.5 Assessing potential for pandemic spread:** We will...leverage EHA's work with DHS to develop FLIRT (Flight Risk Tracker) that tracks the probable pathways for spread for viruses that are able to be transmitted among people....

Commented [PD130]: KEvin to draft

IBIS mines and collates data regarding on-going bioevents from biosurveillance networks and uses data on commercial air traffic to assess their risk of and likely routes of ingress into the United States. In contrast, BAT can use relatively rudimentary, high-level data, such as might be available for a newly discovered biothreat that has not yet caused a bioevent or is not subject to intense biosurveillance, in order to assess the agent's inherent pathogenicity. Thus, BAT and IBIS address distinct, but highly complementary, use cases.

Commented [KJO131]: Pasted in a bunch of stuff, but still need to clean this up.

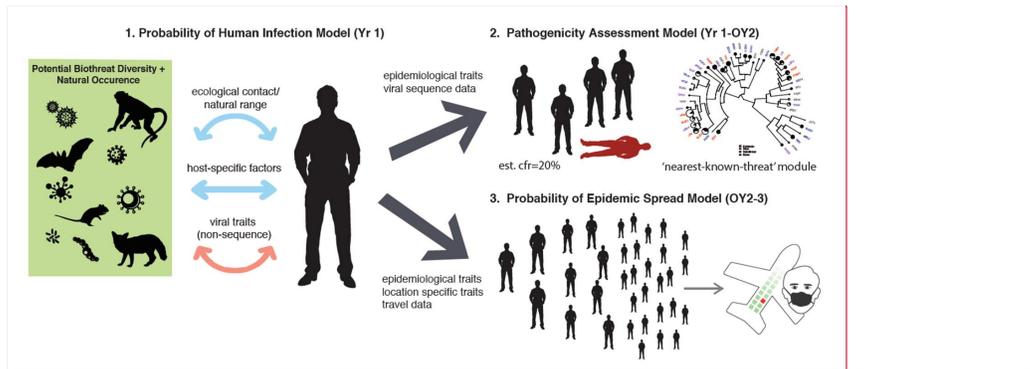

Traditional approaches to pathogen assessment focus only on internal functional components of pathogens and often fail to account for the broader characteristics of host-pathogen interactions now recognized as critical for risk determination. Initial development will focus on characterization of viral pathogens, which constitute the majority of emerging diseases, especially those with pandemic potential. will use statistical models built from collated biological, ecological, and genetic data to predict the likelihood of human infection (or spillover) and pathogenicity for a diverse range of biothreats. The overarching aim of the proposed technology is to improve overall situational awareness of existing and novel infectious agents around the world, allowing DHS to more quickly identify and assess which threats pose the most significant risk to human health and thus either more rapidly deploy resources to respond to and mitigate their impact when necessary.

**Lab-based virology and bacteriology studies are necessary but not sufficient** because they are narrowly-focused and do not consider the broader suite of ecological, evolutionary, and host-specific factors that may affect an infectious agent's pathogenicity and transmissibility.

The initial phase of our work will build upon the existing, curated global-level pathogen and host databases currently housed at EHA. Specifically, we will employ systematic, targeted literature reviews to extend and customize these databases to include viral ecological, epidemiological, and biochemical traits to fit our statistical models and target pathogenicity predictions for the BAT. Predictor variables will span a range of data granularity, and vary according to the four information levels. For example for Level 1, variables may include location of detection (to integrate underlying EID hotspot models based on demographic and geographic factors), and non-human host range and taxonomy. For level 2, coarse-grained viral traits that are independent of sequence data may include: viral family, nucleic acid type, mode of transmission, and phylogenetic host breadth for virus (see Figure 2). For levels 3 and 4 viral sequence data will be integrated by including viral phylogenetic distance and 'nearest-known-threat' analyses (see Figure 3). For the pathogenicity model, human epidemiological data for ~300 viral species known to infect people (case fatality rate, global estimates of number of human cases per year or decade,  $R_0$ , infectious period, and primary symptoms) will be aggregated to use as predictor variables.

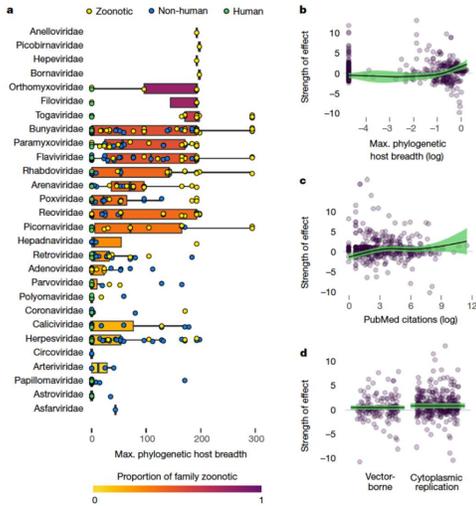

For ease of interpretation and for applicability across a broad range of pathogens, we propose to use two independent but related statistical models that will be used to predict pathogen spillover risk and pathogenicity, respectively. First, a model will be developed using spillover as the relevant outcome. In this case, spillover will

be defined as either a binary variable, with “0” indicating a virus that is not known to spillover into human populations and establish infection whereas “1” will indicate a virus that is capable of spillover (or is solely a human pathogen). This model will enable us to assign a spillover risk probability to a new biothreat agent that is currently not known to infect people. Given the capacity to spillover and infect humans, we would then use a second model to predict pathogenicity of the novel pathogen. We will model pathogenicity in human hosts on a discrete scale from 1 to 10, with 1 representing a pathogen having no discernible negative effect on human health (i.e., asymptomatic infection) and 10 representing the most severely pathogenic bioagents with high case fatality rates. Additional functionality for the BAT (i.e., Option Years 2-3) may include integration of models to assess pathogen spread via travel and travel networks.

**Commented [KJO132]:** From our unfunded DHS proposal a couple of years ago, to modify if we want to include this.

**Figure 1.** Conceptual framework highlighting 3 underlying models of the Biothreat Assessment Tool (BAT) to estimate: **1)** probability of human infection, or spillover, the first necessary step to understand pathogenicity when status of human infection is unknown (Year 1); **2)** pathogenicity, i.e. probability of causing clinical signs, case fatality rate estimates, and other metrics relevant to humans (or domestic animal species) (Year 1 – Option Year 2); **3)** probability of pathogen spread based on ecological, epidemiological, and trade data (Option Years 2-3).

**Figure 2.** Example of analysis using Level 2 information (limited pathogen characterization) to assess likelihood of human infection (zoonotic potential) for a virus. Figure from Olival et al. 2017, analysis of ~500 unique mammalian viruses. Similar analyses will be developed to assess level of pathogenicity.

**From CoV renewal:** use data from 3.3 to identify rank SARSr-CoV strains most likely to infect people and evade therapeutic and vaccine modalities. We will use bat survey and zoological data (101) to build species distribution models (125) and predict the distribution of bat species that harbor low, medium and high risk viral strains. Stacking these modeled distributions for the ~20-30 *Rhinolophus* and related species that occur in the region will allow estimates of SARSr-CoV diversity for a given locality. We will use machine learning models (boosted regression trees) and spatial 'hotspot' mapping approaches to identify the ecological, socio-economic and other correlates of SARSr-CoV diversity and spillover (from serosurveys) (1, 2, 85). We will include data from our human behavioral surveys and sampling to give a direct measure of where risk of spillover to people is likely to be highest in the region.

**Potential problems/alternative approaches: Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases.** Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (123). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the potential public health importance of discovering active spillover of a new henipavirus, filovirus or CoV infection.

**Commented [PD133]:** Add data for Nipah and filio infections

**ALL – the sections below are going to be critical to demonstrate our capacity to do this work. I've not yet started drafting, but please don't hesitate to insert whole sections from other proposals you've done if they're relevant here – we'll need to be creative and get all the language we can from others...**

**Commented [PD134]:** All – I've started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**Additional Instructions – Specific to the EIDRC FOA:**

**Commented [KJO135]:** Peter, I've added in some examples from other grants

**Administrative Plan**

In a clearly labeled section entitled “Administrative Plan”:

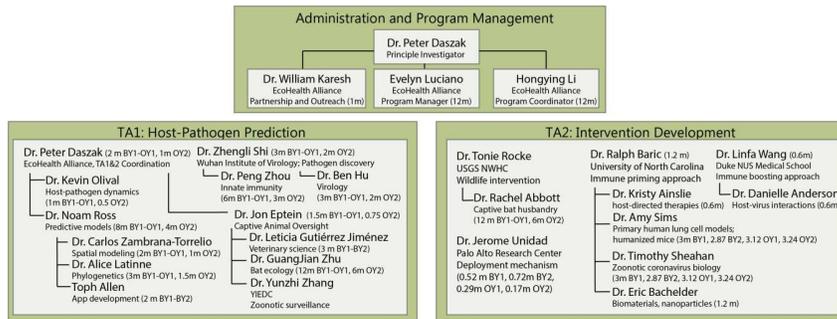

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.
- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

List out all of our involvement with outbreak investigations, ministries of health surveillance etc.

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

FROM DARPA grant:

**Section 1.03 MANAGEMENT PLAN**

Project DEFUSE lead institution is EcoHealth Alliance, New York, an international research organization focused on emerging zoonotic diseases. The PI, Dr. Daszak, has 25+ years' experience

Commented [KJO136]: Figure like this would be good, but instead of breaking down by TA, maybe by country or Specific Aim. Per FOA, Need to also show how we'll link in with the Coordinating Center and other EIDRCs.

managing lab, field and modeling research projects on emerging zoonoses. Dr. Daszak will commit 2 months annually (one funded by DEFUSE, one funded by core EHA funds) to oversee and coordinate all project activities, with emphasis on modeling and fieldwork in TA1. Dr. Karesh has 40+ years' experience leading zoonotic and wildlife disease projects, and will commit 1 month annually to manage partnership activities and outreach. Dr. Epstein, with 20 years' experience working emerging bat zoonoses will coordinate animal trials across partners. Drs. Olival and Ross will manage modeling approaches for this project. Support staff includes a field surveillance team, modeling analysts, developers, data managers, and field consultants in Yunnan Province, China. The EHA team has worked extensively with other collaborators: Prof. Wang (15+ yrs); Dr. Shi (15+ yrs); Prof. Baric (5+ yrs) and Dr. Roche (15+ yrs).

**Subcontracts: #1** to Prof. Baric, UNC, to oversee reverse engineering of SARSr-CoVs, BSL-3 humanized mouse experimental infections, design and testing of targeted immune boosting treatments; **#2** to Prof. Wang, Duke-NUS, to oversee broadscale immune boosting, captive bat experiments, and analyze immunological and virological responses to immune modulators; **#3** to Dr. Shi, Wuhan Inst. Virol., to conduct PCR testing, viral discovery and isolation from bat samples collected in China, spike protein binding assays, humanized mouse work, and experimental trials on *Rhinolophus* bats; **#4** to Dr. Roche, USGS NWHC, to refine delivery

mechanisms for immune boosting treatments. Dr. Rocke will use a captive colony of bats at NWHC for initial trials, and oversee cave experiments in the US and China. #5 to Dr. Unidad, PARC, to develop innovative aerosol platform into a field-deployable device for large-scale inoculation of the bats. Dr. Unidad will collaborate closely with Dr. Rocke in developing a field deployable prototype for both initial trails and cave experiments in China.

**Collaborator Coordination:** All key personnel will join regularly-scheduled web conferencing and conference calls in addition to frequent ad hoc email and telephone interactions between individuals and groups of investigators. Regular calls will include:

- Weekly meetings between the PI and Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.
- Monthly web conferences between key personnel (research presentations/coordination)
- Four in-person partner meetings annually with key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

Evaluation metrics will include the generation of high-quality data, successful achievement of milestones and timelines, scientific interaction and collaboration, the generation of high quality publications, and effective budget management. The PI and subawardee PIs will attend a kickoff meeting and the PI will meet regularly with DAPRA at headquarters and at site visits.

**Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by Dr. Daszak and the Project Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation. Should a resolution not be forthcoming, consultation with our technical advisors and DARPA Program staff may be warranted.

**Risk management:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. A project of this nature requires a different mindset from that typically associated with basic research activities that move at an incremental pace with investigators gradually optimizing experimental systems, refining data, or waiting for additional data before moving ahead with an analysis approach. To maintain our timeline, we will continually evaluate these trade-offs to make decisions about when iteration is appropriate and when necessary to move forward with current information.

#### **Biographies:**

**Dr. Peter Daszak** is President and Chief Scientist of EcoHealth Alliance, Chair of the NASEM Forum on Microbial Threats, member of the Executive Committee and the EHA institutional lead for the \$130 million USAID-EPT-PREDICT. His >300 scientific papers include the first global map of EID hotspots(1, 126), estimates of unknown viral diversity(127), predictive models of virus-host relationships(2), and evidence of the bat origin of SARS-CoV(20) and other emerging viruses (40, 128-130).

**Prof. Ralph Baric** is a Professor in the UNC-Chapel Hill Dept. of Epidemiology and Dept. of Microbiology & Immunology. His work focuses on coronaviruses as models to study RNA virus transcription, replication, persistence, cross species transmission and pathogenesis. His group has developed a platform strategy to assess and evaluate countermeasures of the potential “pre-epidemic” risk associated with zoonotic virus cross species transmission(60, 70, 131-134).

**Prof. Linfa Wang** is the Emerging Infectious Diseases Programme Director at Duke-NUS Medical School. His research focuses on emerging bat viruses, including SARS-CoV, SADS-CoV, henipaviruses, and others(20, 135-138) and genetic work linking bat immunology, flight, and viral tolerance(139-142). A 2014 recipient of the Eureka Prize for Research in Infectious Diseases, he currently heads a Singapore Nat. Res. Foundation grant “Learning from bats” (\$9.7M SGD).

## Data Management Plan

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system

### Language from NIH CoV grant:

**Data Sharing Plan:** Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited in long-term public scientific repositories – all sequence data will be made publicly available via GenBank, species location data via the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestrictive MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Viral isolates will remain at the Wuhan Institute of Virology initially. Isolates, reagents and any other products, should they be developed, will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Sharing Model Organisms:** We do not anticipate the development of any model organisms from this study. Should any be developed, they will be made available to other NIH-funded researchers via applicable Wuhan Institute of Virology and EcoHealth Alliance Material Transfer Agreements and/or licensing agreements.

**Genomic Data Sharing:** We anticipate obtaining genetic sequence data for 100s of novel coronavirus genotypes, including RNA-dependent RNA polymerase (RdRp) and Spike genes for all strains/genotypes. In addition, we will generate full viral genomes for a subset of the bat SARSr-CoVs that we identify. All sequence data will be deposited in the NIH genetic sequence database, GenBank. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also be submitted. The genotype data will be made publicly available no later than the date of initial publication or six months after the receipt of final sequencing data, whichever comes first. We anticipate sequence generation will occur over the 5 year proposed project period.

**Genome Wide Association Studies (GWAS):** Not applicable.

Commented [KJ0137]: From CoV NIH grant

Thailand TRC-EID Chulalongkorn lab: Specimen management and BioBank: The software called PACS

(Pathogen Asset Control System) supported by BTRP DTRA, is now used for managing the specimen from specimen registration (barcoding, and may move to use QR code system soon), aliquoting, tracking, short patient history record, data summary, searching, test reporting and etc. Our biobank system contains 28 freezers (-80C) and liquid N2 system. Its size is around 120 sq meters. There is a separate electric generator for our lab and biobank. There are CC TV cameras at the biobank and laboratory.

Chula TRC-EID has our own server for data management and analysis. We have the necessary software including Bioinformatic tools (Blast Standalone, SAMTOOL, GATK, AliVIEW, RaxML, FigTREE, MAFFT, Guppy, Megan, PoreChop, MEGA), Database (MySQL, MongoDB) Web, jQuery, Node.js, Express.js React, API, PHP, Ruby, Python, Java, C#, HTML5, Bootstrap, CSS, Responsive, Cloud, Linux Command, PACS (sample management system), Virtualbox virtual machines, R programming languages, Perl scripts, Bash shell scripts, Open source software, Microsoft Office running on both Apple Mac OS X, Ubuntu, Linux, and Windows Operating Systems. Chula TRC-EID has a dedicated 16-core Ram 64GB Linux server with 4TB hard drives, dual quad-core Mac Pro Server with 2TB hard drives and another dedicated iMac Pro (Retina 4K, 21.5-inch, 2017) Processor 3.6GHz quad-core Intel Core i7 (Turbo Boost up to 4.2GHz) Ra, 16GB with 512GB hard drives. TRC-EID also has HPC Linux server CPU: 4 x 26cores Intel Xeon = 104 cores 2.1GHz with 52 TB HDD and 2x3.84TB SSD with GPU 2x Tesla v100 (CUDA core = 5120 cores/GPU, Tensor core = 640 cores/GPU). TRC-EID has a dedicated 10/100/1000 of LAN (Local Area Network), 2.4G / 5G Gigabit Wi-Fi 802.11ac.

Commented [KJO138]: From Supaporn for their lab, some may go in Facilities doc?

From DARPA:

**Data Management and Sharing:** EcoHealth Alliance will maintain a central database of data collected and generated via all project field, laboratory, and modeling work. The database will use secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations, and enable compliance with DARPA data requests and disclosure requirements. All archived human sample data will be de-identified. Partners will provide raw and processed data to the central database throughout the course of the project. Project partners will have access to the data they generate in the database at all times, and maintain control over local copies. Release of any data from the database to non-DARPA outside parties or for public release or publication will occur only after consultations with all project partners. EHA has extensive experience in managing data for multi-partner partner projects (PREDICT, USAID IDEEAL, the Global Ranavirus Reporting System).

Commented [KJO139]: Text from DARPA Preempt

### Clinical Management Plan Clinical site selection

Our consortium partners have been conducting lab and human surveillance research, inclusive of human surveillance during outbreaks, for over the past two decades and in that time have developed strong relationships with local clinical facilities and processes. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1. These are regions where we will sample wildlife due to the high potential of zoonotic viral diversity. Additionally, these will be clinical sites that serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. In PREDICT we developed successful working relationships with the major healthcare facilities the hotspot areas in 6 different countries, including Thailand and Malaysia and we will continue to work with these sites going forward. Continuing to work with these hospitals means we will begin this project with successfully established partners and we can begin data collection quickly. This also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites for this study is limited. All that is required of sites will be the ability to enroll patients that meet the clinical case definitions of interest, capacity to collect and temporarily store biological samples, and follow standards for data management and protection. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests,

Commented [EH140]: Is that true

that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently site staff. These will be persons who are locally trained and certified to collect biological specimen from participants including blood draw technique, e.g. doctor or nurse. Last, the clinical site will need the capacity to securely store all personal health information and personally identifiable research data, this will include locked offices with locked filing cabinets to store all paper records and an encrypted computer. Training on project procedures will be provided for all local project staff by local country project management staff and partners from headquarters. The study at clinical sites will begin by developing relationships with local stakeholders at the hospitals and clinics in our geographic areas of interest that serve as catchment facilities for people of within the community surveillance study. We will recruit hospital staff that will be extensively trained for project procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data management plans. During the Development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data (e.g. locked filing cabinet, dry shipper, secure laptop). [Did not specifically address CONDUCT]. Oversight for clinical sites will be managed by the country coordinator for each country. This will be done with regular site visits to the clinical sites and annual visits by headquarter research staff. Site visits will include monitoring and evaluating the process for patient enrollment, collecting and storage of samples, administration of the questionnaire, and secure and data management procedures for secure personal health information and research data. During these visits any additional training will also be provided.

#### **Standardized approach oversight and implementation**

Management and oversight for all study sites will be managed by the local country coordinator who is supported by staff at headquarters. Implementation of a standardized approach across all study sites, community and clinical, will begin by extensive training of staff on procedures on requirements of the project, this includes: enrollment, data collection, and data management. Our research team has over 5 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research. This includes SOPs for screening, enrollment, and retention of participants. In addition to yearly monitoring reports the country coordinator will regularly visit each clinical site to ensure quality standards and compliance of procedures are being met. Through our work with clinical sites in PREDICT we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical research staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll, allowing for minimal disruption and prevents potential enrollees from being overlooked if the research staff is not on duty. At clinical sites that do scheduled outpatient days we may have a trained member of the research staff with the intake nurse to monitor the patients coming to the clinic more rapidly to no delay screening or enrollment in such a fast pace environment. Using the screening tools, we will recruit and enroll patients who present with symptoms that meet the clinical case definitions of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology within the past 10 days. These patients will be enrolled, samples collected and survey conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; 3) environment biosecurity. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either coronaviruses, henipavirus, or filoviruses, serological tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed

and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between coronaviruses, henipavirus, or filoviruses in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. [How do these cohorts be leveraged for new emerging pathogens] Achieving the adequate numbers will be attained through duration of the as clinical participant enrollment. While patient's enrollment is limited by the number of individuals presenting at hospitals, during the PREDICT project we had an average of 105 patients enrolled per year, ranging from 77-244. The country coordinator will be continually monitoring the project database to be sure that we are on track to reach our target.

### Clinical cohort setup, recruitment, enrollment

We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever, of unknown etiology for symptoms reported onset of illness to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 2\* 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples and two nasal or oropharyngeal swabs will be collected. The cases are defined as participants whose samples tested positive for Henipaviruses, Filoviruses, or CoVs by PCR or serological tests. The controls will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500 µL serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms for coronaviruses, henipavirus, or filoviruses infected patients to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

### Utilization of collected data

Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses the are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire allows us to assess relative measures of human-wildlife contact from our survey work that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk.

The biological specimens to be collected (2\*5mL whole blood for whole blood and serum analysis and nasal or oropharyngeal swabs) from all eligible participants and follow up specimen 35 days (3mL of whole blood for serum) after enrollment with the standardized questionnaire. Capacity for specimen collection is not more than standard phlebotomy skills and we will collect by locally trained and certified personnel that are part of the research team in country. Staff we will trainline on ethical guidelines for conducting human subjects research and survey data collection methods. Collection of whole blood, serum, and nasal or oropharyngeal swabs allows us to test the samples for PCR to detect viruses in our priority viral families, serologically test for immunological response and historical exposure to zoonotic diseases of relevance, and the questionnaire will assess individuals evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations are unknown to detect cryptic

**Commented [EH141]:** Will these cohort fulfill the goals of the EIDRC.

**Commented [EH142]:** PREDICT we also make the stipulation that we will collective relative samples if avialble from treatmean collection, eg CSF if the MD is doing a spinal tap we will request an aliquot if possible

**Commented [EH143]:** Please add any information that might address: types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.

**Commented [EH144]:** Please add any information that might address: Describe methods that might be applied to elucidate a zoonotic source

outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

#### **Potential expansion**

Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research or an outbreak in the region. If expansion is required we could rapidly implement research activities in additional clinical or community sites through the same process we on-boarded the initial locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transportation, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provide necessary information for granular understanding of disease spread.

In a clearly labeled section entitled "**Clinical Management Plan**":

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment, including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team is incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics

2. Tekada Sanofi Pasteur dengue

3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

**Statistical Analysis Plan**

In a clearly labeled section within the Research Strategy entitled **"Statistical Analysis Plan"**:

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

**Project Milestones and Timelines**

In a clearly labeled section entitled **"Project Milestones and Timelines"**:

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

**Project Management & Timeline**

PI Daszak will oversee all aspects of the project. Dr. Daszak and has two decades of experience managing international, multidisciplinary research in disease ecology, including successful multi-year projects funded by NSF, NIH and USAID. He will conduct monthly conference calls with all co-PIs, including the China team (see Activity schedule below). He will be assisted by EHA Sr. Personnel Li, who is a US-

based Chinese national with fluent Mandarin. Co-PI Olival will oversee Aim 1 working closely with China PI Tong, who will test samples. Co-PI Ma (China team) will coordinate and lead all Chinese experimental infections, with guidance from co-PI Saif, who will coordinate and lead all US experiments with co-PI Qihong Wang. Sr. Personnel Ross will conduct all modeling activities in Aim 2, working closely with co-PI Saif to parameterize the models. Co-PI Baric and Sr. Personnel Sims will lead infectious clone, recombinant viral and

culture experiments. Consultant Linfa Wang will advise on serology, PCR and other assays. China team co-PIs Shi and Zhou will oversee viral characterization in Aim 1. Sr. Personnel Feferholtz will oversee the economic modeling in close collaboration with Ross.

**Commented [KJO145]:** Text and figure From NSF-NIH SADS grant. Peter will adapt

Another Example of Milestones and specific tasks from a prev DHS (unfunded) proposal:

#### **Expand existing databases to include predictor variables for pathogenicity risk model**

**Task 1:** Collate available human clinical information from the literature for ~300 viral pathogens known to infect humans (Contract Award Date to 6 month)

**Task 2:** Update EHA host-viral association database to include new data for mammalian and avian species from literature 2015-present (Contract Award Date to 3 month)

**Task 3:** Extract and curate full and partial genomic data from Genbank for 5-6 viral families with a high proportion of human-infectious pathogens for phylogenetic analyses – e.g. ‘nearest-known-threat module’. (Month 2 to 6 month)

#### **Develop underlying pathogenicity and spillover risk assessment models**

**Task 4:** Fit generalized linear models in Stan for multiple response variables to measure pathogen impact (Month 7 to 10 month)

**Task 5:** Fit generalized linear models to estimate risk of human infection (spillover) based on host, ecological, and location specific traits (Month 4 to 8 month)

**Task 6:** Validate model effectiveness by simulating early-outbreak, limited-information scenarios from known pandemics to confirm model behavior (Month 8 to 10 month)

**Commented [KJO146]:** Just example, but probably just want to use a Gantt chart format per most of our grants, depending on space.

---

Hi Peter (and all),

Here are mine and Linfa's edits. I will have to add more after some of the CoV stuff has been removed. At the moment it is too CoV specific (I know we took a lot of text from our other grant proposal), but can some of this be removed before we add in the final filo/paramyxo info- see my comments.

In the next version, can you delete the tracked comments if they have been answered or corrected in the text? I didn't delete any comments.

I should have time on Monday afternoon (SG time) to look at this again.

Cheers,  
Dani

---

**Cc:** Aleksei Chmura; Alison Andre; Luke Hamel; Kevin Olival  
**Subject:** CORRECTION - please ignore last email!!! re. EIDRC-SEA v.3

Many apologies – I sent the wrong attachment – here is the correct version!!!

Dear all,

Thanks to everyone for comments and text for the earlier draft at the beginning of the week. Kevin's spent the last couple of days pulling all the comments together into one draft and inserting his changes, and I've now attached a v3 of the draft. It's still rough, and now too long, but it's getting there. I wanted you to look at this rough version because I'm stuck in Liberia in meetings Friday, then flying back home Saturday. I'll continue editing this draft on the plane and will be working solely on this grant from home on Sunday, Monday, Tues, Wed, Thurs.

Please work on this rapidly if possible. If you can all push your comments through, using track changes, and get them back to me **by Sunday evening New York Time**, I will turn round a polished draft by Tuesday, giving us time for significant last go-over on Wed, Thurs. It's tight, but unfortunately, it is what it is, so please commit the time if you can!! As well as general edits (using track changes, with references in comment boxes), please do the following...

Linfa/Danielle – We especially need your input in section 1.1, 1.3, 1.4 and 2.5

Ralph/Amy - Please work your magic on this draft, inserting text, editing and reducing text, and making sure the technical details of the characterization are correct and fit the proposed work on CoVs, PMVs and Henipaviruses

Chris/Eric – Eric – congratulations on your (b) (6) and thanks for working on it at this time!  
Chris – please help and edit/finesse the language in the relevant sections for you

Tom – Your edits crossed over with Kevin's changes, so please insert all the bits that were new in the last version you sent to me, into this version. I think these are mainly the sections and comments from the other Malaysian colleagues, but please check and re-insert all key text. We especially need to be specific about which partner in Malaysia is doing what cohorts, and where, and about who's doing the testing

Thanks again all, and I'm looking forward to non-stop work on this as soon as I get on my flight in 24 hours...

Cheers,

Peter

**Peter Daszak**

## EcoHealth Alliance Capacity/Experience

EcoHealth Alliance (EHA) staff has over two decades' experience conducting cutting edge research on zoonotic disease emergence in international settings. This includes NIH-funded modeling, field and laboratory research on host-pathogen dynamics and spillover of Hendra, Nipah, Ebola, SARS, West Nile, avian influenza, MERS and other emerging viruses<sup>1-12</sup>. EHA epidemiologists, modelers and analysts have produced seminal papers analyzing the origins and hotspots of emerging zoonotic diseases<sup>13-16</sup>, designing strategies to identify the diversity and likely reservoirs of novel viruses<sup>17-24</sup>, and predicting patterns of EID spread<sup>25-30</sup>. In over 20 countries within South and Southeast Asia, Central and West Africa, and Latin America, EHA field staff has conducted human, wildlife and livestock sampling to identify known and novel pathogens, and test for serological evidence of their spillover<sup>31-42</sup>. This includes acting as a key member of the 10-yr USAID-EPT Predict consortium, managing all modeling and analytics, all human behavioral risk research, and conducting wildlife and human surveillance in 11 countries, including managing all Predict activities in Liberia, Brazil and Thailand – the sites for the current proposal. As part of Predict, EHA scientists collected >60,000 samples from humans and wildlife, organized laboratory testing for known and novel viruses (>300,000 PCR tests), and helped build, support or equip around 15 laboratories in EID hotspots, including Liberia, Brazil and Thailand.

## Text for the proposal

**Introduction/Preliminary data:** Analysis by key personnel Daszak, Olival, Ross demonstrate that the countries chosen for the NEIDL EIDRC proposal (Brazil, Liberia, Nigeria, Uganda) are hotspots of disease emergence<sup>14</sup>. These countries have high biodiversity of wildlife (and their viruses), high and rapidly growing human population density, and rapidly increasing levels of deforestation and agricultural intensification – globally significant drivers of EIDs<sup>13</sup>. One of the challenges of managing emerging zoonoses is identifying the key at-risk populations at the critical interfaces for viral spillover *within EID hotspot countries*. This is critical for building capacity where it is most likely to be needed in an outbreak, for supplying therapeutics and vaccines to populations most likely to require them, and for identifying populations with active spill-over to undertake clinical trials of novel compounds. EHA scientists have developed a series of modeling and analytical tools to better target the NEIDL's focus on in-country clinical and community sampling. This includes analysis of all known mammalian virus-host relationships from ICTV data that identifies the geographic distribution of the most wildlife reservoirs most likely to harbor novel and known zoonoses. It also includes mapping the distribution and relative number of unknown viruses likely to spillover into people in the region<sup>24</sup>. Prior work by EHA under USAID-EPT-PREDICT involved collection and testing of samples from >5,000 mammals (bats, rodents, primates) in Brazil, >10,000 mammals in Liberia, leading to the discovery of a reservoir host for EBOV (paper in prep.) and >50 novel paramyxoviruses, coronaviruses and viruses from other zoonotic groups<sup>32,43</sup>. It includes biological sample collection and behavioral risk questionnaire surveys in >500 people to assess high risk behaviors (REF). This is part of broader work that includes collection and testing of >XXXX samples from XXXX individual mammals from 14 countries, the discovery of hundreds of novel viruses from viral families with known zoonoses, and biological sampling and behavioral risk

**Commented [PD1]:** Please get some rough but better estimates for all of the numbers highlighted here...

**Commented [PD2]:** Lizzie Loh's paper from Brazil, anything from Liberia?

**Commented [PD3]:** Include P1 L. American work for EHA

surveys from >5,000 people<sup>43</sup>. **These data are available to the current project to ground-truth risk mapping, and better identify populations most likely to encounter zoonotic spillover events.** Under prior and current NIAID R01 funding, key personnel Daszak, Olival, Noam have demonstrated proof-of-concept of a linked modeling-field surveillance approach to identify high risk wildlife species in China that harbor a large group of SARSr-CoVs, many capable of infecting human cells<sup>3,8,42</sup>. Using analyses that map wildlife reservoir diversity, behavioral risk questionnaires in rural China, and biological sampling of high-risk populations, this has resulted in the identification of a key cave system harboring bats with CoVs that have every genetic element of the SARS-CoV outbreak strain<sup>5</sup>. Recently our group has demonstrated serological evidence for the recent exposure of these high-risk human populations to novel bat-origin SARSr-CoVs<sup>38</sup>. A similar strategy will be used in this proposed work to identify high priority sites for clinical cohort and community sampling where people are at the highest risk of viral spillover.

**Workplan: 1) Modeling to identify high priority sites for clinical trials and community sampling.** We will revise our hotspot mapping to produce fine-scale within-country maps of spillover risk for a) generalized zoonotic viral pathogens; b) specific pathogens (e.g. Lassa fever virus, bat-origin Henipaviruses, flaviviruses, filoviruses and bat-origin Coronaviruses; c) identification of the communities most likely to require interventions. Our hotspot analysis shows that land use change, biodiversity and human population density change are correlated with EID spillover risk<sup>13,14</sup>. We will use databases already acquired, cleaned and gridded at EHA, including annual land cover maps produced by the European Space Agency from 1992-2015 with a 300 m spatial resolution, data on biodiversity mapping from the IUCN spatial database version 2015.2, on land use change, and the CIESIN Global Rural-Urban Mapping Project human population data set, which provides gridded estimates of human population every five years for 1970–2000<sup>44-47</sup>. For each virus or viral group of interest, we will use ICTV data and our own PREDICT sampling data to map the distribution of each known reservoir host, and identify hotspots of reservoir density where populations are most likely to encounter spillover events. We will then use socio-economic data from >10,000 zoonotic risk questionnaires as part of USAID Predict surveillance conducted by EHA in Brazil, Liberia and other countries with similar demographic characters to pinpoint communities most likely to constitute the key wildlife-human interface for spillover.

**2) Modeling to predict the identity and distribution of reservoir hosts.** For many emerging viruses, poor knowledge of reservoir hosts reduces our capacity to predict which human populations are at risk of infection. Even where reservoir host identity is known or suspected, the presence of alternate hosts can lead to underestimates of risk. For example, while the hosts of henipaviruses and filoviruses are thought to be specific frugivorous bats<sup>48-51</sup>, work by EHA and others shows that diverse bat genera, including insectivorous bats can harbor these viral families, and that viral distribution may be much wider than previously thought<sup>40,52-54</sup>. We will adapt our recently-published approach that uses data on all known virus-mammalian host relationships<sup>24</sup>, as well as other modeling frameworks<sup>55</sup> to predict the likely hosts of known viruses of interest to the EIDRC. We will target filoviruses, henipaviruses, coronaviruses, arenaviral relatives of Lassa fever virus, known zoonotic flaviviruses, paramyxoviruses. We will

Commented [PD4]: Can you add 2 or so sentences on what we'd do

then use ecological niche mapping and known mammalian distributions from IUCN to estimate the likely distribution of viral reservoirs, and therefore better assess the risk of spillover to people.

**Commented [PD5]:** Can you add a couple of sentences here with refs. To make it sound clever

**3) Fieldwork/Training:** Research on the potential wildlife reservoirs of lethal agents carries inherent, albeit low (given low viral prevalence in wildlife), risks of exposure. To minimize this, EHA veterinary and other staff has designed protocols, presentations, and SOPs for capacity building and cross-training in resource-poor countries, including those in the current proposal. These have been previously used for training of >300 staff in >14 countries as part of the 10-year USAID-EPT-PREDICT project, 5 NIH-funded R01s for work on select agents in resource-poor countries such as Bangladesh, Malaysia, Indonesia, India, and DTRA-funded capacity building projects in Western Asia, Malaysia, South Africa and Liberia. In the current proposed work, EHA will conduct training exercises for NEIDL and in-country field staff on the safe, humane and secure trapping, handling, and anesthesia of wildlife reservoirs, as well as high quality biological sample collection and storage and cold-chain management. This will include lectures and practicum training with live animals at the NEIDL facility, and fieldwork in Brazil, Uganda, Nigeria and Liberia to train in-country staff. Field training will be given using live individuals of species collected from locales that the modeling work suggests have a high likelihood of harboring known agents.

---

Dear all,

Thanks to everyone for comments and text for the earlier draft at the beginning of the week. Kevin's spent the last couple of days pulling all the comments together into one draft and inserting his changes, and I've now attached a v3 of the draft. It's still rough, and now too long, but it's getting there. I wanted you to look at this rough version because I'm stuck in Liberia in meetings Friday, then flying back home Saturday. I'll continue editing this draft on the plane and will be working solely on this grant from home on Sunday, Monday, Tues, Wed, Thurs.

Please work on this rapidly if possible. If you can all push your comments through, using track changes, and get them back to me **by Sunday evening New York Time**, I will turn round a polished draft by Tuesday, giving us time for significant last go-over on Wed, Thurs. It's tight, but unfortunately, it is what it is, so please commit the time if you can!! As well as general edits (using track changes, with references in comment boxes), please do the following...

Linfa/Danielle – We especially need your input in section 1.1, 1.3, 1.4 and 2.5

Ralph/Amy - Please work your magic on this draft, inserting text, editing and reducing text, and making sure the technical details of the characterization are correct and fit the proposed work on CoVs, PMVs and Henipaviruses

Chris/Eric – Eric – congratulations on your **(b) (6)** and thanks for working on it at this time! Chris – please help and edit/finesse the language in the relevant sections for you

Tom – Your edits crossed over with Kevin's changes, so please insert all the bits that were new in the last version you sent to me, into this version. I think these are mainly the sections and comments from the other Malaysian colleagues, but please check and re-insert all key text. We especially need to be specific about which partner in Malaysia is doing what cohorts, and where, and about who's doing the testing

Thanks again all, and I'm looking forward to non-stop work on this as soon as I get on my flight in 24 hours...

Cheers,

Peter

**Peter Daszak**

*EcoHealth Alliance leads cutting-edge research into the critical connections between human and wildlife health and delicate ecosystems. With this science we develop solutions that prevent pandemics and promote conservation.*

## II. Research Strategy:

### 1. Significance:

Coronaviruses (e.g. SARS-CoV, MERS-CoV), henipaviruses (HeV, NiV) and filoviruses (EBOV, MARV) have led to some of the most important recent emerging zoonoses (1-12). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (13-15). Like most emerging zoonoses, these pathogens originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 1). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (12, 16). However, surveillance and control is hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models and reagents at sites where outbreaks begin (17).

Countermeasure and vaccine development is challenged by the small number of isolates available, and the continuing discovery of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and bat SARS-CoVs in 6/209 people (2.87%) living close to a bat cave in Yunnan, both viruses with unknown clinical impact (18, 19). NiV-like virus/disease in horses and people who ate horses, Philippines, Your study (EHA) in Bangladesh, NiV serology livestock, Mojiang virus, putative henipavirus, correlatively

linked with fatal human illness. Others have shown that ....Any other examples of spillover events into livestock or people, especially from SE Asia?? (REFS). Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70%, and that it is also present in bats in India (REF). Nipah virus was originally misdiagnosed as 'aberrant measles' in West Bengal, India (REF), has now emerged repeatedly in North India, and in Kerala, South India in 2018 and 2019 (ongoing), raising the specter of future spillover at other sites across the region (20, 21).

**Fig. 1: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC proposal targets each stage:

SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (16).

Southeast Asia has significant risk of future viral emergence: it is a well-defined hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of critical ecological and socioeconomic drivers of disease emergence (22). These include dense human populations living in networks of rural and urban communities, with strong cultural and behavioral connection to wildlife and livestock, and intimate connection to global travel networks (23). It is also a region undergoing rapid environmental and demographic change, both of which lead to increased risk of disease emergence and spread (REFS). It is therefore not surprising that a number of recent discoveries have identified near-neighbors of known agents spilling over to livestock and people through often novel pathways, leading to sometimes unusual clinical presentations (Table 1).

In addition to these spillover events, relatives and near-neighbors of known viral pathogens have been reported throughout the region, including by members of our consortium. These include: henipaviruses in *Pteropus* and other? bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, other countries? (24-30); a novel henipavirus Mojiang virus in wild rats in Yunnan (31); serological evidence of filoviruses in bats in Bangladesh and Malaysia (REF); evidence of novel filoviruses in bats in Singapore (32) and China (33-35), including Měnglà virus that appears capable of infecting human cells (36); novel paramyxoviruses in bats and

Commented [EL4]: Preliminary data from DTRA project

rodents consumed as bushmeat in Vietnam (37), a lineage C  $\beta$ -CoV in bats in China that uses the same cell receptor as MERS-CoV and can infect human cells *in vitro* (38); 52 novel SARSr-CoVs in 9 bat species in southern China (172 novel  $\beta$ -CoVs from >16,000 sampled bats) that are also found throughout the region (38-41), a new  $\beta$ -CoV clade ("lineage E") in bats (41); and XX novel wildlife-origin CoVs and paramyxoviruses in Thailand and Malaysia identified as part our work under USAID-PREDICT funding (39, 42). Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (43), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (38-41, 44-46). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-concept for an early warning approach that we will expand in this EIDRC to target key viral groups in one of the world's most high-risk EID hotspots.**

Viral agent	Location, date	Impact	Novelty of event	Ref.
Melaka virus & Kampar virus	Malaysia, 2006;	Caused SARI in family group, individual	1 <sup>st</sup> disease due to bat-origin reoviruses (other reports Singapore, Vietnam etc.)	(47-50)
Reston filovirus	Philippines 2008	Seropositive people killed pigs,	No prior findings of filoviruses in pigs	(51)
Reston filovirus	Shanghai 2011	PCR positive pigs	Further evidence of pig RESTV infection	(52)
Nipah-like virus	Philippines 2015	Killed horses	No prior horse infection for NiV, known for HeV	(53)
SADS-CoV (HKU2)	China 2017	>25,000 pig deaths seronegative people	Novel emergence of bat-origin CoV	(54)
SARSr-CoV & HKU10-CoV	Yunnan, Guangxi 2015	Seropositive people	1 <sup>st</sup> evidence human infection HKU10 & SARSr-CoV since 2003	(19)
Nipah virus	Kerala, 2018 & 2019 (REF)	XX people infected/dead	1 <sup>st</sup> outbreak of NiV outside Bangladesh, W. Bengal focus	(21)

**Table 1:** Recent reports from SE Asia indicating potential for novel pathways of emergence, or unusual presentations for known or close relative viruses. **OTHERS? Could include Melaka but it's in the Reoviridae and not in the RFA (should we only include pathogen groups listed in the RFA in this table?)**

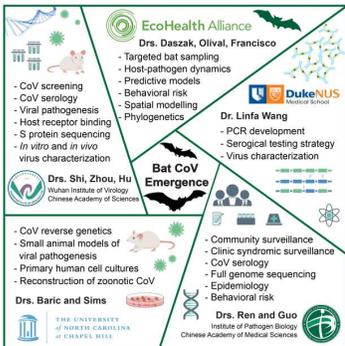

The overall rationale for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. The overarching goal of this proposal is to better understand the diversity of known and closely related CoVs, henipaviruses, and filoviruses in wildlife reservoirs in SE Asia, to test their capacity to infect human cells and mouse models, to develop new specific and sensitive serological and molecular diagnostic tools, and to conduct surveillance of human populations with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover and pandemic potential, and of viruses causing previously 'hidden' clinical syndromes in people.

**2. Innovation:** Previous work by our consortium has developed a system to target surveillance in wildlife and people to better anticipate spillover events and pre-empt outbreaks of emerging viruses (REF). In this EIDRC we take this approach and scale it up to cover three critically high-risk EID hotspot countries in Southeast Asia, within a regional network of collaborators. The innovation in this EIDRC is in: 1) its multidisciplinary approach that combines modeling to target the geography for wildlife and human sampling, novel phylogenetic and *in vitro* and animal model approaches to identifying risk of viral spillover into people, development and transfer of novel serological and molecular diagnostics, and use of parallel large scale cohorts to identify spillover and illness due to known and novel viruses; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people and builds on our successful work on SARSr-CoVs; and 3) the

combination of geographically targeted human populations with high risk of animal contact and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach. **In Aim 1, we will target viruses in new and archived wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, as well as further characterize viruses we have recently discovered. We will use cell culture and animal models to assess their potential for spillover into high-risk human populations. **In Aim 2, we will conduct focused, targeted surveys and sampling of human communities with high exposure to wildlife and other animals.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. We will use behavioral risk data, virological and ecological data to identify the likely reservoirs of viral groups identified. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise 'cryptic' outbreaks.** We will enroll and collect behavioral risk information and biological samples from patients in communities at high risk for disease emergence, who present with syndromes previously linked to known viral agents. We will conduct molecular and serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs.

### 3. Approach

**Research team:** For this EIDRC we have assembled a group of world leaders in emerging virus research with

proven experience collaborating internationally on field, lab and human surveillance research (Fig. 2). Over the past two decades, our consortium partners have collaborated together within the region and globally to conduct high profile research on these and other viral groups. This work includes identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (40, 43, 55-59), discovering SADS-CoV (54), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (44-46, 60-73). It includes substantial experience conducting human surveillance during outbreaks (e.g. - Please insert examples that you've been involved in and REFS), and as part of longitudinal efforts to pre-empt pandemics (74, 75).

**Fig. 2:** Interdisciplinary team & roles in the proposed SE Asian EIDRC. PLACEHOLDER – Hongying to modify

PI Daszak has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5- 20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival, Zambrana, Ross are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, Laing have developed a unique array of *in vitro* cell

culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesadee, Hughes and collaborators have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from DoD, USAID, NIH, DHS and other USG agencies that supports a range of laboratory, analytical and field studies

directly related to the current proposal, and will bring substantial leverage to the EIDRC (See Section XX).

**Fig.3 :** Map of Southeast Asia indicating the three core countries for this proposed EIDRC (White: Thai, Sing, Mal) and those that Key Personnel are actively collaborating with (Green: field sites and collaborating labs indicated with asterisk). PLACEHOLDER – Hongying to modify - please use a map with part of India and Bangladesh. –This map is the perfect range

**Geographical focus:** The three core countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam and Indonesia. It encompasses diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our consortium's extensive network of collaborators in clinics, research institutes and public health laboratories in every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in XX countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Current list of contacts at key human (especially) and wildlife orgs in every SE Asian country from map above – please add to this and send in the full details on the form requested by Luke/Aleksei!**

**NOTE: Everything below is a very rough draft. I've lifted heavily from our recent CoV R01 renewal submission, and indicated in comment boxes the names of the people who I believe know most about each section and can modify or write the new text needed.:**

**Aim 1: Identification and biological characterization of spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (23). In Aim 1, we will analyze these factors to identify regions, species and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and test newly collected and some of the tens of thousands of recently collected samples we have archived in freezers in our labs for known and novel agents. Using previously developed approaches to predict capacity of novel viruses to infect human cells and mouse models, we will characterize these viruses and assess their potential for spillover, using those of high risk as targets for human sampling in Aim 2 and 3. This approach is built on substantial previous proof-of concept preliminary data:

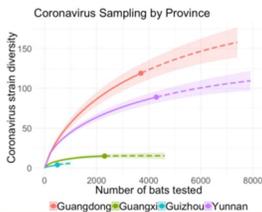

**Geographic targeting:** EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover in a region is (22, 23). For Southeast Asia, these EID hotspots are sites with high wildlife biodiversity, human population density and undergoing rapid land use change (**Fig 4a**). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (76). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (**Fig. 4b**). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (77). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data in an app we have produced with Dept Homeland Security funds (78). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

**Fig. 4:** Our previous work has shown proof-of-concept in geographically targeting sampling to maximize regions as high risk of wildlife-to-human spillover (**Fig. 4a**), and regions with high diversity of predicted 'missing' or as-yet undiscovered viruses, yellow = highest diversity (**Fig 4b**). From (22, 23, 76). Kevin/Alice, please insert high res hotspot map from Allen et al. (Fig 4a), expand the current map from Olival et al. to cover the same region as shown in Fig. 3, and remove the red triangle of course.

Commented [PD5]: Kevin – please edit

**Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primate represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential (76). The bulk of our sampling and sample testing will consist of bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses (79-82) (ADD REFS). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (76). We have used a novel phylogeographic analysis, Maximum Clade Credibility (MCC) tree, to reconstruct the geographic areas of evolutionary origin for  $\beta$ -CoVs that we sequenced in bats (39). This approach allows us to identify the ancestral home of specific zoonotic viral groups in wildlife, where their diversity is likely highest. Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (83, 84) (**Fig. 5**). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. **In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively identify new strains to support experimental infection studies and risk assessment.**

**Fig. 5:** Estimates of SARSr-CoV total strain diversity in bats we sampled in China under a NIAID R01 (strain defined as >10% sequence divergence in RdRp gene). GD and YN harbor highest CoV diversity, but discovery has not yet saturated. We used this to estimate that additional sampling of 5,000 bats will identify >80% of remaining  $\beta$ -CoV strains in bat hosts from these regions. We will apply this approach to our target host and viral taxa, for Thailand, Singapore and Malaysia to calculate sampling targets and success rates.

Commented [PD6]: Kevin to edit

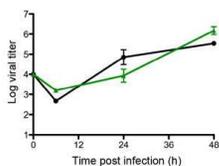

**Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. This includes sampling and PCR-screening >16,000 individual bats from 6 families (16 genera) in southern China for coronaviruses, identifying 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARSr-CoVs). This includes members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus (SADS-CoV) killing >20,000 pigs in Guangdong Province (54). Many of these bat species are found across the region. We have collected XX samples from bats, rodents and primates in Thailand and XX in Malaysia under PREDICT, screening XX and

Commented [PD7]: All to edit

Commented [PD8]: Kevin – need the PREDICT numbers here please

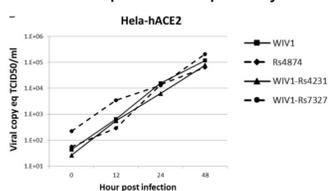

archiving duplicates of all of these which are now available for use in this project. We used family level primers for henipaviruses, filoviruses and CoVs and have already discovered XX, YY and ZZ in these two countries. In the current proposed work, we will attempt to isolate and characterize those that our analyses below suggest are most likely to be able to infect humans. Our collaborative group has worked together on these projects, as well as under DTRA funding in Singapore/Thailand (Co-Is Wacharaplesadee, Wang) to design, cross-train, and use novel serological and PCR tests to investigate xxx, and in Thailand (Co-Is Broder, Laing and Wacharaplesadee) on tech transfer of Luminex-based serology platform for detecting exposure to novel Asiatic filoviruses and known henipaviruses in wildlife and human samples. This is part of a planned DoD regional center of excellence for training in Thailand (details please?).

**In vitro & in vivo characterization viral potential for human infection:** We have used *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3% to 7% (40, 43, 85). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs from a specific cave site in Yunnan China, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (43). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of different variants, including WIV1-Rs4231S and WIV1-Rs7327S. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in HeLa cells that don't express ACE2 (40, 43, 85) (Fig. 5a). We used the SARS-CoV reverse genetics system (64) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence

from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into diverse variants of RBD can use human

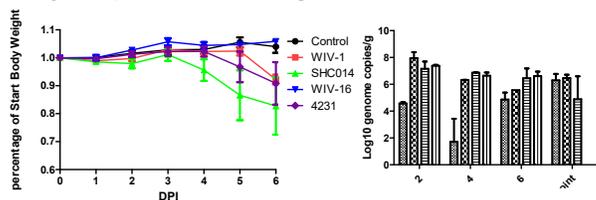

**Fig. 5a (left):** RT-PCR chimeras WIV1-expressing human Urbani (black) and human airway epithelial

cells (44) (Fig. 5b). Thus, SARSr-CoVs with SL-CoV S protein without deletions in their ACE2 as receptor for cell entry.

shows that bat SARSr-CoVs WIV1, Rs4874, and Rs4231S, WIV1-Rs7327S grow in HeLa cells ACE2. **Fig. 5b (right):** Viral replication of SARS-CoV SARS-SHC014S (green) primary air-liquid interface cell cultures at an MOI of 0.01.

We infected transgenic mice expressing hACE2 with 10<sup>5</sup> pfu of full-length recombinant WIV1 and three chimeric viruses (WIV1 backbone with SHC014S, WIV16S and Rs4231S). hACE2 transgenic mice challenged with rWIV1-SHC014S experienced ~20% body weight loss by 6dpi; rWIV1 and rWIV1-4231S produced less body weight loss, and rWIV1-WIV16S led to no body weight loss (Fig. 6a). At 2 and 4 dpi, viral loads in lung tissues of mice challenged with all three chimeras reached > 10<sup>6</sup> genome copies/g, significantly higher than rWIV1 infection (Fig. 6b). This demonstrates that pathogenicity of SARSr-CoVs in humanized mice differs with divergent S proteins, confirming the value of this model in assessing novel SARSr-CoV pathogenicity.

**Fig. 6:** *In vivo* infection of SARSr-CoVs in hACE2 transgenic mice. **6a (left)** Body weight change after infection; **6b (right)** Viral load in lung tissues.

Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity.

Vaccination against SARS-CoV did not reduce severity of clinical signs in mice subsequently infected with rSARS-SHC014S (44). We found 2/4 broad human mAbs against SARS-CoV RBD cross-neutralized WIV1, but none could efficiently neutralize SHC014 which is less similar to SARS-CoV in the RBD (86). We repeated

**Commented [PD9]:** Kevin – likewise need the best numbers, and please reach out to Tom and Suporn to clarify/expand on what's in EIDITH

**Commented [PD10]:** Linfa, Danielle, Suparn – please expand

**Commented [PD11]:** Chris, Eric, Suparn please expand

**Commented [PD12]:** I think this is something that Linfa, Suparn or Chris mentioned?

**Commented [PD13]:** Ralph, Amy – this is directly from our CoV R01 renewal – please reduce the length of this section and adapt for this proposal. We prob don't need all these figures – just one or two would do.

this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, and found that they are unable to use the ACE2 receptor. Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines. The ability of HKU3r-CoVs to infect people, and their receptor binding target, remain unknown.

All – what can we say about Nipah and filoviruses in this section – what is the rationale for a similar approach (e.g. we're looking for viruses somewhere between Cedar and Nipah in the Henipaviruses, and trying to assess the likelihood of some of the novel filoviruses infecting human cells).

Are we just going to use cell culture for henipas and filios, or can we look at spike protein diversity?

### Henipaviruses

Hendra virus and Nipah virus have a broad mammalian tropism with natural infection recorded in bats, horses, pigs, humans, cattle, goats and dogs. This broad species tropism is likely mediated by henipavirus receptor usage of highly conserved ephrins ligands (e.g. ephrin-B2 and -B3) for cell entry. Ephrins are critical in evolutionary developmental process such as cell migration, axonal guidance and angiogenesis (REF), and eprin tissue distribution correlates with the multi-systematic cellular pathology, vasculitis and encephalitis disease presentation during HeV and NiV infection. The third isolated henipavirus is Cedar virus, yet unlike NiV/HeV, CedV does not cause pathogenesis in animal models. Recently, Dr. Broder and Laing have developed a reverse genetics system for Cedar henipavirus and have rescued a recombinant Cedar virus that is used as a model henipavirus tool to understand how ephrin receptor usage/tropism contributes to pathogenicity during henipavirus infections. Ephrin-B3 is distributed in the spinal cord, and usage of ephrin-B3 has been postulated to underlie the enhanced encephalitis seen during NiV infection. Further dissimilar from HeV/NiV, CedV is unable to utilize ephrin-B3 as a receptor (Marsh 2012; Laing 2018) nor does it express the interferon antagonizing virus factors: V and W proteins (Marsh 2012). However, Dr. Broder and Laing have discovered that CedV has a promiscuous/broad ephrin receptor usage and in addition to ephrin-B2 is able to utilize ephrins-B1, -A2 and -A5 for cell entry (Can include microscopy image/column graph for unpublished figure). Additionally, it was discovered that CedV can utilize mouse ephrin-A1, which differs from human ephrin-A1 by one amino acid residue in the key binding pocket, demonstrating the first evidence of henipavirus species-specific receptor use (Can include unpublished figure). Like ephrin-B3, ephrin-B1 is widely distributed throughout spinal cord tissues, however, CedV is non-pathogenic. Pathogenicity of henipaviruses is likely mediated by a contribution of both utility of ephrin receptors and expression of virulence factors V and W proteins. The full genome assemblies of putative henipaviruses, Ghana virus and Mojiang virus, predict expression of V and W proteins. GhV is able to bind to ephrin-B2, but not -B2 (Lee – African emergent henipavirus B2 crystal) and the receptor for MoJV remains unknown (Lee, idiosyncratic 2017), but is unlikely an ephrin. Thus, when we identify novel henipaviruses or paramyxoviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize molecular experimentation with novel henipaviruses that are predicted to interact with ephrin-B2 and expression V/W proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models.

What about using bat cell lines and batized mice from Linfa?

### 1.2 General Approach:

We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new collection from wildlife in high risk locales. We will use serological & PCR testing, to identify viruses, then attempt to isolate and biologically characterize viruses that phylogenetic and

other data suggest have high spillover and pandemic potential. We will then conduct *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease. EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses. A key goal of this work will be technology transfer to the region, including cell culture, animal models, serological and PCR diagnostics, as well as knowledge transfer by embedding staff in partner labs and by regular meetings. This will leverage substantially from the other funding available to consortium partners.

### 1.3 Wildlife samples: 1.3.a Site selection & sample sizes for newly collected and archived samples:

Adapt text from the rationale/innovation above and make brief statements about the work we'll do:

- Geographic targeting: we will use refined hotspot, 'missing viruses', and FLIRT analyses
- Targeting of host species/viral discovery targets: We will use phylogenetic MCC analyses and viral discovery curves
- Additional approaches: mapping of cave sites,

To calculate sample sizes, we will use previous work on SARSr-CoVs in bats in China, the results of bat, rodent and primate sampling under PREDICT in Malaysia and Thailand, and published data. For SARSr-CoVs in China, we found 6.7% mean PCR prevalence of SARSr-CoVs across bat hosts, with a small number of *Rhinolophus* spp. horseshoe bats having significantly higher PCR prevalence than other species sampled (REF).

#### Kevin – below is the language from our R01 CoV renewal proposal as a model:

In Y1 we will use our bat host and viral trait modeling, phylogeographic analyses of RdRp and S Protein sequences, and geographic and host species-based viral discovery curve analyses to identify SARSr-CoV diversity hotspot regions for bat sampling. We will sample at 8 new sites in four provinces. We will use cave site data (87), and demographic information to identify two sites in each of Yunnan, Guangxi, Guangdong, and Guizhou where humans likely have contact with bats. In Yunnan, we will identify two unsampled caves close to, but distinct from, the Jinning cave (43). This will provide adequate coverage of lineage 1 and 2 SARSr-CoVs, including a rich source of new HKU3r-CoVs, which have unknown potential for zoonotic spillover. Sampling will begin towards the end of Y1. We will use survey data from our previous R01 and host-specific viral accumulation curve data to target an additional 10 under-sampled *Rhinolophus* spp., 5 that were SARSr-CoV negative in our study, and a small number of related bat genera (including *Hipposideros* spp. and *Aselliscus* spp.) we previously found PCR positive for SARSr-CoVs (Table 1). We will sample at least 5,000 bats from these 4 provinces (~1250 per province). Given ~5-12% prevalence of SARSr-CoVs in *Rhinolophus* spp. at our previous sites, **this sample size would give us 425 (±175) positive individual bats, and ~125 novel strains.**

**1.3b Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C. One-step hemi-nested RT-PCR (Invitrogen) will be used to detect the presence of CoV sequences using primers that target a 440-nt fragment in the RNA-dependent RNA polymerase gene (RdRp) of all known  $\alpha$ - and  $\beta$ -CoV (88). PCR products will be gel purified and sequenced with an ABI Prism 3730 DNA analyzer.

We will attempt isolation on samples that contain viruses of interest (determined in 1.4, below), using Vero E6 cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). This includes the over XX cell lines maintained at Duke-NUS.

**1.3.c Sequencing S proteins:** Our previous R01 work identified diverse SARSr-CoVs with high propensity for human infection (19, 43, 44). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (Fig. 4) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are

Commented [PD21]: Kevin – please lead the drafting of this section. I've left in the section from our CoV R01 for you to adapt.

Commented [PD22]: Please check section 1.4.b and see if parts of that should be here..

Commented [PD23]: Ralph, Amy, Linfa, Danielle, Chris, Eric - This is from our CoV R01. Please insert details that apply also to henipa and filoviruses.

Commented [PD24]: Linfa, Supaporn, Danielle – is this correct?

Commented [PD25]: Brief description of these please

Commented [PD26]: Ralph et al. – I'm assuming this will still be of value for the CoVs, so a reduced version of this could be in here, but what about spike proteins of filoviruses and henipaviruses – is that not of any use for assessing their capacity to infect human cells. Can we do similar work with filovirus pseudotypes from sequencing the spike proteins, for example, to assess binding to human receptors? If so, please draft some text and point to some references

undersampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (40, 44, 89), suggesting that . However, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis.

For all novel SARSr-CoV strains, we will sequence the complete S gene by amplifying overlapping fragments using degenerate primers as shown previously (40, 43). Full-length genomes of selected SARSr-CoV strains (representative across subclades) will be sequenced via high throughput sequencing method followed by genome walking. The sequencing libraries will be constructed using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR will be performed to fill gaps in the genome. The full length S gene sequences, including the amount of variation in the S receptor binding residues that bind the ACE2 receptor, will be used to select strains for Aim 3 experiments.

**1.4. Assessing risk for spillover. 1.4.a Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, we will use primary human ciliated airway epithelial cells (HAE) cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (44, 45, 90). We will prepare HAE cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) (46, 63). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (45, 91). As controls, the S genes of novel SARSr-CoV will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (92). Polyclonal sera will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (45, 93, 94). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (95) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (96-98).

Filoviruses (primary endothelial cells – ralph has primary lung endos – see if anyone has liver primary hepatocytes. Other option are monocytes) – where will we do this? BSL4? (NEIDL). Duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (See letter of support) for culture and sharing with other agencies. Check on this re. wildlife filoviruses...See if can do training opportunities so they can work with the NEIDL – visiting scholar appointments

**Commented [PD27]:** Ralph, Linfa, Chris – please expand and draft – I think this could be a good role for NEIDL, but don't know what the rules are...

**1.4.xx Host ACE2 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the *intraspecific* scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (62).

**Commented [PD28]:** Kevin/Ralph – I don't think this is relevant for our EIDRC – please let me know and delete if correct.

**1.4.b Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RdRp, Spike, and full genome sequence (when available) data to reconstruct the evolutionary history of the novel bat SARSr-CoVs we identify. We will rerun MCC analyses (Fig. 3) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR-positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (Fig. 4) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (84, 99).

**Commented [PD29]:** KEvIn/Alice – please modify this section for filoviruses and henipaviruses as well (and other hosts) - or does it belong in 1.3.a above?

**1.4.c Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (91, 100-102).

**1.4.d Animal models:** We will use a series of mouse models to assess spillover potential of viruses. First, the Baric lab has a well-established hACE2 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect. Briefly, in BSL3, n=5 10- to 20-week old hACE2 transgenic mice will be intranasally inoculated with  $1 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by SARS-CoV NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV mAbs will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (90, 103). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (45, 90).

For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments. We have used this model for CoV, filo (Ebola), Flaviviruses, alphaviruses infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection.

Duke-NUS has develop two models for bat *in vivo* culture: the 'batized' mouse model (Description) and a colony of *Eonycteris spelaea* (cave dwelling small fruit bat).

**1.5 Potential problems/alternative approaches: Permission to sample bats in sites or provinces we select.** We have a >20-year track record of successful field work in Malaysia, Thailand and >10 years in Singapore, and have worked with local authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based on a range of PCR data and are fairly conservative in our approach. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses. The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate

Commented [PD30]: Ralph – can you reduce this section to a feasible amount of work for this project, and remove a bunch of text

Commented [PD31]: Ralph – please draft a brief para explaining what we'll do with this mouse model

Commented [PD32]: Linfa/Danielle – please draft a brief para explaining how we'll use either or both...

Commented [PD33]: Kevin – please edit/check

Commented [PD34]: Kevin – please check the veracity of these comments

regions (104), do not suggest a strong pattern of seasonality in CoV shedding, although there are studies that suggest this occurs in henipavirus and filovirus (MARV?) shedding (REFS?). Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province.

## **Aim 2: New serological and PCR tools to test evidence of viral spillover in high-risk communities..**

**2.1 Rationale/Innovation:** Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that are the first to get infected. To enhance low statistical probability of identifying these rare events, populations could be targeted that both live in rural locations close to high wildlife biodiversity, and also engage in behaviors that enhance the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will expand from our current work in the region to identify and enroll large cross-sectional samples from human populations that have high behavioral risk of exposure to wildlife origin viruses and live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will use behavioral surveys and repeated biological sampling, design and deploy specific and sensitive serological assays to identify the baseline spillover of known or novel viral pathogens in these populations. Where symptoms are found, we will use PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, attempt to isolate and biologically characterize the pathogen, using the collaborative cross mouse (Aim 1) to identify an appropriate animal model to conduct preliminary pathogenesis work.

**Preliminary data human biological sampling:** Our longterm collaboration in the region has included identification of key at-risk human populations from which we have already collected qualitative and quantitative survey data, and biological samples. These include:

**Peninsular Malaysia:** Data from 1,300 Orang Asli samples, PCR for 5 viral families: 5 known CoVs in 16 people, one Influenza virus. Serology on its way incl. filovirus reactors...

**Sabah:** We have ~25 new CoVs in Sabah. Simon is using HTS to further characterize and Tom will get the data for this proposal from Simon.

Tom will work out all serum samples we have, incl. samples from dead bats.

Kamruddin (UMS Borneo Medical Health Research Center) has identified some high risk communities. We can help with them and build out the BSL-2 lab, as well as work on outbreak response within DHRU (in collab with Sabah CDC?).

Tom will speak with Tim Williams ...He has archived samples from Kudat Monkey bar project – 2,000 human sera already screened for bacteria and parasites, we've been reached out to about this. Data on macaque tracking data/human tracking data also.

**Sarawak:** Dr Tan (Cheng Sieng) Center for Tropical and Emerging Diseases, Faculty of Medicine at UNIMAS – high risk Dayak communities that he's identified. We will do further sampling, questionnaires etc. Has Prelim data on HPV work in Dayak communities in remote Sarawak – we can work with those communities and can reach many by car, others by 4WD or boats. Has also Enterovirus 71 paper and is interested in CoVs. Has access to caves and guano. Will look into what other archived samples he has. Will give us access to Sarawak Forestry and Health Depts.

**Thailand:** Imported MERS cases..Zika patients. 10 yrs ago AFRIMS in Thailand found serological NiV +ve in Children far from the bat colony, prob with publication of data because didn't do neg controls – could do SNT at NEIDL or Wuhan – couldn't get permission Have emailed Andrew Hickey about this. High-risk community cohorts – Loei Province (Guano miners) – whole community

**Singapore:**

**Behavioral risk:** EHA is the global lead organization in the USAID-PREDICT project for assessing human behavioral risk of zoonotic spillover. The general approach has been to conduct qualitative exploratory studies using standardized one-on-one semi-structured ethnographic interviews and observational data in among people engaged in clearly high-zoonotic risk activities (e.g. we interviewed 88 people involved in trading wild bats in China – REF). This allows us to assess local social and cultural norms and individual attitudes underlying wildlife contact. We used qualitative study findings to develop a human behavioral risk questionnaire on the type and frequency of animal contact, wildlife observed in daily life, and unusual illnesses

**Commented [PD35]:** All – please read and share with collaborators to flesh out and correct details here.

**Commented [PD36]:** Linfa, Danielle – are we going to do human sampling in high risk communities in Singapore? If so, what would you propose and do you already have some prelim work you've done. Note these are high risk populations, i.e. high exposure to wildlife. Clinical cohorts are in Aim 3

**Commented [PD37]:** Hongying/Emily to edit

reported over the past 12 months. We conducted cross-sectional studies in high risk populations in >15 countries during the last 5 years, and study participants also provided biological samples (oropharynx swab, serum, plasma). Questionnaires and biological samples were collected from 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, XX from XX sites in Malaysia and XX from XX sites in Thailand. The results of these surveys will be used in Aim 2 to better identify target populations.

**Serological Evidence of Exposure:** In China, we developed serological assays for HKU9 CoVs ( $\beta$ ), SARS-CoV Rp3 ( $\beta$ ), HKU10 CoV ( $\alpha$ ), and MERS-CoV ( $\beta$ ) and used ELISA and Western blot to test serum samples collected in 2016/17. **We found 7 individuals (7/733, 0.95%) living within a 6 km radius of the Jinning Cave, and 6/209 people (2.87%) at one site, with evidence of exposure to bat SARS-CoVs.** We found evidence among human populations in Guangxi Province of people with prior exposure to the bat  $\alpha$ -CoV HKU10 (2/412, 0.48%). This is of potential public health interest because HKU10 is known to be able to jump host species within bats, and therefore may have high propensity for emergence (105). However, the low seroprevalence (0.6%-2.7% at positive sites) suggests we need a larger sample size, and a focused, targeted study to maximize the likelihood of identifying seropositive cases. In Aim 2, we will use combined biological-behavioral risk surveillance in targeted populations within the community and clinical settings to 1) identify risk factors correlated with seropositivity (exposure to) and PCR positive status (infection with) henipaviruses, filoviruses and CoVs; and 2) assess possible health effects of infection in people. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**Risk Factors:** In China, questionnaire response and demographic data suggest specific risk factors included type of occupation, keeping of pets and visiting wet markets. Seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), and are male (6/9). However, these characteristics were common and occurred in ~40% of survey respondents. Although these results are preliminary and don't provide detailed information on routes of exposure, they suggest that further refining use serological tests coupled with qualitative and questionnaire data will identify likely routes of exposure to novel CoVs in China. In Aim 2 of this EIDRC proposal, we identify strategies to better target at-risk people, and conduct focused **questionnaires and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.**

**2.2 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (**Fig. XX**). In Aim 2 we will conduct community-based surveillance with more focused questionnaires and biological sampling to determine the seroprevalence of spillover viruses in at-risk human populations, and to identify risk-factors for viral spillover in these communities. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at sites that include the community-based surveillance sites within their catchment (details in Aim 3). Both community-based and clinic-based syndromic surveillance programs are case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and symptoms.

**2.3 Target population & sample sizes:** We will target sites in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potentially zoonotic viral diversity, in regions that are EID hotspots, and are well-connected to regional travel and trade hubs and the global travel network. We will target specific communities based on our PREDICT behavioral analysis questionnaire data to assess key at-risk populations with high exposure to wildlife, as well as other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will also expand on work currently underway in the following particularly high exposure populations:

**Thailand:** We have conducted behavioral risk surveys and biological sampling in XX guano miners in Loei. These workers visit bat caves and dig fecal material to use as fertilizer, and are therefore highly exposed to bats and rodents in particular.

Commented [PD38]: Hongying/Emily – any information from Thailand or Malaysian surveys?

Commented [PD39]: Hongying/Emily to edit

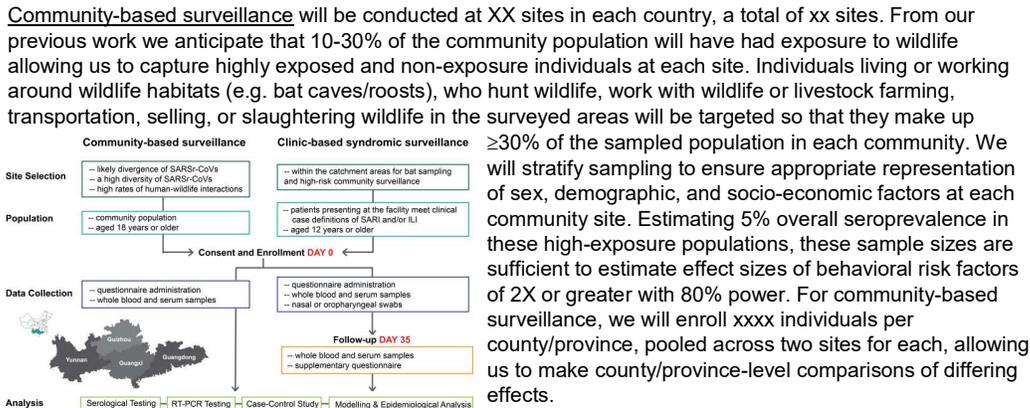

Commented [PD40]: Suporn – please draft plans for what we should do to scale up this work. We could also include other high-risk communities – any ideas?

**Peninsular Malaysia:** We have sampled Orang Asli populations for the past 2 years, enrolling XX people. We will expand this to includeXXX

**Sarawak:** Dr Tan (Cheng Sieng) Center for Tropical and Emerging Diseases, Faculty of Medicine at UNIMAS – high risk Dayak communities that he’s identified. We will do further sampling, questionnaires etc. Has Prelim data on HPV work in Dayak communities in remote Sarawak – we can work with those communities and can reach many by car, others by 4WD or boats. Has also Enterovirus 71 paper and is interested in CoVs. Has access to caves and guano. Will look into what other archived samples he has. Will give us access to Sarawak Forestry and Health Depts.

**Sabah:** \_\_\_\_\_

**Singapore:?**

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**2.4 Data & sample collection:** Following enrollment with signed consent form, **biological specimens** (two whole blood samples, one max. 500 µL; two 500 µL serum samples) will be collected from all eligible participants, and a **questionnaire** will be administered. We will investigate five risk factors, so as to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation; 2) observed or reported interactions with bats in/around house; 3) proximity to nearby bat roosts; 4) working or regular visit to animal markets; 5) self-reported ILI/SARI. With consent from participants, we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

**2.5: Laboratory analysis: 2.5.a Serological testing:**

One of the present challenges in emerging disease surveillance is that viremia can be short-lived, complicating viral-RNA detection (i.e. traditional PCR-based approaches), especially in zoonotic reservoir hosts, and requiring large samples sizes to understand infection patterns or host range. In contrast, antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller samples sizes. However, most serological assays only target a single protein, and it's not always clear which antigen is the most immunodominant during an adaptive humoral immune response – i.e. which is the best target for a serological assay. Henipaviruses, filoviruses and CoVs express envelope receptor-binding proteins (e.g. CoV=spike (S) protein, filoviruses/henipaviruses=glycoprotein (GP/G)), which are the target of protective antibody responses. The Broder lab at USU, a leader in the expression and purification of native-like virus surface proteins for immunoassay application (Bossart 2008), developing monoclonal antibodies (Zhu 2008, Bossart 2009) and as subunit vaccines (Bossart 2012, Mire 2014), is presently developing a novel, multiplex

**Commented [PD41]:** Tom – please start writing some plans for what we could do.

**Commented [PD42]:** All – not sure if we should have one figure for community and clinical cohort surveillance (aim 2 and 3 respectively) or if we should have two separate ones?

**Commented [PD43]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipav, filov and CoVs.

**Commented [PD44]:** Emily/hongying

**Commented [PD45]:** Chris, Eric, Linfa, Dani etc. please draft some language here...

**Commented [EL46]:** Nations, F. a. A. O. o. t. U. in *FAO Animal Production and Health Manual* Vol. No. 12 (ed H.E. Field S.H. Newman, C.E. de Jong and J.H. Epstein.) (Rome, 2011).

microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, filoviruses and coronaviruses (Table XX).

Formatted: Highlight

This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins (Bossart 2008, Chan YP 2009). These oligomeric antigens retain post-translational modifications and quaternary structures. This structural advantage over peptide antigens, allows the capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response.

Serological platforms have been historically limited by the starting antigen, and cross-reactivity between known and unknown related viruses not included in the assay.

The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (Preliminary Figure A). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-like African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (Peel 2012, Chowdury 2014). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific versus henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists within ebolaviruses and between ebolaviruses and marburgviruses, highlighted by studies examining antibody binding between heterologous viruses (Shuh 2019, MacNeill 2011, Natesan 2016). Ongoing work is aimed at validating the MMIA pan-filovirus assay for specificity (Preliminary Figure B). The majority of ebolaviruses are endemic to Africa, however the discovery of Mengla virus in Yunnan, China increased the further demonstrated that a diversity of Asiatic filoviruses with unknown pathogenicity and zoonotic potential exists. Our past work in collaboration with Dr. Smith and Mendenhall at Duke-NUS demonstrated that three under sampled fruit bat species had serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP, suggesting that novel filoviruses circulate within bat hosts (Lainq 2018).

Commented [EL47]: PMID:

29260678

**The below is from our previous CoV proposal:**

In our previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity was detected (19). **While this shows it is a specific test for Rp3, it suggests that if we can expand our serology tests to cover other bat CoVs, we may identify many more seropositive individuals.** In this renewal, we will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoV SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (19), but HKU10 is known to jump from one host bat species to another (105) and is therefore likely to have infected people more widely. Incorporating serological testing for SHC014 is also likely to yield higher seroprevalence because it is readily divergent from SARS-CoV wildtype and therefore unlikely to have been picked up in our earlier testing. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, we recognize that CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or RBD; 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-

human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (54).

**2.5.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

Commented [PD48]: Please modify for Henipass, filoviruses and CoVs

**2.6 Epidemiological analysis:** We will conduct a case-control study to identify risk factors for SARSr-CoVs spillover. "Cases" are defined as participants whose samples tested positive for SARSr-CoVs by serological tests. "Controls" will be selected from the pool of participants admitted to the studies but testing negative. We will use nearest neighbor matching to pair cases demographically with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors including: Activities with likely exposure to 1) bats; 2) livestock; and 3) locations of residence and work. We will use the same procedure to determine how clinical presentation differs between SARSr-CoVs-exposed and unexposed enrollees, in the time course of illness, severity of symptoms, and type of symptoms.

Commented [PD49]: Hongying/Emily

**2.7 Biological characterization of viruses identified:** XXXX

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze risk behavior. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals in likely contact with these species increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, paramyxoviruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact against other risk factors and clinical outcomes to provide useful proxy information for spillover risk. **Serological testing may not match known CoVs due to recombination events.** We will use the three-tiered serological testing system outline in 2.6.a to try to identify these 'novel' CoVs, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

Commented [PD50]: All –Not sure if we should weigh too heavily on this for the community survey – or should it just be serology for Aim 2. If you want include this section, please modify and insert language from Aim 1 here.

### **Aim 3: Clinical cohorts to identify evidence of viral etiology for 'cryptic' outbreaks.**

**3.1 Rationale/Innovation:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not diagnosed. By working with syndromic cohorts reporting to clinics with symptoms similar to known high-impact viral agents, we may be able to capture novel emerging diseases in at-risk communities before they spread into the general population and risk becoming pandemic. This will have clear value for public health in the region, and potentially wider. To do this, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with symptoms typical of high impact zoonotic viruses. We will collect detailed interview data to assess their likely contact with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We'll conduct novel viral discovery on unique clinical + symptomatic cases (maybe w high animal contact too) where testing has already ruled out all normative diseases? If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work.

**Preliminary data clinical surveillance:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes:

**Commented [PD51]:** All – please read and share with collaborators to flesh out and correct details here.

**Thailand:** Sick people cohorts – Chulalongkorn Hospital; EID Center for Thailand – Outbreak investigation Lab surveillance Min public Health Dept of Disease Control, 3 projects testing samples from people (encephalitis, Hand foot mouth disease, viral diarrhea, Influenza) = outbreak identification Dr. Rone. Any cluster of unusual disease samples will be sent to Supaporn. Have been using PREDICT protocol to identify pathogens. Dr. Parvaneh doing lab investigation

**Peninsular Malaysia:**

**Commented [PD52]:** Tom to add – Queen Elizabeth Hospital?

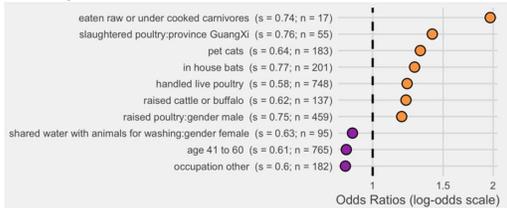

**Sabah:** Linfa has worked with Timothy Williams on an encephalitis cohort from Queen Elizabeth Hospital 1 & 2 (poss has worked with Linfa on these) and this is another possibility. He's doing outbreak response training in August with team from Sabah CDC (Dr. Maria now in Pen. But still collaborating with us, Jikal current director working with us and Dato Cristina dir. Sabah state health Dept and is supportive) this collaborative group is working to develop a Sabah outbreak response team – we will support that – to be based at BMHRC and we will develop this as part of this proposal. Prof. Kamruddin will summarize the serum samples he has. POCs: Sabah State Health Dept (e.g. Dr. Giri Shan Rajahram), Queen Elizabeth Hospital (Dr. LEE Heng-Gee)

**Sarawak:** From Linfa – Dr. Ooi used to work with Jayne Cardosa at UNIMAS and has access to samples of patients with unusual presentation

**Commented [PD53]:** Tom

**Strategy for analysis of self-reported illness:** We have developed a standardized approach in PREDICT to analyzing data on self-reported symptoms of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), and fever with muscle aches, cough, or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between ILI and/or SARI symptoms and contact with animals in the last year. Results have clear biological relevance. In Yunann, China, salient predictors or combination of predictors were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (**Fig. 11**). We will expand this approach for all syndromes in Aim 3, and with questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country.

**Commented [PD54]:** Emily/Hongying

**Fig. 11:** Predictors of self-reported ILI and/or SARI in prior 12 months (s = bootstrap support; n = number +ve out of 1,585 respondents). Orange circles = odds ratios > 1 (positively associated with the outcome); purple = odds ratios < 1 (negatively associated with the outcome).

**3.2 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms typical of high-impact emerging viruses. We will collect interview data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.3 Clinical cohorts. 3.3.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at XX town-level clinics and xx provincial-level hospital in each country, in total xx hospital sites, all within the

**Commented [PD55]:** Hongying/Emily

catchment areas for wildlife sampling, and which are used by people in our community-based surveillance. Patients  $\geq 12$  years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, hemorrhagic fever will be recruited into the study. We will enroll a total of at least xxxx individuals for clinical studies, which accounts for up to 40% loss from follow-up. Study data will be pooled across sites, as clinical patients are limited by the number of individuals presenting at hospitals.

**3.3.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients after initial screening to meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI) of unknown etiology; or 2) Influenza-like illness (ILI) of unknown etiology. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected within 10 days of reported onset of illness to increase the chance of PCR detection of viruses (106). We will follow up 35 days after enrollment to collect an additional two 500  $\mu$ L serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs  $<28$  days after onset of symptoms for SARS patients (107).

Commented [PD56]: Hongying Emily

Commented [PD57]: Need data for Nipah and filovirus patients

**3.3.c Sampling:** Following enrollment with signed consent form, biological specimens (two whole blood samples, one max. 500  $\mu$ L; two 500  $\mu$ L serum samples) will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, so as to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation; 2) observed or reported interactions with bats in/around house; 3) proximity to nearby bat roosts; 4) working or regular visit to animal markets; 5) self-reported ILI/SARI. An additional two nasal or oropharyngeal swabs will be collected from syndromic patients. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

**3.4 Sample testing:** PCR, Serol to link symptoms to etiologic agents

**3.5 Assessing potential for pandemic spread:** We will...leverage EHA's work with DHS to develop FLIRT (Flight Risk Tracker) that tracks the probable pathways for spread for viruses that are able to be transmitted among people....

Commented [PD58]: KEvin to draft

**From CoV renewal: use** data from 3.3 to identify rank SARSr-CoV strains most likely to infect people and evade therapeutic and vaccine modalities. We will use bat survey and zoological data (87) to build species distribution models (108) and predict the distribution of bat species that harbor low, medium and high risk viral strains. Stacking these modeled distributions for the ~20-30 *Rhinolophus* and related species that occur in the region will allow estimates of SARSr-CoV diversity for a given locality. We will use machine learning models (boosted regression trees) and spatial 'hotspot' mapping approaches to identify the ecological, socio-economic and other correlates of SARSr-CoV diversity and spillover (from serosurveys) (22, 23, 77). We will include data from our human behavioral surveys and sampling to give a direct measure of where risk of spillover to people is likely to be highest in the region.

**Potential problems/alternative approaches: Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases.** Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (106). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the potential public health importance of discovering active spillover of a new henipavirus, filovirus or CoV infection.

Commented [PD59]: Add data for Nipah and filo infections

**ALL – the sections below are going to be critical to demonstrate our capacity to do this work. I’ve not yet started drafting, but please don’t hesitate to insert whole sections from other proposals you’ve done if they’re relevant here – we’ll need to be creative and get all the language we can from others...**

**Additional Instructions – Specific to the EIDRC FOA:**

**Commented [PD60]:** All – I’ve started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**Administrative Plan**

In a clearly labeled section entitled “**Administrative Plan**”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.
- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

**List out all of our involvement with outbreak investigations, ministries of health surveillance etc.**

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

**Data Management Plan**

In a clearly labeled section entitled “**Data Management Plan**”:

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

**This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system**

**Clinical Management Plan**

In a clearly labeled section entitled “**Clinical Management Plan**”:

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment. including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and

sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.

- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics

2. Tekada Sanofi Pasteur dengue

3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

### Statistical Analysis Plan

In a clearly labeled section within the Research Strategy entitled "**Statistical Analysis Plan**":

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

### Project Milestones and Timelines

In a clearly labeled section entitled "**Project Milestones and Timelines**":

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the

research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

Hey Peter,

Have a look at some of the proposal suggestions. My (b) (6). I'm running on fumes right now and having difficulty finding time to incorporate suggestions, apologies if the word-dump is disconnected. If these are on point I'll send over some accompanying data figures you can embed.

- Eric

Thanks Eric,

As you go through the text of the grant making revisions, can you add in a bit on preliminary data at the appropriate point re. prior collab with DukeNUS with Gavin and Ian. For example, if this work is on developing the Luminex strategy, put it in that section in Aim 1 under preliminary data (section 1.1) and say something like:

“In a collaboration between USUHS and Duke-NUS, Co-Is Laing and Broder have refined and tested the Luminex serology platform on 500 samples of bats and humans with Duke-NUS (Smith and Mendenhall). The results suggest that we’re all doomed....etc...”

I’ll be talking with Linfa and Danielle tonight and will check in with them on how/if to formally include Gavin and Ian in the proposal.

Cheers,

Peter

**Subject:** Re: EIDRC SE Asia V. Rough first draft for edits

Hi Peter,

I wanted to pass along the names our two collaborators at Duke-NUS: Drs. Gavin Smith and Ian Mendenhall. Gavin is a Professor in the EID Programme that Linfa is chair of and Ian is a Principal Research Scientist in Gavin's lab. Chris and I have worked with Ian and Gavin on 2 wildlife/human interface surveillance projects in SE/South Asia and Gavin/Ian have a large footprint in Cambodia (bats/rats/collaborators). Ian and I also have a small GEIS project thru NAMRU-2 Phnom Penh, Their surveillance projects are independent of Linfa's research at Duke-NUS. I'll leave the decision to fold them into this proposal yours to make. Here are there contact addresses: [gavin.smith@duke-nus.edu.sg](mailto:gavin.smith@duke-nus.edu.sg) [ian.mendenhall@duke-nus.edu.sg](mailto:ian.mendenhall@duke-nus.edu.sg)

Best regards,

Eric

Dear all – here’s the first rough draft.

Please start editing as fast and furious as you all can. I’ve based this on our previous conversations, so there are lots of bits for you to expand on, insert references etc. Also, you’ll see that lots of the text in the Aims is from our recent CoV proposal and will need extending for Henipias, CoVs and Filos, and then editing back on the SARSr-CoV text. Please get stuck into that.

Don’t worry about all editing separately – I can collate this, although it is great if some of you go rapidly and others build on theirs.

Main thing – please draft as much as you can, please use TRACK CHANGES, and please don’t mess up the ENDNOTE! Prob best for references that you just insert them into comment boxes. It’s a bit of a pain, but it’s less work than if the whole library decomposes...

Anyway – thanks for being great collaborators, and I look forward to what you send back

NB Supaporn and Tom – please share with your collaborators, and cc me, luke, aleksei and evelyn so I have their email addresses.

Cheers,

Peter

*EcoHealth Alliance leads cutting-edge research into the critical connections between human and wildlife health and delicate ecosystems. With this science we develop solutions that prevent pandemics and promote conservation.*

The overarching goal of this proposal is to better understand the diversity of known and closely related CoVs, henipaviruses, and filoviruses in wildlife reservoirs in SE Asia, to test their capacity to infect human cells and mouse models, to develop new specific and sensitive serological and molecular diagnostic tools, and to conduct surveillance of human populations with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover and pandemic potential, and of viruses causing previously 'hidden' 'cryptic' clinical syndromes in people. Our work will follow three specific aims:

**Specific Aim 1: Identification and biological characterization of spillover risk of high zoonotic potential viruses from wildlife.** Building on our extensive previous work, we will: 1) analyze some of the tens of thousands of archived wildlife samples in our laboratories in the region, and conduct geographically- and taxonomically-targeted field surveillance in wild mammals (bats, rodents, primates), and use serological & PCR testing, and isolation to identify viruses that are known high-profile zoonotic pathogens, or close relatives with potential to infect people. ~~This includes accessing tens of thousands of samples collected on recent projects and stored in freezers in our laboratories;~~ 2) attempt to isolate and biologically characterize viruses that we have recently identified of that we discover, where that our analyses suggest they have high spillover and pandemic potential; and 3) conduct *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections using humanized mice and the collaborative cross mouse to assess their potential to infect people and cause disease.

**Specific Aim 2: New serological and PCR tools to test evidence of viral spillover in high-risk communities.** Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities and approaches that can deal with the low statistical probability of identifying rare events. To achieve this, we will expand current work in the region to 1) identify and enroll large cross-sectional samples from human populations that have high risk of exposure to wildlife origin viruses in the region, conducting behavioral surveys and taking repeated clinical-biological samples; 2) design and deploy specific and sensitive serological assays to identify the baseline spillover of known or novel viral pathogens in these populations; and 3) use novel PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses in particularly highly-exposed people OR DITCH PCR for Aim 2. When spillover of novel pathogens is identified, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work.

**Specific Aim 3: Clinical cohorts to identify evidence of viral etiology for 'hidden' 'cryptic' outbreaks.** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to: 1) enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other specific symptoms; 2) collect detailed interview data to assess their likely contact with wildlife and livestock; 3) conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. we'll do novel viral discovery on unique clinical + symptomatic cases (maybe w high animal contact too) where testing has already ruled out all normative diseases? If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

In addition, we will conduct regular meetings with key research, public health and community leaders in our collaborative consortium's network across other clinics, research institutes and public health laboratories within Thailand, Singapore and Malaysia, and across SE Asia. This includes >50 leading laboratories/institutions in XX countries that are currently collaborating on other funded work with core members of our consortium. We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and any information from the greater network on likely outbreaks of novel disease.

Sounds great. I'm working on another grant with a Friday deadline - so I will put together some language for you this weekend after I get that out. John is currently traveling, though he is aware of our conversation. He will be back in Thailand next week and I will discuss the potential LOS with him ASAP. Do you have a high level summary and Aims that I can share with John for our discussion? I would also use this to draft the LOS.

Andrew

Thanks very much for the rapid response Andrew, and a pleasure to virtually meet you John.

I really appreciate your willingness to provide a letter of support and I will absolutely respect your caveats below, of course. I think this is a great opportunity because NIAID are looking for leverage and partnerships, and although there's always that issue about one federal agency not being allowed to fund another, there are plenty of ways we can use this to help build up your capacity through cross training and joint research projects.

I've answered some of your questions in the body of your email below, and again thank you for your openness for collaboration.

Cheers,

Peter

**Cc:** Aleksei Chmura; Luke Hamel; Kevin Olival  
**Subject:** RE: Introduction. Andrew. Regards to Ecohealth NIAID submission.

Hi Peter. Thanks for the email. I cannot provide a letter of support individually, but we can consider this as the CDC country office in Thailand.

[Peter Daszak] That's great, because NIAID is looking for us to leverage partnerships I'm adding Dr. John MacArthur who is filling multiple roles currently, including Director- CDC Thailand/SE Asia regional office, HHS Country Rep for Thailand, and Director for the CDC-Thailand Div. of Global Health Protection.

I am happy to share information to help support your grant, but request this be used for the grant only. The data potentially could be published eventually and I don't want to jeopardize that possibility. What kind of information/figures do you need? What is your deadline for this LOS and this information?

[Peter Daszak] We'll definitely keep this solely for this grant and will maintain confidentiality. Given the space constraints, ideally if you could send a few sentences with some explanation of the site, subjects, number of individuals/other data with a reference, and a figure and I'll insert that or reduce a bit. The deadline is June 28<sup>th</sup>, but we're trying to get a final draft by the 19<sup>th</sup>, so if you can get me something by then that would be ideal. Luke will send a sample of the sort of info for the Letter of Support, but it's always best if it's written in your own words...

Chris may have mentioned, our CDC Director recently visited the laboratory and expressed his interest in our office starting some research on bat-borne viruses with the MOPH.

[Peter Daszak] That's very interesting and great news also.

My goal is to make sure the CDC office is positioned to work well with the groups already performing this research in Thailand and not duplicating efforts. I reached out to John already and we plan to talk in July when he comes to Thailand for the bat meeting. Are you coming for the meeting as well? If so, it would be great to connect with you while you are here.

[Peter Daszak] That's perfect re. CDC office collaborating on bat research. We've been working with Supaporn for many years, but there is so much to do there's little chance of duplication and tons of opportunity for collaboration. We are definitely interested in supporting your efforts any way we can. I won't be able to be there in July – but I'll check in with others in the office here to see if any of our staff will be there and can meet with you. I'll be in Malaysia in September and maybe that's a chance to meet also.

Again – thanks for your help and I look forward to future collaboration!

Andrew

**Subject:** RE: Introduction. Andrew. Regards to Ecohealth NIAID submission.

**Importance:** High

Hi Andrew and thanks for the introduction Chris.

We're pulling together an EIDRC proposal with the goal of funding work to identify evidence of hidden, misdiagnosed, or under-reported spillover events in SE Asia. We're working with Supaporn in Thailand, Tom Hughes in Malaysia and Linfa Wang in Singapore. In the USA, we'll be collaborating with Ralph Baric, Chris and Eric and the NEIDL lab (just for sample submission).

As Chris mentioned, I heard about the interesting findings from Supaporn, but wasn't sure what the details are – Chris filled me in. It's particularly interesting to me because our whole premise for this proposal is that viruses like henipaviruses, CoVs and filoviruses are found in wildlife hosts in SE Asia, and likely spillover regularly but the cases are either clinically inconsequential, don't get reported, or get misdiagnosed (e.g. like the original Nipah virus outbreaks in India which were called 'aberrant measles', or like the outbreaks in Bangladesh which we know how occur annually, but prior to 1999 must have been undiagnosed).

We don't have spare funds right now, given that we're pretty close to the deadline and have a full set of partners with their budgets already fixed. But, if you are interested in drafting a letter of support, maybe we could mention the preliminary findings, and make the case that these samples would benefit from further work with this collaborative group. I'm not sure of all the details, but Chris has a good idea of how we could move forwards, and given that we'll be collaborating with him, NEIDL, Linfa, Ralph, I'm sure that there would be availability of resources to run the next step of the diagnostic path to move this to a validated finding. Chris – please let me know if that's correct, or if this is a case of running SNTs, which we could do through NEIDL.

If you were able to sign on, we would certainly appreciate your involvement, and make sure that there would be opportunity for co-authorship of some of the work we're planning, as well as trying to mobilize the findings that you've already made..

Cheers,

Peter

**To:** Hickey, Andrew (CDC/OPHPR/DEO) (CTR); Peter Daszak; Eric Laing  
**Subject:** Introduction. Andrew. Regards to Ecohealth NIAID submission.

Hey Andrew,

I know you are only just getting back to Bangkok.  
Eric and I just had another TelCon with Peter (cc'd here)

Peter is going to submit this RFA:

Letter of Intent: RFA-AI-19-028 Emerging Infectious Diseases Research Centers  
This letter of intent indicates that we plan to submit a proposal in response to the FOA RFA-AI-19-028 “Emerging Infectious Diseases Research Centers”. Below are the details requested in the RFA:

Descriptive Title of Proposed Activity

**Understanding risk of zoonotic virus emergence in EID hotspots of Southeast Asia**

Supaporn is a part of this network. Eric and I will be as well but with only a small budget. In his chat with Supaporn she mentioned preliminary data of NiV spillover evidence in children in Thailand.

This is your data, with Julie. I briefly explained that and how it was left unpublished and told him

you and I chatted again about that just yesterday when discussing the CDC NiV ELISA vs Bioplex in

her bat samples (perhaps we should by some of those ELISAs)

I suggested to Peter that he include you and your folks in this proposal. and also mention that DTRA wants to fund you and get you started as well.

Peter can share with you the LOI and other documents and perhaps have a chat with you.

cheers

Chris

## II. Research Strategy:

### 1. Significance:

Coronaviruses (e.g. SARS-CoV, MERS-CoV), henipaviruses (HeV, NiV) and filoviruses (EBOV, MARV) have led to some of the most important recent emerging zoonoses (1-12). Their outbreaks have caused tens of thousands of deaths, and billions of dollars in economic damages (13-15). Like most emerging zoonoses, these pathogens originate in wildlife reservoirs, sometimes spilling over first into livestock 'amplifier' hosts, or directly into localized human populations with high levels of animal contact (Fig. 1). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (12, 16). However, surveillance and control is hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models and reagents at sites where outbreaks begin (17).

Countermeasure and vaccine development is challenged by the small number of isolates available, and the continuing discovery of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and bat SARSr-CoVs in 6/209 people (2.87%) living close to a bat cave in Yunnan, both viruses with unknown clinical impact (18, 19). Others have shown that ....Any other examples of spillover events into livestock or people, especially from SE Asia?? (REFS). Even when spillover leads to outbreaks of illness and

mortality, they are often unreported, undiagnosed or misdiagnosed. Under a prior NIH R01, we initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that NiV causes repeated annual outbreaks with an overall mortality rate of ~70%, and that it is also present in bats in India (REF). Nipah virus was originally misdiagnosed as 'aberrant measles' in West Bengal, India (REF), has now emerged repeatedly in North India, and in Kerala, South India in 2018 and 2019 (ongoing), raising the specter of future spillover at other sites across the region (20, 21).

**Fig. 1: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (Stage 1, lower panel), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (Stage 2, middle). In some cases, these spread more widely via air travel (Stage 3, upper). Our EIDRC proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; SA2 seeks evidence of their spillover into focused high-risk human populations (stage 2); SA3 identifies their capacity to cause illness and to spread more widely (stage 3). Figure from (16).

Southeast Asia has significant risk of future viral emergence: it is a well-defined hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of critical ecological and socioeconomic drivers of disease emergence (22). These include dense human populations living in networks of rural and urban communities, with strong cultural and behavioral connection to wildlife and livestock, and intimate connection to global travel networks (23). It is also a region undergoing rapid environmental and demographic change, both of which lead to increased risk of disease emergence and spread (REFS). It is therefore not surprising that a number of recent discoveries have identified near-neighbors of known agents spilling over to livestock and people through often novel pathways, leading to sometimes unusual clinical presentations (Table 1).

In addition to these spillover events, relatives and near-neighbors of known viral pathogens have been reported throughout the region, including by members of our consortium. These include: henipaviruses in *Pteropus* and other? bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, other countries? (24-30); a novel henipavirus Mojiang virus in wild rats in Yunnan (31); serological evidence of filoviruses in bats in Bangladesh and Malaysia (REF); evidence of novel filoviruses in bats in Singapore (32) and China (33-35), including Mēnglà virus that appears capable of infecting human cells (36); novel paramyxoviruses in bats and rodents consumed as bushmeat in Vietnam (37), a lineage C  $\beta$ -CoV in bats in China that uses the same cell receptor as MERS-CoV and can infect human cells *in vitro* (38); 52 novel SARSr-CoVs in 9 bat species in

southern China (172 novel  $\beta$ -CoVs from >16,000 sampled bats) that are also found throughout the region (38-41), a new  $\beta$ -CoV clade ("lineage E") in bats (41); and XX novel wildlife-origin CoVs and paramyxoviruses in Thailand and Malaysia identified as part our work under USAID-PREDICT funding (39, 42). Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (43), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (38-41, 44-46). We conducted behavioral risk surveys and biological sampling of human populations living close to this cave and found evidence of spillover (xx serology) in people highly exposed to wildlife. **This work provides proof-of-concept for an early warning approach that we will expand in this EIDRC to target key viral groups in one of the world's most high-risk EID hotspots.**

Viral agent	Location, date	Impact	Novelty of event	Ref.
Melaka virus & Kampar virus	Malaysia, 2006;	Caused SARI in family group, individual	1 <sup>st</sup> disease due to bat-origin reoviruses (other reports Singapore, Vietnam etc.)	(47-50)
Reston filovirus	Philippines 2008	Seropositive people killed pigs,	No prior findings of filoviruses in pigs	(51)
Reston filovirus	Shanghai 2011	PCR positive pigs	Further evidence of pig RESTV infection	(52)
Nipah-like virus	Philippines 2015	Killed horses	No prior horse infection for NIV, known for HeV	(53)
SADS-CoV (HKU2)	China 2017	>25,000 pig deaths seronegative people	Novel emergence of bat-origin CoV	(54)
SARSr-CoV & HKU10-CoV	Yunnan, Guangxi 2015	Seropositive people	1 <sup>st</sup> evidence human infection HKU10 & SARSr-CoV since 2003	(19)
Nipah virus	Kerala, 2018 & 2019 (REF)	XX people infected/dead	1 <sup>st</sup> outbreak of NIV outside Bangladesh, W. Bengal focus	(21)

**Table 1:** Recent reports from SE Asia indicating potential for novel pathways of emergence, or unusual presentations for known or close relative viruses. **OTHERS? Could include Melaka but it's in the Reoviridae and not in the RFA (should we only include pathogen groups listed in the RFA in this table?)**

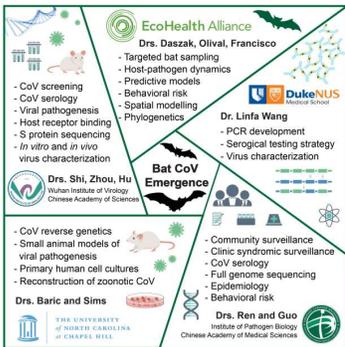

The overall rationale for this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and filoviruses related to known zoonotic pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. The overarching goal of this proposal is to better understand the diversity of known and closely related CoVs, henipaviruses, and filoviruses in wildlife reservoirs in SE Asia, to test their capacity to infect human cells and mouse models, to develop new specific and sensitive serological and molecular diagnostic tools, and to conduct surveillance of human populations with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover and pandemic potential, and of viruses causing previously 'hidden' clinical syndromes in people.

**2. Innovation:** Previous work by our consortium has developed a system to target surveillance in wildlife and people to better anticipate spillover events and pre-empt outbreaks of emerging viruses (REF). In this EIDRC we take this approach and scale it up to cover three critically high-risk EID hotspot countries in Southeast Asia, within a regional network of collaborators. The innovation in this EIDRC is in: 1) its multidisciplinary approach that combines modeling to target the geography for wildlife and human sampling, novel phylogenetic and *in vitro* and animal model approaches to identifying risk of viral spillover into people, development and transfer of novel serological and molecular diagnostics, and use of parallel large scale cohorts to identify spillover and illness due to known and novel viruses; 2) the biological characterization approach that identifies how likely viruses are to be able to spillover into people and builds on our successful work on SARSr-CoVs; and 3) the combination of geographically targeted human populations with high risk of animal contact and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early

warning system approach. **In Aim 1, we will target viruses in new and archived wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, as well as further characterize viruses we have recently discovered. We will use cell culture and animal models to assess their potential for spillover into high-risk human populations. **In Aim 2, we will conduct focused, targeted surveys and sampling of human communities with high exposure to wildlife and other animals.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and filoviruses in these populations. We will use behavioral risk data, virological and ecological data to identify the likely reservoirs of viral groups identified. **In Aim 3, we will use syndromic surveillance of clinical cohorts to identify evidence of viral etiology for otherwise ‘cryptic’ outbreaks.** We will enroll and collect behavioral risk information and biological samples from patients in communities at high risk for disease emergence, who present with syndromes previously linked to known viral agents. We will conduct molecular and serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate and characterize them, and use survey data, ecological and phylogeographic analysis to identify likely reservoir hosts and inform intervention programs.

### 3. Approach

**Research team:** For this EIDRC we have assembled a group of world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (Fig. 2). Over the past two decades, our consortium partners have collaborated together within the region and globally to conduct high profile research on these and other viral groups.

This work includes identifying the wildlife reservoirs for Nipah and Hendra virus, MERS- and SARS-CoVs (40, 43, 55-59), discovering SADS-CoV (54), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and filoviruses (44-46, 60-73). It includes substantial experience conducting human surveillance during outbreaks (e.g. - **Please insert examples that you've been involved in and REFS**), and as part of longitudinal efforts to pre-empt pandemics (74, 75).

**Fig. 2:** Interdisciplinary team & roles in the proposed SE Asian EIDRC. **PLACEHOLDER – Hongying to modify**

PI Daszak has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5- 20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC. Drs. Olival, Zambrana, Ross are leaders in analytical approaches to targeting surveillance and head the modeling and analytics work for USAID-PREDICT. Drs. Wang, Baric, Broder, Anderson, Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other paramyxoviruses, CoVs, filoviruses and many others). Dr. Wacharapluesedee, Hughes and collaborators

have coordinated surveillance of people, wildlife, and livestock within Thailand and Malaysia for the past 10 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from DoD, USAID, NIH, DHS and other USG agencies that supports a range of laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to the EIDRC (**See Section XX**).

**Fig.3 :** Map of Southeast Asia indicating the three core countries for this proposed EIDRC (White: Thai, Sing, Mal) and those that Key Personnel are actively collaborating with (Green: field sites and collaborating labs)

indicated with asterisk). PLACEHOLDER – Hongying to modify - please use a map with part of India and Bangladesh. – This map is the perfect range

**Geographical focus:** The three core countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam and Indonesia. It encompasses diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH and USAID funding. To develop a larger catchment area for emerging zoonoses, we will deploy our consortium's extensive network of collaborators in clinics, research institutes and public health laboratories in every other Southeast Asian country. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in XX countries that are currently collaborating with core members of our consortium via other funded work (Fig. 3). We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Current list of contacts at key human (especially) and wildlife orgs in every SE Asian country from map above – please add to this and send in the full details on the form requested by Luke/Aleksei!**

**NOTE: Everything below is a very rough draft. I've lifted heavily from our recent CoV R01 renewal submission, and indicated in comment boxes the names of the people who I believe know most about each section and can modify or write the new text needed.:**

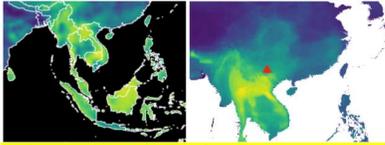

#### **Aim 1: Identification and biological characterization of spillover risk of high zoonotic potential viruses from wildlife**

**1.1 Rationale/Innovation:** Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (23). In Aim 1, we will analyze these factors to identify regions, species and human populations that have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and primates) in these regions and test newly collected and some of the tens of thousands of recently collected samples we have archived in freezers in our labs for known and novel agents. Using previously developed approaches to predict capacity of novel viruses to infect human cells and mouse models, we will characterize these viruses and assess their potential for spillover, using those of high risk as targets for human sampling in Aim 2 and 3. This approach is built on substantial previous proof-of concept preliminary data:

Geographic targeting: EcoHealth Alliance has led the field in conducting analyses to indicate where the highest risk of zoonotic spillover in a region is (22, 23). For Southeast Asia, these EID hotspots are sites with high wildlife biodiversity, human population density and undergoing rapid land use change (Fig 4a). Using host and

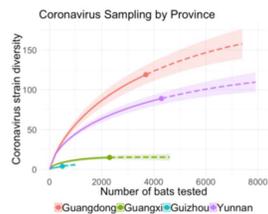

Commented [PD1]: Kevin – please edit

ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (76). Using these data to map unknown viral diversity demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (Fig. 4b). In a separate paper on risk of viruses emerging from bat hosts, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (77). We therefore analyze capacity for viral spread as a separate risk factor, using demographic and air travel data in an app we have produced with Dept Homeland Security funds (78). In the current proposed work, we will use all the above approaches to target wildlife sampling (archive and new field collections), and to inform sites for human sampling in Aim 2, to areas of high risk for spillover and spread.

**Fig. 4:** Our previous work has shown proof-of-concept in geographically targeting sampling to maximize regions as high risk of wildlife-to-human spillover (Fig. 4a), and regions with high diversity of predicted 'missing' or as-yet undiscovered viruses, yellow = highest diversity (Fig 4b). From (22, 23, 76). Kevin/Alice, please insert high res hotspot map from Allen et al. (Fig 4a), expand the current map from Olival et al. to cover the same region as shown in Fig. 3, and remove the red triangle of course.

**Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and primate represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential (76). The bulk of our sampling and sample testing will consist of bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, henipaviruses and filoviruses (79-82) (ADD REFS). Bats also have the highest proportion of predicted zoonotic viruses in any mammalian group (76). We have used a novel phylogeographic analysis, Maximum Clade Credibility (MCC) tree, to reconstruct the geographic areas of evolutionary origin for  $\beta$ -CoVs that we sequenced in bats (39). This approach allows us to identify the ancestral home of specific zoonotic viral groups in wildlife, where their diversity is likely highest. Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (83, 84) (Fig. 5). Using prior data for bat, rodent and primate viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. **In the current proposal, we will use these analyses to estimate geographic and species-specific sampling targets to more effectively identify new strains to support experimental infection studies and risk assessment.**

**Fig. 5:** Estimates of SARSr-CoV total strain diversity in bats we sampled in China under a NIAID R01 (strain defined as >10% sequence divergence in RdRp gene). GD and YN harbor highest CoV diversity, but discovery has not yet saturated. We used this to estimate that additional sampling of 5,000 bats will identify >80% of remaining  $\beta$ -CoV strains in bat hosts from these regions. We will apply this approach to our target host and viral taxa, for Thailand, Singapore and Malaysia to calculate sampling targets and success rates.

**Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. This includes sampling and PCR-screening >16,000 individual bats from 6 families (16 genera) in southern China for coronaviruses, identifying 178  $\beta$ -CoVs, of which 172 were novel (52 novel SARSr-CoVs). This includes members of a new  $\beta$ -CoV clade, "lineage E" (41), diverse HKU3-related CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and the wildlife origin of a new virus (SADS-CoV) killing >20,000 pigs in Guangdong Province (54). Many of these bat species are found across the region. We have collected XX samples from bats, rodents and primates in Thailand and XX in Malaysia under PREDICT, screening XX and archiving duplicates of all of these which are now available for use in this project. We used family level primers for henipaviruses, filoviruses and CoVs and have already discovered XX, YY and ZZ in these two countries. In the current proposed work, we will attempt to isolate and characterize those that our analyses below suggest

Commented [PD2]: Kevin to edit

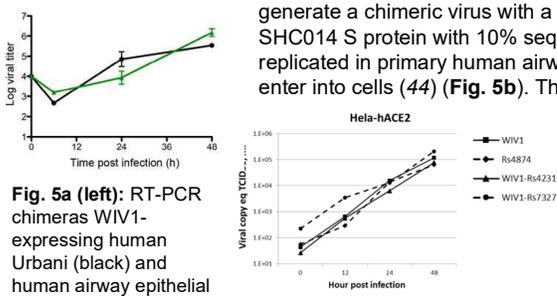

Commented [PD3]: All to edit

Commented [PD4]: Kevin – need the PREDICT numbers here please

Commented [PD5]: Kevin – likewise need the best numbers, and please reach out to Tom and Supaporn to clarify/expand on what's in EIDITH

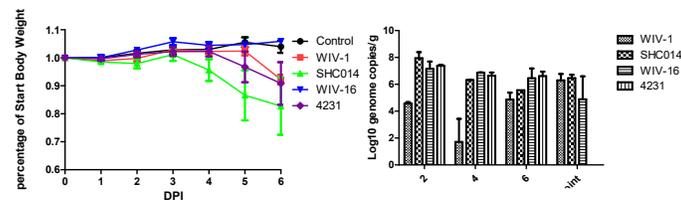

are most likely to be able to infect humans. Our collaborative group has worked together on these projects, as well as under DTRA funding in Singapore/Thailand (Co-Is Wacharapleusadee, Wang) to design, cross-train, and use novel serological and PCR tests to investigate xxx, and in Thailand (Co-Is Broder, Laing and Wacharapleusadee) on tech transfer of Luminex serology platform for wildlife and human samples. This is part of a planned DoD regional center of excellence for training in Thailand (details please?).

**In vitro & in vivo characterization viral potential for human infection:** We have used *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with S protein sequences that diverged from SARS-CoV by 3% to 7% (40, 43, 85). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs from a specific cave site in Yunnan China, some highly similar to outbreak SARS-CoV in the most variable genes: N-terminal domain and receptor binding domain (RBD) of the S gene, ORF8 and ORF3 (43). Using our reverse genetics system, we constructed chimeric viruses with SARSr-CoV WIV1 backbone and the S gene of different variants, including WIV1-Rs4231S and WIV1-Rs7327S. All 3 SARSr-CoV isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, but not in HeLa cells that don't express ACE2 (40, 43, 85) (Fig. 5a). We used the SARS-CoV reverse genetics system (64) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This chimera replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (44) (Fig. 5b). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry.**

**Fig. 5a (left):** RT-PCR chimeras WIV1-expressing human Urbani (black) and human airway epithelial

We infected transgenic mice expressing hACE2 with  $10^5$  pfu of full-length recombinant WIV1 and three chimeric viruses (WIV1 backbone with SHC014S, WIV16S and Rs4231S). hACE2 transgenic mice challenged with rWIV1-SHC014S experienced ~20% body weight loss by 6dpi; rWIV1 and rWIV1-4231S produced less body weight loss, and rWIV1-WIV16S led to no body weight loss (Fig. 6a). At 2 and 4 dpi, viral loads in lung tissues of mice challenged with all three chimeras reached  $> 10^6$  genome copies/g, significantly higher than rWIV1 infection (Fig. 6b). This demonstrates that pathogenicity of SARSr-CoVs in humanized mice differs with divergent S proteins, **confirming the value of this model in assessing novel SARSr-CoV pathogenicity.**

**Fig. 6:** *In vivo* infection of SARSr-CoVs in hACE2 transgenic mice. **6a (left)** Body weight change after infection; **6b (right)** Viral load in lung tissues.

Infection of rWIV1-SHC014S caused mild SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity.** Vaccination against SARS-CoV did not reduce severity of clinical signs in mice subsequently infected with rSARS-SHC014S (44). We found 2/4 broad human mAbs against SARS-CoV RBD cross-neutralized WIV1, but none could efficiently neutralize SHC014 which is less similar to SARS-CoV in the RBD (86). We repeated this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they are unable to use the ACE2 receptor.** Additionally, we were unable to culture HKU3r-CoVs in Vero E6 cells, or human cell lines. **The ability of HKU3r-CoVs to infect people, and their receptor binding target, remain unknown.**

**Commented [PD6]:** Linfa, Danielle, Supaporn – please expand

**Commented [PD7]:** Chris, Eric, Supaporn please expand

**Commented [PD8]:** I think this is something that Linfa, Supaporn or Chris mentioned?

**Commented [PD9]:** Ralph, Amy – this is directly from our CoV R01 renewal – please reduce the length of this section and adapt for this proposal. We probably don't need all these figures – just one or two would do.

All – what can we say about Nipah and filoviruses in this section – what is the rationale for a similar approach (e.g. we're looking for viruses somewhere between Cedar and Nipah in the Henipaviruses, and trying to assess the likelihood of some of the novel filoviruses infecting human cells).

Commented [PD10]: Ralph, Amy, Linfa, Danielle, Chris, Eric – need details for what approach we'll use for henipas and filios

Are we just going to use cell culture for henipas and filios, or can we look at spike protein diversity?

What about using bat cell lines and batized mice from Linfa?

### 1.2 General Approach:

We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new collection from wildlife in high risk locales. We will use serological & PCR testing, to identify viruses, then attempt to isolate and biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will then conduct *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease. EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses. A key goal of this work will be technology transfer to the region, including cell culture, animal models, serological and PCR diagnostics, as well as knowledge transfer by embedding staff in partner labs and by regular meetings. This will leverage substantially from the other funding available to consortium partners.

### 1.3 Wildlife samples: 1.3.a Site selection & sample sizes for newly collected and archived samples:

Adapt text from the rationale/innovation above and make brief statements about the work we'll do:

- Geographic targeting: we will use refined hotspot, 'missing viruses', and FLIRT analyses
- Targeting of host species/viral discovery targets: We will use phylogenetic MCC analyses and viral discovery curves
- Additional approaches: mapping of cave sites,

Commented [PD11]: Kevin – please lead the drafting of this section. I've left in the section from our CoV R01 for you to adapt.

Commented [PD12]: Please check section 1.4.b and see if parts of that should be here..

To calculate sample sizes, we will use previous work on SARSr-CoVs in bats in China, the results of bat, rodent and primate sampling under PREDICT in Malaysia and Thailand, and published data. For SARSr-CoVs in China, we found 6.7% mean PCR prevalence of SARSr-CoVs across bat hosts, with a small number of *Rhinolophus* spp. horseshoe bats having significantly higher PCR prevalence than other species sampled (REF).

**Kevin** – below is the language from our R01 CoV renewal proposal as a model:

In Y1 we will use our bat host and viral trait modeling, phylogeographic analyses of RdRp and S Protein sequences, and geographic and host species-based viral discovery curve analyses to identify SARSr-CoV diversity hotspot regions for bat sampling. We will sample at 8 new sites in four provinces. We will use cave site data (87), and demographic information to identify two sites in each of Yunnan, Guangxi, Guangdong, and Guizhou where humans likely have contact with bats. In Yunnan, we will identify two unsampled caves close to, but distinct from, the Jinning cave (43). This will provide adequate coverage of lineage 1 and 2 SARSr-CoVs, including a rich source of new HKU3r-CoVs, which have unknown potential for zoonotic spillover. Sampling will begin towards the end of Y1. We will use survey data from our previous R01 and host-specific viral accumulation curve data to target an additional 10 under-sampled *Rhinolophus* spp., 5 that were SARSr-CoV negative in our study, and a small number of related bat genera (including *Hipposideros* spp. and *Aselliscus* spp.) we previously found PCR positive for SARSr-CoVs (Table 1). We will sample at least 5,000 bats from these 4 provinces (~1250 per province). Given ~5-12% prevalence of SARSr-CoVs in *Rhinolophus* spp. at our previous sites, **this sample size would give us 425 (±175) positive individual bats, and ~125 novel strains.**

**1.3b Sample testing, viral isolation:** Viral RNA will be extracted from bat fecal pellets/anal swabs with High Pure Viral RNA Kit (Roche). RNA will be aliquoted, and stored at -80C. One-step hemi-nested RT-PCR (Invitrogen) will be used to detect the presence of CoV sequences using primers that target a 440-nt fragment

Commented [PD13]: Ralph, Amy, Linfa, Danielle, Chris, Eric - This is from our CoV R01. Please insert details that apply also to henipa and filoviruses.

in the RNA-dependent RNA polymerase gene (RdRp) of all known  $\alpha$ - and  $\beta$ -CoVs (88). PCR products will be gel purified and sequenced with an ABI Prism 3730 DNA analyzer.

We will attempt isolation on samples that contain viruses of interest (determined in **1.4, below**), using Vero E6 cells and primary cell culture from the wildlife taxonomic order (bat, rodent and primate cell lines). This includes the over XX cell lines maintained at Duke-NUS

**1.3.c Sequencing S proteins:** Our previous R01 work identified diverse SARSr-CoVs with high propensity for human infection (19, 43, 44). Characterization of these suggests SARSr-CoVs that are up to 10%, but not 25% different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (Fig. 4) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are undersampled to allow sufficient power to identify and characterize missing SARSr-CoV strain diversity. Our previous work also suggests that SARSr-CoVs with S proteins that are ~10% divergent from SARS-CoV resist neutralization by therapeutic mAbs and escape SARS-CoV vaccines (40, 44, 89), suggesting that . However, viruses with 10-25% divergence in S proteins may bind to human cell receptors, but completely evade therapeutic and vaccine effects, and could therefore be a higher risk for public health. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis.

For all novel SARSr-CoV strains, we will sequence the complete S gene by amplifying overlapping fragments using degenerate primers as shown previously (40, 43). Full-length genomes of selected SARSr-CoV strains (representative across subclades) will be sequenced via high throughput sequencing method followed by genome walking. The sequencing libraries will be constructed using NEBNext Ultra II DNA Library Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR will be performed to fill gaps in the genome. The full length S gene sequences, including the amount of variation in the S receptor binding residues that bind the ACE2 receptor, will be used to select strains for Aim 3 experiments.

**1.4. Assessing risk for spillover. 1.4.a Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, we will use primary human ciliated airway epithelial cells (HAE) cultures from the lungs of transplant recipients represent highly differentiated human airway epithelium containing ciliated and non-ciliated epithelial and goblet cells, grown on an air-liquid interface for several weeks prior to use (44, 45, 90). We will prepare HAE cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) (46, 63). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (45, 91). As controls, the S genes of novel SARSr-CoV will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (92). Polyclonal sera will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (45, 93, 94). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (95) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (96-98).

Filoviruses (primary endothelial cells – ralph has primary lung endos – see if anyone has liver primary hepatocytes. Other option are monocytes) – where will we do this? BSL4? (NEIDL). Duplicate samples in culture medium from animals PCR +ve for filoviruses will be shipped to NEIDL (See letter of support) for culture and sharing with other agencies. Check on this re. wildlife filoviruses... See if can do training opportunities so they can work with the NEIDL – visiting scholar appointments

**Commented [PD14]:** Linfa, Supaporn, Danielle – is this correct?

**Commented [PD15]:** Brief description of these please

**Commented [PD16]:** Ralph et al. – I'm assuming this will still be of value for the CoVs, so a reduced version of this could be in here, but what about spike proteins of filoviruses and henipaviruses – is that not of any use for assessing their capacity to infect human cells. Can we do similar work with filovirus pseudotypes from sequencing the spike proteins, for example, to assess binding to human receptors? If so, please draft some text and point to some references

**Commented [PD17]:** Ralph, Linfa, Chris – please expand and draft – I think this could be a good role for NEIDL, but don't know what the rules are...

**1.4.xx Host ACE2 receptors:** We will sequence host ACE2 receptors of different bat species or different bat populations from a single species (e.g. *Rhinolophus sinicus*) to identify relative importance of different hosts of high risk SARSr-CoVs and the *intraspecific* scale of host-CoV coevolution. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (62).

**Commented [PD18]:** Kevin/Ralph – I don't think this is relevant for our EIDRC – please let me know and delete if correct.

**1.4.b Host-virus evolution and distribution:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RdRp, Spike, and full genome sequence (when available) data to reconstruct the evolutionary history of the novel bat SARSr-CoVs we identify. We will rerun MCC analyses (Fig. 3) to reconstruct  $\beta$ -CoV evolutionary origins using our expanded dataset. Ecological niche models will be used to predict spatial distribution of PCR-positive species, identify target sites for additional bat sampling, and analyze overlap with people. We will use our viral discovery/accumulation curve approach (Fig. 4) to monitor progress towards discovery of >80% of predicted diversity of SARSr-CoVs (lineage 1 & 2) within species and sites, halting sampling when this target is reached, and freeing up resources for work other work (84, 99).

**Commented [PD19]:** Kevin/Alice – please modify this section for filus and henipas as well (and other hosts) - or does it belong in 1.3.a above?

**1.4.c Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (91, 100-102).

**1.4.d Animal models:** We will use a series of mouse models to assess spillover potential of viruses. First, the Baric lab has a well-established hACE2 transgenic mouse model that we will use this to characterize the capacity of specific SARSr-CoVs to infect. Briefly, in BSL3, n=5 10- to 20-week old hACE2 transgenic mice will be intranasally inoculated with  $1 \times 10^4$  PFU of wildtype WIV-1 or chimeric bat SARSr-CoVs with different spike proteins, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by SARS-CoV NP RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro* and *in vivo*. Existing SARSr-CoV mAbs will be diluted in DMEM starting at 1:20, and serial 2-fold dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs with different spike proteins, then incubated on Vero E6 cells at 37°C for 1 h, then changed to a semi-solid medium (DMEM containing 1% methylcellulose and 2% FBS). Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (90, 103). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (45, 90).

**Commented [PD20]:** Ralph – can you reduce this section to a feasible amount of work for this project, and remove a bunch of text

For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments. We have used this model for CoV, filo (Ebola), Flaviviruses, alphaviruses infections. In subpopulations it reproduces SARS weight loss, hemorrhage in EBOV, enceph in WNV, acute or chronic arthritis in Chikungunya infection.

**Commented [PD21]:** Ralph – please draft a brief para explaining what we'll do with this mouse model

Duke-NUS has develop two models for bat *in vivo* culture: the 'batized' mouse model (Description) and a colony of *Eonycteris spelaea* (cave dwelling small fruit bat).

**Commented [PD22]:** Linfa/Danielle – please draft a brief para explaining how we'll use either or both...

### 1.5 Potential problems/alternative approaches: **Permission to sample bats in sites or provinces we**

**select.** We have a >20-year track record of successful field work in Malaysia, Thailand and >10 years in Singapore, and have worked with local authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based on a range of PCR data and are fairly conservative in our approach. However, as a back-up, we already have identified dozens of novel viruses that are near-neighbors to known high-impact agents, and will continue characterizing these should discovery efforts yield few novel viruses. The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (104), do not suggest a strong pattern of seasonality in CoV shedding, although there are studies that suggest this occurs in henipavirus and filovirus (MARV?) shedding (REFS?). Nonetheless to account for this we will conduct sampling evenly on quarterly basis within each province.

Commented [PD23]: Kevin – please edit/check

Commented [PD24]: Kevin – please check the veracity of these comments

### **Aim 2: New serological and PCR tools to test evidence of viral spillover in high-risk communities..**

**2.1 Rationale/Innovation:** Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that are the first to get infected. To enhance low statistical probability of identifying these rare events, populations could be targeted that both live in rural locations close to high wildlife biodiversity, and also engage in behaviors that enhance the risk of spillover (e.g. hunting and butchering wildlife). In Aim 2 we will expand from our current work in the region to identify and enroll large cross-sectional samples from human populations that have high behavioral risk of exposure to wildlife origin viruses and live close to sites identified in Aim 1 as having high viral diversity in wildlife. We will use behavioral surveys and repeated biological sampling, design and deploy specific and sensitive serological assays to identify the baseline spillover of known or novel viral pathogens in these populations. Where symptoms are found, we will use PCR-based assays to identify presence of known and novel CoVs, henipaviruses and filoviruses, attempt to isolate and biologically characterize the pathogen, using the collaborative cross mouse (Aim 1) to identify an appropriate animal model to conduct preliminary pathogenesis work.

**Preliminary data human biological sampling:** Our longterm collaboration in the region has included identification of key at-risk human populations from which we have already collected qualitative and quantitative survey data, and biological samples. These include:

Commented [PD25]: All – please read and share with collaborators to flesh out and correct details here.

**Peninsular Malaysia:** Data from 1,300 Orang Asli samples, PCR for 5 viral families: 5 known CoVs in 16 people, one Influenza virus. Serology on its way incl. filovirus reactors...

**Sabah:** We have ~25 new CoVs in Sabah. Simon is using HTS to further characterize and Tom will get the data for this proposal from Simon.

Tom will work out all serum samples we have, incl. samples from dead bats.

Kamruddin (UMS Borneo Medical Health Research Center) has identified some high risk communities. We can help with them and build out the BSL-2 lab, as well as work on outbreak response within DHRU (in collab with Sabah CDC?).

Tom will speak with Tim Williams ...He has archived samples from Kudat Monkey bar project – 2,000 human sera already screened for bacteria and parasites, we've been reached out to about this. Data on macaque tracking data/human tracking data also.

**Sarawak:** Dr Tan (Cheng Sieng) Center for Tropical and Emerging Diseases, Faculty of Medicine at UNIMAS – high risk Dayak communities that he's identified. We will do further sampling, questionnaires etc. Has Prelim data on HPV work in Dayak communities in remote Sarawak – we can work with those communities and can reach many by car, others by 4WD or boats. Has also Enterovirus 71 paper and is interested in CoVs. Has access to caves and guano. Will look into what other archived samples he has. Will give us access to Sarawak Forestry and Health Depts.

*Thailand:* Imported MERS cases..Zika patients. 10 yrs ago AFRIMS in Thailand found serological NiV +ve in Children far from the bat colony, prob with publication of data because didn't do neg controls – could do SNT at NEIDL or Wuhan – couldn't get permission Have emailed Andrew Hickey about this.  
High-risk community cohorts – Loei Province (Guano miners) – whole community

Singapore:

**Behavioral risk:** EHA is the global lead organization in the USAID-PREDICT project for assessing human behavioral risk of zoonotic spillover. The general approach has been to conduct qualitative exploratory studies using standardized one-on-one semi-structured ethnographic interviews and observational data in among people engaged in clearly high-zoonotic risk activities (e.g. we interviewed 88 people involved in trading wild bats in China – REF). This allows us to assess local social and cultural norms and individual attitudes underlying wildlife contact. We used qualitative study findings to develop a human behavioral risk questionnaire on the type and frequency of animal contact, wildlife observed in daily life, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in >15 countries during the last 5 years, and study participants also provided biological samples (oropharynx swab, serum, plasma). Questionnaires and biological samples were collected from 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, XX from XX sites in Malaysia and XX from XX sites in Thailand. The results of these surveys will be used in Aim 2 to better identify target populations.

**Serological Evidence of Exposure:** In China, we developed serological assays for HKU9 CoVs ( $\beta$ ), SARSr-CoV Rp3 ( $\beta$ ), HKU10 CoV ( $\alpha$ ), and MERS-CoV ( $\beta$ ) and used ELISA and Western blot to test serum samples collected in 2016/17. **We found 7 individuals (7/733, 0.95%) living within a 6 km radius of the Jinning Cave, and 6/209 people (2.87%) at one site, with evidence of exposure to bat SARSr-CoVs.** We found evidence among human populations in Guangxi Province of people with prior exposure to the bat  $\alpha$ -CoV HKU10 (2/412, 0.48%). This is of potential public health interest because HKU10 is known to be able to jump host species within bats, and therefore may have high propensity for emergence (105). However, the low seroprevalence (0.6%-2.7% at positive sites) suggests we need a larger sample size, and a focused, targeted study to maximize the likelihood of identifying seropositive cases. In Aim 2, we will use combined biological-behavioral risk surveillance in targeted populations within the community and clinical settings to 1) identify risk factors correlated with seropositivity (exposure to) and PCR positive status (infection with) henipaviruses, filoviruses and CoVs; and 2) assess possible health effects of infection in people. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**Risk Factors:** In China, questionnaire response and demographic data suggest specific risk factors included type of occupation, keeping of pets and visiting wet markets. Seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), and are male (6/9). However, these characteristics were common and occurred in ~40% of survey respondents. Although these results are preliminary and don't provide detailed information on routes of exposure, they suggest that further refining use serological tests coupled with qualitative and questionnaire data will identify likely routes of exposure to novel CoVs in China. In Aim 2 of this EIDRC proposal, we identify strategies to better target at-risk people, and conduct focused **questionnaires and serosurveys to produce statistically significant findings for henipaviruses, CoVs and filoviruses.**

**2.2 General Approach/Innovation:** We will use a dual study design to gain in depth understanding of exposure and risk factors for viral spillover (Fig. XX). In Aim 2 we will conduct community-based surveillance with more focused questionnaires and biological sampling to determine the seroprevalence of spillover viruses in at-risk human populations, and to identify risk-factors for viral spillover in these communities. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at sites that include the community-based surveillance sites within their catchment (details in Aim 3). Both community-based and clinic-based syndromic surveillance programs are case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and symptoms.

**Commented [PD26]:** Linfa, Danielle – are we going to do human sampling in high risk communities in Singapore? If so, what would you propose and do you already have some prelim work you've done. Note these are high risk populations, i.e. high exposure to wildlife. Clinical cohorts are in Aim 3

**Commented [PD27]:** Hongying/Emily to edit

**Commented [PD28]:** Hongying/Emily – any information from Thailand or Malaysian surveys?

**2.3 Target population & sample sizes:** We will target sites in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potentially zoonotic viral diversity, in regions that are EID hotspots, and are well-connected to regional travel and trade hubs and the global travel network. We will target specific communities based on our PREDICT behavioral analysis questionnaire data to assess key at-risk populations with high exposure to wildlife, as well as other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.). We will also expand on work currently underway in the following particularly high exposure populations:

**Thailand:** We have conducted behavioral risk surveys and biological sampling in XX guano miners in Loei. These workers visit bat caves and dig fecal material to use as fertilizer, and are therefore highly exposed to bats and rodents in particular.

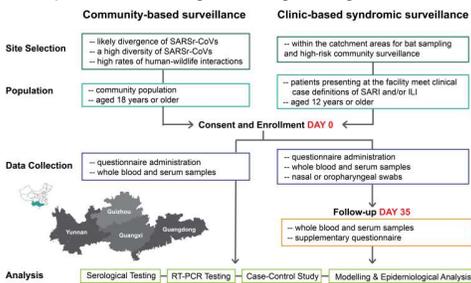

**Peninsular Malaysia:** We have sampled Orang Asli populations for the past 2 years, enrolling XX people. We will expand this to include XXX

**Sarawak:** Dr Tan (Cheng Sieng) Center for Tropical and Emerging Diseases, Faculty of Medicine at UNIMAS – high risk Dayak communities that he’s identified. We will do further sampling, questionnaires etc. Has Prelim data on HPV work in Dayak communities in remote Sarawak – we can work with those communities and can reach many by car, others by 4WD or boats. Has also Enterovirus 71 paper and is interested in CoVs. Has access to caves and guano. Will look into what other archived samples he has. Will give us access to Sarawak Forestry and Health Depts.

**Sabah:**

**Singapore:?**

**Community-based surveillance** will be conducted at XX sites in each country, a total of xx sites. From our previous work we anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so that they make up  $\geq 30\%$  of the sampled population in each community. We will stratify sampling to ensure appropriate representation of sex, demographic, and socio-economic factors at each community site. Estimating 5% overall seroprevalence in these high-exposure populations, these sample sizes are sufficient to estimate effect sizes of behavioral risk factors of 2X or greater with 80% power. For community-based surveillance, we will enroll xxxx individuals per county/province, pooled across two sites for each, allowing us to make county/province-level comparisons of differing effects.

**Fig. XX:** Human survey and sampling study design overview (Aim 2 and 3)

**2.4 Data & sample collection:** Following enrollment with signed consent form, **biological specimens** (two whole blood samples, one max. 500  $\mu$ L; two 500  $\mu$ L serum samples) will be collected from all eligible participants, and a **questionnaire** will be administered. We will investigate five risk factors, so as to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation; 2) observed or reported interactions with bats in/around house; 3) proximity to nearby bat roosts; 4) working or regular visit to animal markets; 5) self-reported ILI/SARI. With consent from participants, we will review clinical records to collect recent data on medical history, clinical syndromes, and patient etiology.

**2.5: Laboratory analysis: 2.5.a Serological testing:**

**Commented [PD29]:** Hongying/Emily to edit

**Commented [PD30]:** Supaporn – please draft plans for what we should do to scale up this work. We could also include other high-risk communities – any ideas?

**Commented [PD31]:** Tom – please start writing some plans for what we could do.

**Commented [PD32]:** All – not sure if we should have one figure for community and clinical cohort surveillance (aim 2 and 3 respectively) or if we should have two separate ones?

**Commented [PD33]:** Hongying– this figure is from our CoV R01 renewal. Please modify to make relevant to SE Asia and henipas, filos and CoVs.

**Commented [PD34]:** Emily/hongying

**Commented [PD35]:** Chris, Eric, Linfa, Dani etc. please draft some language here...

The below is from our previous CoV proposal:

In our previous R01, we expressed his-tagged nucleocapsid protein (NP) of SARSr-CoV Rp3 in *E.coli* and developed a SARSr-CoV specific ELISA for serosurveillance using the purified Rp3 NP. The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity was detected (19). **While this shows it is a specific test for Rp3, it suggests that if we can expand our serology tests to cover other bat CoVs, we may identify many more seropositive individuals.** In this renewal, we will therefore use two serological testing approaches. First, we will expand test all human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV (outbreak strain), a range of lineage 2 SARSr-CoVs (including WIV1 and SHC014), lineage 1 HKU3r-CoVs, MERS-CoV, and the  $\alpha$ -CoVs SADS-CoV and HKU10. We previously found serological evidence of human exposure to HKU10 (19), but HKU10 is known to jump from one host bat species to another (105) and is therefore likely to have infected people more widely. Incorporating serological testing for SHC014 is also likely to yield higher seroprevalence because it is readily divergent from SARS-CoV wildtype and therefore unlikely to have been picked up in our earlier testing. It is possible that non-neutralizing cross reactive epitopes exist that afford an accurate measure of cross reactivity between clade1 and clade 2 strains which would allow us to target exposure to strains of 15-25% divergence from SARS-CoV. Additionally, we will test samples for antibodies to common human CoVs (HCoV NL63, OC43 – see potential pitfalls/solutions below). Secondly, we recognize that CoVs have a high propensity to recombine. To serologically target 'novel' recombinant virus exposure, we will conduct 1) ELISA screening with SARSr-CoV S or RBD; 2) confirm these results by Western blot; then 3) use NP based ELISA and LIPS assays with a diversity of SARSr-CoV NP. For NP ELISA, micro-titer plates will be coated with 100 ng/well of recombinant batCoV NP and incubated with human sera in duplicates followed by detection with HRP labeled goat anti-human IgG antibodies. For confirmation, all ELISA positive samples will be subjected to Western blot at a dilution of 1:100 by using batCoV-NP as antigen. We will use an S protein-based ELISA to distinguish the lineage of SARSr-CoV. As new SARSr-CoVs are discovered, we will rapidly design specific Luciferase immunoprecipitation system (LIPS) assays targeting the S1 genes of bat-CoV strains for follow-up serological surveillance, as per our previous work (54).

**2.5.b RT-PCR testing.** Specimens will be screened using RT-PCR for the RdRp gene (See section 1.3.b for details). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the S glycoprotein gene. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E as rule-outs, and SADS-CoV and HKU10 as an opportunistic survey for potential spillover these CoVs as proposed above.

**2.6 Epidemiological analysis:** We will conduct a case-control study to identify risk factors for SARSr-CoVs spillover. "Cases" are defined as participants whose samples tested positive for SARSr-CoVs by serological tests. "Controls" will be selected from the pool of participants admitted to the studies but testing negative. We will use nearest neighbor matching to pair cases demographically with controls at a 1-to-3 ratio or greater. We will use generalized linear models to analyze correlation between serological/PCR status and risk factors including: Activities with likely exposure to 1) bats; 2) livestock; and 3) locations of residence and work. We will use the same procedure to determine how clinical presentation differs between SARSr-CoVs-exposed and unexposed enrollees, in the time course of illness, severity of symptoms, and type of symptoms.

**2.7 Biological characterization of viruses identified: XXX**

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze risk behavior. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals in likely contact with these species increases the potential for detecting spillover with enough power for statistical analyses, and will shed light on behaviors that

Commented [PD36]: Please modify for Henipap, filoviruses and CoVs

Commented [PD37]: Hongying/Emily

Commented [PD38]: All –Not sure if we should weigh too heavily on this for the community survey – or should it just be serology for Aim 2. If you want include this section, please modify and insert language from Aim 1 here.

predispose to spillover. Third, we will include common human CoVs, paramyxoviruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact against other risk factors and clinical outcomes to provide useful proxy information for spillover risk. **Serological testing may not match known CoVs due to recombination events.** We will use the three-tiered serological testing system outline in **2.6.a** to try to identify these 'novel' CoVs, however, we will also remain flexible on interpretation of data to ensure we account for recombination.

### **Aim 3: Clinical cohorts to identify evidence of viral etiology for 'cryptic' outbreaks.**

**3.1 Rationale/Innovation:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not diagnosed. By working with syndromic cohorts reporting to clinics with symptoms similar to known high-impact viral agents, we may be able to capture novel emerging diseases in at-risk communities before they spread into the general population and risk becoming pandemic. This will have clear value for public health in the region, and potentially wider. To do this, we will expand on current syndromic surveillance activities to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with symptoms typical of high impact zoonotic viruses. We will collect detailed interview data to assess their likely contact with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We'll conduct novel viral discovery on unique clinical + symptomatic cases (maybe w high animal contact too) where testing has already ruled out all normative diseases? If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work.

**Preliminary data clinical surveillance:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes:

**Thailand:** Sick people cohorts – Chulalongkorn Hospital; EID Center for Thailand – Outbreak investigation Lab surveillance Min public Health Dept of Disease Control, 3 projects testing samples from people (encephalitis, Hand foot mouth disease, viral diarrhea, Influenza) = outbreak identification Dr. Rone. Any cluster of unusual disease samples will be sent to Supaporn. Have been using PREDICT protocol to identify pathogens. Dr. Parvnee doing lab investigation

#### **Peninsular Malaysia:**

**Sabah:** Linfa has worked with Timothy Williams on an encephalitis cohort from Queen Elizabeth Hospital 1 & 2 (poss has worked with Linfa on these) and this is another possibility. He's doing outbreak response training in August with team from Sabah CDC (Dr. Maria now in Pen. But still collaborating with us, Jikal current director working with us and Dato Cristina dir. Sabah state health Dept and is supportive) this collaborative group is working to develop a Sabah outbreak response team – we will support that – to be based at BMHRC and we will develop this as part of this proposal. Prof. Kamruddin will summarize the serum samples he has. POCs: Sabah State Health Dept (e.g. Dr. Giri Shan Rajahram), Queen Elizabeth Hospital (Dr. LEE Heng-Gee)

**Sarawak:** From Linfa – Dr. Ooi used to work with Jayne Cardosa at UNIMAS and has access to samples of patients with unusual presentation

**Strategy for analysis of self-reported illness:** We have developed a standardized approach in PREDICT to analyzing data on self-reported symptoms of fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI), and fever with muscle aches, cough, or sore throat (influenza-like illness - ILI) from study participants. We used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between ILI and/or SARI symptoms and contact with animals in the last year. Results have clear biological relevance. In Yunann, China, salient predictors or combination of predictors were, in descending order of odds ratio: 1) having eaten raw or undercooked carnivores; 2) having slaughtered poultry and being a resident of Guangxi province; 3) having had contact with cats or bats in the house; and 4) being a male who has raised poultry (**Fig. 11**). We will expand this approach for all syndromes in Aim 3, and

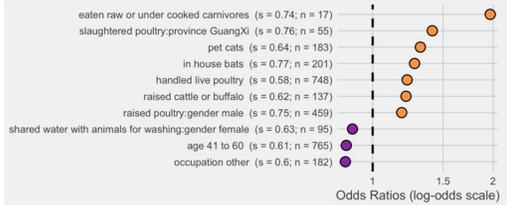

**Commented [PD39]:** All – please read and share with collaborators to flesh out and correct details here.

**Commented [PD40]:** Tom to add – Queen Elizabeth Hospital?

**Commented [PD41]:** Tom

**Commented [PD42]:** Emily/Hongying

with questions designed to assess patient's exposure to wildlife in terms that are relevant to the specific country.

**Fig. 11:** Predictors of self-reported ILI and/or SARI in prior 12 months (s = bootstrap support; n = number +ve out of 1,585 respondents). Orange circles = odds ratios > 1 (positively associated with the outcome); purple = odds ratios < 1 (negatively associated with the outcome).

**3.2 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent is not identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and present at regional clinics with influenza-like illness, severe respiratory illness, encephalitis, and other symptoms typical of high-impact emerging viruses. We will collect interview data tailored to the region to assess contact with wildlife, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.3 Clinical cohorts. 3.3.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at XX town-level level clinics and xx provincial-level hospital in each country, in total xx hospital sites, all within the catchment areas for wildlife sampling, and which are used by people in our community-based surveillance. Patients ≥ 12 years old presenting at the health facility who meet the syndromic and clinical case definitions for SARI, ILI, encephalitis, hemorrhagic fever will be recruited into the study. We will enroll a total of at least xxxx individuals for clinical studies, which accounts for up to 40% loss from follow-up. Study data will be pooled across sites, as clinical patients are limited by the number of individuals presenting at hospitals.

**3.3.b Behavioral and clinical interviews: 2.5 Clinic enrollment and follow-up:** We will recruit inpatients and outpatients after initial screening to meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI) of unknown etiology; or 2) Influenza-like illness (ILI) of unknown etiology. Once enrolled, biological samples will be collected and a questionnaire administered by trained hospital staff that speak appropriate local language. Samples will be taken concurrently when collecting samples for normative diagnostics. For inpatients, samples will be collected within 10 days of reported onset of illness to increase the chance of PCR detection of viruses (106). We will follow up 35 days after enrollment to collect an additional two 500 µL serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. 35 days gives adequate time for development of IgG, which occurs <28 days after onset of symptoms for SARS patients (107).

**3.3.c Sampling:** Following enrollment with signed consent form, biological specimens (two whole blood samples, one max. 500 µL; two 500 µL serum samples) will be collected from all eligible participants, and a questionnaire will be administered. We will investigate five risk factors, so as to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation; 2) observed or reported interactions with bats in/around house; 3) proximity to nearby bat roosts; 4) working or regular visit to animal markets; 5) self-reported ILI/SARI. An additional two nasal or oropharyngeal swabs will be collected from syndromic patients. With permission from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology.

Commented [PD43]: Hongying/Emily

Commented [PD44]: Hongying Emily

Commented [PD45]: Need data for Nipah and filovirus patients

**3.4 Sample testing:** PCR, Serol to link symptoms to etiologic agents

**3.5 Assessing potential for pandemic spread:** We will...leverage EHA's work with DHS to develop FLIRT (Flight Risk Tracker) that tracks the probable pathways for spread for viruses that are able to be transmitted among people....

Commented [PD46]: KEvIn to draft

**From CoV renewal:** use data from 3.3 to identify rank SARSr-CoV strains most likely to infect people and evade therapeutic and vaccine modalities. We will use bat survey and zoological data (87) to build species distribution models (108) and predict the distribution of bat species that harbor low, medium and high risk viral strains. Stacking these modeled distributions for the ~20-30 *Rhinolophus* and related species that occur in the region will allow estimates of SARSr-CoV diversity for a given locality. We will use machine learning models (boosted regression trees) and spatial 'hotspot' mapping approaches to identify the ecological, socio-economic and other correlates of SARSr-CoV diversity and spillover (from serosurveys) (22, 23, 77). We will include data from our human behavioral surveys and sampling to give a direct measure of where risk of spillover to people is likely to be highest in the region.

**Potential problems/alternative approaches:** Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases. Our 35 day follow-up sampling should avoid this because the maximum lag time between SARS infection and IgG development was ~28 days (106). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study, so won't be completely reliant on hospital data to identify PCR- or seropositives. Finally, the risk is outweighed by the potential public health importance of discovering active spillover of a new henipavirus, filovirus or CoV infection.

Commented [PD47]: Add data for Nipah and filio infections

**ALL – the sections below are going to be critical to demonstrate our capacity to do this work. I've not yet started drafting, but please don't hesitate to insert whole sections from other proposals you've done if they're relevant here – we'll need to be creative and get all the language we can from others...**

**Additional Instructions – Specific to the EIDRC FOA:**

Commented [PD48]: All – I've started putting a few notes in this section, but it will need substantial work. Please insert language from other proposals to fit these sections if you have them

**Administrative Plan**

In a clearly labeled section entitled “**Administrative Plan**”:

- Describe the administrative and organizational structure of the EIDCRC Administrative and Leadership Team. Include the unique features of the organizational structure that serve to facilitate accomplishment of the long range goals and objectives.
- Describe how communications will be planned, implemented, and provided to collaborators, teams, or sites. In addition, describe plans to achieve synergy and interaction within the EIDRC to ensure efficient cooperation, communication and coordination.
- Specifically address how the EIDRC Team will communicate with other EIDRCs, the EIDRC CC and NIAID and how the EIDRC will implement plans and guidance from the EIDRC CC to ensure coordination and collaboration across the Emerging Infectious Disease Program as a whole. Describe how the study site will provide information, if any, back to the local health authorities and the study subjects as needed. Note any adjustments or changes needed for rapid and flexible responses to outbreaks in emerging infectious diseases.

**List out all of our involvement with outbreak investigations, ministries of health surveillance etc.**

- Describe the overall management approach, including how resources will be managed, organized and prioritized, including pilot research projects.
- Highlight how the proposed staffing plan incorporates scientific and administrative expertise to fulfill the goal to develop the flexibility and capacity to respond rapidly and effectively to outbreaks in emerging infectious diseases in an international setting.

## Data Management Plan

In a clearly labeled section entitled "**Data Management Plan**":

- Describe internal and external data acquisition strategies to achieve harmonization of systems and procedures for data management, data quality, data analyses, and dissemination for all data and data-related materials generated by the research study with the EIDRC CC.
- Within the plan, indicate the extent to which dedicated systems or procedures will be utilized to harmonize the acquisition, curation, management, inventory and storage of data and samples. Describe how training for the data and sample collection, in terms of the use of electronic data capture systems, will be provided to all staff including those at enrollment sites.
- Describe the quality control procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens.

This includes sample labeling etc. Get a bar-coding system, everyone has a scanner (cf. PREDICT) – Ralph has this for select agents and MERS. Also need a software system

## Clinical Management Plan

In a clearly labeled section entitled "**Clinical Management Plan**":

- Describe plans, processes, and procedures for the following activities: clinical site selection including feasibility, capacity, and capabilities, and study development, conduct, and oversight.
- Describe strategies for oversight and implementation of standardized approaches in the recruitment and clinical characterization of adequate numbers of relevant patient populations to ensure the prompt screening, enrollment, retention and completion of studies. Describe novel approaches and solutions to study enrollment. including the clinical meta-data that will be captured and describe how the staff at each enrollment/collection site will be trained and comply with the quality standards for data and sample collection and compliance with the standardized procedures. Provide a general description of the methods for establishing clinical cohorts and how cohorts may be leveraged for new emerging pathogens.
- Provide general approaches to identification of the types of clinical cohorts needed to fulfill the goals of the EIDRC. Discuss types of clinical cohorts and clinical assessments that will be utilized to study natural history and pathophysiology of disease, including characteristics of the cohort, site for recruitment, types of samples collected and how they can be used for disease surveillance or provide the basis for discovery of novel pathogens, along with a detailed description on how samples can be utilized for immunologic studies, pathogenesis and reagent and diagnostic assay development.
- Describe methods that might be applied to either elucidate a zoonotic source or a vector of transmission.

Our research team incredibly diverse and capable of working with a group of other viral families: Lay out all our additional vector experience incl. my WNV work, our work on Chik etc.

Baric: Flavi, Noro,

Linfa: ...

EHA: ...

- Describe capacity for and approaches to clinical, immunologic and biologic data and specimen collection, and how these data and specimens will address and accomplish the overall goals and objectives of the research study.

## Ralph

1. Norovirus: collaboration with surveillance cohort CDC; first one to publish antigenic characterization of each new pandemic wave virus; and phase 2 and 3 trial of therapeutics

2. Tekada Sanofi Pasteur dengue

3. Nih tetravalent vaccine

- Provide plans for the potential addition of new sites and expanding scientific areas of research when

needed for an accelerated response to an outbreak or newly emerging infectious disease.

Linfa – will launch VirCap platform on outbreak samples.

### Statistical Analysis Plan

In a clearly labeled section within the Research Strategy entitled "**Statistical Analysis Plan**":

- Describe the overall plan for statistical analysis of preliminary research data, including observational cohort data.
- Describe the overall staffing plan for biostatistical support and systems available for following functions: 1) preliminary data analyses, 2) estimates of power and sample size, 3) research study design and protocol development.
- Describe the quality control and security procedures for the data and biological specimens, and how to identify and resolve issues with quality control that maintains integrity of data and specimens. Describe any unique or innovative approaches to statistical analysis that may be utilized.

### Project Milestones and Timelines

In a clearly labeled section entitled "**Project Milestones and Timelines**":

- Describe specific quantifiable milestones by annum and include annual timelines for the overall research study and for tracking progress from individual sites, collaborators, and Teams. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, including, for example, protocol development, case report forms, scheduled clinical visits, obtaining clearances study completion, and analysis of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research study.

Show that for this proposal, we won't be doing the Specific Aims sequentially. We'll begin the human work (SA 2, 3) at the beginning of the project, along with SA1. We'll do the diagnostic assay development initially in Ralph's, Linfa's, Chris's lab, but then begin tech transfer in Y1....

**Importance:** High

---

Dear all – here’s the first rough draft.

Please start editing as fast and furious as you all can. I’ve based this on our previous conversations, so there are lots of bits for you to expand on, insert references etc. Also, you’ll see that lots of the text in the Aims is from our recent CoV proposal and will need extending for Henipass, CoVs and Filoviruses, and then editing back on the SARS-CoV text. Please get stuck into that.

Don’t worry about all editing separately – I can collate this, although it is great if some of you go rapidly and others build on theirs.

Main thing – please draft as much as you can, please use TRACK CHANGES, and please don’t mess up the ENDNOTE! Prob best for references that you just insert them into comment boxes. It’s a bit of a pain, but it’s less work than if the whole library decomposes...

Anyway – thanks for being great collaborators, and I look forward to what you send back

NB Supaporn and Tom – please share with your collaborators, and cc me, luke, aleksei and evelyn so I have their email addresses.

Cheers,

Peter

24 **Abstract**

25 Nipah virus (NiV) is an emerging bat-borne zoonotic virus with pandemic potential that causes near-  
26 annual outbreaks of fatal encephalitis in South Asia – one of the most populous regions on Earth. In  
27 Bangladesh, infection commonly occurs when people drink date palm sap contaminated with bat  
28 excreta. However, outbreaks are sporadic and the factors driving their temporal and spatial distribution  
29 poorly understood. We analyzed data on host ecology, molecular epidemiology, serological dynamics,  
30 and viral genetics to characterize spatio-temporal patterns of NiV dynamics in its wildlife reservoir,  
31 *Pteropus medius* bats. We found that NiV transmission occurred throughout the country and throughout  
32 the year, but local transmission dynamics were driven by density-dependent transmission, acquired  
33 immunity, and recrudescence. Increased transmission followed multi-year periods of declining  
34 seroprevalence due to bat population turnover and individual loss of humoral immunity. Individual bats  
35 had smaller host ranges than other *Pteropus* spp., which likely contributed to the relatively high diversity  
36 of NiV strains we observed, including a Malaysia-clade strain in eastern Bangladesh. We conclude that  
37 discrete multi-annual local epidemics in bat populations contribute to the sporadic nature of Nipah virus  
38 outbreaks in South Asia. At the same time, the broad spatial and temporal extent of NiV transmission  
39 highlights the continued risk of spillover to humans and the importance of limiting human-wildlife  
40 contact to reduce zoonotic viral spillover risk.

44

45 **Introduction.**

46 Outbreaks of zoonotic diseases are often sporadic, rare events that are inherently difficult to predict,  
47 but can have devastating consequences (1). Several emerging viral zoonoses with wildlife reservoirs  
48 have become pandemics, including HIV/AIDS, SARS coronavirus, and 1918 Pandemic Influenza H1N1 (2-  
49 4). Bats are important hosts for many zoonotic viruses (5) including Ebola virus, SARS-CoV, and Nipah  
50 virus, but the ecological drivers and transmission dynamics of these viruses in their reservoir hosts are  
51 poorly understood (6-10). A better understanding of the transmission dynamics of zoonotic pathogens  
52 in their natural reservoirs may help anticipate and prevent outbreaks (9, 11).

53 Nipah virus (NiV) is an emerging zoonotic paramyxovirus (genus *Henipavirus*) that has  
54 repeatedly spilled over from bats to cause outbreaks in people and livestock with high case fatality rates  
55 across a broad geographic range, making it a significant threat to global health. Nipah virus was first  
56 discovered in Malaysia in 1998 where it caused a significant outbreak in pigs and people (12).  
57 Subsequently it has caused repeated outbreaks in Bangladesh and India, with a mean case fatality rate  
58 greater than 70% (13-15). A single genus of frugivorous bats (*Pteropus*) appears to be the main reservoir  
59 for henipaviruses throughout Asia and Australia (16-20), including *Pteropus medius* (formerly *Pteropus*  
60 *giganteus* (21)) in Bangladesh and India (22-25). Nipah virus has several characteristics that make it a  
61 significant threat to human and animal health (26-28): 1) Its bat reservoir hosts are widely distributed  
62 throughout Asia, overlapping dense human and livestock populations, providing broad opportunity to  
63 cause outbreaks; 2) it can be transmitted directly to humans by bats, or via domestic animals; 3) it can  
64 be transmitted from person to person; 4) spillover has repeatedly occurred in highly populous and  
65 internationally connected regions, giving it pandemic potential; 5) it is associated with high mortality  
66 rates in people; and 6) there are currently no commercially available vaccines or therapeutics. As a  
67 result, the World Health Organization has listed Nipah virus among the ten most significant threats to  
68 global health (29). To date, human Nipah virus infections have been identified in India, Bangladesh,  
69 Malaysia, Singapore, and the Philippines (12, 13, 23, 30, 31). In May 2018, an outbreak of Nipah virus  
70 encephalitis associated with a 91% mortality rate, occurred in a new location - Kerala, India - more than  
71 1,100 km southwest of previous Indian and Bangladeshi outbreaks (32).

72 Although the primary pathway of spillover among bats, humans and livestock has been  
73 identified, the underlying spatio-temporal dynamics in bats and the extent and importance of genetic  
74 variation in the virus has not. Consumption of cultivated food resources contaminated with bat excreta  
75 such as mangoes in Malaysia and date palm sap in Bangladesh and India have been identified as the

76 predominant cause of spillover to pigs and people respectively (33). Human outbreaks occur almost  
77 annually in Bangladesh and the seasonal timing (November-April) and spatial distribution of outbreaks  
78 coincide with patterns of raw date palm sap consumption in a region termed the “Nipah belt” (34).  
79 However, there is variability in the number of spillover events that occur each year (35), and spillover  
80 has occasionally occurred outside the predominant season and region of date-palm sap consumption  
81 (36). The drivers of temporal patterns of viral transmission in bats, including seasonal and year-to-year  
82 variation, and the geographic extent of viral circulation within Bangladesh, and indeed within the range  
83 of this species (e.g. southern India) are poorly understood, which limits our understanding of how these  
84 processes influence spillover into humans.

85           Previous research on the transmission dynamics of Nipah and Hendra viruses (both in the genus  
86 *Henipavirus*) in *Pteropus* spp. bats have produced mixed and sometimes contradictory findings. Nipah  
87 virus, like Ebola, Marburg, Hendra and some bat coronaviruses, might be hypothesized to have seasonal  
88 spikes in infection that coincide with annual or semi-annual synchronous birth pulses (16, 37-42).  
89 Seasonal periods of Nipah virus shedding were observed in *P. lylei* in Thailand (43), but not in *P.*  
90 *vampyrus* or *P. hypomelanus* in Peninsular Malaysia (20). Hendra virus prevalence in Australian pteropid  
91 bats has shown multi-year inter-epidemic periods where very little virus can be detected, followed by  
92 periods of increased viral shedding, suggesting that viral dynamics are not annual (44-46). It has been  
93 hypothesized that multi-year periodicity in infection dynamics could arise from a build-up and waning of  
94 herd immunity in the reservoir host, with re-introduction of virus via immigration or recrudescence or  
95 viral persistence due to large population sizes (10, 47, 48). Some pteropid bat species are migratory and  
96 interconnected colonies form a metapopulation which could allow for viral re-introductions (9, 20, 49,  
97 50). In addition, NiV recrudescence has been observed in *P. vampyrus*, and either of these phenomena  
98 could allow it to persist regionally during periods of high local immunity (51). However, no study has yet  
99 shown evidence in free-ranging bat populations that favors one or the other hypothesis in driving NiV  
100 transmission dynamics.

101           Two distinct clades of NiV have been described: A Bangladesh clade, which includes sequences  
102 identified in India and Bangladesh; and a Malaysian clade, which comprises sequences from Malaysia,  
103 Cambodia, and Thailand (52). Strains of NiV from these two clades are associated with differences in  
104 pathogenesis, epidemiological and clinical profiles in humans and animal models and observed shedding  
105 patterns in bats (43, 53-57). Phenotypic variation in Nipah virus could influence observed human  
106 outbreak patterns by altering transmission to, or pathogenesis in, humans, and the likelihood of smaller

107 outbreaks being identified or reported (58). In Bangladesh, human-to-human transmission via contact  
108 with respiratory and other secretions has been regularly observed (59), whereas transmission among  
109 people was not a common feature of the Malaysia outbreak, despite close contact between cases and  
110 health care providers (60, 61). Primate models and human clinical data indicate that the Malaysia strain  
111 is less pathogenic than the Bangladesh strain and has less upper respiratory tract involvement, which  
112 may influence transmission (57). However, Nipah virus cases in Bangladesh have shown more strain  
113 diversity than in the Malaysia outbreak (62), and the diversity of NiV strains in *P. medius* has not been  
114 well characterized. Characterizing the diversity of NiV in bats may help determine whether more  
115 virulent or transmissible genotypes of NiV exist in bats that may eventually emerge in humans (27, 34).

116 The goal of the current study was to understand the distribution and drivers of NiV infection  
117 dynamics in *Pteropus medius* in Bangladesh. We examined spatial, temporal and demographic variation  
118 in serological dynamics in bats over a six-year period to determine the spatio-temporal drivers and  
119 dynamics of virus transmission. We also studied local and long-range movements of individual bats and  
120 analyzed NiV phylogenetics to understand patterns of spatial mixing, and strain diversity.

121

122

123

## 124 **Results**

125 *Cross sectional Nipah virus study of bats inside and outside the Nipah Belt and concurrent longitudinal*  
126 *bat study inside the Nipah Belt (2006-2012)*

127 We caught and tested 883 *P. medius* (approximately 100 per district) from eight different  
128 districts across Bangladesh. We detected anti-Nipah IgG antibodies in all colonies (**Figure 1**). Viral  
129 detection was rare. Overall, we detected NiV RNA in 11 individuals, 3 pooled oropharyngeal samples,  
130 and 21 pooled roost urine samples. We detected viral RNA in bats from four study sites: from individual  
131 bats in Faridpur and Rajbari and from pooled samples from Thakurgaon and Comilla. We also detected  
132 virus in pooled urine collected from bats associated with human outbreaks in Bhanga and Joypurhat  
133 (Table 1). The viral prevalence in Rajbari in January 2006 was 3.8% (95% CI: 0% -11%; n=78). In Faridpur,  
134 where we conducted an intensive longitudinal study (see below), viral prevalence estimates ranged from  
135 0% to 3% (95% CI: 0%-10%; n=100 at each of 18 sampling times) (**Table 1** and **Figure 2**). Nipah virus RNA  
136 was detected in individual bats from inside (Rajbari, Thakurgaon, and Faridpur) and outside (Comilla) the  
137 Nipah Belt (**Figure 1 and 2**). Urine samples provided the highest detection rate. Detection rates in  
138 individual bats by sample type were: urine/urogenital swab = 4% (n=2,126); oropharyngeal swab 3%

139 (n=2,088); and rectal swab = 1.3% (n=79). The estimated detection rate from pooled urine samples  
140 across the entire study was 2.7% (+/- 1.6%; n=829).

141

#### 142 *Factors associated with NiV IgG serostatus in P. medius*

143 Among adult and juvenile bats across the cross-sectional study (n=844), including the eight  
144 colonies previously described, seropositivity was 2.4 times more likely among adults than juveniles, and  
145 1.6 times more likely among males than females. Seropositivity was higher in pup-carrying (4 times) and  
146 pregnant (1.5 times) females (**Figure 2**). Weight or forearm length did not consistently correlate with  
147 seropositivity. Seroprevalence varied among sites within regions, but there was no effect on  
148 seroprevalence based on being inside or outside of the Nipah belt (**Figure 2**). Finally, serostatus was  
149 strongly correlated in mother-pup pairs, with 71/80 pairs (89%) having matching status.

150

#### 151 *NiV serodynamics over time in a population of P. medius, Faridpur district (2006-2012)*

152 We conducted an intensive longitudinal study of NiV serology in a population of bats in the  
153 Faridpur district and used flexible generalized additive models (GAMs) to characterize changes over  
154 time. There were significant fluctuations in adult and juvenile seroprevalence over the six-year study  
155 period (**Figure 3A**). Juvenile seroprevalence ranged from 0% to 44% (95%CI 37%-51%), and decreased  
156 over the first year of life for bats born in each year, consistent with loss of maternal antibodies in  
157 juveniles. A more pronounced decrease occurred from mid-October to mid-December. However, the  
158 GAM indicating this had only marginal better fit ( $\Delta AIC < 1$ ), than one with a linear decrease over the  
159 whole year (**Figure 3B**). While the effect of birth cohort was significant on overall seroprevalence.

160 Adult seroprevalence ranged from 31% (95% CI: 20%-46%) to 82% (95% CI: 77%-87%) and went  
161 through three periods of significant increase over the course of the study (**Figure 3A**). We found no  
162 evidence of regular seasonal fluctuations; a GAM with annual cyclic terms fit worse than one without  
163 ( $\Delta AIC > 10$ ). Each of these periods was preceded by a period of significantly decreasing seroprevalence.  
164 Viral RNA detections occurred in periods of both increasing, decreasing, and stable seroprevalence.

165 We fitted a series of age-stratified mechanistic models to examine different biological processes  
166 influencing serodynamics, including density- vs. frequency-dependent transmission, recrudescence,  
167 immigration of infected individuals, and seroreversion (loss of antibodies) in both juveniles and adults  
168 (**Figure 4**). Density-dependent models were a far better fit to the data than frequency-dependent  
169 models (difference in log-likelihood 10.0;  $\Delta AIC = 20.0$ ), suggesting that movements of bats and  
170 fluctuations in colony size alter spatio-temporal variation in the risk of NiV epidemic spillover to humans.

171 In this colony during the period of sampling, the roost population declined from approximately 300 bats  
172 to 185, which decreased transmission (**Figure S1**). In the six-year study period, the number of infected  
173 bats increased when the seroprevalence of adults fell below 72% (when bat counts were highest - in  
174 2006) and 52% (when bat counts were lowest).  $R_0$  in adult bats was estimated to decrease from 3.5 to  
175 2.1 as the number of bats in the colony decreased. Serodynamics in juveniles were strongly driven by  
176 inheritance and loss of maternal antibodies. The rate of loss of maternal antibodies was 17.6 weeks  
177 (95% CI: 13.7-25.0), which was much quicker than the loss of antibodies in adults (290.8 weeks, 95% CI:  
178 245.0-476.4) (**Table S1**). Finally, models with recrudescence fit the data better than models without  
179 recrudescence (**Table S1**; difference in log-likelihood 32.6;  $\Delta$ AIC = 30.6), and models with recrudescence  
180 fit the data better than models with immigration ( $\Delta$ AIC = 3.76).

181

#### 182 *Mark-recapture and seroconversion/seroreversion*

183 A total of 2,345 bats from the Faridpur/Rajbari region were sampled and microchipped.  
184 Between 2007 and 2012 there were 56 recapture events (**Table S2**). Thirty-one bats were recaptured at  
185 a roost other than the original capture location. This network of roosts or “roost complex” formed a  
186 polygon covering approximately 80 Km<sup>2</sup> and included 15 roosts sampled during the longitudinal study  
187 (**Figure S2**). Ten instances of seroconversion (change from IgG negative to IgG positive) and 9 instances  
188 of seroreversion (positive to negative) were observed (**Table S2**). The mean time between positive and  
189 negative tests in *adults* (excluding juveniles with maternal antibodies) was 588 days (n=6) (range: 124-  
190 1,082 days).

191

#### 192 *Homerange and inter-colony connectivity analysis*

193 Home range analysis of satellite telemetry data from 14 bats showed that the majority of bats  
194 roosted within 10 km of where the bats were collared for the Faridpur (Nipah belt) colony, within 7 km  
195 of the bats were originally collared for the Cox’s Bazaar colony (315km east of Faridpur). The average  
196 foraging radius was 18.7 km (s.d. 21.5 km) for the Faridpur bats and 10.8 km (s.d. 11.9 km) for the Cox’s  
197 Bazaar bats (**Figure S2**). Homerange analysis suggests that bats in Faridpur and Cox’s Bazaar would have a  
198 <5% probability of intermingling (**Figure 5**). Homerange size was significantly larger during the wet  
199 season than the dry season (2,746 km<sup>2</sup> vs. 618 km<sup>2</sup>) (**Figures S3 & S4**).

200

#### 201 *Phylogenetic analysis.*

202 Phylogenetic analysis of NiV sequences from a 224nt section of the N gene (nt position 1290-  
203 1509 [position ref [gb|FJ513078.1](#) India]) suggests that two clusters are present in Bangladesh bats –  
204 one that aligns with previously reported sequences from Bangladesh and India, including the 2018  
205 Kerala outbreak virus (group I), and one that aligns with those previously reported from Malaysia and  
206 Thailand (group II) (**Figure 6**). This finding is supported by an analysis of near-whole N gene sequences  
207 (~1720 nt) from bats, pigs, and humans, including those from a subset of *P. medius* from this and a more  
208 recent study by our group (**Figure S5**) (63). Eleven 224nt N gene sequences obtained from bats  
209 between 2006 and 2012 (all from the Faridpur population) were identical. Overall, the N gene  
210 sequences identified from the Faridpur, Rajbari and Bhanga colonies between 2006 and 2011 had  
211 98.21%-100% shared nucleotide identity. Sequences from Rajbari district obtained in January 2006 and  
212 January 2011 had only a single nucleotide difference resulting in a synonymous substitution (G to A) at  
213 position 1304, which was found in four other bat NiV sequences from this study, as well as in the NiV  
214 isolate from *P. vampyrus* in Malaysia. The five Human NiV N gene sequences collected from various  
215 locations within the Nipah belt over the same time period as our bat study show more nucleotide  
216 diversity than those from the Faridpur *P. medius* population, but across the country and including in  
217 Kerala, India, human NiV sequences were nested within the diversity found in *P. medius* (**Figure 6**). By  
218 contrast, the sequences found in Comilla, a location 150Km to the east of Faridpur, showed 80.8%-  
219 82.59% shared nucleotide identity with sequences from *P. medius* in Faridpur and clustered within the  
220 Malaysia group of NiV sequences. The two Comilla sequences were identical to each other, and had up  
221 to 87.95% shared nucleotide identity to sequences from *P. lylei* in Thailand. *Pteropus lylei* bats in  
222 Thailand were also found to carry NiV strains from both Malaysia and Bangladesh groups.

223

## 224 **Discussion**

225 Our study provided new insights into Nipah virus (NiV) transmission dynamics within bat hosts in  
226 Bangladesh, and demonstrates how understanding viral dynamics in wildlife hosts can help explain  
227 patterns of outbreaks in people. Firstly, we undertook the most geographically extensive survey of bat  
228 roosts in Bangladesh to date, and demonstrated that NiV transmission occurs throughout the country.  
229 This has important implications for NiV spillover because previous studies have shown that human NiV  
230 outbreaks occur only within a defined region in western Bangladesh, termed the “Nipah belt” (14, 34,  
231 64). Our sample testing data show no significant difference in bat NiV seroprevalence between colonies  
232 inside and outside the Nipah belt. This suggests infection patterns in bats within the region of human  
233 NiV outbreaks are not unique, and that other factors such as differences in intensity or timing of date

234 palm sap collection are more likely to underpin the heightened spillover risk within the Nipah belt (34,  
235 36, 58). We did find variation in seroprevalence among roosts, but these are likely to be a product of  
236 the timing of sample collection which was only conducted once in sites other than Faridpur and Comilla.

237

238 Secondly, analysis of serological data from our longitudinal study suggests that the underlying  
239 mechanism driving the timing of NiV transmission in bats and its spillover to people is the waning of  
240 herd immunity in discrete bat populations allowing heightened viral transmission. Our modeling  
241 indicates that NiV is primarily driven by density-dependent transmission dynamics among bats, with  
242 cycles of higher seroprevalence that would dampen intra-colony transmission followed by waning of  
243 antibody titers within individuals. Our large sample size provided the first data from recapture of  
244 sampled and released bats leading to the first reported evidence for the loss of detectable NiV IgG  
245 antibodies in recaptured individual free-ranging bats. The model outputs suggest that spikes in viral  
246 transmission occur after virus is reintroduced into the colony via recrudescence of viral transmission  
247 within bats that have previously been infected. This would likely occur in individuals with antibody titers  
248 that have waned below a neutralizing titer, and would lead to outbreaks only when overall population-  
249 level (herd) immunity drops below a level that would dampen transmission. Previous authors have  
250 proposed a number of mechanisms that could lead to maintenance of acute viral infections in bat  
251 metapopulations, including synchronous birthing and subsequent loss of maternal antibodies (10, 38,  
252 40), lowered immunity within pregnant females due to stress, nutritional stress and other factors (42)  
253 immigration of infected individuals from other colonies (49, 65, 66), and recrudescence within  
254 previously-infected individuals (10, 51, 67). Our findings and analyses provide strong multi-year data to  
255 support the hypothesis that recrudescence and natural loss of immunity due to waning antibodies are  
256 the primary cause of NiV transmission spikes within bats, with immigration as another likely factor in  
257 maintenance. The consistently lower and decreasing seroprevalence in juveniles suggests that they lose  
258 maternal antibodies over their first year, and likely in the first 6-7 months, consistent with other studies  
259 of maternal antibodies against henipaviruses in pteropodid bats (42, 68, 69). However, our analysis  
260 refutes the hypothesis that seasonal pulses of these new seronegative individuals are the primary driver  
261 of new outbreaks in adults (40). Recrudescence of henipavirus infection has been observed for NiV in  
262 captive *P. vampyrus* (51), for henipavirus in captive *E. helvum* (70), and has also been observed in  
263 humans infected by NiV (71) and Hendra virus (72).

264

265 Studying local and migratory bat movements can provide important ecological information related to  
266 viral transmission, including how bats move between different colonies (49). Our satellite telemetry  
267 data suggest that *P. medius* exists as a metapopulation, but we found that *Pteropus medius* appear to  
268 travel shorter distances and remain within a smaller home range (321.46km<sup>2</sup> and 2,865.27km<sup>2</sup> for two  
269 groups) compared to *P. vampyrus* in Malaysia (64,000 km<sup>2</sup> and 128,000 km<sup>2</sup>) and *Acerodon jubatus* in  
270 the Philippines which are similarly sized fruit bats (49, 73). Pteropodid bat migration is primarily driven  
271 by seasonal food resource availability (50, 74-76). In Bangladesh, *P. medius* prefer to roost in human-  
272 dominated environments in highly fragmented forests (77). The anthropogenic colonization and  
273 conversion of land over recent human history has likely led to increased food availability for *P. medius*  
274 and reduced necessity for long-distance migration (33). This may reflect a similar adaptation to  
275 anthropogenic food resources as observed over the last few decades in Australian *Pteropus* species (66).  
276 It may also create a more patchy landscape of viral dynamics and diversity across bat populations in  
277 Bangladesh. Less connectivity among flying fox populations on NiV transmission may be longer inter-  
278 epidemic periods and larger amplitude fluctuations in population level immunity compared to more  
279 migratory species (66).

280         There are limitations to these field studies. Firstly, our study size limits comparison of male and  
281 female bat migratory trends, whereas previous studies report that males disperse more often from  
282 roost sites to search for new territory, exposing them to different populations (78). This phenomenon  
283 could affect NiV transmission dynamics as we found that male bats have higher seroprevalence than  
284 females, in contrast to other henipaviruses that appear to have no sex-based difference in  
285 seroprevalence (42, 45, 79). Males may be more likely to be exposed to NiV through territorial bouts  
286 with other males at multiple roost sites and mating interactions with females (78, 80). Secondly, the  
287 observation of bats at multiple roost sites suggests that bats sampled from nearby roosts could be  
288 considered part of the same population. It also suggests that changes in roost size, which our models  
289 suggest impacts transmission dynamics, could reflect local shifting rather than true fluctuations in  
290 population due to wider dispersal – a limitation in our model parameterization where the latter  
291 interpretation was used.

292         Analyzing viral strain diversity in wildlife hosts may have relevance to identifying viral genetic  
293 markers associated with specific clinical outcomes in humans. We found that there is more N-gene  
294 diversity in bat and human NiV sequences from disparate locations compared to the nearly identical  
295 sequences in bats at our longitudinal site over the same six-year period. This suggests that there may be  
296 locally prevalent NiV genotypes that persist over time within bat colonies. Human genotype diversity is

297 likely a reflection of the relative diversity of the NiV strains in the local bats where outbreaks begin (9).  
298 Our report of a NiV strain in *P. medius* from Comilla that clusters phylogenetically within the Malaysia  
299 NiV clade corroborates a similar finding of two NiV strains in *P. lylei* in Thailand (81). It suggests that  
300 there has been historical interaction among bats in eastern Bangladesh and those in Myanmar and  
301 Thailand. Genetic studies of *P. medius* show interbreeding between these two species (Olival *et al.*, in  
302 review.). Connectivity among bat populations in eastern Bangladesh, Myanmar and Thailand may  
303 explain the genetic diversity observed between NiV sequences from Faridpur and Comilla. Malaysia and  
304 Bangladesh NiV strains have been associated with differences in pathogenesis, epidemiological and  
305 clinical profiles in humans and animal models. Animal models as well as human clinical data indicate  
306 strain differences among Bangladesh and Malaysia NiV, with the latter being less pathogenic, resulting in  
307 less oral secretion and upper respiratory tract involvement – factors that may influence transmission  
308 (53-57, 82). The N gene of the Comilla NiV strain differs from those reported from bats in the Nipah belt  
309 by 20%, whereas NiV Malaysia and NiV Bangladesh differ by 6-9% despite different clinical  
310 outcomes. Therefore it is plausible that the clinical profile of a 20% divergent NiV strain differs  
311 significantly from known strains. Mild or asymptomatic cases would be unlikely to be detected by  
312 national surveillance systems and it's possible that cryptic spillover has occurred in Bangladesh (62).  
313 Future studies comparing NiV genotypes with clinical and epidemiological outcomes may provide  
314 important insights about the ability of specific strains found in bats to cause significant outbreaks.

315 Finally, our study may explain the sporadic nature of NiV outbreaks with multi-year inter-  
316 epidemic periods in South Asia. Firstly, PCR tests show that overall NiV incidence in *P. medius* is low,  
317 similar to previous studies of Hendra virus (42, 45, 79). The data and our modeling suggests that PCR-  
318 positive samples are only likely to be identified during viral transmission spikes after periodic  
319 reintroduction into populations that have become susceptible through waning population-level  
320 immunity (10). This is likely a rare or at least sporadic event. In the current study, observed  
321 seroprevalence patterns and the fitted model suggest that three periods of transmission occurred over  
322 the 6 years of sampling, each of which followed periods of low adult seroprevalence, though not all  
323 measurements of low seroprevalence were followed by outbreaks. We detected NiV RNA during  
324 periods of both increasing and decreasing seroprevalence, supporting the fitted model which suggested  
325 that shedding can occur at low levels in bats even in periods without sustained transmission. Our  
326 observation that not every instance of rising seroprevalence resulted in detectable viral shedding  
327 suggests that not all episodes of viral circulation in bats are of equal magnitude, and that other factors  
328 (e.g. variation in human-bat contact and exposure) may affect likelihood of spillover. Together, this

329 evidence suggests that outbreaks can occur in bats when the population falls below a protective  
330 threshold of immunity in any season, but variability in how many bats become infected may impact the  
331 likelihood of spillover to humans, assuming a route of transmission is available. This could explain  
332 variation in the number of human outbreaks from year-to year in Bangladesh. Thus, the timing of  
333 multiple factors involved in driving transmission dynamics needs to align for intra-colony NiV  
334 transmission events and further align with human behavior and availability of a route of spillover for  
335 human outbreaks to occur, as previously hypothesized (83). This, and the seasonality and specific  
336 geography of date palm sap consumption in Bangladesh likely explains the somewhat sporadic nature of  
337 human outbreaks in the region, albeit that when spillover occurs, it is within the well-defined date palm  
338 sap collection season and geographic zone (34).

339         These findings suggest that Nipah virus outbreaks in other regions where *Pteropus* spp. bats  
340 occur, are also likely to be sporadic and rare, leading to under-reporting or a lack of reporting,  
341 particularly given that human neurologic symptoms are similar to other common infections, e.g.  
342 Japanese encephalitis, malaria, measles (84). Our work and other reports suggest that Nipah virus  
343 transmission is possible wherever *Pteropus* spp. bats and humans live in close association and at any  
344 time of year, provided there is an available route of transmission, as illustrated by the May 2018  
345 outbreak in Kerala, India – more than 1100km from Bangladesh and prior Indian outbreaks (15). In  
346 countries where NiV surveillance occurs, the absence of a sufficient bat-human interface may explain  
347 the lack of cases. However, improving capacity for NiV surveillance where it is enzootic is crucial for  
348 determining whether cryptic human infections are indeed occurring – especially if it is a relatively rare  
349 event (85). Interventions should focus on raising awareness of the potential for contamination of fruit  
350 or date palm sap in regions where pteropid bats are present, and in protecting food resources to limit  
351 the opportunity for human or livestock exposure to Nipah virus. These interventions are critical to  
352 reducing the risk of a more transmissible strain of Nipah virus, or a yet undiscovered virus, from  
353 emerging and causing an epidemic with significant human and animal mortality.

354

355 **Methods**

356 The study period was between January 2006 and November 2012. The study was conducted under Tufts  
357 University IACUC protocol #G929-07. Locations were selected based on whether the district had any  
358 previously recorded human NiV encephalitis clusters at the time of this study (Rajbari, Tangail,  
359 Thakurgaon, and Kushtia) or whether they had not (Comilla, Khulna, Sylhet, and Chittagong) so that  
360 infection rates could be compared between regions inside and outside of the “Nipah Belt.” The  
361 Thakurgaon study was conducted as part of an NiV outbreak investigation, and coincided with ongoing  
362 human transmission (86). Between 2006-2012, three different studies of *Pteropus medius*, with similar  
363 bat sampling protocols were performed: 1) a cross-sectional spatial study with a single sampling event in  
364 each of the eight locations listed above; 2) a longitudinal study of a Faripur bat colony with repeated  
365 sampling approximately every 3 months from July 2007 to November 2012; and 3) a longitudinal study  
366 of the Rajbari colony with repeated sampling at a monthly interval between 12 month period between  
367 April 2010 and May 2011. Opportunistic sampling of *Pteropus medius* was also performed during this  
368 time period during NiV outbreak investigations [Bangha, Faridpur (Feb 2010), Joypurhat (Jan 2012),  
369 Rajbari (Dec 2009), West Algi, Faridpur (Jan 2010)]. These data are included here because NiV testing of  
370 bat samples during these investigations supported the aims of the study. Bats were captured using mist  
371 nets at locations within eight different districts across Bangladesh between January 2006 and December  
372 2012 (**Figure 1**).

373

374 *Capture and sample collection*

375 For the country-wide cross-sectional and Faridpur longitudinal study, on average, 100 bats were  
376 sampled at each sampling event, which lasted 7-10 days. This sample size allowed us to detect at least  
377 one exposed bat (IgG antibody-positive) given a seroprevalence of 10% with 95% confidence. Bats were  
378 captured using a custom made mist net of approximately 10 m x 15 m suspended between bamboo  
379 poles which were mounted atop trees close to the target bat roost. Catching occurred between 11 pm  
380 and 5 am as bats returned from foraging. To minimize bat stress and chance of injury, nets were  
381 continuously monitored and each bat was extracted from the net immediately after entanglement. Bats  
382 were placed into cotton pillow cases and held for a maximum of 6 hours before being released at the  
383 site of capture. Bats were sampled at the site of capture using a field lab setup. Bats were anesthetized  
384 using isoflurane gas (87) and blood, urine, oropharyngeal swabs were collected. For some sampling  
385 periods, rectal swabs were collected but due to resource constraints, these samples were deemed to  
386 likely be lower yield than saliva and urine for NiV, and therefore were not collected consistently. For

387 each bat sampled we recorded age, weight, sex, physiologic and reproductive status, and morphometric  
388 measurements as described previously (22). Bats were classified as either juveniles (approximately four  
389 to six months - the age by which most pups are weaned) to two years old (the age when most *Pteropus*  
390 species reach sexual maturity) or adults (sexually mature) based on body size and the presence of  
391 secondary sexual characteristics, pregnancy, or lactation - indicating reproductive maturity (22, 88).  
392 Up to 3.0 mL of blood were collected from the brachial vein and placed into serum tubes with serum  
393 clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box and  
394 serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and placed in  
395 a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton Cryogenics, NJ,  
396 USA). Sterile pediatric swabs with polyester tips and aluminum shafts were used to collect urogenital  
397 and rectal samples, and larger polyester swabs with plastic shafts (Fisher, USA) were used to collect  
398 oropharyngeal samples. All swabs were collected in duplicate, with one set being placed individually in  
399 cryotubes containing lysis buffer (either tri-reagent or NucliSENS Lysis buffer, BIOMERIEUX, France) and  
400 the second set in viral transport medium. All tubes were stored in liquid nitrogen in the field then  
401 transferred to a -80C freezer.

402 During each sampling event, pooled urine samples were collected beneath bat roosts using  
403 polyethylene sheets (2' x 3') distributed evenly under the colony between 3 am and 6 am. Urine was  
404 collected from each sheet either using a sterile swab to soak up droplets, or a sterile disposable pipette.  
405 Swabs or syringed urine from a single sheet were combined to represent a pooled sample. Each urine  
406 sample was divided in half and aliquoted into lysis buffer or VTM at an approximate ratio of one part  
407 sample to two parts preservative.

408

#### 409 *Serological and molecular assays*

410 Sera from the cross-sectional survey were heat inactivated at 56°C for 30 minutes as described (89) prior  
411 to shipment to the Center for Infection and Immunity at Columbia University (New York, USA) for  
412 analysis. Samples were screened for anti-NiV IgG antibodies using an enzyme linked immunosorbent  
413 assay (ELISA) as described in (22). Sera from the longitudinal studies were sent to the Australian Animal  
414 Health Laboratory and were gamma irradiated upon receipt. Because of the large sample size and  
415 development of a high throughput multiplex assay of comparable specificity and sensitivity, for these  
416 samples we used a Luminex-based assay to detect anti-Nipah G IgG antibodies reactive to a purified NiV  
417 soluble G protein reagent (90, 91).

418 Total nucleic acids from swabs and urine samples were extracted and cDNA synthesized using  
419 Superscript III (Invitrogen) according to manufacturer's instructions. A nested RT-PCR and a real-time  
420 assay targeting the N gene were used to detect NiV RNA in samples (92). A RT-qPCR designed to detect  
421 the nucleocapsid gene of all known NiV isolates was also utilized (93). Oligonucleotide primers and  
422 probe were as described (93). Assays were performed using AgPath-ID One-StepRT-PCR Reagents  
423 (Thermofisher) with 250 nM probe, 50 nM forward and 900 nM reverse primers. Thermal cycling was  
424 45°C for 10 min, followed by 45 cycles of 95°C for 15 s and 60°C for 45 s. Cut-off values were cycle  
425 threshold ( $C_T$ )  $\leq 40$  for positive and  $C_T \geq 45$  for negative. Results with  $C_T$  values between 40 and 45 were  
426 deemed indeterminate, i.e. not conclusively positive or negative. Samples with NiV RNA detected by real  
427 time PCR were confirmed by gel electrophoresis and product sequencing.

428 A subset of NiV-positive samples was processed by high-throughput sequencing (HTS) on the Ion  
429 Torrent PGM platform in order to obtain additional NiV genomic sequence. Libraries were prepared  
430 according to the manufacturer's instructions, and 1 million reads allocated per sample. HTS reads were  
431 aligned against host reference databases to remove host background using bowtie2 mapper, and host-  
432 subtracted reads primer trimmed and filtered based on quality, GC content and sequence complexity.  
433 The remaining reads were de novo assembled using Newbler (v2.6) and mapped to the full length NiV  
434 genome. Contigs and unique singletons were also subjected to homology search using MegaBlast  
435 against the GenBank nucleotide database, in case variance in parts of the genome precluded efficient  
436 mapping. From these data, N, P, and G gene consensus sequences were constructed using Geneious v  
437 7.1, and used for phylogenetic analyses.

438

#### 439 *Phylogenetic analysis*

440 All *P. medius* NiV sequences will be submitted to Genbank and included in supplemental material upon  
441 acceptance for publication. Sequence alignments were constructed using ClustalW in Geneious v7.1  
442 software (94). Phylogenetic trees of NiV N-gene, P-gene, and G-gene sequences were constructed using  
443 Neighbor-Joining, Maximum-Likelihood algorithms in MEGA v. 5 (95) and figures constructed in FigTree  
444 1.4.2.

445

#### 446 *Satellite telemetry and homerange analysis*

447 We developed a collar system to attach 12g solar-powered Platform Terminal Transmitters (PTT)  
448 (Microwave Telemetry, Colombia, MD, USA) to adult bats using commercial nylon feline collars with the  
449 buckle removed and 0-gauge nylon suture to attach the PTT to the collar and to fasten the collar around

450 the bat's neck. Collars were fitted to the bat such that there was enough space to allow for normal neck  
451 movement and swallowing, but so that the collar would not slip over the head of the animal (**Figure S6**).  
452 PTTs were programmed with a duty cycle of 10 hours on and 48 hours off. Data was accessed via the  
453 Argos online data service (argos-system.org; France). A total of 14 collars were deployed as follows:  
454 Feb 2009: 3 males, 3 females from a colony in Shuvarampur, Faridpur district; Feb 2011: 3 males, 2  
455 females from the same colony; and April 2011 Cox's Bazaar, 3 bats from a colony in Cox's Bazaar,  
456 Chittagong district. Adult bats were selected based on size such that the total weight of the collar (~21g)  
457 was less than 3% of the bat's body mass.

458 The individual telemetry dataset was combined for each region and its aggregate utilization  
459 distributions (UD) computed in R using package 'adehabitatHR' (96). Population-specific home range is  
460 represented by the \*95% area enclosure of its UD's volume. The volume of intersection between the  
461 colonies quantifies the extent of home range overlap. To evaluate the potential for contact with the  
462 Sylhet colony, we calculated the most likely distance moved ('mldm') for each sampled bat at Faridpur  
463 where the population was more intensively monitored. Movement distance was measured in kilometers  
464 with respect to a centroid location ( $\omega$ ) shared by the whole colony; assuming random spatial distribution  
465 in tracking rate, we estimated its kernel density function per individual and defined mldm as the mode.

466

#### 467 *Statistical approach – cross-sectional study*

468 We fit a full Bayesian generalized linear model with a logit link and a Bernoulli distribution to  
469 identify potential predictors which influenced a bat's serostatus. We included age, sex, age- and sex-  
470 normalized mass and forearm length, mass:forearm ratio, body condition, and whether the bat was  
471 pregnant, lactating, or carrying a pup. We included location of sampling a random effect nested within  
472 Nipah Belt or non-Nipah Belt regions. We fit the models and performed posterior predictive checks in R  
473 3.4.3 , using the **brms** and **rstan** packages.

474

#### 475 *Statistical approach – longitudinal study*

476 We fit binomial general additive models (GAMs) (97) to the time series of adult and juvenile  
477 seroprevalence in the longitudinal study. For juveniles, we modeled the birth cohort of bats as separate  
478 random effects in a pooled model of juveniles' dynamics starting from June of their birth year, June  
479 being the earliest month we sampled free-flying juveniles in any cohort. We determined the cohort year  
480 of juveniles by using cluster analysis to group individuals by weight, assuming those in the smallest  
481 group were born in the year prior to sampling and those in the larger group were born the previous

482 year. 92% of juveniles captured were yearlings. For adults, we modeled dynamics of adults as a single  
 483 pool over the entire course of the study. We tested models with and without annual cyclic effects.

484 Where time series had significant temporal autocorrelation (adults only), we aggregated data by  
 485 week. We determined periods of significant increase in decrease as those where the 95% confidence  
 486 interval of the GAM prediction's derivative did not overlap zero. We fit the models and performed  
 487 checks in R 3.4.3, using the **mgcv** package.

488 We fit an age-structured (adult and juvenile) maternally immune (M)-susceptible (S)-infected (I)-  
 489 recovered (R) model with recrudescence (R to I) and loss of immunity (R to S) to the seroprevalence  
 490 data on a weekly timescale:

491

$$\frac{dS_J}{dt} = -S_J(\beta_{JJ}I_J + \beta_{AJ}I_A) - \mu_J S_J + bN_A(t-5)\frac{S_A}{N_A} - bN_A(t-52)\frac{S_J}{N_J}(1-\mu_J)^{52} + \lambda M_J$$

$$\frac{dI_J}{dt} = S_J(\beta_{JJ}I_J + \beta_{AJ}I_A) - \gamma I_J - bN_A(t-52)\frac{I_J}{N_J}(1-\mu_J)^{52}$$

$$\frac{dR_J}{dt} = \gamma I_J - \mu_J S_J - \mu_J R_J - bN_A(t-52)\frac{R_J}{N_J}(1-\mu_J)^{52}$$

492

$$\frac{dM_J}{dt} = bA(t-5)\frac{R_A}{N_A} - \lambda M_J - \mu_J M_J - bN_A(t-52)\frac{R_A}{N_A}(1-\mu_J)^{52} \lambda^{52}$$

$$\frac{dS_A}{dt} = -S_A(\beta_{AA}I_A + \beta_{JA}I_J) - \mu_A S_A + \tau R_A + bN_A(t-52)\frac{S_J}{N_J}(1-\mu_J)^{52}$$

$$\frac{dI_A}{dt} = S_A(\beta_{AA}I_A + \beta_{JA}I_J) - \gamma I_A - \mu_A I_A + bN_A(t-52)\frac{I_J}{N_J}(1-\mu_J)^{52} + \Delta R_A$$

$$\frac{dR_A}{dt} = \gamma I_A - \mu_A R_A + bN_A(t-52)\frac{R_J}{N_J}(1-\mu_J)^{52} - \tau R_A - \Delta R_A$$

493 We included a class M for the density of juvenile bats with maternal antibodies to allow for the biological  
 494 possibility that maternal antibodies are lost at a much higher rate than antibodies acquired following  
 495 infection. The subscripts J refer to juveniles and A to adults,  $\beta$  is the transmission rate,  $\gamma$  is the recovery  
 496 rate,  $\mu$  is the mortality rate,  $\tau$  is the rate of loss of adult immunity,  $\lambda$  is the rate of loss of maternal  
 497 antibodies(68),  $\Delta$  is the adult recrudescence rate (R to I), b is the birth rate (pups join the juvenile  
 498 population after 5 weeks). Juveniles transition to adults after 52 weeks. We included terms for loss of  
 499 antibody in adults ( $\tau$ , S to R), and viral recrudescence ( $\Delta$ , R to I) based on previous studies on captive bats  
 500 that demonstrated the existence of these processes without providing enough data to characterize them  
 501 precisely (51, 69). We fit this deterministic model to the seroprevalence data by maximum likelihood,  
 502 which assumes that deviations from the model are due to observation error. We estimated the

503 confidence intervals around maximum likelihood parameter estimates using likelihood profiles using the  
504 *profile* function in package *bbmle* in R v3.2.2.

505 We used model fitting and model comparison to examine the need for several of the biological  
506 processes in the model above that could influence NiV dynamics. First, we examined both density and  
507 frequency-dependent transmission by comparing the fit of the model above to one with transmission  
508 terms that have population size ( $N_A$  or  $N_I$ ) in the denominator. Second, we examined the confidence  
509 intervals of the parameters describing viral recrudescence, loss of antibodies in adult bats, and loss of  
510 antibodies in juvenile bats. If the confidence bounds for these parameters included zero, then these  
511 biological processes are not needed to explain the serological dynamics. Finally, we examined the  
512 confidence bounds for parameters describing the loss of maternal and non-maternal antibodies ( $\tau$  and  
513  $\lambda$ ), to determine if the rate of loss of these two types of immunity were different. We note that this  
514 model structure has similarities to a susceptible-infected-latently infected(L)-infected (SILI) model (if  
515 latently infected individuals are seropositive), but the model above differs in allowing for the possibility  
516 of individuals to transition from the R class back to the S class.

#### 517 *Code availability*

518 SIR model code written in R is available upon request.

519

#### 520 *Data availability*

521 All molecular sequences will be available via Genbank. The datasets generated during and/or analysed  
522 during the current study are available from the corresponding author on reasonable request.

523

524 **Acknowledgements:** We thank Pitu Biswas, Md. Sheikh Gofur, Abdul Hai, and Craig Smith for assistance  
525 in the field, Christopher Allen, and Parviez Hosseini for technical input, Eliza Choi; Yan-Ru Feng and  
526 Lianying Yan for preparing recombinant viral glycoproteins; Jennifer Barr, Vishal Kapoor, Neil Renwick,  
527 and Mohammad Ziadur for laboratory diagnostic and technical support, and the Government of

769

770  
 771 **Figure 1.** Map showing age-stratified seroprevalence in *Pteropus medius* colonies, Bangladesh. Bats from eight  
 772 colonies were sampled and tested for anti-NiV IgG antibodies: four within the “Nipah Belt” (orange shaded) and  
 773 four outside. Seroprevalence of adults (blue, purple), juveniles (red, orange) and total seroprevalence (green, light  
 774 blue) are shown. Number (n) of Adult, Juvenile, and Total bats sampled (clockwise): Tangail [53,41,94], Sylhet [63,  
 775 37, 100], Comilla 2008 [73,27,100], Comilla 2011 [30,20,50], Chittagong [72,24,96], Khulna[85,15,100], Rajbari  
 776 [65,15, 80], Kushtia [64,36,100], Thakurgaon [89,29,118]. The shaded region represents the “Nipah Belt” where  
 777 previous human NiV outbreaks have been reported. Seroprevalence varied by location ( $\chi^2 = 55.61, p < .001$ ), but  
 778 there was no statistical difference between seroprevalence in bats inside the Nipah Belt and outside. Adult bats  
 779 had equal or greater seroprevalence than juveniles in each location.  
 780

### GLM Estimates: Factors Affecting Nipah Serostatus

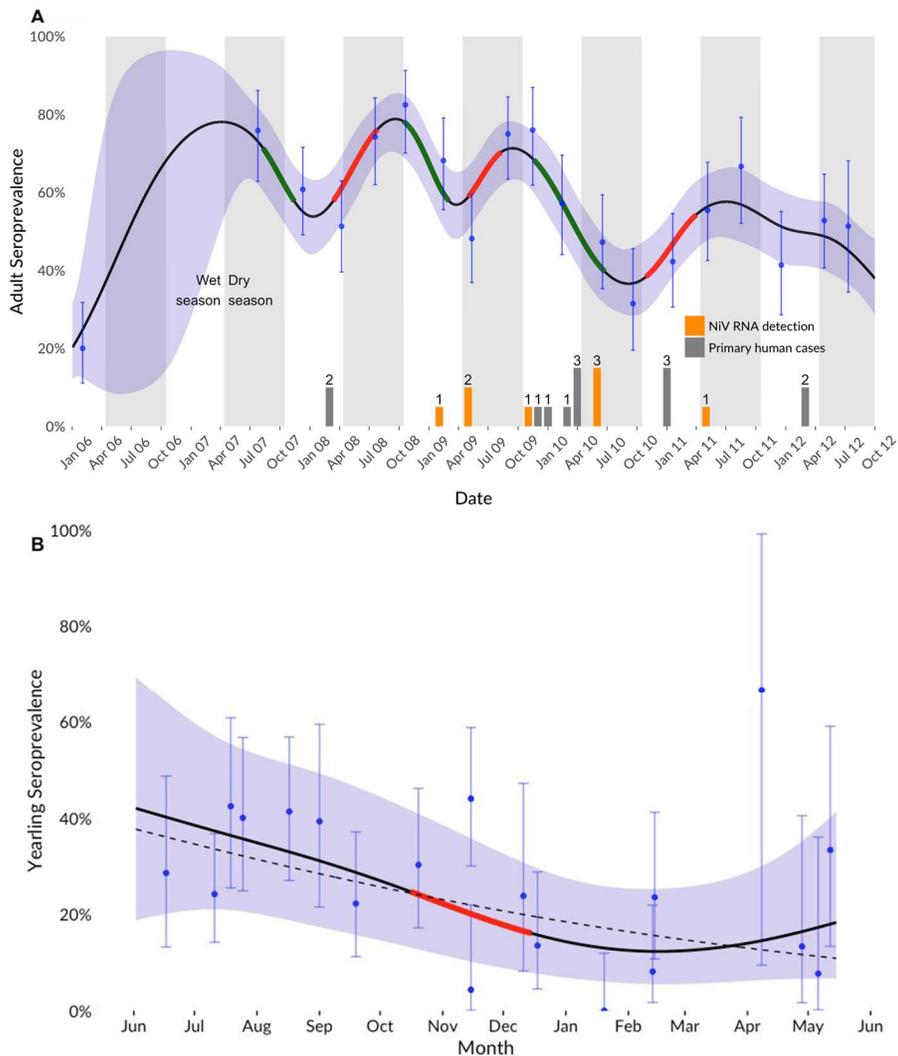

781

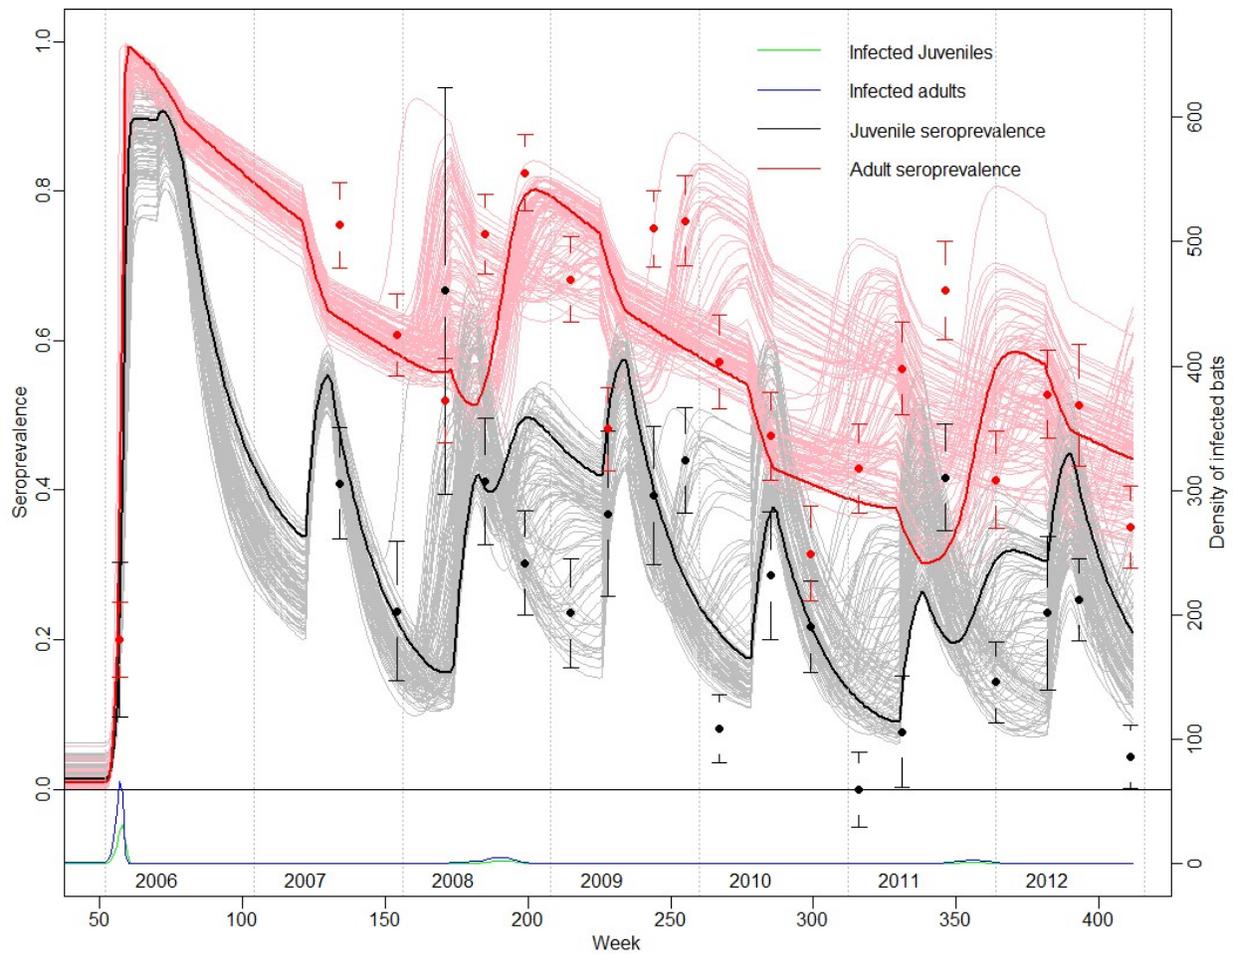

782 **Figure 2.** Results of Bayesian GLM of factors affecting Nipah serostatus in bats in cross-sectional study. Bars  
 783 indicate odds ratios and 50% (inner) and 95% (outer) credible intervals for model parameters. Factors with  
 784 asterisks (\*) have 95% CIs that do not overlap 1. Model intercept (predicted probability of seropositivity for a  
 785 juvenile, female, bat outside the Nipah belt of mean size and good body condition) was 0.26, (95% CI 0.12-0.56).  
 786 Random effect of location (not shown) had an estimated SD of 0.63 (95% CI 0.29-1.27)

787

Nipah virus IgG antibody serodynamics in adult and juvenile *Pteropus medius*, Faridpur, Bangladesh 2006-2012

788  
 789 **Figure 3 A & B.** Serodynamics of the Faridpur bat population. (A) Adult serodynamics, with measured values and  
 790 95% CI in blue, and mean GAM prediction and 95% shown with line and surrounding shaded areas. Periods of  
 791 significant increase (red) and decrease (green) shown where the GAM derivative's 95% CI does not overlap zero.  
 792 Counts of primary human cases from local district (orange, and bat viral detections (dark grey, see Table 1), shown  
 793 on bottom. (B) Juvenile serodynamics during the first year of life, with all years' measurements overlain to show  
 794 cohort-level dynamics across all years. Measured values and 95% CI in blue, and mean and 95% CI for the GAM  
 795 model pooled across cohorts shown with line and surrounded shaded areas. The period of significant decline in  
 796 the GAM is shown in red. Also shown is the mean prediction of a model with only a linear mean term, with similar  
 797 fit ( $\Delta AIC < 1$ ) as the GAM (dotted line).  
 798

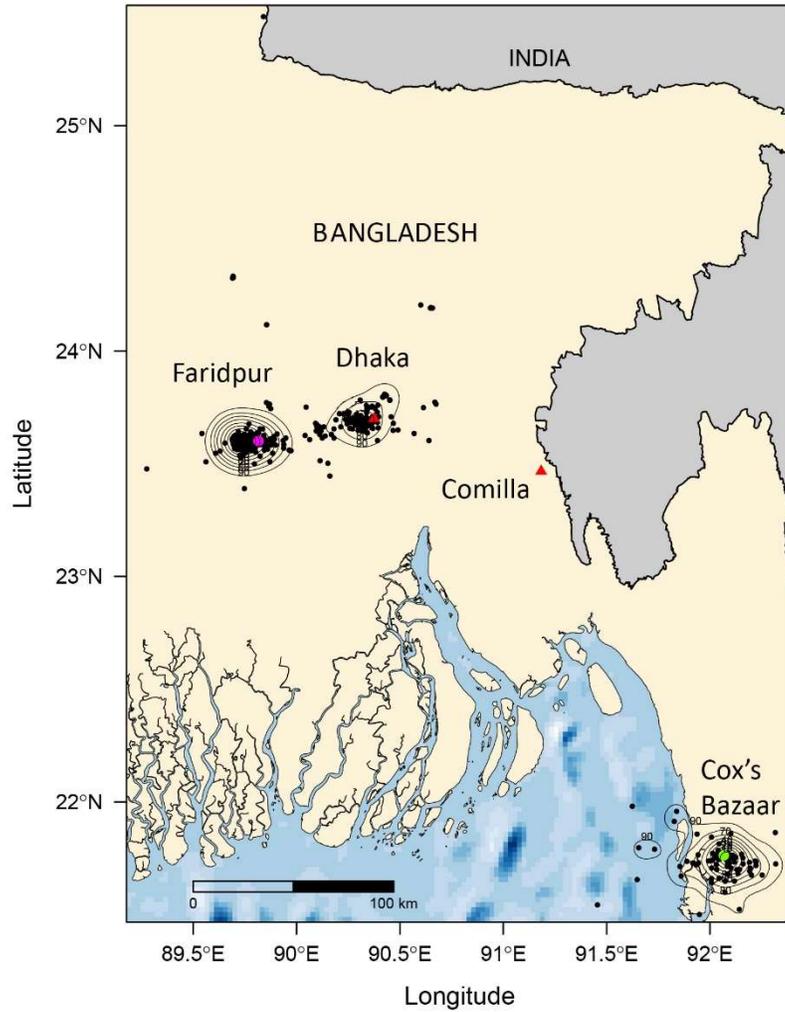

800

801 **Figure 4. NiV serological dynamics in adult and juvenile bats.** The observed data (red and black points  $\pm 1$  SE) and  
 802 model fit (solid lines) for the fraction of adults and juveniles seropositive for NiV (left axis), and the model  
 803 estimated density of infected adult and juvenile bats (bottom panel and right axis). See Methods for details of  
 804 model structure.

**Figure 5.** Satellite telemetry and homerange analysis. Location data from satellite collars (n=14) placed on 11 bats from Faridpur and 3 bats from Cox's Bazaar, Chittagong collected between 2009 and 2011, were used to calculate local and long-range movement patterns and home range for these two groups.

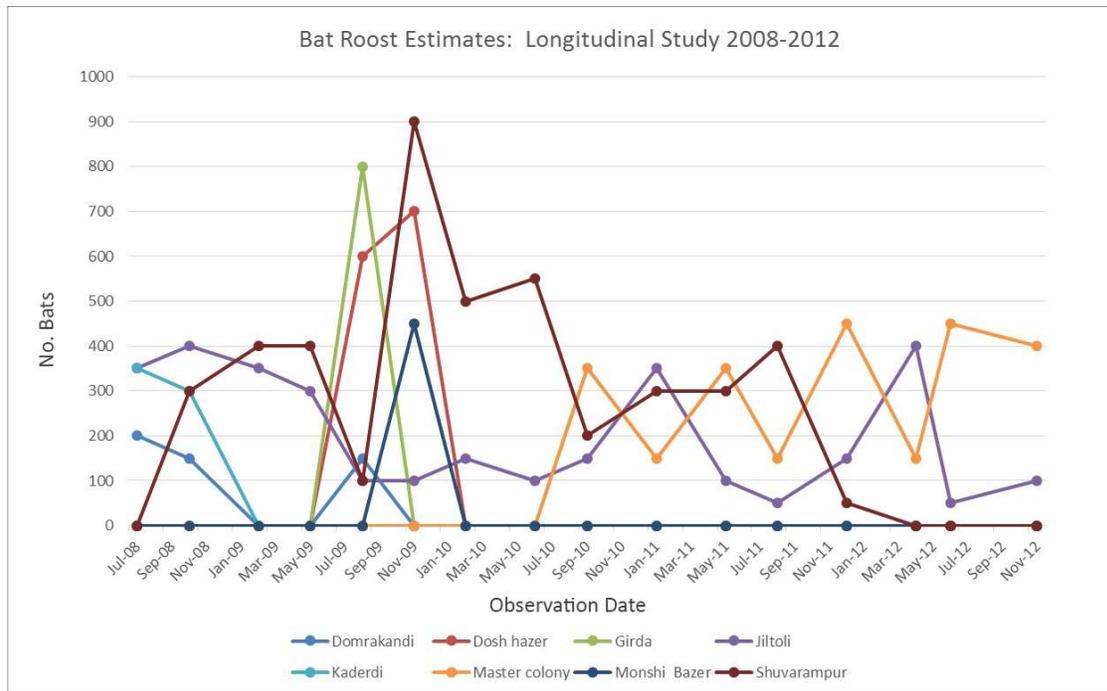

858 **Figure 6. Nipah Virus N gene phylogenetic tree (224nt):** Tree created in MEGA X using the Maximum Likelihood  
 859 method and Tamura-Nei model (98). The percentage of trees in which the associated taxa clustered together is  
 860 shown next to the branches. The tree is drawn to scale, with branch lengths measured in the number of substitutions  
 861 per site. Hendra virus was used as an outgroup. Evolutionary analyses were conducted in MEGA X (99). Genbank  
 862 accession numbers are included in the label for each sequence.

863 **Table 1.** PCR detection of NiV RNA in *Pteropus medius* 2006-2012.

864 \*NiV RNA was detected in three pooled oropharyngeal samples, confirmed by sequencing, although confirmation from individual samples could  
 865 not be made. These data re not used in prevalence estimates. <sup>α</sup> Detection by qPCR, Ct ranges 20-38.

868 **Figure S1.** *Pteropus medius* counts from roosting sites within the Faridpur roost complex: 2008-2012.  
869 Domrakandi and Kaderdi were the two primary roost sites sampled for the longitudinal study, although recapture  
870 data showed intermixing among all of these roost sites in the Faridpur Roost Complex.  
871

872

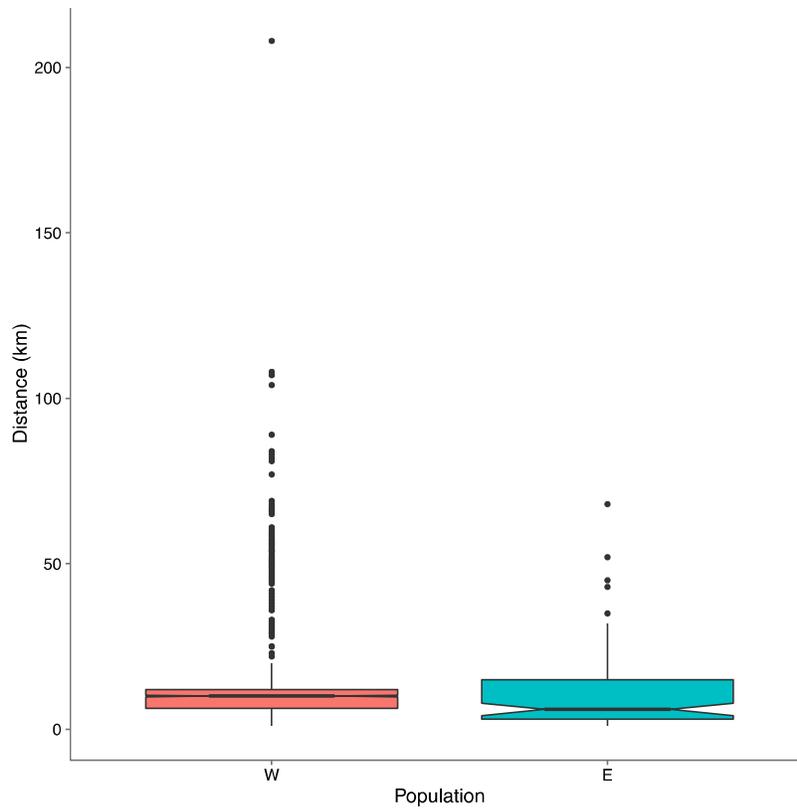

873

874 **Figure S2.** Faridpur Roost Complex. 51 Individual bats were recaptured during the longitudinal study at various  
875 locations. 33 bats were recaptured at a different site from where they were originally sampled. 15 unique roosts  
876 within an 80km<sup>2</sup> area were identified.

Mean foraging distance from roost in western and eastern colonies, based on satellite telemetry

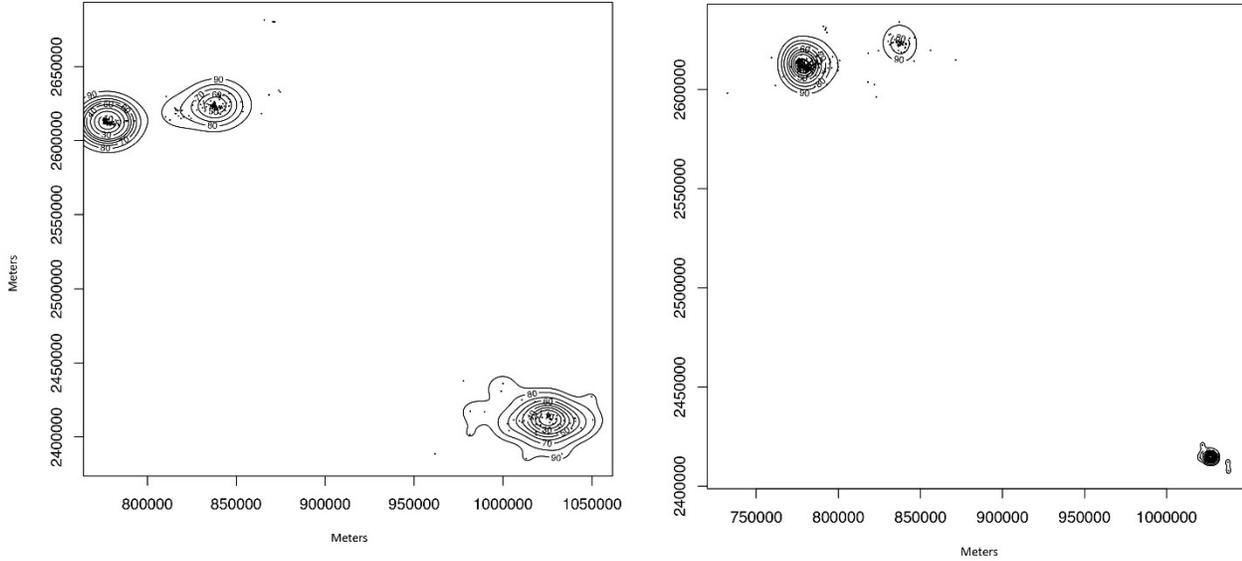

**Figure S3.** Mean foraging distance of western (W) and eastern (E) bat populations, based on satellite telemetry locations obtained between 1800h and 0600h, when *P. medius* typically forages.

919

920

Home range of *Pteropus medius* in wet and dry seasons.

921 **Figure S4.** a) Homerange of *Pteropus medius* during the wet season (left) and dry season (right). Maps  
922 are projected in UTM (Universal Transverse Mercator) Zone 45 where units are represented in meters.  
923 The mean wet season homerange size was 2,746 km<sup>2</sup>. Homerange size in the dry season is contracted  
924 and represents less than a quarter (618 km<sup>2</sup>) of the homerange in the wet season.

**Figure S5. Nipah Virus phylogenetic tree, N gene:** Clustal W alignment using nearly whole N gene consensus sequence from *P. medius* (1,592 nt) using Geneious Prime 2019 (100). The evolutionary history was inferred by using the Maximum Likelihood method and Hasegawa-Kishino-Yano model (101). The percentage of trees in which the associated taxa clustered together is shown next to the branches. The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. Evolutionary analyses were conducted in MEGA X (99). Genbank accession numbers for sequences (from top to bottom): *P. medius* Maniganj & Sylhet pending (63); JN808864, AY988601, MH396625, FJ513078, JN808863, JN808857, AY858110, FN869553, AJ627196, AJ564623, AY029767, AF376747, AY029768, JN255803.

---

All,

I wanted to update you that our manuscript on Nipah virus dynamics in bats is being re-submitted to *Science Advances*. Although it was originally rejected, the reviews were positive enough that the Deputy Editor has agreed to receive the revised manuscript as a new submission and send it out again for review. Thank you all for your input into this manuscript in its various stages of development. I'll follow up once we receive reviewers' comments.

Attached is the submitted version.

Cheers,  
Jon

--

Jonathan H. Epstein DVM, MPH, PhD

Vice President for Science and Outreach

EcoHealth Alliance  
460 West 34th Street, Ste. 1701

New York, NY 10001

EcoHealth Alliance leads cutting-edge scientific research into the critical connections between human and wildlife health and delicate ecosystems. With this science, we develop solutions that prevent pandemics and promote conservation.

## **Budget Justification**

### **PERSONNEL**

#### **Key Personnel**

Dr. Christopher Broder will serve as Co-PI at 2.5% effort. Dr. Broder will be responsible for supervising the activity of all USU personnel engaged in the project and providing project oversight. Dr. Broder will not require salary support since he is an employee of the federal government.

Dr. Eric Laing will serve as a scientist on this project with 10% of effort. He will be responsible for the day to day USU project oversight related to production of recombinant protein materials, and actively direct and participate in the development of the immunoassay, validation and data analysis. Also, he will be responsible for long-term milestone planning, and supervising the research activities of the technical staff. Dr. Laing will also lead material and technology transfer and in-country training at Jordan University of Science and Technology (JUST), Jordan and R. Lugar Center, Georgia in Years 1 and 2. Additionally, Dr. Laing will participate in data analysis of serological data generated throughout the performance period and data analysis training on-site at JUST and Lugar in Year 3 with EcoHealth Alliance scientists and PI. Salary support for Dr. Laing will not be requested.

#### **Other Personnel**

Laingyang Yan will serve as the senior research technician on this project with 20% effort.

Spencer Sterling will serve as the research assistant II on this project with 20% effort.

A TBD research assistant will provide 100% effort.

The research assistants will be responsible for the recombinant materials at the USU laboratory, and will perform quality-control experiments, and data analysis prior to deliverance of reagents to Jordan University of Science and Technology (JUST), Jordan and R. Lugar Center, Georgia. This will enhance early virus detection through serological biosurveillance at Jordan University of Science and Technology (JUST), Jordan and R. Lugar Center, Georgia, and improve situational awareness for Middle Eastern Respiratory Syndrome (MERS)-coronavirus in USCENTCOM and USEUCOM theaters. The personnel listed above will provide custom reagent support and on-site staff training with Luminex-based technologies and a multiplex microsphere immunoassay that we have developed.

The salary support requested does budget for a small merit increase per year for each research assistant position.

### **SUPPLIES**

The proposed budget includes costs for the production of coronavirus surface proteins and nucleoprotein, MagPIX magnetic beads, reagents necessary for the purification of polyclonal antibodies that complement the custom virus proteins as controls and laboratory disposables required in the production process and assay validation. The current proposal includes the production costs of 10 virus protein antigens, including production of custom MERS, SARS, MERS-related and SARS-related coronavirus spike proteins. The Principal Investigator (PI), Kevin Olival, EcoHealth Alliance, has indicated that the projected sample size of this biosurveillance study is ~2400 individual sera samples and the proposed budget has been designed to meet this sample size. Additionally, included is the cost of ordering 10 uniquely colored compatible MagPIX magnetic beads to correspond with each virus protein. Size exclusion and affinity purification are used to purify each virus protein.

	<u>Year 1</u>	<u>Year 2</u>	<u>Year 3</u>
Protein Production (Cov) ~1500/each	\$19,000.00	\$15,000.00	\$7,500.00
Magnetic beads (725/bottle - 10 plex)	\$7,250.00		
Cell culture materials - disposables	\$10,000.00	\$10,000.00	\$10,000.00
Polyclonal rabbit antisera	\$7,200.00		
Affinity matrices and control IgG materials	\$4,000.00	\$4,000.00	\$4,000.00
Shipments	<u>\$3,000.00</u>	<u>\$3,000.00</u>	<u>\$3,000.00</u>
TOTAL	\$50,450.00	\$32,000.00	\$24,500.00

**TRAVEL**

USU/HJF staff will travel to JUST, Jordan and the R. Lugar Center, Georgia to complete on-site training of research staff and laboratory personnel. We anticipate travel and training during each fiscal year of funding. In Year 1 we will require separate trips to perform trainings at both JUST and R. Lugar Center; in Year 2 we will host a second training in Jordan and anticipate attendance at a conference where data generated from this project will be presented; and in Year 3 we will conduct a data analysis training at the R. Lugar Center. In this budget we are estimating sums for per diem, airfare, and lodging costs to cover 7 days of staff travel including 5 days of on-site training for two USU/HJF scientists per year. The costs associated with travel has been generated using the published GSA rates.

	<u>Year 1</u>	<u>Year 2</u>	<u>Year 3</u>
Foreign / International Travel	\$ 14,400.00	\$15,000.00	\$8,200.00

**OTHER DIRECT COSTS**

An AKTA chromatography machine is used for purification and a service contract is required for proper machine maintenance. Instrument (Bio-Rad Bio-Plex 200) usage fees at the USU Biomedical Instrumentation Center (BIC) have been estimated on a yearly usage basis. The BIC instrumentation is necessary to validate and perform control test with the virus antigens produced in the USU laboratory. The estimated cost will be **\$4,500 per year**, for all 3 years.

**Indirect and Fringe Benefit**

The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc. (HJF) indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The IDC applied is 29.48% (USU On-site Overhead) or 4.19% (USU Off-site Overhead) for all allowable direct costs, less sub-awards. Additionally, a 14.30% (Companywide G&A) rate is applied on the total direct costs less subawards plus the USU On-site Overhead rate. For proposals including subawards, 1.60% is applied to the total subaward costs.

The fringe rate is 31.70% for Tier 1 HJF employees, and 5.45% for Tier 2 HJF employees. All HJF employees on this proposal are Tier 1.

The above provisional indirect cost and fringe benefit rates for FY 2019 were approved by the U.S. Army Medical Research Acquisition Activity on December 12, 2017.

### EDUCATION/TRAINING

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Florida Institute of Technology, Melbourne, FL	B.S.	06/1983	Biological Science
Florida Institute of Technology, Melbourne, FL	M.S.	12/1985	Molecular Biology
University of Florida, Gainesville, FL	Ph.D.	05/1989	Immunology and Med-Micro

### A. Personal Statement

The main objective of this proposal is to determine the seroprevalence of MERS-CoV across the human-camel value chain in Jordan and be able to inform locations, seasons, and epidemiological interfaces of greatest risk. We will make use of a Luminex-based microsphere multiplex assay using immunologically relevant soluble and native-like viral envelope glycoproteins. We are well experienced in making soluble viral glycoprotein spikes from henipaviruses, filoviruses and other viruses, and we already have related soluble SARS coronavirus S proteins multiplexed. Once developed we can transfer the technology and multiplex serological assay to partner nation laboratories (Jordan and Georgia) to accelerate early detection capabilities for emerging zoonotic diseases. The proposed project will also leverage an ongoing DoD-funded bat-borne disease surveillance project in CENTCOM and EUCOM countries to screen specimens for coronaviruses using multiplex serological assays. We have been collaborating with EcoHealth Alliance along similar serological surveillance projects for more than 6 years with a focus on the detection of henipaviruses and filoviruses in wildlife, livestock and indigenous human populations. I have been an active researcher in enveloped virus-host cell interactions for the past 29 years and, together with my collaborators, have made significant contributions to this field. I developed the first oligomeric HIV-1 gp140 glycoprotein subunit vaccine, the vaccinia virus-based reporter gene assay for measuring viral glycoprotein-mediated membrane fusion, defined the fusion tropism of HIV-1 followed by the discovery of the HIV-1 coreceptors (CXCR4 and CCR5). My lab has studied the entry and inhibition of Australian bat lyssavirus (ABLV) a rabies-like virus, including the first reverse genetics system to rescue ABLV and also the henipavirus, Cedar virus. In 1999, I established a collaborative international group of experts in Hendra virus and Nipah virus research, in areas from structural biochemistry, animal models and *in vivo* pathogenesis, to the development and testing of vaccines and therapeutics. My work includes the discovery of the Hendra and Nipah virus entry receptors (ephrin-B2/B3), and the development of the feline, ferret and African green monkey models of Hendra and Nipah virus pathogenesis with my collaborators. My lab's henipavirus glycoprotein work, with collaborators, have made the structural solutions and characterization of the F and the G-ephrin receptor glycoprotein interactions, and the discovery and development of antiviral human monoclonal antibodies to ABLV and Hendra and Nipah viruses; one (m102.4) having a Phase I clinical trial completed in May 2016, and has been used by emergency protocol in 13 people in Australia and one in the U.S. because of significant risk of infection. I also developed the Hendra/Nipah subunit vaccine based on soluble Hendra G glycoprotein (HeV-sG); called Equivac® HeV (Zoetis, Inc.) the first commercialized vaccine to a BSL-4 agent, and now being developed as a human use Nipha/Hendra vaccine supported by CEPI. More recently, and relevant to the present proposal, my lab has developed a panel of nearly 20 different soluble viral envelope glycoproteins for serological surveillance studies, and have the tools required to conduct the studies in the present proposal.

## B. Positions and Honors

### Positions and Employment

- 1990-1992 National Research Council, Research Associate, Laboratory of Viral Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland.
- 1993-1996 IRTA Fellow, LVD, NIAID, NIH, Bethesda, Maryland.
- 1996-2000 Assistant Professor, Department of Microbiology and Immunology, Joint appointment, Molecular and Cell Biology Graduate Program, Uniformed Services University, Bethesda, Maryland.
- 2000-2005 Associate Professor, Department of Microbiology and Immunology, Joint appointment, Emerging Infectious Diseases Graduate Program, USUHS, Bethesda, Maryland.
- 2005-pres. Professor, Department of Microbiology and Immunology, Joint appointment, Emerging Infectious Diseases Graduate Program, USUHS, Bethesda, Maryland.
- 2006-pres. Director, Emerging Infectious Diseases Graduate Program, USUHS, Bethesda, Maryland.

### Other Experience and Professional Affiliations

- 2009 Member, National Veterinary Stockpile Nipah virus Countermeasures Workshop; United States Department of Agriculture. Geelong, Australia.
- 2011 Member, Discontools Nipah Virus Infection Panel Expert Group. Gap analysis. International Federation for Animal Health Europe, Brussels, Belgium.
- 2011 Invited expert, National Academies, Washington, DC. Evaluation of site-specific risk assessment for the National Bio- and Agro-Defense Facility (NBAF) in Manhattan, Kansas.
- 2007- Editorial board, *Journal of Virology*.
- 2010- Editorial board, *Virology*.
- 2011- Editorial board, *Viruses*.
- 2011- Editorial board, *Pathogens*.
- 2012- Editorial board, *Virologica Sinica*

### Honor and Awards

- 1987-1988 National Institutes of Health Training Grant Award
- 1989 Medical Guild Graduate Research Award, University of Florida College of Medicine
- 1990-1992 National Research Council Research Associateship Award
- 1993-1996 NIH Intramural Research Training Award (IRTA) Fellowship
- 1996 The Fellows Award for Research Excellence, Office of Science Education, NIH
- 1995-1996 American Association for the Advancement of Science: Breakthrough of the Year, Science Magazine; Newcomb Cleveland Prize
- 2001 Outstanding Instructor in Virology, USUHS, School of Medicine.
- 2008 The Henry Wu Award for Excellence in Basic Science Research.
- 2013 The 3rd Sidney Pestka Lecture; 22nd Annual Philadelphia Infection & Immunity Forum.
- 2013 The 2013 Federal Laboratory Consortium Award for Excellence in Technology Transfer.
- 2013 Second Finalist for the Australian Infectious Diseases Research Centre Eureka Prize.
- 2013 The CSIRO Chairman's Medal. The Commonwealth Scientific and Industrial Research Organisation (CSIRO); Australia's national science agency.
- 2014 The Cinda Helke Award for Excellence in Graduate Student Advocacy.
- 2016 The James J. Leonard Award for Excellence in Translational/Clinical Research.

### Patents issued and pending

- Bacterial plasmin receptors as fibrinolytic agents: U.S. Pat. No. 5,237,050.

- Oligomeric HIV-1 envelope glycoproteins (gp140): U.S. Pat. Nos. 6,039,957 and 6,171,596.
- Modified Oligomeric HIV-1 gp140 Envelope Proteins. U.S. Serial No. 60/608,144; pending.
- CCR5 DNA, new animal models and therapeutic agents for HIV infection: U.S. Pat. No. 7,151,087.
- Cells expressing both human CD4 and CXCR4 associated with HIV infection: U.S. Pat. No. 6,197,578.
- Compositions and methods for the inhibition of membrane fusion by paramyxoviruses: U.S. Pat. Nos. 7,666,431 and 8,114,410.
- Soluble forms of Hendra and Nipah virus G glycoproteins. U.S. Pat. Nos. 8,865,171; 9,045,532; 9,533,038; Australian Patent No. 2005327194.
- Human monoclonal antibodies against Hendra and Nipah viruses. U.S. Pat. Nos. 8,313,746, 8,858,938.
- Soluble Forms of Hendra and Nipah Virus F Glycoprotein and Uses Thereof: Australian Patent No. 2013276968. U.S. Patent No. 10,040,825.
- Antibodies against F glycoprotein of Hendra and Nipah viruses. U.S. Patent No. 9,982,038.
- Novel Paramyxovirus and Methods of Use (Cedar virus). U.S. Patent app. No. 61/667,194.

### C. Contributions to Science

1. My Ph.D. thesis centered on the characterization of a specific receptor for human plasmin on Group A Streptococci that I discovered during a rotation project as a first year student. My studies revealed that certain group A streptococci elaborated receptors that could bind selectively a key fibrinolytic enzyme, plasmin, while having no binding ability for the zymogen precursor plasminogen or other serine proteases. The bacterium-bound plasmin remained enzymatically active including its ability to hydrolyze a fibrin clot. Bound plasmin could not be inhibited by its physiological regulator, alpha 2-plasmin inhibitor. Thus, since these organisms produced streptokinase, a protein that complexes with plasminogen producing an active enzyme that can convert plasminogen to plasmin, they could accelerate the destruction of the extracellular matrix environment: findings that formed a molecular-pathogenic model for the "flesh-eating streptococci".

2. My independent work as a postdoctoral fellow focused on the early stages of HIV-1 envelope glycoprotein mediated membrane fusion as a surrogate model of HIV-1 entry. I established a vaccinia virus-based reporter gene assay for measuring viral (HIV-1) glycoprotein-mediated membrane fusion and generated the first panel of T-cell tropic and Macrophage-tropic HIV-1 envelope glycoprotein (Env) encoding recombinant vaccinia virus vectors and I used these tools to be the first to hypothesize that the cellular tropism of HIV-1 could be explained by specific membrane fusion factors required for the different classes of HIV-1 Envs. I also developed the first soluble and secreted full-length oligomeric HIV-1 gp140 glycoprotein and explored the importance of its native oligomeric structure in terms of its presentation of conformational and virus-neutralizing epitopes through the development and characterization of more than 100 murine mAbs.

3. My early studies on the cellular and viral membrane fusion tropism of HIV-1 and the development of a sensitive and specific reporter gene assay of cell-cell membrane fusion facilitated the discovery of the first membrane fusion accessory factor (fusin, now known as CXCR4) that we earlier hypothesized existed, and this rapidly led to the discovery by us and others of the second factor for macrophage-tropic Envs (CCR5); the HIV-1 coreceptors. These findings were a significant breakthrough in HIV research leading to numerous new directions in understanding HIV-1 pathogenesis as well as new therapeutic strategies.

Differential utilization of CCR5 by macrophage and T cell tropic simian immunodeficiency virus strains. *PNAS. USA*. 94:4005-4010, 1997.
4. My initial work on HIV-1 entry led to further independent studies which focused on follow-up investigations characterizing the roles of the HIV-1 coreceptors in the virus entry process. These studies revealed the interplay between the HIV-1 entry receptors, mapped important domains of the coreceptors involved in HIV-1 Env interaction, and also revealed possible avenues of how an HIV-1 Env might engage and differently utilize the CXCR4 and CCR5 coreceptors for infection. In addition, I also engaged in collaborative follow-up studies exploring the utility of soluble oligomeric HIV-1 envelope glycoproteins as subunit vaccine immunogens (gp140) which I initiated at NIH while a postdoctoral fellow. This work on the unusual R2 HIV-1 Env isolate provided important data on the renewed potential of a subunit vaccine approach against HIV-1 and our work with the laboratory of Dr. Gerald Quinnan led to the first NIAID program project grant at USU.

5. More recently, my research efforts have centered on emerging viruses that impact human and domestic livestock populations; including Australian bat lyssavirus (rabies-like virus), filoviruses (Ebola and Marburg) and the henipaviruses (Hendra and Nipah). In 1999 I established a collaborative international group of experts in Hendra virus and Nipah virus biology. My lab was the first to publish on Hendra virus outside of Australia. Initial work focused on the structural and functional analysis of the Hendra glycoproteins F and G. I obtained the first NIAID funded project providing monetary support on select agent research to an overseas laboratory (2003). Henipavirus research has been the major focus of my laboratory over the past 15 years, covering areas from structural biochemistry, *in vivo* pathogenesis and animal model development to the development and testing of vaccines and therapeutics. My group developed the first peptide henipavirus fusion inhibitors, subunit vaccine and neutralizing human monoclonal antibodies (mAb), and supported the development of the feline and ferret models of Hendra and Nipah infection and pathogenesis and helped support the development of the first nonhuman primate model for Hendra and Nipah. We and our collaborators tested the *in vivo* efficacy of the Hendra soluble G glycoprotein vaccine (HeV-sG) and an anti-henipavirus G-specific neutralizing human mAb. One human mAb (m102.4) has been used by compassionate emergency protocol in 13 people in Australia and one individual in the United States; a Phase I clinical trial was completed in May, 2016. The henipavirus subunit vaccine, HeV-sG, has been launched; called Equivac<sup>®</sup> HeV (Pfizer Animal Health (Zoetis, Inc.)) and is the first commercialized and deployed vaccine to a BSL-4 agent. My group's additional findings include the discovery of the henipavirus

cellular receptors (ephrin-B2/B3) and produced soluble versions of the G and F glycoproteins facilitating their structural solutions with our collaborators; developed the first reverse genetics system for an authentic Cedar virus based BSL-2 virus system; and these native like soluble viral membrane glycoproteins have now been used to develop a panel of more than 16 different envelope glycoproteins from all the filoviruses and henipaviruses for serological surveillance studies. Altogether I have contributed to more than 60 publications and book chapters on Hendra and Nipah virus since 2002.

## **D. Research Support**

### **Ongoing**

"Serological Biosurveillance for Spillover of Henipaviruses and Filoviruses at Agricultural and Hunting Human-Animal Interfaces in Peninsular Malaysia"

Co-Principal Investigator: Christopher C. Broder, Ph.D.

Agency: DTRA: HDTRA1-17-10037: With: Ecohealth Alliance, New York, New York. Period:05/01/17-04/30/20

Major goals: The overarching goal is to characterize the distribution and detect the spillover of henipaviruses and filoviruses among indigenous farming and hunting communities in Peninsular Malaysia. As part of this process, we will build capacity at key government labs in human and animal health sectors to enhance serological surveillance in animals and human populations for these high consequence pathogens.

"Collaborative development and evaluation of an equine vaccine against Hendra virus"

Principal Investigator: Christopher C. Broder, Ph.D.

Agency: Pfizer (Zoetis)/CRADA

Period: July 1, 2012 to September 30, 2040

A cooperative research and development agreement for of an equine vaccine against Hendra virus.

"A Recombinant Cedar Virus-based Henipavirus Replication Platform for High-throughput Inhibitor Screening"

Agency: NIH/NIAID: R21 AI137813-01 Period: 04/01/2018 to 03/31/20

Major goals: Develop, characterize and adapt a rCedPV luciferase reporter virus for use in HTS; Optimize the HTS parameters of recombinant virus infection and reporter activities; Pilot a HTS assay using a small molecule library.

Kevin J. Olival, PhD  
Vice President for Research  
EcoHealth Alliance  
460 West 34th Street – 17th floor  
New York, NY 10001

Dear Kevin,

We are very excited to expand my group's collaboration with you and EcoHealth Alliance on our emerging virus surveillance activities. Your new proposal entitled "*Strengthening biosurveillance and early detection capabilities for MERS-CoV and other coronaviruses in USCENCOM and USEUCOM*" to the FOA Program Announcement identification information (*Global Health Engagement Research Initiative (GHERI) FOA, VP-18-011*) will be an ideal opportunity for us to expand on our combined efforts with a focus on Middle East Respiratory Syndrome Coronavirus (MERS-CoV), a critically important pathogenic emerging virus threat. Indeed, MERS-CoV has recently been recognized by the WHO as an emerging threat with pandemic potential and one needing immediate research focus. Further, the Coalition for Epidemic Preparedness Innovations (CEPI) has also made MERS-CoV vaccine research a priority this year.

We will develop recombinant MERS-CoV envelope spike protein for a multiplex microsphere-based serological assay. Using this new method for MERS-CoV we will be able determine the seroprevalence of MERS-CoV across the human-camel value chain in Jordan and be able to inform locations, seasons, and epidemiological interfaces of greatest risk. As you know we are well experienced in making native-like viral glycoprotein spikes from henipaviruses, filoviruses and others, and we already have related soluble SARS coronavirus S proteins multiplexed. Once developed we can transfer the technology and multiplex serological assay to partner nation laboratories (Jordan and Georgia) to accelerate early detection capabilities for emerging zoonotic diseases.

As always, I and my group will continue to provide our expertise and available resources to you and this exciting project, and I look forward to this continued collaboration.

Sincerely,

(b) (6)

Christopher C. Broder, Ph.D.  
Professor and Chair  
Department of Microbiology and Immunology

## Statement of Work (USU-Broder)

### Major Milestones, Tasks and Timeline.

We have laid-out a series of aims and hypotheses that will contribute significant insight into the prevalence of Middle Eastern Respiratory Syndrome (MERS)-coronavirus (MERS-CoV) and related Severe Acute Respiratory Syndrome (SARS)-CoV at human-animal interfaces in Jordan and Georgia. A Luminex-based, multiplex immunoassay will be the primary serological approach for the detection of antiviral antibodies to quantify the presence of MERS-CoV in camels, bats and human populations. The findings generated from the proposed studies will facilitate the development of a sustainable approach to serological biosurveillance and early detection of MERS-CoV at Department of Defense partner laboratories in Jordan (Jordan University of Science and Technology, JUST) and Georgia (R. Lugar Center). Epidemiological data generated through this serological approach will inform a risk analysis of MERS-CoV hotspots in these regions that will ultimately be used to improve situational awareness and force health protection. The major Milestones and associated tasks to be conducted by Uniformed Services University, along with a timeline of this proposal's goals are shown below.

#### **Major Milestones:**

•Milestone 1: Complete the production of 6 coronavirus spike protein constructs, develop polyclonal antisera, and test all new antigens for utility in Luminex bead-based platforms, ELISA and Western blot assays: FY19-20.

Five recombinant coronavirus surface spike (S) proteins will be designed and constructed for the purposes of producing two high quality, native like, oligomeric virus S proteins and two monomeric S subunit proteins. An additional MERS-CoV nucleoprotein (N) will be designed and constructed as an additional virus antigen. These recombinant viral S and N proteins will be used as the capture antigens in the proposed serological, multiplex microsphere immunoassays as well as secondary or validation assays including, ELISA and Western blotting. The details of the nature and unique properties of these glycoproteins are provided in the Technical Proposal. The individual subtasks linked to this specific Milestone 1 for USU are:

- *Subtask 1.1:* Construct and produce the full-length, native-like, trimeric MERS-CoV S protein.
- *Subtask 1.2:* Construct and produce the full-length, native-like, trimeric SARS-CoV S protein.
- *Subtask 1.3:* Construct and produce the monomeric MERS-CoV S<sub>1</sub> protein.
- *Subtask 1.4:* Construct and produce the monomeric MERS-CoV S<sub>2</sub> protein.
- *Subtask 1.5:* Construct and produce the oligomeric MERS N protein.
- *Subtask 1.6:* Construct and produce a monomeric Uganda MERS-related CoV S<sub>1</sub> protein
- *Subtask 1.7:* Use the completed MERS-CoV purified protein preparations to produce polyclonal rabbit serum for each individual glycoprotein as positive controls for assay validation.
- *Subtask 1.8:* Test the utility of each individual virus protein by Luminex bead-based platform, ELISA and Western blotting with matching rabbit polyclonal antisera and control camel and bat sera provided by supporting collaborators (Dr. Vincent Munster, RML, NIAID, NIH).

•Milestone 2: Establishing MERS-CoV multiplex microsphere immunoassays at partner labs in Jordan (JUST) and Georgia (R. Lugar Center) and training laboratory personnel to utilize Luminex bead-based platforms (MagPIX) to identify serological exposure to coronaviruses: FY19-20.

To enhance early detection and biosurveillance capacity at USCENCOM and USEUCOM partner labs we will transfer MERS-CoV antigenic material and the multiplex microsphere immunoassay and conduct in-country staff training sessions at both JUST and R. Lugar Center in the fourth quarter of Year 1 and into Year 2. EcoHealth Alliance will procure necessary MagPIX machines and other equipment for transfer to partner countries. The individual subtasks linked to this specific Milestone 2 for USU are:

- *Subtask 2.1:* Transfer MERS-CoV and SARS-CoV protein-coupled microspheres to JUST and R. Lugar Center
- *Subtask 2.2:* Transfer matching antigen reactive rabbit polyclonal antisera for use as assay positive controls to JUST and R. Lugar Center
- *Subtask 2.3:* Train staff in the theoretical development of the antigens, the Luminex bead-based platforms (MagPIX), advantages of this approach to standard ELISA and in the practical hands-on use and setup of the multiplex microsphere immunoassay in-country at JUST and R. Lugar Center. One 5-day training will take place in each Jordan and Georgia during FY19-20 including USU scientists and technicians and EcoHealth Alliance scientists.
- *Subtask 2.4:* Run positive control rabbit polyclonal antisera with the multiplex microsphere immunoassay in-country as part of trainings with in-country laboratory technicians at JUST and R. Lugar Center

•Milestone 3: Validation of the MERS-CoV multiplex microsphere immunoassay as a research and diagnostic tool: FY19-21.

Several commercial ELISA that use a single MERS-CoV antigens (e.g. S<sub>1</sub>) have been used with varying degrees of success to detect serological evidence of exposure to MERS-CoV in livestock and human populations. We will validate a MERS-CoV multiplex serological assay and a more sensitive Luminex bead-based approach for virus surveillance. Details are provided in the Technical Proposal. The individual subtasks linked to this specific Milestone 3 for USU are:

- *Subtask 3.1:* Obtain MERS-CoV infection control polyclonal sera from supporting partners at Rocky Mountain Laboratories, NIH and Colorado State University
- *Subtask 3.2:* Test the MERS-CoV multiplex immunoassay with camel and bat positive and negative infected control sera to determine assay specificity and sensitivity
- *Subtask 3.3:* Compare detection capabilities of the MERS-CoV S and N proteins multiplex microsphere immunoassay to a traditional ELISA assay
- *Subtask 3.4:* Statistically validate the MERS-CoV S and N proteins multiplex microsphere immunoassay as a surveillance research and diagnostic tool

•Milestone 4: Data analysis and analysis training to determine seroprevalence of MERS-CoV in targeted populations: FY20-21.

Sera samples will be tested at JUST and R. Lugar Center by in-country staff after training. The interpretation of serological data requires the appropriate controls and statistical methods to determine whether individual samples contain target MERS-CoV specific antibodies and to determine populations level seroprevalence. USU and EcoHealth Alliance scientists will train laboratory staff at JUST and R.

Lugar Center how to interpret positive and negative sera data generated by screening with the multiplex microsphere immunoassay. The individual subtasks linked to this specific *Milestone 4* are:

- *Subtask 4.1:* Use control rabbit polyclonal sera to analyze data for assay sensitivities and positive value cutoff thresholds
- *Subtask 4.2:* Use distribution analysis methods to determine positive and negative cutoffs with camel, bat and human sera tested at JUST and R. Lugar Center
- *Subtask 4.3:* Determine seroprevalence for MERS-CoV and SARS/SARS-like CoV in the camel, bat and human populations tested

**BIOGRAPHICAL SKETCH**

Provide the following information for the Senior/key personnel and other significant contributors.  
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

**A. Personal Statement**

This project leverages ongoing DoD disease surveillance with partner nation laboratories in Jordan and Georgia and aligns with CENTCOM and EUCOM objectives to strengthen partner nation readiness and capabilities for early detection of emerging coronaviruses. MERS-coronavirus (CoV), like the related SARS-CoV, can be a fatal respiratory illness. Building surveillance capacity at partner labs will contribute to the development of informed risk-assessments and improvement of force health protection in the regions. I have had a collaborative research relationship with the PI, Kevin Olival (EcoHealth Alliance), dating back to 2014 when I was a co-chair of a symposium on bat ecology and emerging viruses where Dr. Olival was an invited speaker. This proposal will allow for an important extension of our collaboration and mutual research interests on emerging viruses and disease surveillance. Since 2017, I have been collaborating with EcoHealth Alliance, as a Co-PI, on a related DoD-funded virus biosurveillance project and am also involved in DoD-funded disease surveillance and capacity training projects in India, Thailand, and Cambodia that are aimed at understanding the geographic distribution/serological footprint of filoviruses and henipaviruses, the wild and domestic animals that are natural hosts of these viruses, and the at-risk human populations for virus spillover. I have led international capacity training with multiple collaborators including: 3+ years of collaboration at Duke-National University of Singapore, Singapore; 1+ year laboratory-based training at the National Wildlife and Forensic Laboratory and the National Public Health Laboratory, Kuala Lumpur, Malaysia; <1 year laboratory-based training at the National Centre for Biological Sciences, Bangalore, India. I have both the expertise in virology, biosurveillance and capacity training to successfully contribute to the aims of this proposal. In addition to serological biosurveillance, I have training in molecular virology techniques and optimized a reverse genetics approach to rescue a recombinant Cedar virus reporter virus, a non-pathogenic *Henipavirus* species that will be used as a model *Henipavirus* to explore host cell-pathogen interactions, cellular tropism, and test novel therapeutics against henipaviruses. Our laboratory is capable of producing native-like virus antigens that are used to capture conformationally-dependent antibodies and used in a serological multiplex assay as demonstrated by our successful biosurveillance for zoonotic select agents in the *Ebolavirus* and *Henipavirus* genera. We have piloted expression of select coronavirus antigens and this project will provide the opportunity to further develop our research into MERS-CoV disease surveillance.

**B. Positions and Honors****Positions and Employment**

2003-04 Howard Hughes Medical Institute student intern, Cellular and Developmental Neurobiology Section, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD.

2005-06	Undergraduate research assistant, Department of Animal and Avian Sciences, University of Maryland, College Park, MD.
2007-08	Undergraduate research assistant, Biology Departmental Honors research, Department of Biology, University of Maryland, College Park, MD.
2008-09	Lab technician, Department of Pharmacology, Uniformed Services University, Bethesda, MD.
2010	Lab technician, Department of Microbiology, Uniformed Services University, Bethesda, MD.
2010-16	Graduate research student, Department of Microbiology, Uniformed Services University, Bethesda, MD.
2016-17	Postdoctoral fellow, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD.
2017 -	Junior scientist, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD.

### **Other Experience and Professional Memberships**

2009	Mentor, At-Risk Student Mentoring, Bethesda Chevy Chase High School, Bethesda, MD.
2009-10	Mentor, EnvironMentors, Washington, D.C.
2013	Mentor, high school, undergraduate, and graduate students, Uniformed Services University, Bethesda MD.
2014	Participant, American Society of Microbiology Kadner Institute
2014-15	Volunteer, AAAS/Senior Scientists and Engineers STEM Volunteer Program
2014-17	Member, American Society of Tropical Medicine and Hygiene
2014-17	Member, American Society of Microbiology
2015-16	Member, USU Global Health Interest Group

### **Honors and Fellowships**

2004-07	Maryland House of Delegates Scholarship
2005-07	Semester Academic Honors
2006	College Park Life Sciences Scholars Program Citation
2008	High Honors, Biology Departmental Honors Program
2015	USU Research Days Graduate Student Poster Presentation Finalist (Won)
2015	NSF East Asia and Pacific Summer Institutes (EAPSI) Fellowship
2015-16	Val G. Hemming Fellowship, Henry M. Jackson Foundation

## **C. Contribution to Science**

**1. Surveillance of emerging zoonotic viruses.** My most recent research experiences have focused on the application of Luminex-based serological screening for virus surveillance. This research investigates the geographic distribution of ebolaviruses, marburgviruses, and henipaviruses through biosurveillance of wildlife, domestic animals, and human populations within Southeast Asia and India. These studies resulted in the expansion of a Luminex-based multiplex binding assay to include envelope glycoproteins from all known species of ebolaviruses, marburgviruses, and henipaviruses, and the identification of previously un-sampled bat populations that may contribute to the maintenance of these viruses in the environment. Present research efforts are focused on improving the interpretation of serological findings on individual and populations levels, antigenic-mapping, and building capacity for collaborating international laboratories to conduct screening in-country.

**2. Studies of virus-host cell interactions.** My Ph.D. thesis research was to understand the bat as a host of zoonotic viruses. One aim of this work was focused on exploring the antiviral mechanisms that enable cellular persistence of viruses in bats. These findings revealed that the autophagy pathway is induced upon infection with Australian bat lyssavirus (ABLV), a Rabies-virus related virus carried by Australian *Pteropus* bats. The combined pharmacological and genetic studies of the autophagy pathway in the context of this virus-host

## EXECUTIVE SUMMARY

*Henipavirus* is the taxonomic genus for a group of viruses in the family Paramyxoviridae that includes *Hendra virus* (HeV) and *Nipah virus* (NiV). These viruses are zoonotic agents that are highly pathogenic in humans with case fatality rates of 40% to 70%. As such, these viruses are classified as Biosafety Level 4 (BSL-4) agents, requiring the highest level of laboratory biocontainment. Importantly, they have many of the physical attributes to serve as potential agents of bioterrorism, and are also considered emerging zoonotic pathogens with increasing geographical distribution in Australia, New Caledonia, Southeast Asia, and Madagascar.

Hendra virus first emerged in 1994 in Australia spilling over from bats to horses to humans, causing several disease outbreaks since with significant fatality rates. Nipah virus emerged in Malaysia in 1999, resulting in nearly 300 human cases with over 100 deaths.

The Nipah virus outbreak in Malaysia was especially concerning, causing widespread panic and fear because of the high mortality rate in people and the inability to control the disease initially. There were also considerable social disruptions and tremendous economic loss to an important pig-rearing industry. This highly virulent virus, believed to be introduced into pig farms by fruit bats, spread easily and silently among pigs and was transmitted to humans who came into close contact with infected animals. A NiV outbreak in Bangladesh in 2001 resulted from direct bat to human transmission via contaminated date palm juice with further spread within the human population. From 2001 to 2012, the World Health Organization (WHO) reported a total of 209 cases, with 161 deaths due to of NiV infections. In 2014, the WHO reported a NiV outbreak in fourteen districts of Bangladesh, resulting in 24 cases and 21 deaths. In 2015, three fruit bats tested positive for NiV in New Caledonia at the Noumea National Park, including three bats at the Noumea Zoo.

This gap analysis report focuses primarily on NiV and its potential impact on agricultural swine production. However, information is also provided on the threat henipaviruses pose to public health, both as emerging zoonotic agents and as potential agents of bioterrorism. Included in this report is scientific information on *Henipavirus* virology, epidemiology, pathogenesis, immunology, and an assessment of the available veterinary medical countermeasures to detect, prevent, and control disease outbreaks. Importantly, gaps are provided to inform research needs and priorities. Some of the major gaps and obstacles for disease control can be summarized as follows:

### ***Diagnostics***

The availability of safe laboratory diagnostic tests are limited. Virus isolation and serum neutralization assays require live NiV; thus, BSL-4 containment laboratories are required. Nucleic acid-based assays, such as RT-PCR are available, but genetic variation amongst henipaviruses are reported to impact sensitivity and real time RT-PCR may not be able to detect all divergent and novel henipavirus strains. Serological assays are limited in their ability to differentiate between known and unknown henipaviruses, as cross-reactivity to one or more known viruses is possible. Commercial diagnostic test kits are not available. International standards for NiV assay validation are needed. Gaps include a lack of positive experimental and field samples for test validation (or even evaluation) and there are restrictions on material transfer (e.g., obtaining animal samples that could be used to validate tests) due to biosecurity concerns. Low biosafety level reference sera

against various isolates are not yet available. There is a need for high throughput antibody assays for disease outbreaks, recovery and surveillance purposes. There is also a need to develop operator-safe diagnostics tests and reagents that can be produced in low biocontainment facilities.

### ***Vaccines***

There is currently a commercial vaccine available for horses, but there are no vaccines for swine or humans. There are several experimental vaccine candidates that may be safe and effective in swine and other domestic animals. However, all these vaccine candidates will require further research to establish their efficacy, and they will need to be fully developed to be licensed and stockpiled for rapid use in an emergency disease outbreak in swine.

### ***Surveillance***

Surveillance is the first line of defense against a disease outbreak. Rapid and accurate detection affects the time when control measures can be implemented and affects the extent of the disease outbreak. Because of limitations with laboratory diagnosis, surveillance programs are dependent on the reporting of clinical signs in populations at risk. Diagnosis of NiV infections based on clinical presentation has a low positive predictive value as there are numerous etiologies for encephalitis in humans, and clinical signs in pigs are difficult to differentiate from many common endemic infectious diseases.

### ***Depopulation***

Depopulation is the primary countermeasure to reduce virus shedding and stop the spread of NiV in livestock. Disease outbreaks have shown that the control of NiV in pig populations through stamping out is complex due to the zoonotic nature of the agent. In addition, depopulation may be logistically difficult and may be impossible in a rapidly spreading outbreak in countries where there are pig dense regions with millions of pigs, such as the states of Iowa, North Carolina, and Minnesota in the United States, or South East China.

# INTRODUCTION

Nipah virus (NiV) is an emerging zoonotic virus. First isolated in pigs and people from an outbreak in Malaysia in 1998 (Ang *et al.* 2018), this emerging virus causes severe disease in humans. The source of transmission was determined to be from bats to pigs to humans, through close contact with infected animals. The virus is named after the location where it was first detected in Sungai Nipah, a village in the Malaysian Peninsula where exposed pig farmers became severely ill with encephalitis.

Nipah virus is closely related to another zoonotic virus called Hendra virus (HeV), formerly called Equine *Morbillivirus*, and named after the town where it first appeared in Australia. Hendra virus infection was first recognized in 1994, when it caused an outbreak of acute, fatal respiratory disease that killed 14 horses. Three human cases, leading to two deaths were recorded during the outbreak. The precise mode of virus transmission to the three Australian patients is not fully understood. All three individuals appear to have acquired their infection as a result of close contact with horses, which were ill and later died.

Although members of this group of viruses have only caused a few focal outbreaks, their ability to infect a wide range of animal hosts and to produce a high mortality rate in humans has made this emerging zoonotic viral disease a significant public health threat.

Certain species of bats of the genus *Pteropus* (fruit bats, also called flying foxes) are the principal natural reservoir hosts for NiV and HeV – see Table I. Bats are susceptible to infection with these viruses but do not develop disease. Fruit bats are distributed across an area encompassing Australia, Southeast Asia; including Indonesia, Malaysia, the Philippines and some of the Pacific Islands, the Indian subcontinent, and Madagascar (See Fig. 1). There is also growing evidence that viruses related to NiV and HeV circulate in non-pteropid fruit bats across the globe (Clayton, 2017).

The exact mode of transmission of henipaviruses is uncertain, but appears to require close contact with contaminated tissue or body fluids from infected animals. The role of domestic species other than pigs in transmitting NiV infection to other animals has not yet been determined. In 2014, an outbreak was reported in the Philippines involving the consumption of meat from NiV-infected horses, further expanding the potential routes of transmission for henipaviruses.

Despite frequent contact between fruit bats and humans there is no serological evidence of human infection among persons that are in contact with bats. Pigs were the apparent source of infection among most human cases in the Malaysian outbreak of NiV in 1998-1999. Nipah virus has continued to spillover over from animals with at least six outbreaks resulting in human fatalities in Bangladesh in 2013, one in India in 2014, and two in Bangladesh in 2015. The World Health Organization (WHO) had not reported any NiV cases 2016-2017, but in 2018 twenty three new cases and 21 deaths were reported in Kerala, India - See Table II.

The spread of henipaviruses to new geographical areas is a concern. In 2014, the Philippines reported an outbreak with a zoonotic paramyxovirus in horses and people. There is further evidence for broader distribution of NiV in pteropid fruit bats species. There is also growing evidence that viruses related to NiV and HeV also circulate in non-pteropid fruit bats worldwide.

## BACKGROUND

### ***Organization of the Gap Analysis Working Groups on Nipah Virus (2009 and 2017)***

The United States Department of Agriculture (USDA) organized the first Nipah virus gap analysis workshop in Australia in 2009 with the support of the Australian Animal Health Laboratory (AAHL). The working group was charged by the USDA National Veterinary Stockpile Steering Committee with making recommendations on specific materials, commercially available and in the pipeline, which will ensure the United States has an arsenal of highly efficacious countermeasures to control and mitigate the impact of an outbreak of Nipah virus. Nipah virus experts representing laboratories in South East Asia, Australia, Canada, and the United States were invited to participate and contributed to this report. The second workshop was organized in 2017 by the Special Pathogens Unit, National Centre for Foreign Animal Disease, Canadian Food Inspection Agency (CFIA), in collaboration with BSL4ZNet and DISCONTTOOLS (<http://www.discontools.eu/>). The participants were charged with assessing available veterinary medical countermeasures to control and respond to a Nipah virus disease outbreak. In addition, the workshop participants agreed to update the gap analysis conducted at the AAHL in Geelong, Australia, in 2009.

### ***Report Updates***

This report will be updated periodically with new scientific information, research breakthroughs, and/or the successful development of veterinary medical countermeasures. This report was last updated with the support of Henipavirus experts November 2018.

## **DEFINITION OF THE THREAT**

The threat for a natural introduction of henipaviruses in the United States is low, but there is significant concern that henipaviruses could be used for nefarious purposes to harm agriculture and people. Both Hendra virus and Nipah virus are on the HHS and USDA list of overlap Select Agents and Toxins. Henipaviruses are listed as APHIS Tier 3 high-consequence foreign animal diseases and pests. Henipaviruses are promiscuous in their ability to cause severe morbidity in several animal species, including people, and human infections result in a very high mortality rate. The mortality rate in pigs is actually reported as about 2.5% in adult pigs – high morbidity, but low mortality. Mortality rates in humans range from 40% (Malaysia) to 75% (up to 100%) in Bangladesh. The animal reservoir includes several species of bats, and henipaviruses may thus be readily available in these wildlife reservoirs.

### ***INFECTION IN PEOPLE***

Between September 1998 and June 1999, a NiV outbreak in Malaysia resulted in severe viral encephalitis in 105 patients (Goh *et al.*, 2000; Epstein *et al.*, 2006). Ninety-three percent had had direct contact with pigs, usually within two weeks prior to the onset of illness, suggesting that there was direct viral transmission from pigs to humans and a short incubation period. The main presenting features were fever, headache, dizziness, and vomiting. Fifty-two patients (55%) had a reduced level of consciousness and prominent brain-stem dysfunction. Distinctive clinical signs included segmental myoclonus, areflexia and hypotonia, hypertension, and tachycardia. The initial cerebrospinal fluid findings were abnormal in 75% of patients. Antibodies against Hendra virus were detected in serum or cerebrospinal fluid in 76 percent of 83 patients tested. Thirty patients (32%) died after rapid deterioration in their condition. An abnormal doll's-eye reflex and tachycardia were factors associated with a poor prognosis. Death was probably due to severe brain-stem involvement. Neurologic relapse occurred after initially mild disease in three patients. Fifty patients (53%) recovered fully, and 14 (15%) had persistent neurologic deficits.

Unlike Malaysia, the NiV outbreaks in Bangladesh were strictly confined to human populations with significantly higher mortality rate (Hossain *et al.*, 2008). NiV outbreaks in Bangladesh have continued annually since 2008 resulting in a total of 207 reported cases, 152 of which were fatal resulting in a 70% mortality rate (Clayton, 2017). In 2018, NiV infection was confirmed in Kerala, India, where 23 confirmed cases were reported and case fatality rates were 90% (Arunkumar *et al.*, 2018).

### ***INFECTION IN PIGS***

The NiV outbreak in Malaysia in 1999 was facilitated by the rapid spread of the virus in pig populations. Although some pigs demonstrated a febrile respiratory illness with epistaxis, dyspnoea, and cough, few animals exhibit neurological signs, and the majority of pigs had subclinical infections. There are no clinical signs in pigs that are specific for NiV infection. Both, apparently healthy pigs and pigs showing clinical signs shed significant amount of virus.

### ***ECONOMIC IMPACT***

The NiV outbreak in Malaysia in 1999 destroyed the main market for Malaysian hogs in Singapore. The Malaysia outbreak resulted in an 80% drop in pork consumption in the domestic market. Over half the standing pig population in the country was culled to halt the outbreak. Half the pig farms

went out of business. The cumulative economic losses based on government figures was estimated to be approximately \$217 million USD.

### ***BIOTERRORISM***

NiV has many of the physical attributes needed for a biological weapon, including easy access to virus resulting from its wide distribution in nature and laboratories, easy to produce, easy to disseminate, and the potential for high morbidity and mortality in people.

# GAP ANALYSIS

The following section summarizes what we know about henipaviruses, gaps in our knowledge, and the threat of bioterrorism.

## ***VIROLOGY***

The following summarizes our current knowledge of viral strains, taxonomy, reservoir, genome, morphology, determinants of virulence, host range, and tissue tropism.

### Virus species

*Nipah virus* (NiV) was first isolated in 1999 from samples collected during an outbreak of encephalitis and respiratory illness among pig farmers. The name Nipah originated from Sungai Nipah, a village in the Malaysian Peninsula where pig farmers became sick. There are currently two genotypes identified: NiV-Malaysia and NiV-Bangladesh. Different strains/genotypes of NiV have emerged: Malaysia, Bangladesh, and Cambodia. NiV Malaysia resulted in the culling of a million pigs and 250 human cases (106 fatal). NiV Bangladesh is associated with outbreaks in people (Clayton, 2017).

*Hendra virus* (HeV) was first isolated in 1994 from specimens obtained during an outbreak of respiratory and neurologic disease in horses and humans in Hendra, a suburb of Brisbane, Australia.

*Cedar virus* (CedV) is a novel *Henipavirus* isolated from Australian bats, which appears to be non-pathogenic in lab animal experiments (Marsh et al. 2012).

*Ghanaian bat henipavirus* (GhV) is a species of henipaviruses assembled from sequences collected from *Eidolon helvum*, a bat species in the family Pteropodidae (Drexler et al. 2009; Drexler et al. 2012). No isolates have been reported, and both pathogenicity and the cross-species transmission remain unknown. Partial sequences of 19 phylogenetically novel African henipaviruses have also been discovered, suggestive of a further diversity of African henipaviruses.

*Mòjiāng henipavirus* (MojV) was discovered during retrospective surveillance for the etiologic agent responsible for cases of fatal respiratory illness in cave-miners, China. A full-genome was assembled from sequences detected from a cave-dwelling rodent species (Wu Z. et al. 2014). MojV is circumstantially associated with the fatal respiratory illness, however, pathogenicity studies have not been completed.

### Taxonomy

NiV and HeV are members of the family Paramyxoviridae, order *Mononegavirales*. Comparison of nucleic acid and deduced amino acid sequences with other members of the family confirms that NiV and HeV are members of the family Paramyxoviridae, but with limited homology with members of the *Morbillivirus*, *Rubulavirus* and *Respirovirus* genera (See Fig. 2). The name *henipavirus* was recommended for the genus of both HeV and NiV (Wang et al., 2000). HeV appear to be less diverse than NiV but molecular epidemiology studies are needed to identify new isolates that may bridge the gap between HeV and NiV.

### Reservoir

The natural reservoir, or primary animal host, of the henipaviruses are fruit bats mainly from the genus *Pteropus* (flying foxes). Nucleic acid and antibody signatures of exposure to NiV or NiV-like viruses has been documented in a diversity of bat species across the globe (Table 1).

### Genome

The complete genomes of both HeV and NiV have been sequenced (Wang *et al.*, 2001). Henipaviruses have a large non-segmented genome comprised of single-stranded negative-sense RNA. Their genomes are 18.2 kb in size and contain six genes corresponding to six structural proteins. All genes are of similar size to homologues in the respirovirus and morbillivirus genera, with the exception of P which is 100-200 amino acids longer (See Fig. 3). Most of the increase in genome length is due to longer untranslated regions between genes, mainly at the 3' end of each gene. The role of these long untranslated regions are not understood. Henipaviruses employ an unusual process called RNA editing to generate multiple proteins from a single gene. The process involves the insertion of extra guanosine residues into the P gene mRNA prior to translation. The number of residues added determines whether the P, V or W proteins are synthesized. The C protein is made via an alternative translational initiation mechanism. The functions of the V, W, and C proteins are unknown, but they may be involved in disrupting host antiviral mechanisms (see Immunology below). The function of the G protein is to attach the virus to the surface of a host cell via the major receptors ephrin-B2 and ephrin-B3 ligands, highly conserved proteins present in many mammals. G glycoprotein is the major neutralizing antigen and the target protein for vaccine development. X-ray crystal structure for NiV G complex with ephrin-B3 has been determined. This interaction is highly conserved between NiV and HeV. This interaction is a prime candidate for developing henipavirus specific therapeutics. The F protein fuses the viral membrane with the host cell membrane, releasing the virion contents into the cell. It also causes infected cells to fuse with neighboring cells to form large multinucleated syncytia.

The genome size and organization of CedPV is very similar to that of HeV and NiV. The nucleocapsid protein displays antigenic cross-reactivity with henipaviruses and CedPV uses the same receptor molecule (ephrin-B2) for entry during infection. Clinical studies with CedPV in *Henipavirus* susceptible laboratory animals confirmed virus replication and production of neutralizing antibodies although clinical disease was not observed. In this context, it is interesting to note that the major genetic difference between CedPV and HeV or NiV lies within the coding strategy of the P gene, which is known to play an important role in evading the host innate immune system. Unlike NiV and HeV, and almost all known paramyxoviruses, the CedPV P gene lacks both RNA editing and also the coding capacity for the highly conserved, interferon pathway antagonists, V or W proteins (Marsh *et al.* 2012).

Although, GhV and MojV have not yet been isolated from hosts, sequence constructed genomes are similar in size, organization, and coding capacity to HeV, NiV, and CedV (Wu Z *et al.* 2014, Drexler *et al.* 2012). Like HeV and NiV, both GhV and MojV are predicted to possess the RNA editing site in the P gene and presumably coding capacity for V and W proteins. Receptor-usage studies with recombinant GhV G glycoprotein demonstrated that like CedV, GhV G was capable of binding to

ephrin-B2, but not ephrin-B3 (Lee B *et al.* 2015). A receptor remains undiscovered for MojV; however, ephrin-B2, -B3 appear to be unlikely candidates (Rissanen I *et al.* 2017).

### Morphology

Henipaviruses are pleomorphic ranging in size from 40 to 600 nm in diameter. They possess a lipid membrane overlying a shell of viral matrix protein. At the core is a single helical strand of genomic RNA tightly bound to the nucleocapsid (N) protein and associated with the large (L) and phosphoprotein (P) proteins, which provide RNA polymerase activity during replication. Embedded within the lipid membrane are spikes of fusion (F) protein trimers and attachment (G) protein tetramers.

### Determinants of virulence, host range, and tissue tropism

Molecular determinants of virulence, host range and cell tropism have been extensively studied and are well understood for many paramyxoviruses. Infectivity is determined by the cell-attachment and fusion glycoproteins and the presence of appropriate P gene products modulate virulence by antagonizing the cellular interferon response.

Henipaviruses have a large host range, unlike other members of the Paramyxoviridae, which generally have a very narrow host range. The cell attachment protein, unlike many other members for the paramyxovirus subfamily, does not have haemagglutinating activity and as a consequence does not bind sialic acid on the surface of cells.

The receptor for henipavirus is present on many different cultured cell types from many different species. The receptors for HeV and NiV are the same and have been identified as ephrin-B2 and ephrin-B3. Ephrin-B2 or -B3 are highly conserved across vertebrate species and are members of a family of receptor tyrosine kinase ligands. Ephrin-B2 is highly expressed on neurons, smooth muscle, arterial endothelial cells and capillaries, which closely parallels the known tissue tropism of HeV and NiV *in vivo*. Ephrin-B3 is also widely expressed but particularly in specific regions of the central nervous system and may facilitate pathogenesis in certain neural subsets.

### Virology Research Priorities

- Molecular epidemiology and determinants of strain variation
- Need sequencing of henipaviruses from bats, especially Bangladesh
- Determine molecular basis for virulence

## ***PATHOGENESIS***

The following summarizes our current knowledge of viral pathogenesis, including routes of infection, tissue tropism, pathogenesis, clinical signs, and clinical pathology reported in naturally acquired infections. It should be noted that experimental infection in other animal models have been developed. NiV and HeV (henipaviruses) are distinguished from all other paramyxoviruses particularly by their broad species tropism and ability to cause fatal disease in multiple vertebrate hosts including humans, monkeys, pigs, horses, cats, dogs, ferrets, hamsters and guinea pigs, spanning 6 mammalian Orders (Broder CC *et al.*, 2012; Geisbert TW *et al.*, 2012).

NiV infections in humans and pigs are linked to contact with bats. Clinical signs in human cases indicate primarily involvement of the central nervous system with 40% of the patients in the Malaysian outbreak having also respiratory syndromes, while in pigs the respiratory system is considered the primary virus target, with only rare involvement of the central nervous system.

### Humans

The main histopathological findings include a systemic vasculitis with extensive thrombosis and parenchymal necrosis, particularly in the central nervous system (Wong *et al.*, 2002). Endothelial cell damage, necrosis, and syncytial giant cell formation are seen in affected vessels. Characteristic viral inclusions are seen by light and electron microscopy. Immunohistochemistry (IHC) analysis shows the widespread presence of NiV antigens in endothelial and smooth muscle cells of blood vessels (Hooper *et al.*, 2001). Abundant viral antigens are also seen in various parenchymal cells, particularly in neurons. The brain appears to be invaded via the hematogenous route and virus has been isolated from the cerebrospinal fluid of patients with NiV encephalitis (Wong *et al.*, 2002). Infection of endothelial cells and neurons as well as vasculitis and thrombosis seem to be critical to the pathogenesis of this new human disease.

NiV infection can rarely cause a late-onset encephalitis up to a couple of years following a non-encephalitic or asymptomatic infection, or a relapsed encephalitis in patients who had previously recovered from acute encephalitis (Wong *et al.*, 2001; Goh *et al.*, 2000; Tan *et al.*, 2002).

The most recent NiV outbreak, and first reported in South India, resulted in 23 human cases with a case-fatality rate of 91% (Arunkumar *et al.*, 2018). The clinical manifestations and high fatality rate among people were similar to those of earlier NiV outbreaks in India and Bangladesh, and the NiV isolate from this outbreak showed a 97% genetic similarity to the NiV-B lineage. All human cases, following the index case, were due to nosocomial transmission in three different hospitals. Although it was not possible to establish the exact NiV transmission event to the identified index case, the most likely zoonotic route was from *P. giganteus* (Indian flying fox). It was noted that in Kerala, date palms are not used for obtaining sap, and the narrow-mouthed vessels used to collect sap from coconut and Asian Palmyra palm do not allow access by bats. The human-to-human transmission rate was very high in this recent outbreak, and the index case transmitted NiV to 19 contacts (primary cases), while three cases were reported as secondary (Arunkumar *et al.*, 2018). These nosocomial transmissions to the primary cases were concomitant with the index case presenting with a persistent cough and near the terminal stage of NiV illness. Of the 23 cases, 20 (87%) had respiratory symptoms presumably increasing the possibility of human-to-human transmission by droplet, and it was reported that only those with direct exposure to the patient's coughing appeared to have acquired NiV infection.

### Pigs

Experimental challenge studies in piglets conducted at the National Centre for Foreign Animal Diseases, Winnipeg, Canada, demonstrated neurological signs in several inoculated pigs (Weingartl *et al.*, 2005; Berhane *et al.*, 2008; Weingartl, H.M., personal communication of unpublished data). The rest of the pigs remained clinically healthy. NiV was detected in the respiratory system (turbinates, nasopharynx, trachea, bronchus, and lung), the lymphoreticular system (endothelial cells of blood and lymphatic vessels), submandibular and bronchiolar lymph nodes, tonsil, and spleen, with observed necrosis or lymphocyte depletion in lymphoid tissues, most importantly in lymph nodes (Hooper *et al.*,

2001, Weingartl *et al.*, 2006; Berhane *et al.*, 2008). NiV presence was confirmed in the nervous system of both sick and apparently healthy animals (cranial nerves, trigeminal ganglion, brain, and cerebrospinal fluid). No virus was detected in urine, although NiV antigen was found in kidneys of field swine cases (Tanimura *et al.*, 2004). This study suggests NiV invaded the porcine host central nervous system via cranial nerves after initial virus replication in the upper respiratory tract, and later in the infection also by crossing the blood-brain barrier as a result of viremia. Additional information on NiV and HeV pathogenesis in pigs are summarized in Middleton and Weingartl, 2012.

### Cats

Cats were recognized as a naturally susceptible host for NiV during the 1998-99 Malaysian outbreak (Hooper *et al.*, 2001). Experimental infections of cats revealed they are highly susceptible to productive infection by both HeV and NiV and disease is severe. HeV infected cats develop fever and elevated respiratory rates, and there is rapid progression to severe illness and death within 24 hours of the onset of clinical signs (Westbury *et al.*, 1996). HeV disease in cats is similar to that observed in horses, with wide-spread vasculitis and parenchymal lesions in a wide range of organ systems particularly the lungs (Hooper *et al.*, 2001; Hooper *et al.*, 1997). Experimental NiV infection in the cat is essentially identical in outcome as compared to HeV infection and closely resembles most of the pathogenic processes seen in cases of henipavirus infection of people (Broder *et al.*, 2012).

### Dogs

Middleton *et al.*, 2017, conducted experimental infections with HeV in dogs and determined that the virus is not highly pathogenic in dogs but their oral secretions pose a potential transmission risk to people. The time window for potential oral transmission corresponded to the period of acute infection.

### Horses

The pathology caused by HeV or NiV in horses (natural or experimental infection with HeV or natural infection with NiV) is more severe than that caused by either virus in pigs. Naturally acquired HeV infection in horses is often associated with severe disease, and experimental infections are essentially uniformly fatal. Animals initially become anorexic and depressed with general uneasiness and ataxia, with a developing fever with sweating. Respiration becomes rapid, shallow and labored with pulmonary edema and congestion with nasal discharge being a common terminal feature 1 to 3 days following the onset of clinical signs. Neurologic disease is also present but less frequent and noted in both terminally ill horses and in those that recovered from respiratory infection (Rogers *et al.*, 1996; Williamson *et al.*, 1998). Infection is wide-spread with an endothelial cell tropism with syncytia (Hooper *et al.*, 2001; Hooper *et al.*, 1997; Marsh *et al.*, 2011; Murray *et al.*, 1995; Williamson *et al.*, 1998). Experimental infection of horses with NiV has not been carried out, but the brain and spinal cord of one naturally infected horse was confirmed and revealed non-suppurative meningitis (Hooper *et al.*, 2001).

### Bats

Fruit bats in the *Pteropus* genus have been identified as the reservoir hosts for HeV, NiV, and CedV. Henipaviruses have been isolated to date in *Pteropus* spp. from Australia (HeV, CedV) and Malaysia/Bangladesh/Cambodia/Thailand (NiV). Serological evidence of NiV or NiV-like exposure was detected in bats sampled in Madagascar and Ghana (Iehle C., *et al.*, 2007, Hayman *et al.*, 2008). Subsequently, 19 novel henipavirus sequences and one full-length genome of an African henipavirus,

GhV, were identified from related pteropodid bats, *Eidolon helvum*, sampled in Ghana (Drexler *et al.*, 2009; Drexler *et al.*, 2012). Nucleic acid and antibody signatures of henipaviruses have been detected serologically and by PCR in non-*Pteropus*, but related pteropodid bats in Central and West Africa, China, and Southeast Asia (Table 1); however the role that these non-*Pteropus* spp. play in the maintenance and transmission of henipaviruses remains unclear. The genome of MojV was constructed from sequences collected from a rodent, *Rattus flavipectus*, but comprehensive surveys have not been performed to rule out whether bats also host MojV.

There is no significant pathology in bats, and the frequency of viral shedding from wild bats is rare, with prevalence ranging from (1-3%) with temporal variation of infection and viral shedding observed among different bat populations (Gurley *et al.*, 2017 and Wacharapulusadee *et al.* 2010, 2016). Henipavirus isolation from bat excreta is challenging, potentially due to low viral load.

### Pathogenesis Research Priorities

- Identify determinants of virulence in pigs
- Develop experimental infection models in bats to study shedding
- Comparative genomic studies of contemporaneous NiV strains collected from bats and humans during outbreaks.
- Expand knowledge of spectrum of henipaviruses in bat hosts in NiV hotspots (e.g. western Bangladesh & West Bengal India)
- Determine whether the innate immune system in bats is responsible for limiting viral replication
- Determine how the net reproductive value of henipaviruses are sustained in bats
- Determine how transmission effected within bats, and between bats and other species

## ***IMMUNOLOGY***

The following summarizes our current knowledge of NIV immunology, including innate and adaptive immune responses to wild-type virus, immune evasion mechanisms, and protective immunity.

### Innate and adaptive immune responses to wild-type NiV

Viral RNA can be detected by both cytoplasmic and endosomal pattern recognition receptors (PRRs), resulting in innate immune Type I IFN induction/ and signaling pathways:

- Retinoic Acid-inducible Gene I (RIG- I)- recognizes 5' triphosphorylated RNA
- Melanoma Differentiation Antigen 5 (Mda-5)-recognizes cytosolic dsRNA
- RNA-dependent Protein Kinase (PKR)- recognizes cytosolic dsRNA
- Toll-like Receptor (TLR) 3- recognizes endosomal dsRNA
- TLR 7-8- recognizes endosomal ssRNA

### Immune evasion mechanisms

The NiV uses unusual processes called RNA editing and internal translational initiation to generate multiple proteins from the phosphoprotein (P) gene, resulting in 4 proteins (P, C, V, and W) that function in inhibiting Type I interferon pathways:

- NiV P, V, and W have individually been shown to bind STAT1 and STAT2, effectively preventing STAT1 phosphorylation in type I IFN-stimulated cells.
- The V protein localizes to the cytoplasm, while the W protein localizes to the nucleus.

- The C protein can partially rescue replication of an IFN-sensitive virus, but the mechanism is unknown.
- Nuclear localization of W enables it to inhibit both dsRNA and TLR 3 (IRF-3 dependent) IFN- $\beta$  induction pathways.
- A single point mutation in the V protein abrogates its ability to inhibit of IFN signaling.
- The V proteins of paramyxoviruses interact with the intracellular helicase Mda-5, and inhibits its IFN- $\beta$  induction, but not with RIG-I.
- NiV V, W, and P bind polo-like kinase (PLK) via the STAT1 binding domain (Ludlow *et al.*, 2008).
- The P, V, and W proteins of NiV Malaysia and NiV Bangladesh inhibit IFN-stimulated response element (ISRE), which have a role in inducing transcription of IFN-stimulated genes (ISGs). Some of these ISGs include IRF-7, 2'5' Oligoadenylate Synthetase (OAS), RnaseL, p56, and double-stranded RNA-induced protein kinase (PKR). These ISGs all contribute to the generation of an 'antiviral state' in the cell.

### Protective immunity

The G and F protein induce neutralizing antibodies that protect against challenge. Recent evidence from vaccination challenge studies indicates that both serum neutralizing antibody and T cell-mediated immunity are needed for protection from NiV infection in pigs (Pickering *et al.*, 2016).

### Research needs

- Innate immunity and immunosuppression
  - Need studies in NiV infected cells and animal models
  - Need to study infection in various cell types, including cells of the immune system and bat cells
  - Use infectious clone to study virulence determinants
  - Identify targets for antiviral agents
  - Cytokine response to infection in human and bat cell lines
  - Need to study the potential for type 1 interferon or other cytokines to provide early protection from Nipah virus infection, transmission and/or clinical signs.
- Protective Immunity
  - Need to better define correlates of protection
  - Study T lymphocyte subset responses and cellular targets (e.g., N)

## ***EPIDEMIOLOGY***

Certain species of fruit bats of the genus *Pteropus* are the principal natural reservoir hosts for NiV and HeV. Bats are susceptible to infection with these viruses but do not develop disease. Other zoonotic viruses like Ebola, Marburg, and SARS virus, have also been identified in various bats (Leroy *et al.* 2005; Towner *et al.* 2009; Li W *et al.* 2005). Fruit bats are distributed across an area encompassing Australia, Southeast Asia; including Indonesia, Malaysia, the Philippines and some of the Pacific Islands, the Indian subcontinent, and Madagascar (See Fig. 1). There is further evidence for broader

distribution of NiV in pteropid fruit bats species across their range (Wacharapluesadee S. and Hemachudha T., 2007). There is also growing evidence that viruses related to NiV and HeV also circulate in non-pteropid fruit bats worldwide.

### ***Hendra Virus***

Hendra virus infection was first recognized in 1994 in Australia, when it caused an outbreak of acute, fatal respiratory disease that killed 14 horses. Three human cases, leading to two deaths were recorded during the outbreak. In 1995, a horse was infected with associated human cases. The precise mode of virus transmission to the three Australian patients is not fully understood. All three individuals appear to have acquired their infection as a result of close contact with horses, which were ill and later died.

There have been several recognized outbreaks in Australia since 1994. Hendra virus reemerged in 1999, 2004, and 2006-2010. All known HeV cases have occurred in Queensland or northern New South Wales. From 1994 to 2010, HeV was confirmed on 11 premises in Queensland and one premise in northern New South Wales. In Australia, GlobalincidentMap.com reported: 21 cases in 2011; 12 cases in 2012; 10 cases in 2013; four cases in 2014; three cases in 2015; one case in 2016; and four cases in 2017. All cases have involved horses as an intermediate host along with some additional human infections, resulting in several fatalities. The Australian Veterinary Association's national president, Dr. Ben Gardiner, was quoted as stating "no state or territory was immune from the virus."

The natural reservoirs for HeV are flying foxes found in Australia. Bats are susceptible to infection with these viruses but do not develop disease.

Hendra virus infection has also been detected in two dogs that were in close contact with infected horses. Both dogs remained clinically normal with no history of related illness.

Updated statistics on HeV outbreaks, including locations, dates and confirmed human and animal cases may be found on the [Australian Veterinary Association website](#) (Assessed July 22, 2018).

### ***Nipah Virus***

Nipah virus is a recently-recognized, zoonotic paramyxovirus that causes severe disease and high fatality rates in people. Outbreaks have occurred in Malaysia, Singapore, India and Bangladesh, and a putative Nipah virus was also recently associated with human disease in the Philippines (Clayton, 2017). The following summarizes our current knowledge of NiV epidemiology taking into account disease outbreaks in Malaysia and Bangladesh.

#### ***Malaysia***

Nipah virus was first described in 1999 in Malaysia. The outbreak in Malaysia resulted in over a million pigs culled, 800 pig farms demolished, 36,000 jobs lost, \$120+ million exports lost, and over 300 human cases (106 fatal, ~35% mortality) in pig farmers (Chinese) and Singapore abattoir workers (Field *et al.*, 2001). The NiV outbreak in pigs was described as highly infectious, frequently asymptomatic, low mortality rate (~5%), with respiratory and neurological syndromes. The pig farm pattern of disease included 30% morbidity and 5% mortality with sows first affected, followed by weaners, growers and finishers. The duration of clinical disease on a farm lasted ~ 2 weeks with a sero-prevalence approaching 100% in some cases. The outbreak in Malaysian pigs was associated

with an increased incidence of human viral encephalitis cases, strongly associated with pig farm workers, with temporal and spatial links to disease in pigs.

During the outbreak, evidence of NiV infection was found in domestic animals such as goats and cats, but especially dogs (Field *et al.*, 2001). After pig populations were destroyed, but before residents were allowed to return to their homes, studies were undertaken in the epidemic area to determine whether domestic animal populations maintained active infection in the absence of infected pigs (Mills *et al.*, 2009). Dogs were especially suspected because they live commensally with both pigs and humans. However, serologic screening showed that in the absence of infected pigs, dogs were not a secondary reservoir for NiV.

Although human-to-human transmission of NiV during the 1998-1999 outbreak in Malaysia was not reported, a small number of infected people had no history of contact with pigs, suggesting human-to-human transmission occurred in these cases (Clayton, 2017).

The reservoir and natural host of NiV was determined to be fruit bats. Fruit bats have a wide geographic distribution, high antibody prevalence (17-30%), but no apparent clinical disease. A NiV neutralizing antibody study (Yob *et al.*, 2001) from 237 wild-caught bats surveyed on Peninsular Malaysia April 1–May 7, 1999, found four different species of fruit bats, and one species of insectivorous bats, tested positive for NiV (see Table I).

The routes of NiV excretion in bats include urine, saliva, and foetal tissues and fluids but the exact modes of transmission have yet to be determined.

The drivers of the emergence of NiV in Malaysia were determined to be large piggery (30,000+) adjacent to primary forest/fruit bat habitat and a network of other large farms close by. The stages of emergence associated with the outbreak included a spillover from flying foxes to domestic pigs near Ipoh (see Fig. 4), where farming practices and high pig densities facilitated the dissemination of the infection. Transportation of pigs for commerce led to the southern spread of the outbreak with the amplifying pig host facilitating the transmission of the virus to humans.

The epidemic enhancement of the outbreak included the initial introduction of infection in a naive pig population resulting in a rapid epidemic peak, followed by burn-out and localized human infections. Subsequent introduction(s) into partially immune pig populations resulted in a lower epidemic peak but prolonged duration and increased total number of infectious pigs, increasing the chances of spread to surrounding farms.

### Bangladesh

Bangladesh experienced its first reported NiV outbreak in Siliguri and Naogaon in 2001 (Fig. 5). Unlike Malaysia, outbreaks in Bangladesh appeared to be strictly confined to human populations and significantly higher mortality rate. From 2001 to 2018, the WHO reported a total of 261 cases, with 198 deaths (76% mortality) due to NiV infection (see Table II).

The transmission of NiV to humans in Bangladesh was determined to be associated with drinking date palm juice, considered a delicacy in this region of the world. In the Tangail outbreak of 2005, it was

estimated that persons drinking raw date palm sap had a 7.0 odds ratio of developing a NiV infection when compared to controls (95% confidence level, 1.6).

NiV cases in Bangladesh have been seasonal, with human cases reported between the months of January and April. This coincides with the season for collecting date palm sap, late November through April. However, there is significant heterogeneity in the number of spillovers detected by district and year that remains unexplained. Cortes et al., in 2018 analyzed data from all 57 spillovers occurring during 2007–2013 and found that temperature differences explained 36% of the year-to-year variation in the total number of spillovers each winter, and that distance to surveillance hospitals explained 45% of spatial heterogeneity. January, when 40% of the spillover events occurred, was the month with the lowest mean temperature during every year of the study.

Bats are recognized as a nuisance and frequently drink the juice, defecate into juice, and occasionally drown in the palm sap collecting pot. Measures have been put in place to prevent bats access to the sap collecting pot, which has been very effective in reducing the spread of NiV from bats to humans in Bangladesh.

### India

In 2001, an outbreak occurred within a hospital in Siliguri, West Bengal. Nosocomial transmission likely occurred, though it is unknown how primary cases were infected. Another outbreak in 2007 was reported in Nadia, West Bengal. Consumption of date palm sap was identified as the likely route of infection of primary cases there. In May of 2018, another outbreak was reported in Kerala. A total of 85 cases were reported in these three outbreaks in 2001, 2007, and 2018, with 62 deaths (73% mortality) due to NiV infection (see Table II).

In 2012, Yadav et al. surveyed the Indian states of Maharashtra and West Bengal to evaluate the presence of viral RNA and IgG against NiV in different bat populations belonging to the species *Pteropus giganteus*, *Cynopterus sphinx* and *Megaderma lyra*. The authors found NiV RNA in *Pteropus* bat thus suggesting it may be a reservoir for NiV in India.

In 2018, an outbreak of 23 cases of NiV disease was reported in Kerala, India. This was the first spillover in NiV in South India. 18 cases were lab-confirmed and the case fatality rate during this outbreak was 91% (Arunkumar G *et al.* 2018).

### Philippines

In 2014, the Philippines reported an outbreak with a zoonotic paramyxovirus in horses and people that is very closely related to NiV based on sequence analysis. Virus isolation was unsuccessful so it was impossible to confirm that there was transmission from presumably bats to horses, from horses to people, and also human to human (Ching P.K., *et al.*, 2015; Clayton, 2017).

### New Caledonia

In 2015, three fruit bats tested positive for NiV in New Caledonia at the Noumea National Park, including three bats at the Noumea Zoo.

## Research needs

- Improved understanding of infection dynamics in flying foxes: modes of transmission, immune response, evidence of disease, and the implications of co-infection with NiV and other henipaviruses
- Better understanding of co-circulation of different strains / species of henipaviruses within Pteropus populations and the effect of waning herd immunity on outbreaks.
- Other animals such as infected dogs and cats need to be further studied to determine their potential role in the transmission of NiV.
- Improved understanding of infection dynamics in humans: modes of transmission, implications of genetic diversity of the virus for infection, transmission & pathogenicity
- Research into bat populations: additional research regarding bat distributions & ecological impacts
- Research aimed at improving the capacity to diagnose henipavirus infections and improve human health outcomes
- Research into infection and clinical signs in pigs in Bangladesh and potential for pig to human and human to pig transmission.

## ***BIOTERRORISM***

The following summarizes the rationale for considering NiV as a potential agent of bioterrorism.

NiV is classified by CDC as a Category C pathogen – emerging pathogens that could be engineered for mass dissemination in the future. Category C include pathogens are readily available, easy to produce, easy to disseminate, and have the potential for high morbidity and mortality with major health impact.

NiV has many of the physical attributes to serve as a potential agent of bioterrorism. The outbreak in Malaysia caused widespread panic and fear because of its high mortality and the inability to control the disease initially. There were considerable social disruptions and tremendous economic loss to an important pig-rearing industry. This highly virulent virus, believed to be introduced into pig farms by fruit bats, spread easily among pigs and was transmitted to humans who came into close contact with infected animals. From pigs, the virus was also transmitted to other animals such as dogs, cats, and horses.

## Nipah Virus Bioterrorism Threat Assessment

### **Virology**

- Reverse genetic methods are available for negative strand RNA viruses, including Nipah, and all genomic sequence data is available.
- Many laboratories are actively engaged in research programs on the cell biological properties of the henipaviruses.

- Virus can be amplified to reasonably high unconcentrated titers ( $>10^7$ ). Several cell culture lines can be used, Vero cell use most often reported, and wild-type virus can be grown and harvested from cell cultures.
- A major constraint in handling Nipah is the requirement for BSL4 facilities; , however, potential terrorists may not respect this need.
- Inactivation of virus can be achieved with a variety of agents typically used for envelope viruses; but extensive environmental stability testing not reported.
- Vaccines and passively-delivered countermeasures are under development both for human and veterinary use. A commercial Hendra virus vaccine is available for horses, and the soluble G protein based vaccine has shown experimental efficacy against Nipah virus in nonhuman primates.
- Bats are sold (often live) in markets throughout their range, providing a potential source of virus; and serological tests are available for identifying henipaviruses

### **Economic Impact**

- Destroyed the main market for Malaysian hogs in Singapore
- ~80% drop in pork consumption in the domestic market.
- Over half the standing pig population in the country was culled to halt the outbreak.
- Half the pig farms went out of business.
- During the outbreak cumulative economic losses based on government figures  $> \$217$  million USD.
- Cumulative government costs in operations and lost revenues  $> \$298$  million USD.
- Other countries in South East Asia often have a higher pig density than Malaysia. China, with approximately half of the pigs in the world, is especially vulnerable to an economic and public health disaster if NiV were to emerge and be rapidly transmitted between pigs and from pigs to people.

### **Epidemiology and Clinical Disease**

- In outbreaks to date henipaviruses do not appear to be highly infectious. Infection requires close contact with secretions of diseased animals. Many infections can be mild to asymptomatic.
- In the initial 1998-99 outbreak the virus was *initially misdiagnosed* as Japanese Encephalitis; amplification occurred from veterinary reuse of needles in immunization programs to control JE, increasing outbreak severity and extent.
- Time from exposure to signs of infection averages ~2 weeks for humans and seroconversion occurs within a month of onset (dose / route dependent).
- Transmission directly to the vascular system could occur through bites from infected animals or broken skin exposed to secretions of infected animals.
- It is quite likely that an outbreak in animals would result in transmissions to humans.
- An outbreak of Nipah pneumonia or ARDs-like disease with human-to-human transmission as demonstrated in the Bangladesh outbreak could cause significant mortality. Nipah could cause more severe or different disease presentations in older or sick populations.

### **Viral Transmission**

- Deliberate release of virus in some manner is possible.

- Aerosol delivery might transmit the disease effectively to domestic animals, but the environmental requirements for maintaining virus stability are not well known.
- Transmission to humans through consumption of contaminated food has been documented.
- The veterinary reuse of needles in the Japanese Encephalitis immunization campaign and in artificial insemination may have been a factor in the near 100% infection level of Nipah in pigs observed on affected farms.
- Deliberate contamination of veterinary needles could initiate an outbreak in susceptible domestic animals.
- Human-to-human transmission through travel has not been documented, but is possible.
- Transport of infected pigs on trucks was a transmission route in the Malaysian outbreak. Generalizing-- transportation of infected humans on crowded airplanes, buses or trains could also transmit the disease. Human cases have been transported to highly populous cities (e.g. Dhaka) where risk of exposure and spread among the public is increased.

### Summary

- Nipah (henipaviruses) can be isolated from animal hosts.
- Several species of fruit bats, including *Pteropus spp.* widely distributed throughout Southeast Asia. The live animals are sold in food markets.
- A Nipah outbreak in swine producing areas can cause an economic crisis, even if human cases do not occur.
- Nipah virus can be amplified in permissive cell cultures (e.g., Vero cells) providing adequate laboratory facilities are available (Biosafety Level 4), although a bioterrorist group would not be restricted from growing the virus because of the lack of BSL-4 facilities.
- Effective aerosol delivery is likely possible but unpredictable on the basis of publicly available information. General unknowns are-- titers necessary for infection, virion stability in vitro, and how infectious the virus would be with this delivery.
- Effective surveillance programs, particularly in pig farming areas, are the best defense for early detection and containment of infection, whatever the source.

## **SUMMARY OF OBSTACLES TO PREVENTION AND CONTROL**

The 2017 gap analysis working group determined that the following countermeasures were important but several weaknesses were identified.

### ***DIAGNOSIS***

NiV and HeV are zoonotic paramyxoviruses capable of causing severe disease in humans and animals. These viruses require biosafety level 4 (BSL-4) containment. The availability of safe laboratory diagnostic tests is limited. Sequence variation affects molecular diagnostics; both Clifton Beach (2007) and Redlands (2008) reported that Hendra virus strains failed in AAHL Hendra virus specific real-time PCR. Most published diagnostic PCRs only detect HeV or NiV, but not both. There is a need for a more general PCR to detect divergent and novel strains. Pan-paramyxovirus PCR assays exist and are in use to detect henipaviruses, but limitations in sensitivity limit diagnostic value. The USAID PREDICT program previously used its pan-paramyxovirus PCR assay for surveillance in more than 20 countries in Africa and Asia. Virus isolation and serum neutralization assays require live NiV. There is a need for diagnostics that can be used safely in the laboratory. There is a need for rapid nucleic acid-based assays that can detect all henipaviruses. There is also a critical need for improved antibody-based assays for disease outbreaks and disease surveillance. Importantly, there is a need to develop operator-safe diagnostic tests for which reagents can be produced without requiring high containment facilities.

Currently there are no expectations that validated tests will become available for livestock (or other species) in the near future. Nothing has been done in terms of test harmonization since 2009; however, a number of technology transfers have occurred: from AAHL to laboratories in Asia (Malaysia mainly); limited transfer from NCFAD to India (Bhopal High Containment Animal Health Laboratory); limited transfer from AAHL to the FLI and bilateral transfers between NCFAD and FLI.

### ***VACCINATION***

There is currently a commercially available vaccine for horses but no vaccines for swine or human vaccines. The goal for a HeV vaccine for horses is to vaccinate horses in areas at risk for transmission from bats to horses in order to prevent bat to horse transmission and subsequent horse to human transmission. The goal for a NiV vaccine for swine is to have a large stockpile of vaccine available for rapid use in an outbreak situation to prevent swine to swine, swine to human, and perhaps human to swine transmission to control the outbreak. A large stockpile of NiV vaccine, or vaccine antigen concentrate, for rapid emergency use in swine to control a potential outbreak that spreads too quickly to be stamped out in swine dense areas is needed. The vaccine should be licensed in the U.S., E.U or Australia for stockpiling as well as in the countries where NiV is endemic in bats. The stockpile should be available for use internationally where ever it may be needed.

### ***SURVEILLANCE***

Passive surveillance is the primary and most economical method used. Passive surveillance in commercial swine herds based on clinical signs has many weaknesses due to the difficulty of differentiating NiV from many common endemic infectious diseases of pigs; e.g., classical swine

fever, porcine reproductive and respiratory syndrome, pseudorabies, swine enzootic pneumoniae, and porcine pleuropneumonia.

In the case of infections in swine where recognition of Nipah symptoms is less likely, surveillance activities must be based on diagnostic testing to supplement surveillance based on clinical signs.

Active surveillance programs are expensive and would have to rely on direct diagnostic tests such as viral isolation and nucleic acid-based assays but available tests have significant weaknesses and have not been validated.

Rapid confirmation of cases is essential. Knowledge on serological cross-reactions with other henipaviruses and/or morbilliviruses in bats is improving. There is an urgent need to establish diagnostic capacity for Nipah virus in countries that are most likely to experience spillovers from the bat reservoirs.

### ***DEPOPULATION***

Depopulation is the primary countermeasure to reduce virus shedding and stop the spread of Nipah virus in swine. Recent outbreaks have shown that the control of Nipah virus in pig populations through stamping out is complex due to the zoonotic nature of the agent and may be very expensive, particularly in areas with high pig densities. Because Nipah virus spreads rapidly and silently in pigs, a large number of animals would need to be pre-emptively culled if an outbreak occurred in the U.S, or in other swine dense countries in order to minimize the virus spread in the vicinity of infected herds. Thus, this method of control would have significant financial implications due to the culling of thousands or millions of animals.

# COUNTERMEASURES ASSESSMENT

## ***ASSUMPTIONS***

The following captures assumptions made by the gap analysis working group to assess potential countermeasures to enhance our ability to contain and eradicate an outbreak of NiV.

### ***Situation***

Countermeasures assessed for worst case scenario: A coordinated intentional distribution of NiV-contaminated material in a high density highly populated pig region of the United States.

### ***Target Population***

Countermeasures assessed for target pig production segments in priority order:

1. Backyard pigs
2. Comprehensive commercial swine operations (farrowing, nursery, and finishing)
3. Commercial indoor farrowing operations
4. Large intensive indoor pig farms
5. Valuable commercial genetic swine stock

### ***Scope of Outbreak***

Countermeasures assessed for multiple outbreaks occurring simultaneously in backyard pigs, three farrowing commercial operations, a finishing pig commercial operation, a sow replacement operation, and evidence of infection in feral swine.

## ***DECISION MODEL***

The quantitative Kemper-Trego (KT) decision model was used to assess available vaccines and diagnostics. For the criteria and weights used to assess NiV vaccines and diagnostics (See Appendices II, III).

### ***Criteria***

The following critical criteria were selected to enable the comparison of countermeasures using a pertinent and valid analysis, as follows:

#### Vaccines

- Efficacy
- Safety
- One dose
- Manufacturing safety
- DIVA compatible
- Manufacturing yield
- Rapid production
- Reasonable cost
- Short withdrawal period
- Long shelf life

### Diagnostics

- Sensitivity
- Specificity
- DIVA detection
- Multispecies
- Validation to purpose
- Speed of scale-up
- Throughput
- Pen-side test
- Rapid result
- No need for a confirmatory test
- Easy to perform
- Safe to operate
- Availability
- Storage/Distribution
- Low cost to implement
- Perform at BSL-2
- Does not require use of live virus to prepare reagents

### ***Weight***

Each criterion was weighted to allow a quantitative comparison of the impact of the selected interventions (See Appendices II and III).

### ***Product profile***

To ensure a consistent and meaningful assessment, the desired product profile (i.e., the benchmark) was identified for each countermeasure:

### Desired Vaccine Profile

1. Highly efficacious: prevent transmission; efficacy in all age animal target hosts, including maternal antibody override; cross protection across all henipavirus strains; quick onset of immunity; multiple animal target hosts; one year duration of immunity
2. Safe in all age animal target hosts; no reversion to virulence for live vaccines
3. One dose
4. Safe vaccine strain for manufacturing
4. DIVA compatible
5. Manufacturing method yields high number of doses
6. Rapid speed of production and scale-up
7. Reasonable cost
8. Short withdrawal period for food consumption
9. Long shelf life

### Desired Diagnostic Test Profile

1. Detect all henipavirus
2. Identify Nipah virus specific strains
3. Direct tests for control and eradication
4. Indirect tests for post-control monitoring
5. Rapid test
6. >95% specificity
7. >95% sensitivity
8. Pen-side test
9. DIVA Compatible
10. Field validated
11. Easy to perform/easily train NAHLN's personnel
12. Scalable
13. Reasonable cost
14. Operator safe
15. Reagents can be produced in low containment

### ***Values***

The values assigned for each of the interventions reflect the collective best judgment of members of the gap analysis working groups (See Appendices I and II)

### ***VACCINES***

The human infections in the 1999 outbreak in Malaysia were linked to transmission of NiV from pigs. Accordingly, a swine vaccine able to prevent virus transmission would be an important tool to safeguard commercial swine operations and people at risk. In addition, since henipaviruses have a very broad host range, a vaccine that is efficacious in multiple susceptible animal species would be desirable. Although the 2017 gap analysis working group determined that there are still no NiV commercial vaccines available, there are several vaccine candidates that may be safe and effective in swine and other domestic animals that were recently reviewed in: (Weingartl H.M., 2015; Broder, C.C., *et al*, 2016; and Satterfield, B.A., *et al.*, 2016). After these reviews were published, a manuscript was published demonstrating the efficacy of a virus-like-particle (VLP) Nipah virus vaccine in hamsters for inducing virus neutralizing antibodies and protection from challenge (Walpita P., *et al.*, 2017). Another manuscript was published that concluded that an adjuvanted Hendra soluble G vaccine in pigs induced neutralizing antibody titers considered to be protective against Nipah virus without detectable T cell-mediated immunity to Nipah, which did not protect from challenge with Nipah virus. However, pigs that had been previously challenged with a low dose of NiV developed neutralizing antibodies and cell-mediated immune memory and were protected from a high challenge dose of NiV. The conclusion of this manuscript was that both virus neutralizing antibodies and cell-mediated immunity were necessary for protection from NiV challenge (Pickering B.S., *et al.*, 2016). Subsequent unpublished research demonstrated that a different adjuvant used with the soluble Hendra G vaccine caused the induction of both high titered virus neutralizing antibody and detectable T cell-mediated immunity in pigs to NiV. Challenge studies were not conducted (J.A. Roth, personal communication). All of these vaccine candidates would need further research and development to be licensed, and would need to be made available as a stockpile for rapid use in an emergency if an outbreak in swine were to occur that could not be effectively stamped out. A swine vaccine would

also be needed if the Nipah virus were to mutate to be efficiently transmitted between people and between people and pigs.

### Summary

- Vaccination against NiV has been successfully demonstrated
- Experimental henipavirus vaccines can prevent clinical disease
- Experimental henipavirus vaccines elicit systemic and mucosal immunity
- Experimental henipavirus vaccines prevent viral replication in target tissues
- HeV commercial vaccine Equivac® HeV does not cross protect against NiV infection in swine
- Henipavirus vaccines appear to be effective in several mammalian animal species

### Assessment of Commercial Vaccines

A commercial vaccine (Equivac® HeV) against Hendra virus approved for use in horses (Middleton D.J. *et al.*, 2014) was registered by Zoetis in Australia in 2015. A six month booster dose is required for full protection, followed by annual vaccination. The vaccine is also approved for pregnant mares. There is currently no NiV vaccine approved for swine. Likewise, there is no vaccine against HeV or NiV approved for human use.

### Assessment of Experimental Vaccines

The working group felt that limited information was available to assess and contrast experimental vaccines that have been reported in the literature. Experimental animal vaccines under investigation are summarized in Table I. Experimental vaccines for humans are summarized in Table II. Several of the working group members have directly or indirectly been involved in the research associated with these vaccines so that an assessment could be made (See Appendix I). The following describes some of the most promising experimental vaccine technologies.

#### *1) Canarypox-vectored NiV Vaccines*

The ALVAC canarypox virus-based recombinant vaccine vector (Taylor *et al.*, 1994) was used to construct two experimental NiV vaccines (Weingartl *et al.*, 2006). These experimental vaccines were engineered by Merial.

The first construct carries the gene for NiV attachment glycoprotein G (ALVAC-G). The second construct carries the NiV fusion protein F (ALVAC-F).

The efficacy of both the ALVAC-G and ALVAC-F were tested in pigs either as monovalent vaccine or in combination (ALVAC-G/F). The vaccine dose used was 10(8) PFU. The vaccine regimen was two doses administered 14 days apart. Both non-vaccinated controls and vaccinated pigs were challenged with 2.5 x 10(5) PFU of NiV two weeks later.

The combined ALVAC-F/G vaccine induced the highest levels of neutralization antibodies. Despite the low neutralizing antibody levels induced by ALVAC-F all vaccinated animals were protected against challenge. Virus was not isolated from the tissues of any of the vaccinated pigs post-challenge, and a real-time reverse transcription (RT)-PCR assay detected only small amounts of viral

RNA in several samples. In challenge control pigs, virus was isolated from a number of tissues or detected by real-time RT-PCR. Vaccination of pigs with the ALVAC-F/G stimulated both type 1 and type 2 cytokine responses. No virus shedding was detected in vaccinated animals, in contrast to challenge control pigs, from which virus was isolated from the throat and nose.

Based on the data generated in this one study, both the ALVAC-G or the combined ALVAC-F/G vaccine appears to be a very promising vaccine candidate for swine.

## 2) *Soluble G Henipavirus Vaccine*

HeV and NiV infect cells by a pH-independent membrane fusion event mediated by their attachment (G) and fusion (F) glycoproteins. Scientists at the Uniformed Services University of the Health Sciences in Bethesda, Maryland, in collaboration with the Australian Animal Health Laboratory characterized HeV- and NiV-mediated fusion activities and detailed their host-cell tropism characteristics. These studies suggested that a common cell surface receptor was utilized by both viruses. To further characterize the G glycoprotein and its unknown receptor, soluble forms of HeV G (sG) were constructed by replacing its cytoplasmic tail and transmembrane domains with an immunoglobulin kappa leader sequence coupled with an S-peptide tag (sG) to facilitate purification and detection. Expression of sG was verified in cell lysates and culture supernatants by specific affinity precipitation. Analysis of sG by size exclusion chromatography and sucrose gradient centrifugation demonstrated tetrameric, dimeric, and monomeric species, with the majority of the sG released as a disulfide-linked dimer. Immunofluorescence staining revealed that sG specifically bound to HeV and NiV infection-permissive cells. The scientists further reported that administration of sG to rabbits can elicit a potent cross-reactive neutralizing antibody response against infectious HeV and NiV (Bossart *et al.* 2005). The HeV sG subunit vaccine has been the most extensively studied NiV/HeV vaccine platform because of its ability to elicit a potent cross-protective immune response to NiV and has been shown to induce potent cross-reactive neutralizing antibody responses in a variety of animals including mice, rabbits, cats, ferrets, monkeys and horses.

Experimental subunit vaccine formulations containing either HeV sG or NiV sG were first evaluated as potential NiV vaccines in the cat model. Two cats were immunized with HeV sG and two cats were immunized with NiV sG. Immunized animals and two additional naïve controls were then challenged subcutaneously with 500 TCID<sub>50</sub> of NiV. Naïve animals developed clinical disease 6 to 13 days post-infection, whereas none of the immunized animals showed any sign of disease (Mungall *et al.*, 2006).

In a subsequent experiment, an experimental subunit formulation containing HeV sG and CpG adjuvant was evaluated as a potential NiV vaccine in the cat model. Vaccinated animals demonstrated varying levels of NiV-specific Ig systemically and importantly, all vaccinated cats possessed antigen-specific IgA on the mucosa. Upon oronasal challenge with NiV (50,000 TCID<sub>50</sub>), all vaccinated animals were protected from disease although virus was detected on day 21 post-challenge in one animal. (McEachern *et al.*, 2008).

Additional studies with the HeV-sG vaccine in the ferret model formulated in CpG and Allhydrogel™ and could provide complete protection from a 5,000 TCID<sub>50</sub> dose of HeV (100 times the minimal lethal dose) with no disease or evidence of virus or viral genome in any tissues or body fluids and only a low level of HeV genome detected in the nasal washes from 1 of 4 animals in a low-dose vaccine

group, and no infectious HeV could be recovered from any immunized ferrets (Pallister J, et al. A recombinant Hendra virus G glycoprotein-based subunit vaccine protects ferrets from lethal Hendra virus challenge. *Vaccine*. 2011;29:5623-30) In a similar study with NiV-B, vaccinated ferrets remained disease free, and virus or viral genome was undetectable in all tissues and fluids with no observed pathology in examined tissues. The study also revealed good durable immunity with other ferrets challenged 434 days post-vaccination, with 5 of 5 animals were disease free following challenge and viral genome was detected only from the nasal secretions of one ferret and the bronchial lymph nodes of another ferret that were given an intermediate vaccine dose (Pallister JA, et al. Vaccination of ferrets with a recombinant G glycoprotein subunit vaccine provides protection against Nipah virus disease for over 12 months. *Virology*. 2013;10:237).

The HeV-sG subunit vaccine has also been evaluated in the African green monkey (AGM), which is the only nonhuman primate model that has uniformly recapitulated human disease for both NiV and HeV infection (Rockx B, et al. A novel model of lethal Hendra virus infection in African green monkeys and the effectiveness of ribavirin treatment. *J Virol*. 2010;84:9831-9; Geisbert TW, et al. Development of an acute and highly pathogenic nonhuman primate model of Nipah virus infection. *PLoS One*. 2010;5:e10690). HeV-sG was initially tested by formulation in Allhydrogel™ and CpG and animals were challenged by intratracheal administration with a 10-fold lethal dose of NiV ( $1 \times 10^5$  TCID50). Complete protection was observed in all vaccinated animals with no evidence of clinical disease, virus replication, or pathology in any vaccinated subject with some having pre-challenge NiV neutralizing titers as low as 1:28. A second study demonstrated HeV-sG vaccination and protection from a HeV in the AGM model and also showed that HeV-sG in Allhydrogel™ alone was sufficient to confer complete protection from infection and disease (Mire CE, et al. A recombinant Hendra virus G glycoprotein subunit vaccine protects nonhuman primates against Hendra virus challenge. *J Virol*. 2014;88:4624-31). The HeV-sG subunit vaccine is now being evaluated as a NiV/HeV vaccine for human use with support from the Coalition for Epidemic Preparedness Innovations (CEPI) (*Hum Vaccin Immunother*. 2017 Dec 2;13(12):2755-2762. doi: 10.1080/21645515.2017.1306615. Vaccines for epidemic infections and the role of CEPI. Plotkin SA)

A recent publication demonstrated that an adjuvanted HeV-sG vaccine in pigs induced SN antibody titers considered to be protective against NiV without detectable T cell-mediated immunity to NiV which did not protect from challenge with NiV. Pigs which had been previously challenged with a low dose of NiV developed SN antibodies and cell-mediated immune memory and were protected from a high challenge dose of NiV. The conclusion of this manuscript was that both SN antibodies and cell-mediated immunity were necessary for protection from NiV challenge (Protection against henipaviruses in swine requires both, cell-mediated and humoral immune response, B.S. Pickering, J.M. Hardham, G. Smith, E.T. Weingartl, P.J. Dominowski, D.L. Foss, D. Mwangi, C.C. Broder, J.A. Roth, H.M. Weingartl, *Vaccine* 34(40): 4777-4786, 2016). Subsequent unpublished research demonstrated that a different adjuvant used with the soluble HeV-sG vaccine caused the induction of both high titered SN antibody and detectable T cell-mediated immunity in pigs to NiV. Challenge studies were not conducted (J.A. Roth, personal communication).

### 3) *Vaccinia-vectored NiV Vaccine*

The NYVAC vaccinia virus-based recombinant vaccine vector (Tartaglia *et al.*, 1992) was used to construct an experimental NiV vaccine where the vaccinia virus expresses both the NiV glycoproteins G and F (Guillaume *et al.*, 2004). This experimental vaccine was engineered by the Pasteur Institute.

Scientists at the Pasteur Institute in collaboration with University of Malaysia scientists showed that both of the NiV glycoproteins G and F when expressed as vaccinia virus recombinants induced an immune response in hamsters that protected against a lethal challenge with NiV. Furthermore, this team of scientists demonstrated passive transfer of antibody induced by either of the glycoproteins protected the animals.

## ***DIAGNOSTICS***

The gap analysis working group determined that the availability of validated diagnostic tests for surveillance, early detection, and recovery during a NiV outbreak were critical to minimize the spread of disease and reduce the economic and public impact.

Currently the diagnosis of NiV infection is by virus isolation, detection of viral RNA, or demonstration of viral antigen in tissue collected at necropsy. Specific antibody detection can also be useful, particularly in pigs where NiV infection may go unnoticed. Demonstration of specific antibody to NiV in either animals or humans is of diagnostic significance because of the rarity of infection and the serious zoonotic implication of NiV transmission.

### Summary

- Antibody responses to NiV take at least 14 days and therefore early diagnosis based on serology will be less reliable than antigen or molecular tests
- Recombinant N-ELISA will likely not pick up all infected pigs
- The concept of a pen-side test is attractive, but the development and regulation of such a test will be extremely challenging

### Assessment of Laboratory Diagnostic Tests (See Appendix II)

Details in the OIE Manual of Diagnostic Tests and Vaccines for Terrestrial Animals 2015, Chapter 2.1.14 Hendra and Nipah Virus Diseases, provides recommendations for the following tests.

### **Identification of the agent**

1. Virus isolation and characterization
  - 1.1. sampling and submission of specimens
  - 1.2. isolation in cultured cells
  - 1.3. Identification: immunostaining and Immuno EM
2. Viral identification: differentiation of HeV and NiV
  - 2.1 comparative immunostaining
  - 2.2. immunofluorescence
  - 2.3. microtiter neutralization
3. Molecular methods
  - 3.1. real-time RT-PCR
  - 3.2. Conventional RT-PCR and Sanger sequencing

#### 4. Immunohistochemistry

##### **Serological tests**

1. Virus neutralization tests
2. Enzyme-linked immunosorbent assay
3. Bead-based assays

##### **Histopathology**

1. Veterinary diagnostic labs might use histopathology to make the first diagnosis
2. NiV does not produce pathognomonic lesions, but a generalized vasculitis with fibrinoid necrosis in several tissues (e.g. lung and kidneys) is characteristic; NiV might be considered in the initial differential diagnosis by experienced veterinary pathologists.

##### Assessment of Available Diagnostic Tests

Australia, Canada, and Germany have diagnostic capability for henipaviruses in livestock; India (e.g. NIHSAD) is building its veterinary diagnostic capability; U.S. veterinary diagnostic laboratories do not have diagnostic capability to detect NiV in livestock, although the Center for Disease Control (CDC) in Atlanta, Georgia, is an OIE collaborating center for NiV.

Currently, there are no expectations of validated tests for livestock (or other species). Nothing has been done in terms of test harmonization for serological, antigen, or nucleic acid detection assays; however, successful technology transfers have taken place, as follows: from AAHL to laboratories in Asia (Malaysia mainly); limited transfer from NCFAD to India (Bhopal High Containment Animal Health Laboratory); limited transfer from AAHL to FLI and bilateral transfers between NCFAD and FLI.

Serologic testing plays an important role in the diagnosis and detection of NiV infections. Serologic tests are the most straightforward and practical means to confirm acute cases of disease and serologic evidence of infection is used in screening programs for reservoir hosts and domestic animals. However, serological assays are limited in their ability to differentiate between known and unknown henipaviruses, as cross-reactivity to one or more known viruses is possible. Both serum neutralization and Luminex assays have shown positive reactivity to both NiV and HeV in bats where the presence of a yet-to-be characterized henipavirus could not be ruled out.

Several standard and new experimental technologies that are currently being used or considered for the detection of NiV in the laboratory or as pen-side tests for field use. Shedding of NiV in oral fluids starts early post-infection and rope sampling could prove convenient for collecting samples that could be used to test larger numbers (i.e., pen tests) of pigs. Suitability of oral fluid samples for various test platforms should be investigated. There is a need to develop a formalized worldwide structure for test validation and ring trials (i.e., inter-laboratory comparisons).

The following describes some of the most promising diagnostic platforms with potential application for NiV detection.

1) *Quantitative (q) real-time PCR*

Real-time PCR is a sensitive and useful approach to the detection of henipavirus genome in specimens. Due to its nature, rRT-PCR may not be able to detect all divergent and novel henipavirus strains, although adaptation of molecular tests to new virus variants could be rapid. Test methods and primers used depend on the technology platform and associated chemistry being used in individual laboratories. Test procedures have been described by different laboratories (Mungall *et al.*, 2006; Wacharapluesadee and Hemachudha, 2007; Guillaume *et al.*, 2004; Chang *et al.*, 2006; Feldman *et al.*, 2009).

The AAHL has developed a quantitative real-time PCR to detect NiV or HeV RNA synthesis. The most commonly targeted amplification regions are directed against the N gene (Feldman *et al.*, 2009).

RT-PCR targeting the N gene of NiV will detect both, NiV-M and NiV-B, with somewhat lower sensitivity for NiV-B. Confirmatory RT-PCR targeting the F gene specific only for NiV-B has therefore been developed (publication in preparation; H.M. Weingartl, personal communication).

2) *Conventional PCR*

Classical RT-PCR followed by sequencing may be more successful in detecting novel henipavirus strains. Combination of both approaches may need to be considered. Genomic RNA detection can be performed on blood or serum samples collected from live animals as well as tissues from dead animals. RNA is extracted using an RNA extraction kit [e.g., RNeasy Mini Kit (Qiagen)]. Extracted total cellular RNA is first subjected to first-stand cDNA synthesis using a reverse transcriptase kit [e.g., SensiScript (Qiagen)] and a reverse transcriptase primer. The resulting cDNA is amplified using a Master Mix PCR kit (Qiagen) and primers that are designed to target HeV and NiV positive-sense mRNA from the N, M and G genes and negative-sense genomic viral RNA (vRNA) at the N/P, M/F and F/G gene junctions.

3) *Field PCR*

Not available. Isothermal real-time RT-PCR is promising as a field deployable assay.

While this will be costly and not be practical to have in large numbers, it is worth considering having the capabilities to establish in several strategically located regions across the nation to respond rapidly in an emergency situation. Technically it will not be difficult to achieve if there is the will and financial support.

#### 4) *Virus isolation (VI)*

Virus isolation in permissive cell culture is considered the “gold standard” for isolating all strains of henipaviruses. Virus isolation greatly facilitates identification procedures and definitive diagnosis should be undertaken where operator safety can be guaranteed. Isolation is especially relevant in any new case or outbreak, particularly in countries or geographical areas where infection by NiV or HeV has not been previously documented. Implication of wildlife species as natural hosts of the viruses requires positive serology, PCR or virus isolation from wild-caught animals (Daniels *et al.*, 2007). The range of tissues yielding virus in natural and experimental cases include the brain, lung, kidney and spleen (Cramer G., *et al.* 2002).

Henipaviruses grow rapidly to high titers in a large number of cell lines. African green monkey kidney (Vero) and rabbit kidney (RK-13) cells have been found to be particularly susceptible. A CPE usually develops within 3 days, but two 5-day passages are recommended before judging the attempt unsuccessful. After low multiplicity of infection, the CPE is characterised by formation of syncytia that may, after 24–48 hours, contain over 60 or more nuclei. Syncytia formed by NiV in Vero cell monolayers are significantly larger than those created by HeV in the same time period. Although the distribution of nuclei in NiV-induced syncytia early in infection resembles that induced by HeV, with nuclei aggregated in the middle of the syncytia, nuclei in mature NiV-induced syncytia are distributed around the outside of the giant cell (Hyatt *et al.*, 2001).

Very low virus load in bats makes isolation very difficult. Linfa Wang and colleagues at the AAHL have increased sensitivity of cell lines by “rational engineering,” consisting of a single point mutation in ephrinB2 resulting in enhanced affinity for NiV.

#### 5) *Pen-side test*

Not yet developed.

While the concept is attractive, it is a huge challenge technically and in regulatory sense, especially considering how presumable false positive results would be handled.

#### 6) *N and G ELISA*

Indirect recombinant N- ELISA and G-ELISA have been developed, and are now in the stage of diagnostic evaluation (Fisher K., *et al.*, 2018). The N-ELISA protocol was transferred to HSADDL (India) and validated and used for surveillance (Kulkarni *et al.*, 2016).

Problems with specificity (i.e., false positives) could arise. For example, swine sero-surveillance in West Bengal, India, appears to be negative; however, 8/328 samples tested positive (i.e., presumably false positive) using the anti-N antigen ELISA antibody detection test. Evaluation of the indirect IgG ELISA based on the recombinant NiV-N antigen using swine samples from Canada yielded similar results, including an indirect IgG ELISA based on the G glycoprotein. In Canadian context, the problem is the diagnostic specificity, with 5% false positives, resulting in the decision to complement with the G-ELISA. Only sera positive on both tests are considered

positive. Confirmatory testing may be required, if this was to be the first case reported in non-endemic area.

A diagnostic test for differentiating infected from vaccinated animals (DIVA) would have to most likely target the N antigen, or alternatively P gene coded products depending on the level of expression and antigenicity in animals, and the number of reactors in non-endemic areas.

The N ELISA assay could fulfill DIVA requirements if the canarypox vectored NiV-G-NiV-F vaccine is used because antibodies to N would only occur after NiV infection.

#### 7) *IgM ELISA*

The U.S Center for Disease Control and Prevention (CDC) developed an IgM ELISA for human serology. Detection of IgM was used to confirm recent infection with NiV in both Malaysia and Bangladesh. NiV-infected cells that have been inactivated by gamma irradiation are used as antigens.

In theory the same can be done for different animal species as long as we have the right anti-species antibodies. For bats, that is still a challenge.

#### 8) *Virus neutralization test (VNT)*

VNT serves as the traditional gold standard of serological investigations. The VNT requires live virus and thus BSL-4 containment facilities are required (Crameri *et al.*, 2002). It has proven to be a very valuable specific and sensitive tool in the diagnosis of NiV.

VNT rely on quantification methods. Three different procedures are available to titer HeV and NiV. In the traditional plaque and microtiter assay procedures, the titer is calculated as plaque forming units (PFU) or the tissue culture infectious dose capable of causing CPE in 50% of replicate wells (TCID<sub>50</sub>), respectively.

In an alternative procedure, the viruses are titrated on Vero cell monolayers in 96-well plates and after 18–24 hours, foci of infection are detected immunologically in acetone-fixed cells using anti-viral antiserum (Crameri G., *et al.* 2002). The virus titre is expressed as focus-forming units (FFU)/ml.

Neutralisation assays using these three methods are described in the OIE Manuel of Diagnostic Tests and Vaccines for Terrestrial Animals.

Virus quantification procedures should be conducted at BSL4. A new version of the differential neutralisation test has been recently described, which avoids the use of infectious virus by the use of ephrin-B2-bound biospheres (Bossart *et al.*, 2007). Although the test has yet to be formally validated, it appears to have the potential to be a screening tool for use in countries without BSL4 facilities.

### 9) *Pseudotype virus plaque reduction neutralization test (PRNT)*

The standard plaque reduction neutralization assay (PRNT) used to detect NiV and HeV must be performed in BSL-4 containment and takes several days to complete. The CDC and the AAHL have modified the PRNT by using recombinant Vesicular Stomatitis Virus (VSV) derived from the cDNA of VSV Indiana to construct pseudotype particles expressing the F and G proteins of NiV (pVSV-NiV-F/G) as target antigens (Chang *et al.*, 2006; Tamin *et al.*, 2009; Kaku *et al.*, 2009). This rapid assay can be performed at BSL-2. The PRNT was evaluated using serum samples from outbreak investigations and more than 300 serum samples from an experimental NiV vaccination study in swine. The results of the neutralization assays with pVSV-NiV-F/G as antigen showed a good correlation with those of standard PRNT. The PRNT titers give an indication of protective immunity. Therefore, this new method has the potential to be a rapid and cost-effective diagnostic method, especially in locations that lack high containment facilities, and will provide a valuable tool for basic research and vaccine development. A similar assay has been developed by the Japanese-Australian group (Kaku *et al.*, 2009), which proved to be as specific as the VNT and much more sensitive than VNT.

### 10) *Serological Binding Assay*

Currently, a Luminex<sup>®</sup>-based (e.g. Bio-Rad Bio-Plex) multiplex microsphere immunoassay for the detection of antibodies specific to HeV and NiV G glycoproteins is used for bat surveillance at the AAHL, and by other research investigators. This multiplex microsphere immunoassay detects antibodies to recombinant soluble G (sG) proteins from NiV and HeV in a multiplexed assay. In contrast to traditional ELISAs, these Luminex-based platforms are more sensitive and require less sample sera to generate results with multiple analytes. The sG proteins retain their ability to bind the cellular receptor molecule, indicating their native conformation is maintained, which is important for the detection of neutralizing antibodies. Since the G specific antibody response to both NiV and HeV can be measured simultaneously, this assay can differentiate between the serologic responses to NiV and HeV. A variety of statistical models have been developed to determine thresholds to determine the cutoff value between negative and positives median fluorescence intensities (MFI). Instances when negative control sera is available, a MFI value three standard deviations above the z score can be used to interpret the cutoff for positive values.

### 11) *Luminex<sup>®</sup> multiplexed nucleic acid detection assay*

Foord *et al.*, 2012, reported microsphere suspension array systems enable the simultaneous fluorescent identification of multiple separate nucleotide targets in a single reaction using commercially available oligo-tagged microspheres (Luminex<sup>®</sup> MagPlex-TAG) to construct and evaluate multiplexed assays for the detection and differentiation of HeV and NiV. Assays were developed to target multiple sites within the nucleoprotein (N) and phosphoprotein (P) encoding genes. The relative specificities and sensitivities of the assays were determined using reference isolates of each virus type, samples from experimentally infected horses, and archival veterinary diagnostic submissions. Results were assessed in direct comparison with an established qPCR. Foord reported the microsphere array assays achieved unequivocal differentiation of HeV and NiV

and the sensitivity of HeV detection was comparable to qPCR, indicating high analytical and diagnostic specificity and sensitivity.

### *12) Blocking Luminex® Assay*

This is an extension of the Binding Luminex Assay, developed as a surrogate VNT in the sense that it measures antibodies that block the binding of the soluble henipavirus G protein to the ephrin-B2 receptor molecule. It is highly specific, but needs further validation with field samples.

## ***DEPOPULATION***

Preemptive culling of herds in the neighborhood of an infected herd is an effective and even indispensable measure in the control of a NiV epidemic in areas with high pig densities. The purpose of this measure is to prevent infection of new herds, which would generate massive infectious virus production, and thus to reduce the virus infection load in an area. This reduced infection load subsequently results in a reduction of the between-herd virus transmission. However, recent outbreaks have shown that the control of Nipah virus in pig populations through stamping out is complex due to the zoonotic nature of the agent. In addition, depopulation may be logistically difficult and very expensive in swine dense area, and would not be effective if the Nipah virus mutates to become easily transmitted between people and from people to pigs. Depopulation will not be possible in situation like those that occurred in Bangladesh in which NiV was transmitted from bats to humans without an amplifying host. Depopulation of swine may be impossible in a rapidly spreading outbreak in a pig dense region with hundreds of millions of swine, such as in southeast China (Vergne T. *et. al.* 2017).

## ***SURVEILLANCE***

The initial expression of NiV in U.S swine would be variable and unpredictable due to the myriad of host factors and the broad diversity of virulence among strains of henipaviruses. Different surveillance strategies will be required to detect the different clinical manifestations.

For acute infection, surveillance activities can be based on clinical signs, but signs are unlikely to be noticed by producers and practitioners. It would be prudent to develop surveillance activities based on diagnostic testing to supplement surveillance based on clinical signs.

The following surveillance programs are in place to meet the objective of rapid detection of henipaviruses in Malaysia and Australia:

1. Population-based passive reporting of suspicious NiV cases. Efforts to enhance reporting will be focused on high risk areas.
2. Laboratory-based surveillance of serum and tissue submitted from sick pigs.

There is no diagnostic capability for henipaviruses in United States veterinary diagnostic laboratories due to the lack of BSL-4 laboratory space. The only diagnostic capability for henipaviruses in the U.S is the Center for Disease Control and Prevention (CDC). There are no active or passive surveillance

programs. Henipavirus suspect samples would be sent to the CDC, the OIE reference laboratory at the Australian Animal Health Laboratory, or the National Canadian Foreign Animal Disease Center, in Winnipeg, Canada.

### ***DRUGS***

There are no licensed anti-viral drugs available to treat people or animals against Henipaviruses.

### ***DISINFECTANTS***

People: Soaps and detergents.

Fomite disinfection: Sodium hypochlorite to supply 10,000 ppm chlorine or Virkon.

### ***PERSONAL PROTECTIVE EQUIPMENT (PPE)***

PPE should be suitable to prevent farm-to-farm virus spread by diagnostic or vaccination teams.

# RECOMMENDATIONS

## ***RESEARCH***

The 2017 gap analysis working group recommended the implementation of the following research priorities.

### **Viral Pathogenesis**

- Determine early events of NiV infection, immune evasion and identify determinants for virulence and host susceptibility

### **Immunology**

- Characterize the antibody and cell-mediated immune response to NiV infection and vaccination
- Develop the basic knowledge of the mechanisms NiV uses to evade the innate immune response
- Characterize the ability of interferons to inhibit virus replication and shedding early in infection.

### **Vaccine Discovery and Development Research.**

- Implement comprehensive vaccine research program to deliver next generation NiV vaccines (e.g., DIVA [differentiate infected from vaccinated animals] capable), and specifically design strategies for control in priority susceptible hosts
- Investment in Nipah vaccine development needs to include conducting studies to demonstrate safety and efficacy necessary for licensure by authorities in countries that may have an emergency need for vaccine in swine.

### **Diagnostics**

- Develop a panel of reference standards for both molecular and serologic tests that can be made available to all of the laboratories performing diagnostic tests for henipaviruses. This panel should also include monoclonal antibodies and recombinant antigens that would be readily available as low biosecurity BSL-2 reagents.
- Develop a formalized structured worldwide network for reference panel development and assay validation and harmonization.
- Develop and validate broadly reactive PCR assays targeting highly conserved genetic targets within the henipaviruses. Evaluate the relative sensitivity and specificity of the currently used PCR assays.
- Develop and validate field tests (both protein- and nucleic acid-based) to detect henipaviruses.
- Explore new antigen detection assays, including antigen capture, Loop Mediated Isothermal Amplification Protocol (LAMP) suitable for resource limited situations, and nanotechnology.
- Develop species specific reagents to improve the quality of serologic assays.
- Evaluate the relative sensitivity and specificity of molecular and serologic tests, especially new serologic tests that could replace serum neutralization titers (SNT) and meet DIVA requirements.
- Explore the use of serological assays based on recombinant antigens that could be produced at BSL-2. Classical serological tests using low biosecurity (recombinant) reagents produced at BSL-2 facilities could be developed reasonably quickly and at a reasonable cost.
- Develop species independent serologic assays using recombinant antigens.

## **Epidemiology**

- The epidemiology of NiV in disease outbreaks needs to be assessed and modeled on the level of the individual pig, the herd, and the demographics of the region.
- Epidemiological investigations should be performed on the implementation of emergency vaccination and the use of ‘DIVA’ and other diagnostic tests to detect infected pigs in vaccinated populations
- Risk assessments need to be performed with regard to control or spread of henipaviruses
- The epidemiological evaluation of wildlife needs to be carried out in order to improve the risk estimates of outbreaks in domestic animal and human populations

## ***PREPAREDNESS***

Many of the countermeasures discussed in this report will require preparation and integration in a coordinated disease control program and funding for a stockpile for use in an emergency response plan for an outbreak of NiV infection. The Henipavirus gap analysis working group recommends investing in the implementation of the following preparedness plan to ensure the effective use of the countermeasures in the NVS:

- See the Ausvetplan:  
<https://www.animalhealthaustralia.com.au/our-publications/ausvetplan-manuals-and-documents/>  
Assessed July 22, 2018
- See Guidelines for Veterinarians Handling potential Hendra Virus infection in Horses (QDPI):  
[https://www.daf.qld.gov.au/\\_data/assets/pdf\\_file/0005/126770/2913\\_-\\_Guidelines-for-veterinarians-handling-potential-Hendra-virus-infection-in-horses-V5.1.pdf](https://www.daf.qld.gov.au/_data/assets/pdf_file/0005/126770/2913_-_Guidelines-for-veterinarians-handling-potential-Hendra-virus-infection-in-horses-V5.1.pdf)  
Accessed July 22, 2018

## **Surveillance**

Routine surveillance for NiV is now limited to serologic screening of pigs in several Southeast Asian countries.

- Develop a regional surveillance strategy, including laboratory, to detect spillovers of NiV into domestic and agricultural animals.
- Determine the optimal surveillance strategy to detect circulation of NiV in the bats reservoirs and other wild life.
- Improve surveillance capacity to detect henipaviruses in high risk countries.
- Establish a formal laboratory network for henipavirus surveillance that includes standardized specimen collection, laboratory testing scheme, quality control, specimen referral and accreditation.

## **Biosecurity**

Design NiV-specific on-farm biosecurity programs to implement in a disease outbreak situation.

## **Personal Protective Equipment and Decontamination**

Assessed July 22, 2018

### **Depopulation and Disposal**

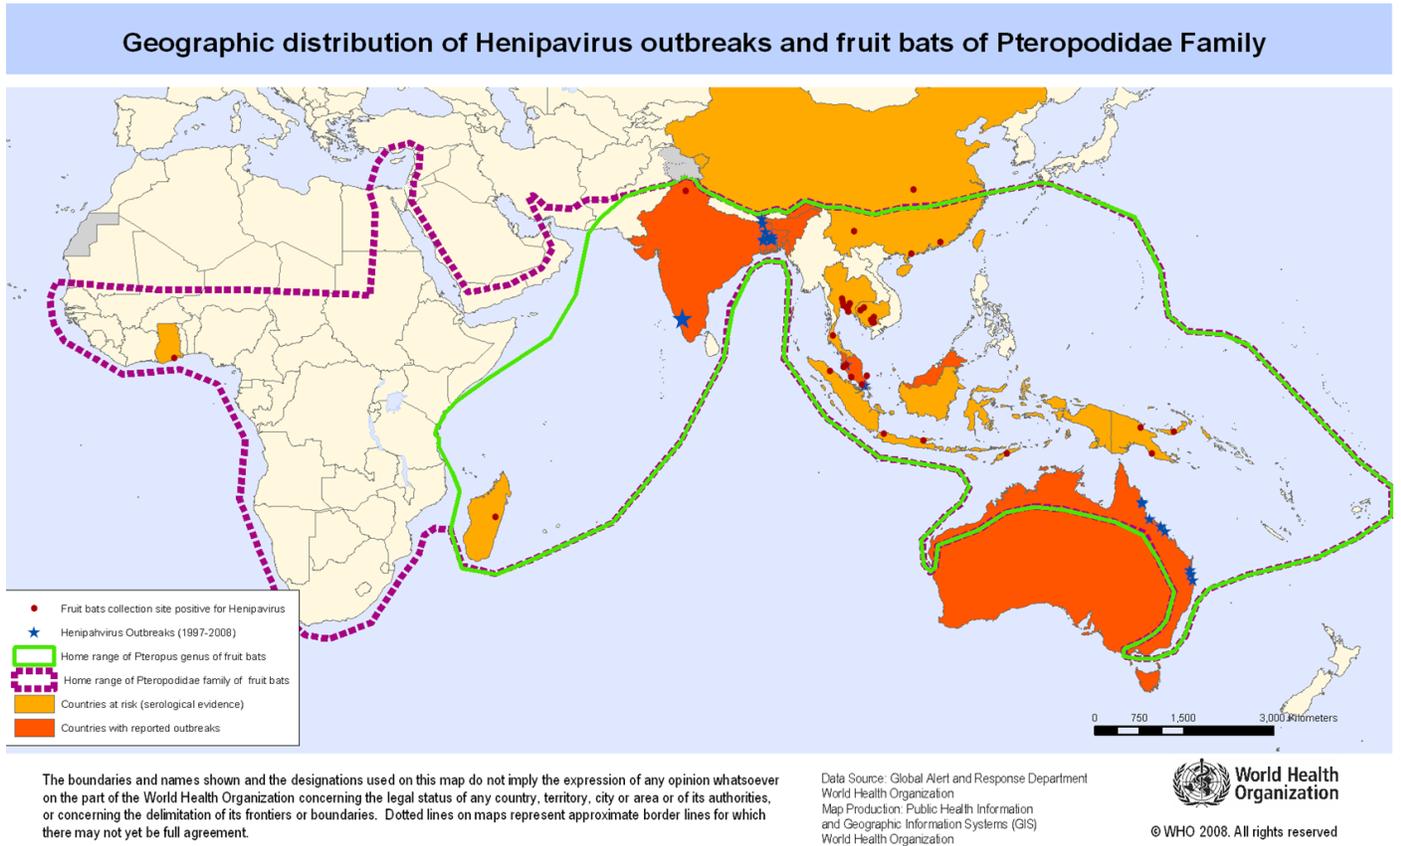

Develop plans for handling disposal of animals infected with a zoonotic agent, including an emergency plan to dispose of infected swine and decontaminate facilities and equipment determined to be infected.

- FAO (Food and Agriculture Organization) – Manual on the Diagnosis of Nipah Virus in Animals:  
Chapter 5: Control and eradication  
<http://www.fao.org/docrep/005/AC449E/ac449e08.htm#bm08>

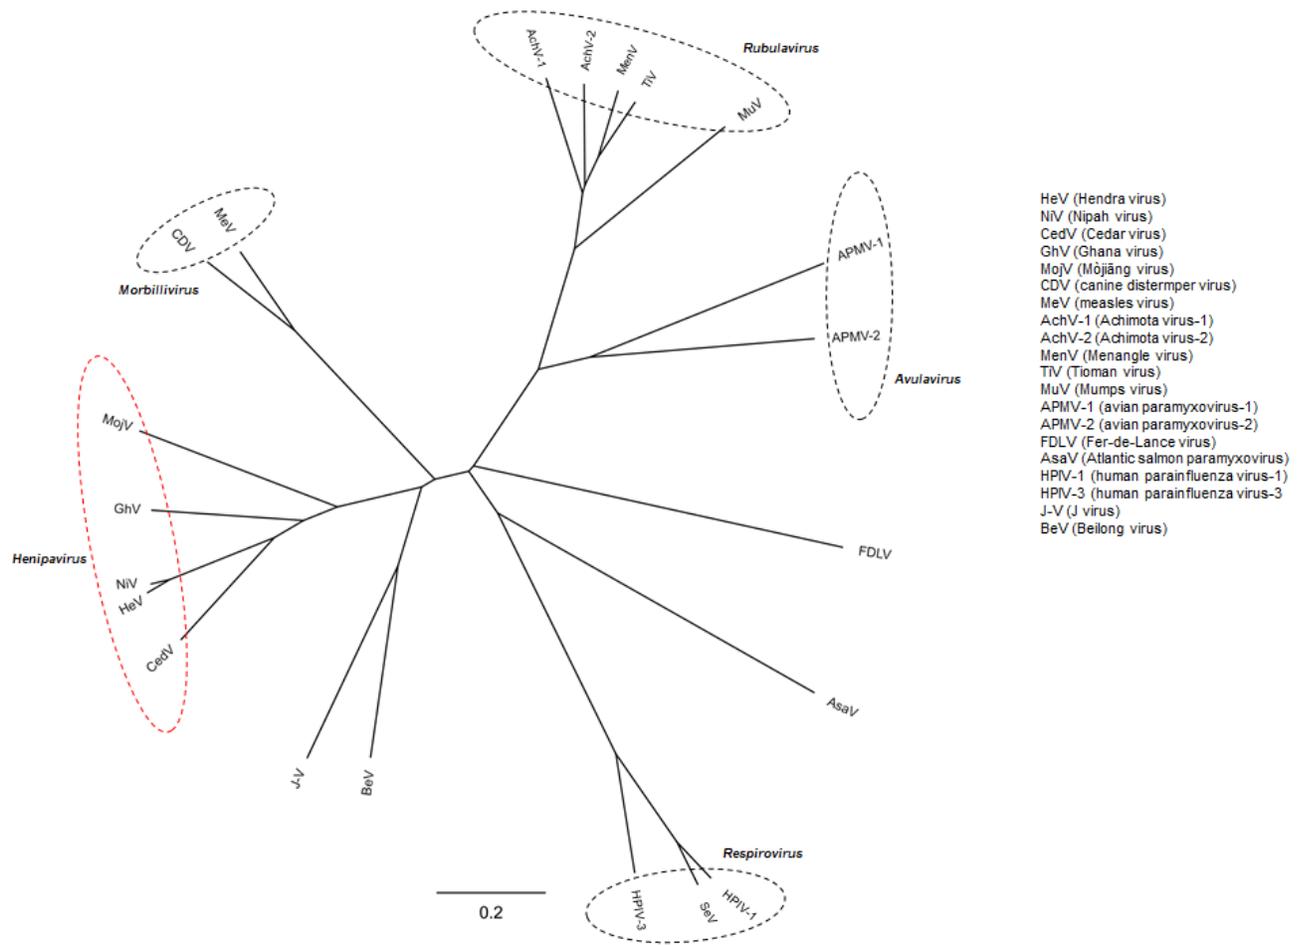

## CONCLUSION

The threat of an outbreak with a henipavirus in the United States due to a natural transmission from a reservoir host is very low since the reservoirs are known to be bats in South East Asia, South Asia, and Asia. However, an outbreak that is not controlled in swine or in people in Asia could result in infection being introduced accidentally into North America or Europe. There is considerable concern that henipaviruses could be used as a weapon of mass destruction (WMD) because they have many of the characteristics of the ideal biological weapon, including causing one of the highest mortality rate in people known for an infectious disease. The possibility of an intentional criminal spread at least in short clusters of terrorist attacks is a distinct possibility, for example by aerosolization in confined public spaces, or through infection of pigs. Surveillance brings challenges and weaknesses of diagnostic methods may impede the early detection of an outbreak in the United States. There are no commercially available diagnostic tests and although laboratory tests are available they have not been field validated. Depopulation is the primary method to eradicate NiV but present very high risks since henipaviruses are BSL-4 zoonotic agents. There are commercially available vaccines for horses, but none for swine and people. Accordingly, the gap analysis working group recommends investing in the research and development of countermeasures and ensure their use and integration in planning for preparedness and future control campaigns. Priority should be given to funding research to improve surveillance, diagnostics, and vaccines. Specific goals include 1) improving diagnostic tests to rapidly identify new disease outbreaks; 2) epidemiological research to better understand virus transmission in wildlife and maintain a passive surveillance program in high risk commercial livestock operations; and 3) develop safe and effective vaccines specifically designed for control and eradication. The United States should stockpile NiV vaccines when they become available for use in contact herds to create a buffer zone as an additional control measure to prevent the spread of henipaviruses should an outbreak ever occur.

## TABLE III – VACCINE PLATFORMS

C.C. Broder et al. / Vaccine 34 (2016) 3525–353

**Table 1**

Advanced active vaccination and passive immunization platforms tested in Hendra virus and/or Nipah virus animal challenge models.

Platform	Viral antigen target or immunogen	Animal challenge model
Active vaccination		
Recombinant vaccinia virus	Nipah F and/or G glycoprotein	Hamster <sup>a</sup> (NiV)
Recombinant canarypox virus	Nipah F and/or G glycoprotein	Pig <sup>b</sup> (NiV)
Recombinant VSV	Nipah F and/or G glycoprotein	Ferret <sup>c</sup> (NiV), Hamster <sup>d</sup> (NiV), nonhuman primate <sup>e</sup> (NiV)
Recombinant AAV	Nipah G glycoprotein	Hamster <sup>f</sup> (NiV, HeV)
Recombinant measles virus	Nipah G glycoprotein	Hamster and nonhuman primate <sup>g</sup> (NiV)
Recombinant subunit	Hendra soluble G glycoprotein	Cat <sup>h</sup> (NiV), Ferret <sup>i</sup> (HeV, NiV), nonhuman primate <sup>j</sup> (HeV, NiV), horse <sup>k</sup> (HeV)
Passive immunization		
Human monoclonal antibody m102.4	Hendra/Nipah G glycoprotein	Ferret <sup>l</sup> (NiV) Nonhuman primate <sup>m</sup> (HeV, NiV)

<sup>a</sup> Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vaccinia viruses were protected against disease following intraperitoneal challenge with  $10^3$  PFU of NiV [137].

<sup>b</sup> Pigs immunized with NiV F and/or G glycoprotein encoding recombinant canarypox viruses were protected against intranasal challenge with  $2.5 \times 10^5$  PFU of NiV [138].

<sup>c</sup> Ferrets immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intranasal challenge with  $5 \times 10^3$  PFU of NiV [141].

<sup>d</sup> Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intraperitoneal challenge with  $10^5$  TCID<sub>50</sub> of NiV [143]; or  $6.8 \times 10^4$  TCID<sub>50</sub> of NiV [142].

<sup>e</sup> African green monkeys immunized with a NiV G encoding recombinant VSV vector were protected against lethal intratracheal challenge with  $10^5$  TCID<sub>50</sub> of NiV [156].

<sup>f</sup> Hamsters immunized with a NiV G encoding recombinant adeno-associated virus (AAV) vector were protected against lethal intraperitoneal with  $10^4$  PFU of NiV [139].

<sup>g</sup> Hamsters and African green monkeys immunized with a NiV G encoding recombinant measles virus vector were protected against lethal intraperitoneal challenge with  $10^3$  TCID<sub>50</sub> of NiV (hamsters) or  $10^5$  TCID<sub>50</sub> of NiV (monkeys) [140].

<sup>h</sup> Hendra virus soluble G glycoprotein (HeV-sG) used to immunize cats protects against lethal subcutaneous ( $500$  TCID<sub>50</sub>) [120] or oronasal ( $5 \times 10^4$  TCID<sub>50</sub>) NiV challenge [145].

<sup>i</sup> HeV-sG used to immunize ferrets protects against lethal oronasal challenge with  $5 \times 10^3$  TCID<sub>50</sub> of HeV [124] or  $5 \times 10^3$  TCID<sub>50</sub> of NiV challenge [146].

<sup>j</sup> HeV-sG used to immunize African green monkeys protects against lethal intratracheal challenge with  $10^5$  TCID<sub>50</sub> of NiV [157] or  $5 \times 10^5$  PFU of HeV [147].

<sup>k</sup> HeV-sG used to immunize horses protects against lethal oronasal challenge with  $2 \times 10^6$  TCID<sub>50</sub> of HeV [15].

<sup>l</sup> A NiV and HeV cross-reactive G glycoprotein specific neutralizing human mAb (m102.4) protects ferrets against lethal oronasal challenge with  $5 \times 10^3$  TCID<sub>50</sub> of NiV [125] or  $5 \times 10^3$  TCID<sub>50</sub> of HeV (J. Pallister and C. Broder, unpublished) by post-exposure infusion.

<sup>m</sup> Human mAb m102.4 protects African green monkeys by post-exposure infusion following lethal intratracheal challenge with  $4 \times 10^5$  TCID<sub>50</sub> of HeV [153] or lethal intratracheal challenge with  $5 \times 10^5$  PFU of NiV [154].

## TABLE IV – CURRENT VACCINE CANDIDATES

B.A. Satterfield et al. / Vaccine 34 (2016) 2971–2975

**Table 1**

Development status of current vaccine candidates.

Candidate name/ identifier: institution	Preclinical	Developers	Ref
<i>Subunit vaccine</i>			
HeV sG	X	Zoetis, Inc./USU	[16,18,34,39]
<i>Vectored vaccines</i>			
VSV-NiV <sub>B</sub> F and/or G	X	UTMB	[17]
VSV-NiV <sub>M</sub> G	X	CDC	[15]
VSV-NiV <sub>M</sub> G	X	RML	[14,19]
VSV-NiV <sub>M</sub> F and/or G	X	Yale University	[40]

# APPENDIX I: COUNTERMEASURES WORKING GROUP INSTRUCTIONS

## *Decision Model*

We will use a decision model to assess potential countermeasures to stockpile. These countermeasures must significantly improve our ability to control and eradicate an outbreak of Nipah virus in a disease-free country. The decision model is a simple tool that will allow us to focus on critical criteria for the National Veterinary Stockpile, and rank the available interventions relative to each other. The decision model is available as a Microsoft Excel spread sheet, which has been prepared to quantitatively assess the rankings we assign to a set of selected criteria that will lead to the selection of the highest cumulative option. We can use as many criteria as we want but the objective is to get down to the ones that will make or break success. The criteria for each intervention will be selected by the Countermeasures Working Group, but a preliminary set has been identified to expedite the process. You are encouraged to review the criteria prior to coming to the meeting and be prepared to modify the criteria as needed with the working group. The following provides an example of criteria and assumptions for assessing vaccines.

## *Criteria*

If a vaccine is going to be used as an emergency outbreak control tool for Nipah virus, then we need to know: 1) is it efficacious (does it effectively eliminate shedding or just reduce shed by a known log scale); 2) does it work rapidly with one dose (probably do not have time for a second dose); 3) whether it is available today from the perspective of having a reliable & rapid manufacturing process (need to know it can be up & running rapidly and will yield a predictable amount of vaccine; 4) can we get the product to the outbreak site rapidly & safely; 5) once at the site, can we get it into the target population rapidly; 6) type of administration- mass or injected, people and equipment to do the job become important); and 7) are diagnostics available to monitor success and or DIVA compliant. While cost is important, the cost of the vaccine in an outbreak will be small in comparison to the other costs. In addition, how fast the product can be made is important because that will have a big impact on how big a stockpile will be needed. Accordingly, you will see from the Excel sheets that have been prepared for vaccines that the following critical criteria and assignment of weights for each criterion are proposed.

<b>Weight</b>	<b>Critical Criteria</b>
10	Efficacy
6	Safety
8	One dose
6	Speed of Scale up
2	Shelf life
2	Distribution/storage
10	Quick Onset of Immunity
8	DIVA Compatible
2	Withdrawal
2	Cost to Implement

## APPENDIX IV - CONTRIBUTORS

**Christopher C. Broder, Ph.D (2009 and 2017)**

Professor and Director, F. Edward Hebert School of Medicine  
Department of Microbiology  
Uniformed Services University *of the Health Services*  
4301 Jones Bridge Rd, Bethesda, MD 20814-4799  
Tel (301) 295-3401  
Fax (301) 295-1545/3773  
Email: [christopher.broder@usuhs.edu](mailto:christopher.broder@usuhs.edu)

**Anne Balkema-Buschman, Ph.D (2017)**

Friedrich-Loeffler-Institut - Federal Research Institute for Animal Health  
Institute of Novel and Emerging Infectious Diseases  
Greifswald - Insel Riems, Germany  
Email: [Anne.Balkema-Buschmann@fli.de](mailto:Anne.Balkema-Buschmann@fli.de)

**Bruce A. Carter, DVM (2017)**

Global Vaccine Manager  
Animal and Plant Health Inspection Service  
Veterinary Services  
Center for Veterinary Biologics  
1920 Dayton Ave.  
Ames, Iowa 50010  
Tel 515 337 6610  
Fax 515 337 6120  
Email: [bruce.a.carter@aphis.usda.gov](mailto:bruce.a.carter@aphis.usda.gov)

**Dr. Paul Chua (2009)**

National Public Health Laboratory  
Ministry of Health Malaysia  
Email: [chuakawbing@yahoo.com.sg](mailto:chuakawbing@yahoo.com.sg)

**Gary Crameri (2009)**

New & Emerging Zoonotic Diseases  
Australian Biosecurity CRC  
CSIRO Australian Animal Health Laboratory Geelong, Australia.  
Tel (03) 5227 5305  
Fax (03) 5227 5555  
Email: [gary.crameri@csiro.au](mailto:gary.crameri@csiro.au)

**Dr. Peter Daniels (2009 and 2017)**

OIE Biological Standards Commission, OFFLU  
Email: [Danielpeter19@gmail.com](mailto:Danielpeter19@gmail.com)

**Dr. Sandra Diederich (2017)**

Friedrich-Loeffler-Institut - Federal Research Institute for Animal Health  
Greifswald - Insel Riems  
Germany  
Email: [Sandra.diederich@fli.de](mailto:Sandra.diederich@fli.de)

**Jon Epstein, DVM, Ph.D (2017)**

EcoHealth Alliance  
New York, NY  
Email: [epstein@ecohealthalliance.org](mailto:epstein@ecohealthalliance.org)

**Dr. Hume Field (2009)**

Principle Veterinary Epidemiologist (Emerging Diseases)  
Biosecurity Sciences Laboratory  
Animal Research Institute  
Department of Primary Industries and Fisheries  
Queensland Government  
665 Fairfield Road, Yeerongpilly Qld 4105  
LMB4 Moorooka Queensland 4105  
Australia  
Tel: +61 (0) 3362 9566  
Fax: +61 (0) 7 3362 9457  
E-mail: [hume.field@dpi.qld.gov.au](mailto:hume.field@dpi.qld.gov.au)  
Website : [www.dpi.qld.gov.au](http://www.dpi.qld.gov.au)

**Pierre B. H. Formenty, DVM (2009)**

Epidemic and Pandemic Alert and Response Department (HSE/EPR)  
World Health Organization (WHO)  
20 Avenue Appia  
CH-1211 Geneva 27 - SWITZERLAND  
Tel: +41 22 791 25 50

**Cyril Gerard Gay, DVM, Ph.D (2009 and 2017, Chair 2009)**

Senior National Program Leader  
Animal Production and Protection  
Office of National Programs, ARS, REE, USDA  
5601 Sunnyside Avenue  
Beltsville, MD 20705  
Tel (301) 504-4786  
Fax (301) 504-5467  
Email: [cyril.gay@ars.usda.gov](mailto:cyril.gay@ars.usda.gov)

**Eric Laing, Ph.D (2018)**

Scientist

Henry M. Jackson Foundation for the Advancement of Military Medicine

Department of Microbiology and Immunology

Uniformed Services University

4301 Jones Bridge Road

Bethesda, MD 20814

(301) 295-9616 (lab)

eric.laing.ctr@usuhs.edu

**Dr. Glenn Marsh (2009 and 2017)**

CSIRO Livestock Industries

Australian Animal Health Laboratory

5 Portarlinton Rd, East Geelong, VIC 3220

Australia

Tel: (03) 5227 5125

Email: [glenn.marsh@csiro.au](mailto:glenn.marsh@csiro.au)

**Steve Luby, MD (2009)**

Agency Head

Centers for Disease Control and Prevention

US Embassy, Bangladesh

Head, Programme on Infectious Diseases and Vaccine Sciences

ICDDR, B

GPO Box 128

Dhaka – 1000, Bangladesh

68, Shaheed Tajuddin Ahmed

Sarani, Mohakhali, Dhaka 1212

Tel: 880-2-9881761 (Direct)

880-2-8860523-32 Ext. 2502

Fax: 880-2-8823963

E-mail: [sluby@icddrb.org](mailto:sluby@icddrb.org)

Website : [www.icddrb.org](http://www.icddrb.org)

**Professor John S. Mackenzie (2009)**

Australian Biosecurity CRC

Curtin University of Technology

GPO Box U1987

Perth, WA6845

Australia

Tel +61-3-9822 6223

Fax +61-8-9266 1650

Email: [J.MacKenzie@curtin.edu.au](mailto:J.MacKenzie@curtin.edu.au)

**Jenn McEachern BSc (2009)**

Research Assistant  
CSIRO Livestock Industries  
Australian Animal Health Laboratory  
5 Portarlinton Rd, East Geelong, VIC 3220  
Tel: (03) 5227 5094  
Email: [jennifer.mceachern@csiro.au](mailto:jennifer.mceachern@csiro.au)

**Deborah Middleton, DVM, Ph.D (2009)**

Transforming Animal Biosecurity  
Australian Animal Health Laboratory  
Common Wealth Scientific and Industrial Research Organisation (CSIRO)  
Geelong, Australia  
Email: [Deborah.middleton@csiro.au](mailto:Deborah.middleton@csiro.au)

**Samia Metwally, DVM, Ph.D (2009)**

Animal Health Officer (Virologist)  
AGAH, AGA Division  
Food and Agriculture Organization of UN  
Viale delle Terme di Caracalla, 00153 Rome, Italy  
Tel: +39 06 570 55838  
Email: [Samia.Metwally@fao.org](mailto:Samia.Metwally@fao.org)  
EMPRES-i: <http://empres-i.fao.org/empres-i/home>  
GLEWS: <http://www.glews.net>

**Dr. Jackie Pallister (2009)**

New & Emerging Zoonotic Diseases  
Australian Biosecurity CRC  
CSIRO Australian Animal Health Laboratory, Geelong, Australia.  
Email: [Jackie.Pallister@csiro.au](mailto:Jackie.Pallister@csiro.au)

**Dr. Brad Pickering (2017)**

National Center for Foreign Animal Disease; Canadian Food Inspection Agency  
Winnipeg, MB, Canada  
Email: [Bradley.Pickering@inspeciton.gc.ca](mailto:Bradley.Pickering@inspeciton.gc.ca)

**Dr. Ashwin A. Raut (2017)**

ICAR-National Institute of High Security Animal Diseases  
OIE Reference Laboratory for Avian Influenza  
Anandnagar, Bhopal, India  
Email: [ashwin.hsadl@gmail.com](mailto:ashwin.hsadl@gmail.com)

**Paul A. Rota, Ph.D (2009)**

Lead Scientist, Measles Team  
Measles, Mumps, Rubella and Herpesviruses Laboratory Branch  
Division of Viral and Rickettsial Diseases  
Centers for Disease Control and Prevention  
MS-C-22, 1600 Clifton Rd  
Atlanta, GA, USA 30333  
Tel 1-404-639-4181 (voicemail)  
Fax 1-404-639-4187  
Email: [par1@cdc.gov](mailto:par1@cdc.gov)

**James A. Roth, DVM, PhD (2009 and 2017)**

Director, Center for Food Security and Public Health  
Executive Director, Institute for International Cooperation in Animal Biologies  
College of Veterinary Medicine Iowa State University Ames, Iowa 50010  
Phone: 515-294-8459  
Fax: 515-294-8259  
Email: [jaroath@iastate.edu](mailto:jaroath@iastate.edu)

**Dr. Ellie Virtue (2009)**

New & Emerging Zoonotic Diseases  
Australian Biosecurity CRC  
CSIRO Australian Animal Health Laboratory, Geelong, Australia.  
Email: [Elena.Virtue@csiro.au](mailto:Elena.Virtue@csiro.au)

**Linfa Wang, Ph.D (2009)**

Senior Principal Research Scientist  
CEO Science Leader  
CSIRO Livestock Industries  
Australian Animal Health Laboratory  
PO Bag 24, Geelong, VIC 3220  
Australia  
Tel (61-3)-52275121  
Fax (61-3)-52275555  
Email: [Linfa.Wang@csiro.au](mailto:Linfa.Wang@csiro.au)

**Hana M. Weingartl, Ph.D (2009 and 2017, Chair 2017)**

Head, Special Pathogens Unit  
National Centre for Foreign Animal Disease  
Canadian Food Inspection Agency  
1015 Arlington St.  
Winnipeg, Manitoba  
R3J 0C2  
Canada  
Tel 204 789 2027  
Email: [hweingartl@inspection.gc.ca](mailto:hweingartl@inspection.gc.ca)

---

Dear Colleagues,

Just a quick note to let you know that our gap analysis report was updated with new information on emerging henipaviruses and detection in bats in new geographical areas of Africa and Asia. Many thanks to Eric Laing and Chris Broder at USUHS for their help in updating the report. The updated report is attached for your use. The reference and URL remain the same:

**To cite this report:**

Henipavirus Gap Analysis Workshop Report. 2018. U.S. Department of Agriculture, Agricultural Research Service, Washington, DC. <http://go.usa.gov/xnHgR>.

Also, you may have seen this already but our report was highlighted in Bat News – see below.

Thanks again everyone for all your help with this report and please send me updates in the future as needed. Next steps will be to share the report with funders of research to support the implementation of the research priorities identified in our report.

Wishing everyone a Merry Christmas, Happy Holidays, and success in 2019!

Best regards,

Cyril

### **Henipavirus Gap Analysis Workshop Report**

Henipavirus Gap Analysis Workshop Report. 2018. U.S. Department of Agriculture, Agricultural Research Service, Washington, DC. <http://go.usa.gov/xnHgR>

“...The United States Department of Agriculture (USDA) organized the first Nipah virus gap analysis workshop in Australia in 2009 with the support of the Australian Animal Health Laboratory (AAHL). The working group was charged by the USDA National Veterinary Stockpile Steering Committee with making recommendations on specific materials, commercially available and in the pipeline, which will ensure the United States has an arsenal of highly efficacious

countermeasures to control and mitigate the impact of an outbreak of Nipah virus. Nipah virus experts representing laboratories in South East Asia, Australia, Canada, and the United States were invited to participate and contributed to this report. The second workshop was organized in 2017 by the Special Pathogens Unit, National Centre for Foreign Animal Disease, Canadian Food Inspection Agency (CFIA)...The participants were charged with assessing available veterinary medical countermeasures to control and respond to a Nipah virus disease outbreak. In addition, the workshop participants agreed to update the gap analysis conducted at the AAHL in Geelong, Australia, in 2009.” Download the report from the [STAR-IDAZ website](#) or at the link above.

## White-nose syndrome

### How to vaccinate a wild bat

22/11/2018 Scientific American [Article](#): “This probably won’t come as a surprise, but vaccinating wild bats is a difficult task. It’s also an important one: many bat populations are now endangered by white-nose syndrome, a serious fungal disease that invades the skin of bats... There’s a vaccine against the fungus, but this requires painstaking capture and manual application of the medicine. It would be far better to administer vaccine to many bats at once, if it were possible to spray the vaccine onto the bats as they enter and exit their dwellings. The vaccine would then be consumed by the animals as they groom the sprayed material from their fur. Which is why the National Wildlife Health Center, a unit of the U.S. Geological Survey, recently partnered with PARC, a Xerox company, to undertake a wildlife protection project in Madison, Wisconsin. The goal is to explore the use of new spraying technologies to treat wild bats with topical vaccines...”

### Groundbreaking science at TRU aims to save bats

29/11/2018 BC Local News [Article](#): “...Fontaine is working with a team of researchers... to stop White-Nose Syndrome (WNS) from decimating the western North American bat populations... They’re using the principle of probiotics — the application of good bacteria — in order to prevent the fungus that causes WNS... The probiotic was developed in Dr. Xu’s lab based on bacteria that Cheeptham and her team discovered on the wings of healthy bats. Lab tests have shown the probiotic is effective at inhibiting the growth of the deadly fungus... Results from this first small-scale study are expected within the next two weeks, and another larger study is expected to begin next spring...”

### Mammoth Cave scientists studying white-nose syndrome

27/11/2018 Glasgow Daily Times [Article](#): “Scientists at Mammoth Cave National Park are taking part in two studies regarding white-nose syndrome, or WNS... The study involves testing bacteria found on bats in caves in New Mexico and Arizona to see if the bacteria has antagonistic effects against WNS... MCNP scientists have been afraid the bacteria that could be used to suppress the growth of WNS could harm cave crickets, cave beetles and other creatures found inside Mammoth Cave, so they have been working with researchers in New Mexico and New York to conduct preliminary tests in petri dishes to see what effect the bacteria might have on cave organisms... The other study MCNP is involved with is using ultra-violet light to see how it might affect cave organisms...”

## What secrets are hidden inside the call of a bat?

20/11/2018 Connecticut Public Radio [Article](#): “The fungal disease white-nose syndrome has killed off millions of bats across America... Now, scientists are trying to learn more about the impact of this devastating disease, by listening to the calls of the bats left behind...”

Winter 2018/2019 bat submission guidelines and updates from the 2017/2018 white-nose syndrome surveillance season [USA]

29/12/2018 USGS National Wildlife Health Center [Article](#): “Updated guidance from the USGS National Wildlife Health Center (NWHC) is now available for bat submissions for the 2018/2019 white-nose syndrome (WNS) surveillance season... Included are reference charts and an updated WNS Management Area map to assist submitters in identifying priority species and collecting appropriate samples for submission to a diagnostic laboratory. These guidelines support surveillance objectives of the WNS National Plan designed to identify new geographic locations and bat species impacted by *Pseudogymnoascus destructans* (*Pd*) and WNS... Surveillance conducted last season documented an expansion in the distribution of *Pd*... and an increase in the number of North American bat species on which the fungus has been detected. Specifically, WNS was confirmed in two new states (Kansas and South Dakota) and two additional Canadian provinces (Manitoba and Newfoundland)... Additionally, *Pd* in absence of clinical signs of WNS was detected on bats from Mississippi, Texas, and Wyoming...” The updated guidelines are available from the [USGS website](#).

For Australian information on WNS including how to identify and report a suspect case of WNS and sample submission guidelines for veterinarians, go to the [Wildlife Health Australia website](#).

## Other news

### Heat stress – media

To report flying-fox heat stress events, fill out the [flying-fox heat-stress data form](#) from the Lab of Animal Ecology, Western Sydney University. For alerts, go to the [Flying-fox Heat Stress Forecaster](#).

A selection of media:

- 30/11/2018 The Guardian [Article](#) **Queensland flying fox species decimated by record heatwave:** “Thousands of threatened flying foxes have dropped dead due to heat stress brought on by extreme temperatures in far north Queensland this week. Conservationists and wildlife volunteers estimate more than 4,000 have perished this week during the record heatwave, which has seen temperatures in Cairns reach all-time highs of 42.6C. The species of flying fox affected is the spectacled flying fox, an endemic Queensland species found in north Queensland. It’s currently listed as vulnerable under national environment laws but conservationists have been pushing to have the species up-listed to endangered because of declines in the population. Volunteer carers that have been counting dead animals and taking orphaned young into care say it is the first time the species has suffered mass deaths because of extreme heat....”
- 28/11/2018 The Australian [Article](#) **Qld heatwave decimates bat population:** “Thousands of heat-stressed bats are dropping from trees and creating a health hazard in far north Queensland, as a record-breaking heatwave blasts the region. About 3500 flying foxes are estimated to have perished since the furnace-like conditions began on Sunday. However, Trish Wimberley of the Australian Bat Clinic says that’s a conservative estimate, with thousands more likely to perish before the heatwave ends...”
- 27/11/2018 Sunshine Coast Daily [Article](#) **Heatwave contributes to rise in bat bites:** “Cairns and Hinterland Hospital and Health Service have advised people to be wary of bats, as the heatwave sends them falling from trees and into biting range... He said some bats may be infected with the potentially deadly Australian bat lyssavirus (ABLV)...”

## **'It's extremely cruel': backyard netting killing, maiming fruit bats**

5/12/2018 Sydney Morning Herald [Article](#): “...Habitats and food sources of the fruit bat, also known as the grey-headed flying fox, have been so heavily encroached by urban sprawl and development, the animals are driven to backyard fruit trees. But the wide-holed nets used by backyard gardeners to protect their fruit trees are killing and maiming the native animals. And babies are dying because their injured, or dead, mothers are not returning to feed them... Wildlife Victoria has already responded to more than 600 bat rescue call-outs this year, with 77 of them being entanglement cases...”

## **Flying foxes detect new invaders**

Biosecurity Queensland [Article](#): “An innovative surveillance project is underway to see if flying fox camps can provide an early warning system for potentially invasive plant species. Biosecurity Queensland, in partnership with the City of Gold Coast and the Queensland Herbarium, are surveying vegetation around flying fox camps to establish an 'early warning surveillance system' for serious new weed species, particularly Miconia and Mexican bean trees... Flying foxes eat the fruit of a variety of plant species and digest seeds through their waste under their overnight camps. If we find high-risk new weeds growing under the camp, we know that the species is growing in gardens or bushland nearby. We can focus our public awareness and on-ground surveillance activity to a specific radius and find it before it has a chance to develop into a major problem...”

## **MSU project to prevent bat-borne diseases wins \$10 million**

## grant

3/12/2018 Montana State University [Article](#): “In an effort to prevent some of the world's most lethal diseases, an international research team spanning five continents and led by Montana State University will study bats in Australia, Bangladesh, Madagascar and Ghana. Raina Plowright, assistant professor in the Department of Microbiology and Immunology in MSU's College of Agriculture and College of Letters and Science, is leading a project to unravel the complex causes of bat-borne viruses that have recently made the jump to humans, causing concern among global health officials. The research team — which includes more than 20 scientists from Johns Hopkins, Cornell, Cambridge, UCLA, Penn State, Rocky Mountain Laboratories in Montana, Griffith University in Australia and five other universities and institutions — is supported by a \$10 million cooperative agreement with the Defense Advanced Research Projects Agency...”

## 'Pest-controlling' bats could help save rainforests

11/12/2018 ScienceDaily [Article](#): “A new study shows that several species of bats are giving Madagascar's rice farmers a vital pest control service by feasting on plagues of insects. And this, a zoologist at the University of Cambridge believes, can ease the financial pressure on farmers to turn forest into fields...”

## Betting on bats for genetic treasures

29/10/2018 Knowable Magazine Article: “Most of us think of bats only when it’s time to decorate for Halloween. But a large group of scientists finds them fascinating all year round — so much so that they’ve launched an ambitious research program, known as the Bat1K Project, to sequence the genomes of every one of the world's 1,300-odd bat species. And the payoffs could be surprisingly high...”

## National Wildlife Biosecurity Guidelines

26/11/2018 WHA [Article](#): “Wildlife Health Australia this week released an unprecedented and valuable resource to help Australians who work with wildlife; the National Wildlife Biosecurity Guidelines... CEO of Wildlife Health Australia, Rupert Woods said: “These new Guidelines draw together the latest information and insights on how wildlife workers in all fields and working across Australia can adopt best-practices in applying biosecurity controls to every aspect of their work. If everyone working with wildlife; from vets to government agencies, students to carers, adopt practices that protect biosecurity, this will be critical to protecting wild animal populations and communities, and Australia’s animal industries from new and emerging diseases.” The guidelines can be downloaded from the [Wildlife Health Australia website](#) (or with this [direct link](#) to the PDF). WHA has also a one-page [information sheet](#).

## National Flying-Fox Forum – Presentations available

The 3<sup>rd</sup> Annual National Flying-Fox Forum was held in Cairns on 8th November 2018. “This Forum follows on from successful events held in 2017 and 2016, bringing together over 100 dedicated individuals from all levels of government, non-government organisations, universities, environmental consultancies and community groups to explore the issues of flying-fox management

and conservation...” Presentations from the forum are now available to download from the [Ecosure website](#).

## Publications

### ***Polychromophilus melanipherus* and haemoplasma infections not associated with clinical signs in southern bent-winged bats (*Miniopterus orianae bassanii*) and eastern bent-winged bats (*Miniopterus orianae oceanensis*)**

Holz PH et al (2018). *Polychromophilus melanipherus* and haemoplasma infections not associated with clinical signs in southern bent-winged bats (*Miniopterus orianae bassanii*) and eastern bent-winged bats (*Miniopterus orianae oceanensis*). *International Journal for Parasitology: Parasites and Wildlife*, 8, 10-18 [Article](#) [Open access]

Abstract: “...The southern bent-winged bat (*Miniopterus orianae bassanii*) is a critically endangered subspecies endemic to south-eastern Australia. As part of a larger study... southern bent-winged bats from several locations in Victoria and South Australia were captured and examined for the presence of the blood parasite, *Polychromophilus melanipherus*, and haemoplasmas (*Mycoplasma* sp.)... Both organisms were found in both subspecies... with no association between the probability of infection, body weight, abnormal blood parameters or any other indicators of ill health. However, Victorian southern bent-winged bats had heavier burdens of *P. melanipherus* than both the South Australian southern bent-winged bats and eastern bent-winged bats. Further investigations are required to determine if these differences are impacting population health.”

### **Alston virus, a novel paramyxovirus isolated from bats causes upper respiratory tract infection in experimentally challenged ferrets**

Johnson RI et al (2018). Alston Virus, a novel paramyxovirus isolated from bats causes upper respiratory tract infection in experimentally challenged ferrets. *Viruses*, 10(12), 675 [Article](#) [Open access]

Abstract: “Multiple viruses with zoonotic potential have been isolated from bats globally. Here we describe the isolation and characterization of a novel paramyxovirus, Alston virus (AlsPV), isolated from urine collected from an Australian pteropid bat colony in Alstonville, New South Wales. Characterization of AlsPV by whole-genome sequencing and analyzing antigenic relatedness revealed it is a rubulavirus that is closely related to parainfluenza virus 5 (PIV5)... Oronasal challenge of ferrets resulted in subclinical upper respiratory tract infection, viral shedding in respiratory secretions, and detection of viral antigen in the olfactory bulb of the brain...”

## **Slow growth and delayed maturation in a Critically Endangered insular flying fox (*Pteropus natalis*)**

Todd CM et al (2018). Slow growth and delayed maturation in a Critically Endangered insular flying fox (*Pteropus natalis*). *Journal of Mammalogy*, 99(6), 1510-1521 [Abstract](#)

Abstract: “Flying foxes (family Pteropodidae) have distinct life histories given their size, characterized by longevity, low reproductive output, and long gestation. However, they tend to decouple the age at which sexual maturity is reached from the age at which they reach adult dimensions. We examined growth, maturation, and reproduction in the Critically Endangered Christmas Island flying fox (*Pteropus natalis*) to determine the timing of sex-specific life cycle events and patterns of growth... Growth and maturation are even slower in *P. natalis* than in the few other *Pteropus* species studied to date. The slow growth and delayed maturation of *P. natalis* imply slower potential population growth rates, further complicating the recovery of this Critically Endangered single-island endemic.”

## **Active and passive surveillance for bat lyssaviruses in Italy revealed serological evidence for their circulation in three bat species**

Leopardi S et al (2018). Active and passive surveillance for bat lyssaviruses in Italy revealed serological evidence for their circulation in three bat species. *Epidemiology & Infection*, doi: 10.1017/S0950268818003072 [Abstract](#) [Open access]

Abstract: “The wide geographical distribution and genetic diversity of bat-associated lyssaviruses (LYSVs) across Europe suggest that similar viruses may also be harboured in Italian insectivorous bats. Indeed, bats were first included within the passive national surveillance programme for rabies in wildlife in the 1980s, while active surveillance has been performed since 2008. The active surveillance strategies implemented allowed us to detect neutralizing antibodies directed towards *European bat 1 lyssavirus* in six out of the nine maternity colonies object of the study across the whole country. Seropositive bats were *Myotis myotis*, *M. blythii* and *Tadarida teniotis*...”

## **Lleida Bat Lyssavirus isolation in *Miniopterus schreibersii* in France**

Picard-Meyer E et al (2018). Lleida Bat Lyssavirus isolation in *Miniopterus schreibersii* in France. *Zoonoses and Public Health*, doi: 10.1111/zph.12535 [Abstract](#)

Abstract: “Bat rabies cases are attributed in Europe to five different Lyssavirus species of 16 recognized Lyssavirus species causing rabies. One of the most genetically divergent Lyssavirus spp. has been detected in a dead *Miniopterus schreibersii* bat in France... The analysis of the complete genome sequence confirmed the presence of Lleida bat lyssavirus (LLEBV) in bats in France with 99.7% of nucleotide identity with the Spanish LLEBV strain (KY006983).”

## **Active sero-survey for European bat lyssavirus type-1 circulation in North African insectivorous bats**

Serra-Cobo J et al (2018). Active sero-survey for European bat lyssavirus type-1 circulation in North African insectivorous bats. *Emerging Microbes & Infections*, 7, 213 [Article](#) [Open access]

Article: "...In Africa, to date, three lyssaviruses have been identified in bats... Little is known about the circulation and distribution of insectivorous bat lyssaviruses in North Africa, as well as the impact such viruses may have on public health... The aim of this study was to assess the potential circulation of European bat lyssaviruses in Northern Africa from 2007 to 2012..."

time. *Nature Ecology & Evolution*, 3, 116-124 [Abstract](#)

Abstract: “The host-associated microbiome affects individual health and behaviour, and may be influenced by local environmental conditions... Here, we investigate longitudinal changes in the fur microbiome of captive and free-living Egyptian fruit bats. We find that, in contrast to patterns described in humans and other mammals, the prominent dynamics is of change over time at the level of the colony as a whole...”

## **Handling stress and sample storage are associated with weaker complement-mediated bactericidal ability in birds but not bats**

Becker D et al (2019). Handling stress and sample storage are associated with weaker complement-mediated bactericidal ability in birds but not bats. *Physiological and Biochemical Zoology*, 92(1), 37-48 [Abstract](#)

Abstract: “Variation in immune defense influences infectious disease dynamics within and among species. Understanding how variation in immunity drives pathogen transmission among species is especially important for animals that are reservoir hosts for zoonotic pathogens. Bats, in particular, have a propensity to host serious viral zoonoses without developing clinical disease themselves. The immunological adaptations that allow bats to host viruses without disease may be related to their adaptations for flight... A number of analyses report greater richness of zoonotic pathogens in bats than in other taxa, such as birds (i.e., mostly volant vertebrates) and rodents (i.e., nonvolant small mammals), but immunological comparisons between bats and these other taxa are rare. To examine interspecific differences in bacterial killing ability (BKA), a functional measure of overall constitutive innate immunity, we use a phylogenetic meta-analysis to compare how BKA responds to the acute stress of capture and to storage time of frozen samples across the orders Aves and Chiroptera...”

## **Mass-culling of a threatened island flying fox species failed to increase fruit growers' profits and revealed gaps to be addressed for effective conservation**

Florens FBV & Baider C (2018). Mass-culling of a threatened island flying fox species failed to increase fruit growers' profits and revealed gaps to be addressed for effective conservation. *Journal for Nature Conservation*, doi: 10.1016/j.jnc.2018.11.008 [Abstract](#)

Abstract: “Human-wildlife conflicts (HWC) pose a growing threat to biodiversity worldwide and solutions can be as sound as the understanding of the HWC itself... In this context, Mauritius implemented what may be the first mass-culls of an already threatened native species when it culled the flying fox (*Pteropus niger*)... We synthesized the best literature available locally and also elsewhere in relevant situations, to critically appraise the setting, nature, timeline of events and outcome of both completed mass-culling campaigns to explore why and how they happened so as to help towards devising better approaches to such conflicts...”

# EXECUTIVE SUMMARY

*Henipavirus* is the taxonomic genus for a group of viruses in the family Paramyxoviridae that includes *Hendra virus* (HeV) and *Nipah virus* (NiV). These viruses are zoonotic agents that are highly pathogenic in humans with case fatality rates of 40% to 70%. As such, these viruses are classified as Biosafety Level 4 (BSL-4) agents, requiring the highest level of laboratory biocontainment. Importantly, they have many of the physical attributes to serve as potential agents of bioterrorism, and are also considered emerging zoonotic pathogens with increasing geographical distribution in Australia, New Caledonia, Southeast Asia, and Madagascar.

Hendra virus first emerged in 1994 in Australia spilling over from bats to horses to humans, causing several disease outbreaks since with significant fatality rates. Nipah virus emerged in Malaysia in 1999, resulting in nearly 300 human cases with over 100 deaths.

The Nipah virus outbreak in Malaysia was especially concerning, causing widespread panic and fear because of the high mortality rate in people and the inability to control the disease initially. There were also considerable social disruptions and tremendous economic loss to an important pig-rearing industry. This highly virulent virus, believed to be introduced into pig farms by fruit bats, spread easily and silently among pigs and was transmitted to humans who came into close contact with infected animals. A NiV outbreak in Bangladesh in 2001 resulted from direct bat to human transmission via contaminated date palm juice with further spread within the human population. From 2001 to 2012, the World Health Organization (WHO) reported a total of 209 cases, with 161 deaths due to of NiV infections. In 2014, the WHO reported a NiV outbreak in fourteen districts of Bangladesh, resulting in 24 cases and 21 deaths. In 2015, three fruit bats tested positive for NiV in New Caledonia at the Noumea National Park, including three bats at the Noumea Zoo.

This gap analysis report focuses primarily on NiV and its potential impact on agricultural swine production. However, information is also provided on the threat henipaviruses pose to public health, both as emerging zoonotic agents and as potential agents of bioterrorism. Included in this report is scientific information on *Henipavirus* virology, epidemiology, pathogenesis, immunology, and an assessment of the available veterinary medical countermeasures to detect, prevent, and control disease outbreaks. Importantly, gaps are provided to inform research needs and priorities. Some of the major gaps and obstacles for disease control can be summarized as follows:

## ***Diagnostics***

The availability of safe laboratory diagnostic tests are limited. Virus isolation and serum neutralization assays require live NiV; thus, BSL-4 containment laboratories are required. Nucleic acid-based assays, such as RT-PCR are available, but genetic variation amongst henipaviruses are reported to impact sensitivity and real time RT-PCR may not be able to detect all divergent and novel henipavirus strains. Serological assays are limited in their ability to differentiate between known and unknown henipaviruses, as cross-reactivity to one or more known viruses is possible. Commercial diagnostic test kits are not available. International standards for NiV assay validation are needed. Gaps include a lack of positive experimental and field samples for test validation (or even evaluation) and there are restrictions on material transfer (e.g., obtaining animal samples that could be used to validate tests) due to biosecurity concerns. Low biosafety level reference sera

against various isolates are not yet available. There is a need for high throughput antibody assays for disease outbreaks, recovery and surveillance purposes. There is also a need to develop operator-safe diagnostics tests and reagents that can be produced in low biocontainment facilities.

### ***Vaccines***

There is currently a commercial vaccine available for horses, but there are no vaccines for swine or humans. There are several experimental vaccine candidates that may be safe and effective in swine and other domestic animals. However, all these vaccine candidates will require further research to establish their efficacy, and they will need to be fully developed to be licensed and stockpiled for rapid use in an emergency disease outbreak in swine.

### ***Surveillance***

Surveillance is the first line of defense against a disease outbreak. Rapid and accurate detection affects the time when control measures can be implemented and affects the extent of the disease outbreak. Because of limitations with laboratory diagnosis, surveillance programs are dependent on the reporting of clinical signs in populations at risk. Diagnosis of NiV infections based on clinical presentation has a low positive predictive value as there are numerous etiologies for encephalitis in humans, and clinical signs in pigs are difficult to differentiate from many common endemic infectious diseases.

### ***Depopulation***

Depopulation is the primary countermeasure to reduce virus shedding and stop the spread of NiV in livestock. Disease outbreaks have shown that the control of NiV in pig populations through stamping out is complex due to the zoonotic nature of the agent. In addition, depopulation may be logistically difficult and may be impossible in a rapidly spreading outbreak in countries where there are pig dense regions with millions of pigs, such as the states of Iowa, North Carolina, and Minnesota in the United States, or South East China.

# INTRODUCTION

Nipah virus (NiV) is an emerging zoonotic virus. First isolated in pigs and people from an outbreak in Malaysia in 1998 (Ang *et al.* 2018), this emerging virus causes severe disease in humans. The source of transmission was determined to be from bats to pigs to humans, through close contact with infected animals. The virus is named after the location where it was first detected in Sungai Nipah, a village in the Malaysian Peninsula where exposed pig farmers became severely ill with encephalitis.

Nipah virus is closely related to another zoonotic virus called Hendra virus (HeV), formerly called Equine *Morbillivirus*, and named after the town where it first appeared in Australia. Hendra virus infection was first recognized in 1994, when it caused an outbreak of acute, fatal respiratory disease that killed 14 horses. Three human cases, leading to two deaths were recorded during the outbreak. The precise mode of virus transmission to the three Australian patients is not fully understood. All three individuals appear to have acquired their infection as a result of close contact with horses, which were ill and later died.

Although members of this group of viruses have only caused a few focal outbreaks, their ability to infect a wide range of animal hosts and to produce a high mortality rate in humans has made this emerging zoonotic viral disease a significant public health threat.

Certain species of bats of the genus *Pteropus* (fruit bats, also called flying foxes) are the principal natural reservoir hosts for NiV and HeV – see Table I. Bats are susceptible to infection with these viruses but do not develop disease. Fruit bats are distributed across an area encompassing Australia, Southeast Asia; including Indonesia, Malaysia, the Philippines and some of the Pacific Islands, the Indian subcontinent, and Madagascar (See Fig. 1). There is also growing evidence that viruses related to NiV and HeV circulate in non-pteropid fruit bats across the globe (Clayton, 2017).

The exact mode of transmission of henipaviruses is uncertain, but appears to require close contact with contaminated tissue or body fluids from infected animals. The role of domestic species other than pigs in transmitting NiV infection to other animals has not yet been determined. In 2014, an outbreak was reported in the Philippines involving the consumption of meat from NiV-infected horses, further expanding the potential routes of transmission for henipaviruses.

Despite frequent contact between fruit bats and humans there is no serological evidence of human infection among persons that are in contact with bats. Pigs were the apparent source of infection among most human cases in the Malaysian outbreak of NiV in 1998-1999. Nipah virus has continued to spillover over from animals with at least six outbreaks resulting in human fatalities in Bangladesh in 2013, one in India in 2014, and two in Bangladesh in 2015. The World Health Organization (WHO) had not reported any NiV cases 2016-2017, but in 2018 fourteen new cases and 12 deaths were reported in Kerala, India - See Table II.

The spread of henipaviruses to new geographical areas is a concern. In 2014, the Philippines reported an outbreak with a zoonotic paramyxovirus in horses and people. There is further evidence for broader distribution of NiV in pteropid fruit bats species. There is also growing evidence that viruses related to NiV and HeV also circulate in non-pteropid fruit bats worldwide.

## BACKGROUND

### ***Organization of the Gap Analysis Working Groups on Nipah Virus (2009 and 2017)***

The United States Department of Agriculture (USDA) organized the first Nipah virus gap analysis workshop in Australia in 2009 with the support of the Australian Animal Health Laboratory (AAHL). The working group was charged by the USDA National Veterinary Stockpile Steering Committee with making recommendations on specific materials, commercially available and in the pipeline, which will ensure the United States has an arsenal of highly efficacious countermeasures to control and mitigate the impact of an outbreak of Nipah virus. Nipah virus experts representing laboratories in South East Asia, Australia, Canada, and the United States were invited to participate and contributed to this report. The second workshop was organized in 2017 by the Special Pathogens Unit, National Centre for Foreign Animal Disease, Canadian Food Inspection Agency (CFIA), in collaboration with BSL4ZNet and DISCONTTOOLS (<http://www.discontools.eu/>). The participants were charged with assessing available veterinary medical countermeasures to control and respond to a Nipah virus disease outbreak. In addition, the workshop participants agreed to update the gap analysis conducted at the AAHL in Geelong, Australia, in 2009.

## DEFINITION OF THE THREAT

The threat for a natural introduction of henipaviruses in the United States is low, but there is significant concern that henipaviruses could be used for nefarious purposes to harm agriculture and people. Both Hendra virus and Nipah virus are on the HHS and USDA list of overlap Select Agents and Toxins. Henipaviruses are listed as APHIS Tier 3 high-consequence foreign animal diseases and pests. Henipaviruses are promiscuous in their ability to cause severe morbidity in several animal species, including people, and human infections result in a very high mortality rate. The mortality rate in pigs is actually reported as about 2.5% in adult pigs – high morbidity, but low mortality. Mortality rates in humans range from 40% (Malaysia) to 75% (up to 100%) in Bangladesh. The animal reservoir includes several species of bats, and henipaviruses may thus be readily available in these wildlife reservoirs.

### ***Infection in people***

Between September 1998 and June 1999, a NiV outbreak in Malaysia resulted in severe viral encephalitis in 105 patients (Goh *et al.*, 2000; Epstein *et al.*, 2006). Ninety-three percent had had direct contact with pigs, usually within two weeks prior to the onset of illness, suggesting that there was direct viral transmission from pigs to humans and a short incubation period. The main presenting features were fever, headache, dizziness, and vomiting. Fifty-two patients (55%) had a reduced level of consciousness and prominent brain-stem dysfunction. Distinctive clinical signs included segmental myoclonus, areflexia and hypotonia, hypertension, and tachycardia. The initial cerebrospinal fluid findings were abnormal in 75% of patients. Antibodies against Hendra virus were detected in serum or cerebrospinal fluid in 76 percent of 83 patients tested. Thirty patients (32%) died after rapid deterioration in their condition. An abnormal doll's-eye reflex and tachycardia were factors associated with a poor prognosis. Death was probably due to severe brain-stem involvement. Neurologic relapse occurred after initially mild disease in three patients. Fifty patients (53%) recovered fully, and 14 (15%) had persistent neurologic deficits.

Unlike Malaysia, the NiV outbreaks in Bangladesh were strictly confined to human populations with significantly higher mortality rate (Hossain *et al.*, 2008). NiV outbreaks in Bangladesh have continued annually since 2008 resulting in a total of 207 reported cases, 152 of which were fatal resulting in a 70% mortality rate (Clayton, 2017).

### ***Infection in pigs***

The NiV outbreak in Malaysia in 1999 was facilitated by the rapid spread of the virus in pig populations. Although some pigs demonstrated a febrile respiratory illness with epistaxis, dyspnoea, and cough, few animals exhibit neurological signs, and the majority of pigs had subclinical infections. There are no clinical signs in pigs that are specific for NiV infection. Both, apparently healthy pigs and pigs showing clinical signs shed significant amount of virus.

### ***Economic impact***

The NiV outbreak in Malaysia in 1999 destroyed the main market for Malaysian hogs in Singapore. The Malaysia outbreak resulted in an 80% drop in pork consumption in the domestic market. Over half the standing pig population in the country was culled to halt the outbreak. Half the pig farms went out of business. The cumulative economic losses based on government figures was estimated to be approximately \$217 million USD.

### ***Bioterrorism***

NiV has many of the physical attributes needed for a biological weapon, including easy access to virus resulting from its wide distribution in nature and laboratories, easy to produce, easy to disseminate, and the potential for high morbidity and mortality in people.

# GAP ANALYSIS

The following section summarizes what we know about henipaviruses, gaps in our knowledge, and the threat of bioterrorism.

## VIROLOGY

The following summarizes our current knowledge of viral strains, taxonomy, reservoir, genome, morphology, determinants of virulence, host range, and tissue tropism.

### Virus species

*Nipah virus* (NiV) was first isolated in 1999 from samples collected during an outbreak of encephalitis and respiratory illness among pig farmers. The name Nipah originated from Sungai Nipah, a village in the Malaysian Peninsula where pig farmers became sick. There are currently two genotypes identified: NiV-Malasia and NiV-Bangladesh. Different strains/genotypes of NiV have emerged: Malaysia, Bangladesh, and Cambodia. NiV Malaysia resulted in the culling of a million pigs and 250 human cases (106 fatal). NiV Bangladesh is associated with outbreaks in people (Clayton, 2017).

*Hendra virus* (HeV) was first isolated in 1994 from specimens obtained during an outbreak of respiratory and neurologic disease in horses and humans in Hendra, a suburb of Brisbane, Australia.

*Cedar virus* (CedPV) is a novel *Henipavirus* isolated from Australian bats, which appears to be non-pathogenic in lab animal experiments (Marsh et al. 2012).

### Taxonomy

NiV and HeV are members of the family Paramyxoviridae, order *Mononegavirales*. Comparison of nucleic acid and deduced amino acid sequences with other members of the family confirms that NiV and HeV are members of the family Paramyxoviridae, but with limited homology with members of the *Morbillivirus*, *Rubulavirus* and *Respirovirus* genera (See Fig. 2). The name *henipavirus* was recommended for the genus of both HeV and NiV (Wang et al., 2000). HeV appear to be less diverse than NiV but molecular epidemiology studies are needed to identify new isolates that may bridge the gap between HeV and NiV.

### Reservoir

The natural reservoir of the henipaviruses are fruit bats mainly from the genus *Pteropus* (flying foxes).

### Genome

The complete genomes of both HeV and NiV have been sequenced (Wang et al., 2001). Henipaviruses have a large non-segmented genome comprised of single-stranded negative-sense RNA. Their genomes are 18.2 kb in size and contain six genes corresponding to six structural proteins. All genes are of similar size to homologues in the respirovirus and morbillivirus genera, with the exception of P which is 100-200 amino acids longer (See Fig. 3). Most of the increase in genome length is due to longer untranslated regions between genes, mainly at the 3' end of each gene. The role of these long untranslated regions are not understood. Henipaviruses employ an unusual process called RNA editing to generate multiple proteins from a single gene. The process involves the

insertion of extra guanosine residues into the P gene mRNA prior to translation. The number of residues added determines whether the P, V or W proteins are synthesized. The C protein is made via an alternative translational initiation mechanism. The functions of the V, W, and C proteins are unknown, but they may be involved in disrupting host antiviral mechanisms (see Immunology below). The function of the G protein is to attach the virus to the surface of a host cell via the major receptor ephrin B2, a highly conserved protein present in many mammals. G glycoprotein is the major neutralizing antigen and the target protein for vaccine development. X-ray crystal structure for NiV G complex with ephrin-B3 has been determined. This interaction is highly conserved between NiV and HeV. This interaction is a prime candidate for developing henipavirus specific therapeutics. The F protein fuses the viral membrane with the host cell membrane, releasing the virion contents into the cell. It also causes infected cells to fuse with neighboring cells to form large multinucleated syncytia.

The genome size and organization of CedPV is very similar to that of HeV and NiV. The nucleocapsid protein displays antigenic cross-reactivity with henipaviruses and CedPV uses the same receptor molecule (ephrin- B2) for entry during infection. Clinical studies with CedPV in *Henipavirus* susceptible laboratory animals confirmed virus replication and production of neutralizing antibodies although clinical disease was not observed. In this context, it is interesting to note that the major genetic difference between CedPV and HeV or NiV lies within the coding strategy of the P gene, which is known to play an important role in evading the host innate immune system. Unlike NiV and HeV, and almost all known paramyxoviruses, the CedPV P gene lacks both RNA editing and also the coding capacity for the highly conserved V protein (Marsh *et al.* 2012).

### Morphology

Henipaviruses are pleomorphic ranging in size from 40 to 600 nm in diameter. They possess a lipid membrane overlying a shell of viral matrix protein. At the core is a single helical strand of genomic RNA tightly bound to the nucleocapsid (N) protein and associated with the large (L) and phosphoprotein (P) proteins, which provide RNA polymerase activity during replication. Embedded within the lipid membrane are spikes of fusion (F) protein trimers and attachment (G) protein tetramers.

### Determinants of virulence, host range, and tissue tropism

Molecular determinants of virulence, host range and cell tropism have been extensively studied and are well understood for many paramyxoviruses. Infectivity is determined by the cell-attachment and fusion glycoproteins and the presence of appropriate P gene products modulate virulence by antagonizing the cellular interferon response.

Henipaviruses have a large host range, unlike other members of the Paramyxoviridae, which generally have a very narrow host range. The cell attachment protein, unlike many other members for the paramyxovirus subfamily, does not have haemagglutinating activity and as a consequence does not bind sialic acid on the surface of cells.

The receptor for henipavirus is present on many different cultured cell types from many different species. The receptors for HeV and NiV are the same and have been identified as ephrin-B2 and ephrin-B3. Ephrin-B2 or -B3 are highly conserved across vertebrate species and are members of a family of receptor tyrosine kinase ligands. Ephrin-B2 is highly expressed on neurons, smooth muscle, arterial endothelial cells and capillaries, which closely parallels the known tissue tropism of

HeV and NiV *in vivo*. Ephrin-B3 is also widely expressed but particularly in specific regions of the central nervous system and may facilitate pathogenesis in certain neural subsets.

#### Virology Research Priorities

- Molecular epidemiology and determinants of strain variation
- Need sequencing of henipaviruses from bats, especially Bangladesh
- Determine molecular basis for virulence

### **PATHOGENESIS**

The following summarizes our current knowledge of viral pathogenesis, including routes of infection, tissue tropism, pathogenesis, clinical signs, and clinical pathology.”\

NiV infections in humans and pigs are linked to contact with bats. Clinical signs in human cases indicate primarily involvement of the central nervous system with 40% of the patients in the Malaysian outbreak having also respiratory syndromes, while in pigs the respiratory system is considered the primary virus target, with only rare involvement of the central nervous system.

#### Humans

The main histopathological findings include a systemic vasculitis with extensive thrombosis and parenchymal necrosis, particularly in the central nervous system (Wong *et al.*, 2002). Endothelial cell damage, necrosis, and syncytial giant cell formation are seen in affected vessels. Characteristic viral inclusions are seen by light and electron microscopy. Immunohistochemistry (IHC) analysis shows the widespread presence of NiV antigens in endothelial and smooth muscle cells of blood vessels (Hooper *et al.*, 2001). Abundant viral antigens are also seen in various parenchymal cells, particularly in neurons. The brain appears to be invaded via the hematogenous route and virus has been isolated from the cerebrospinal fluid of patients with NiV encephalitis (Wong *et al.*, 2002). Infection of endothelial cells and neurons as well as vasculitis and thrombosis seem to be critical to the pathogenesis of this new human disease.

NiV infection can rarely cause a late-onset encephalitis up to a couple of years following a non-encephalitic or asymptomatic infection, or a relapsed encephalitis in patients who had previously recovered from acute encephalitis (Wong *et al.*, 2001; Goh *et al.*, 2000; Tan *et al.*, 2002).

#### Pigs

Experimental challenge studies in piglets conducted at the National Centre for Foreign Animal Diseases, Winnipeg, Canada, demonstrated neurological signs in several inoculated pigs (Weingartl *et al.*, 2005; Berhane *et al.*, 2008; Weingartl, H.M., personal communication of unpublished data). The rest of the pigs remained clinically healthy. NiV was detected in the respiratory system (turbinates, nasopharynx, trachea, bronchus, and lung), the lymphoreticular system (endothelial cells of blood and lymphatic vessels), submandibular and bronchiolar lymph nodes, tonsil, and spleen, with observed necrosis or lymphocyte depletion in lymphoid tissues, most importantly in lymph nodes (Hooper *et al.*, 2001, Weingartl *et al.*, 2006; Berhane *et al.*, 2008). NiV presence was confirmed in the nervous system of both sick and apparently healthy animals (cranial nerves, trigeminal ganglion, brain, and cerebrospinal fluid). No virus was detected urine, although NiV antigen was found in kidneys of field swine cases (Tanimura *et al.*, 2004). This study suggests NiV invaded the porcine host central nervous

system via cranial nerves after initial virus replication in the upper respiratory tract, and later in the infection also by crossing the blood-brain barrier as a result of viremia. Additional information on NiV and HeV pathogenesis in pigs are summarized in Middleton and Weingartl, 2012.

### Dogs

Middleton *et al.*, 2017, conducted experimental infections with HeV in dogs and determined that the virus is not highly pathogenic in dogs but their oral secretions pose a potential transmission risk to people. The time window for potential oral transmission corresponded to the period of acute infection.

### Bats

*Pteropus* spp. fruit bats have been identified as the reservoir hosts for henipaviruses. Henipaviruses have been isolated to date in bats from Australia (HeV), Asia (NiV), and recently serological evidence of infection in bats in Madagascar (Hayman D.T.S., *et al.*, 2008). Related henipaviruses have been detected serologically and by PCR in non-*Pteropus*, but related pteropodid bats in Central and West Africa, and in insectivorous bats in China, expanding the host and geographical range beyond *Pteropus*.

There is no significant pathology in bats, and the frequency of viral shedding from wild bats is rare, with prevalence ranging from (1%-3%) with temporal variation of infection and viral shedding observed among different bat populations (Gurley *et al.*, 2017 and Wacharapulsadee *et al.* 2010, 2016). Henipavirus isolation from bat excreta is challenging, potentially due to low viral load.

### Pathogenesis Research Priorities

- Identify determinants of virulence in pigs
- Develop experimental infection models in bats to study shedding
- Comparative genomic studies of contemporaneous NiV strains collected from bats and humans during outbreaks.
- Expand knowledge of spectrum of henipaviruses in bat hosts in NiV hotspots (e.g. western Bangladesh & West Bengal India)
- Determine whether the innate immune system in bats is responsible for limiting viral replication
- Determine how the net reproductive value of henipaviruses are sustained in bats
- Determine how transmission effected within bats, and between bats and other species

## **IMMUNOLOGY**

The following summarizes our current knowledge of NIV immunology, including innate and adaptive immune responses to wild-type virus, immune evasion mechanisms, and protective immunity.

### Innate and adaptive immune responses to wild-type NiV

Viral RNA can be detected by both cytoplasmic and endosomal pattern recognition receptors (PRRs), resulting in innate immune Type I IFN induction/ and signaling pathways:

- Retinoic Acid-inducible Gene I (RIG- I)- recognizes 5' triphosphorylated RNA
- Melanoma Differentiation Antigen 5 (Mda-5)-recognizes cytosolic dsRNA
- RNA-dependent Protein Kinase (PKR)- recognizes cytosolic dsRNA

- Toll-like Receptor (TLR) 3- recognizes endosomal dsRNA
- TLR 7-8- recognizes endosomal ssRNA

### Immune evasion mechanisms

The NiV uses unusual processes called RNA editing and internal translational initiation to generate multiple proteins from the phosphoprotein (P) gene, resulting in 4 proteins (P, C, V, and W) that function in inhibiting Type I interferon pathways:

- NiV P, V, and W have individually been shown to bind STAT1 and STAT2, effectively preventing STAT1 phosphorylation in type I IFN-stimulated cells.
- The V protein localizes to the cytoplasm, while the W protein localizes to the nucleus.
- The C protein can partially rescue replication of an IFN-sensitive virus, but the mechanism is unknown.
- Nuclear localization of W enables it to inhibit both dsRNA and TLR 3 (IRF-3 dependent) IFN- $\beta$  induction pathways.
- A single point mutation in the V protein abrogates its ability to inhibit of IFN signaling.
- The V proteins of paramyxoviruses interact with the intracellular helicase Mda-5, and inhibits its IFN- $\beta$  induction, but not with RIG-I.
- NiV V, W, and P bind polo-like kinase (PLK) via the STAT1 binding domain (Ludlow *et al.*, 2008).
- The P, V, and W proteins of NiV Malaysia and NiV Bangladesh inhibit IFN-stimulated response element (ISRE), which have a role in inducing transcription of IFN-stimulated genes (ISGs). Some of these ISGs include IRF-7, 2'5' Oligoadenylate Synthetase (OAS), RnaseL, p56, and double-stranded RNA-induced protein kinase (PKR). These ISGs all contribute to the generation of an 'antiviral state' in the cell.

### Protective immunity

The G and F protein induce neutralizing antibodies that protect against challenge. Recent evidence from vaccination challenge studies indicates that both serum neutralizing antibody and T cell-mediated immunity are needed for protection from Nipah virus infection in pigs (Protection against henipaviruses in swine requires both, cell-mediated and humoral immune response, B.S. Pickering, J.M. Hardham, G. Smith, E.T. Weingartl, P.J. Dominowski, D.L. Foss, D. Mwangi, C.C. Broder, J.A. Roth, H.M. Weingartl, Vaccine 34(40): 4777-4786, 2016

### Research needs

- Innate immunity and immunosuppression
  - Need studies in NiV infected cells and animal models
  - Need to study infection in various cell types, including cells of the immune system and bat cells
  - Use infectious clone to study virulence determinants
  - Identify targets for antiviral agents
  - Cytokine response to infection in human and bat cell lines
  - Need to study the potential for type 1 interferon or other cytokines to provide early protection from Nipah virus infection, transmission and/or clinical signs.

- Protective Immunity
  - Need to better define correlates of protection
  - Study T lymphocyte subset responses and cellular targets (e.g., N)

## EPIDEMIOLOGY

Certain species of fruit bats of the genus *Pteropus* are the principal natural reservoir hosts for NiV and HeV (see Table I). Bats are susceptible to infection with these viruses but do not develop disease. Other zoonotic viruses like Ebola, Marburg, and SARS virus, have also been identified in various *Pteropus* spp. fruit bats (Angeletti et al., 2016). Fruit bats are distributed across an area encompassing Australia, Southeast Asia; including Indonesia, Malaysia, the Philippines and some of the Pacific Islands, the Indian subcontinent, and Madagascar (See Fig. 1). There is further evidence for broader distribution of NiV in pteropid fruit bats species across their range (Wacharapluesadee S. and Hemachudha T., 2007). There is also growing evidence that viruses related to NiV and HeV also circulate in non-pteropid fruit bats worldwide.

### ***Hendra Virus***

Hendra virus infection was first recognized in 1994 in Australia, when it caused an outbreak of acute, fatal respiratory disease that killed 14 horses. Three human cases, leading to two deaths were recorded during the outbreak. In 1995, a horse was infected with associated human cases. The precise mode of virus transmission to the three Australian patients is not fully understood. All three individuals appear to have acquired their infection as a result of close contact with horses, which were ill and later died.

There have been several recognized outbreaks in Australia since 1994. Hendra virus reemerged in 1999, 2004, and 2006-2010. All known HeV cases have occurred in Queensland or northern New South Wales. From 1994 to 2010, HeV was confirmed on 11 premises in Queensland and one premise in northern New South Wales. In Australia, GlobalincidentMap.com reported: 21 cases in 2011; 12 cases in 2012; 10 cases in 2013; four cases in 2014; three cases in 2015; one case in 2016; and four cases in 2017. All cases have involved horses as an intermediate host along with some additional human infections, resulting in several fatalities. The Australian Veterinary Association's national president, Dr. Ben Gardiner, was quoted as stating "no state or territory was immune from the virus."

The natural reservoirs for HeV are flying foxes found in Australia. Bats are susceptible to infection with these viruses but do not develop disease.

Hendra virus infection has also been detected in two dogs that were in close contact with infected horses. Both dogs remained clinically normal with no history of related illness.

Updated statistics on HeV outbreaks, including locations, dates and confirmed human and animal cases may be found on the [Australian Veterinary Association website](#) (Assessed July 22, 2018).

### ***Nipah Virus***

Nipah virus is a recently-recognized, zoonotic paramyxovirus that causes severe disease and high fatality rates in people. Outbreaks have occurred in Malaysia, Singapore, India and Bangladesh, and a putative Nipah virus was also recently associated with human disease in the Philippines (Clayton,

2017). The following summarizes our current knowledge of NiV epidemiology taking into account disease outbreaks in Malaysia and Bangladesh.

### Malaysia

Nipah virus was first described in 1999 in Malaysia. The outbreak in Malaysia resulted in over a million pigs culled, 800 pig farms demolished, 36,000 jobs lost, \$120+ million exports lost, and over 300 human cases (106 fatal, ~35% mortality) in pig farmers (Chinese) and Singapore abattoir workers (Field *et al.*, 2001). The NiV outbreak in pigs was described as highly infectious, frequently asymptomatic, low mortality rate (~5%), with respiratory and neurological syndromes. The pig farm pattern of disease included 30% morbidity and 5% mortality with sows first affected, followed by weaners, growers and finishers. The duration of clinical disease on a farm lasted ~ 2 weeks with a sero-prevalence approaching 100% in some cases. The outbreak in Malaysian pigs was associated with an increased incidence of human viral encephalitis cases, strongly associated with pig farm workers, with temporal and spatial links to disease in pigs.

During the outbreak, evidence of NiV infection was found in domestic animals such as goats and cats, but especially dogs (Field *et al.*, 2001). After pig populations were destroyed, but before residents were allowed to return to their homes, studies were undertaken in the epidemic area to determine whether domestic animal populations maintained active infection in the absence of infected pigs (Mills *et al.*, 2009). Dogs were especially suspected because they live commensally with both pigs and humans. However, serologic screening showed that in the absence of infected pigs, dogs were not a secondary reservoir for NiV.

Although human-to-human transmission of NiV during the 1998-1999 outbreak in Malaysia was not reported, a small number of infected people had no history of contact with pigs, suggesting human-to-human transmission occurred in these cases (Clayton, 2017).

The reservoir and natural host of NiV was determined to be fruit bats. Fruit bats have a wide geographic distribution, high antibody prevalence (17-30%), but no apparent clinical disease. A NiV neutralizing antibody study (Yob *et al.*, 2001) from 237 wild-caught bats surveyed on Peninsular Malaysia April 1–May 7, 1999, found four different species of fruit bats, and one species of insectivorous bats, tested positive for NiV (see Table I).

The routes of NiV excretion in bats include urine, saliva, and foetal tissues and fluids but the exact modes of transmission have yet to be determined.

The drivers of the emergence of NiV in Malaysia were determined to be large piggery (30,000+) adjacent to primary forest/fruit bat habitat and a network of other large farms close by. The stages of emergence associated with the outbreak included a spillover from flying foxes to domestic pigs near Ipoh (see Fig. 4), where farming practices and high pig densities facilitated the dissemination of the infection. Transportation of pigs for commerce led to the southern spread of the outbreak with the amplifying pig host facilitating the transmission of the virus to humans.

The epidemic enhancement of the outbreak included the initial introduction of infection in a naive pig population resulting in a rapid epidemic peak, followed by burn-out and localized human infections. Subsequent introduction(s) into partially immune pig populations resulted in a lower epidemic peak

but prolonged duration and increased total number of infectious pigs, increasing the chances of spread to surrounding farms.

### Bangladesh

Bangladesh experienced its first reported NiV outbreak in Siliguri and Naogaon in 2001 (Fig. 5). Unlike Malaysia, outbreaks in Bangladesh appeared to be strictly confined to human populations and significantly higher mortality rate. From 2001 to 2018, the WHO reported a total of 261 cases, with 198 deaths (76% mortality) due to NiV infection (see Table II).

The transmission of NiV to humans in Bangladesh was determined to be associated with drinking date palm juice, considered a delicacy in this region of the world. In the Tangail outbreak of 2005, it was estimated that persons drinking raw date palm sap had a 7.0 odds ratio of developing a NiV infection when compared to controls (95% confidence level, 1.6).

NiV cases in Bangladesh have been seasonal, with human cases reported between the months of January and April. This coincides with the season for collecting date palm sap, late November through April. However, there is significant heterogeneity in the number of spillovers detected by district and year that remains unexplained. Cortes et al., in 2018 analyzed data from all 57 spillovers occurring during 2007–2013 and found that temperature differences explained 36% of the year-to-year variation in the total number of spillovers each winter, and that distance to surveillance hospitals explained 45% of spatial heterogeneity. January, when 40% of the spillover events occurred, was the month with the lowest mean temperature during every year of the study.

Bats are recognized as a nuisance and frequently drink the juice, defecate into juice, and occasionally drown in the palm sap collecting pot. Measures have been put in place to prevent bats access to the sap collecting pot, which has been very effective in reducing the spread of NiV from bats to humans in Bangladesh.

### India

In 2001, an outbreak occurred within a hospital in Siliguri, West Bengal. Nosocomial transmission likely occurred, though it is unknown how primary cases were infected. Another outbreak in 2007 was reported in Nadia, West Bengal. Consumption of date palm sap was identified as the likely route of infection of primary cases there. In May of 2018, another outbreak was reported in Kerala. A total of 85 cases were reported in these three outbreaks in 2001, 2007, and 2018, with 62 deaths (73% mortality) due to NiV infection (see Table II).

In 2012, Yadav et al. surveyed the Indian states of Maharashtra and West Bengal to evaluate the presence of viral RNA and IgG against NiV in different bat populations belonging to the species *Pteropus giganteus*, *Cynopterus sphinx* and *Megaderma lyra*. The authors found NiV RNA in *Pteropus* bat thus suggesting it may be a reservoir for NiV in India.

### Philippines

In 2014, the Philippines reported an outbreak with a zoonotic paramyxovirus in horses and people that is very closely related to NiV based on sequence analysis. Virus isolation was unsuccessful so it was impossible to confirm that there was transmission from presumably bats to horses, from horses to people, and also human to human (Ching P.K., et al., 2015; Clayton, 2017).

### New Caledonia

In 2015, three fruit bats tested positive for NiV in New Caledonia at the Noumea National Park, including three bats at the Noumea Zoo.

### Research needs

- Improved understanding of infection dynamics in flying foxes: modes of transmission, immune response, evidence of disease, and the implications of co-infection with NiV and other henipaviruses
- Better understanding of co-circulation of different strains / species of henipaviruses within Pteropus populations and the effect of waning herd immunity on outbreaks.
- Other animals such as infected dogs and cats need to be further studied to determine their potential role in the transmission of NiH .
- Improved understanding of infection dynamics in humans: modes of transmission, implications of genetic diversity of the virus for infection, transmission & pathogenicity
- Research into bat populations: additional research regarding bat distributions & ecological impacts
- Research aimed at improving the capacity to diagnose henipavirus infections and improve human health outcomes
- Research into infection and clinical signs in pigs in Bangladesh and potential for pig to human and human to pig transmission.

## **BIOTERRORISM**

The following summarizes the rationale for considering NiV as a potential agent of bioterrorism.

NiV is classified by CDC as a Category C pathogen – emerging pathogens that could be engineered for mass dissemination in the future. Category C include pathogens are readily available, easy to produce, easy to disseminate, and have the potential for high morbidity and mortality with major health impact.

NiV has many of the physical attributes to serve as a potential agent of bioterrorism. The outbreak in Malaysia caused widespread panic and fear because of its high mortality and the inability to control the disease initially. There were considerable social disruptions and tremendous economic loss to an important pig-rearing industry. This highly virulent virus, believed to be introduced into pig farms by fruit bats, spread easily among pigs and was transmitted to humans who came into close contact with infected animals. From pigs, the virus was also transmitted to other animals such as dogs, cats, and horses.

## Nipah Virus Bioterrorism Threat Assessment

### **Virology**

- Reverse genetic methods are available for negative strand RNA viruses, including Nipah, and all genomic sequence data is available.
- Many laboratories are actively engaged in research programs on the cell biological properties of the henipaviruses.
- Virus can be amplified to reasonably high unconcentrated titers ( $>10^7$ ). Several cell culture lines can be used, Vero cell use most often reported, and wild-type virus can be grown and harvested from cell cultures.
- A major constraint in handling Nipah is the requirement for BSL4 facilities; , however, potential terrorists may not respect this need.
- Inactivation of virus can be achieved with a variety of agents typically used for envelope viruses; but extensive environmental stability testing not reported.
- Vaccines and passively-delivered countermeasures are under development both for human and veterinary use. A commercial Hendra virus vaccine is available for horses, and the soluble G protein based vaccine has shown experimental efficacy against Nipah virus in nonhuman primates.
- Bats are sold (often live) in markets throughout their range, providing a potential source of virus; and serological tests are available for identifying henipaviruses

### **Economic Impact**

- Destroyed the main market for Malaysian hogs in Singapore
- ~80% drop in pork consumption in the domestic market.
- Over half the standing pig population in the country was culled to halt the outbreak.
- Half the pig farms went out of business.
- During the outbreak cumulative economic losses based on government figures  $> \$217$  million USD.
- Cumulative government costs in operations and lost revenues  $> \$298$  million USD.
- Other countries in South East Asia often have a higher pig density than Malaysia. China, with approximately half of the pigs in the world, is especially vulnerable to an economic and public health disaster if NiV were to emerge and be rapidly transmitted between pigs and from pigs to people.

### **Epidemiology and Clinical Disease**

- In outbreaks to date henipaviruses do not appear to be highly infectious. Infection requires close contact with secretions of diseased animals. Many infections can be mild to asymptomatic.
- In the initial 1998-99 outbreak the virus was *initially misdiagnosed* as Japanese Encephalitis; amplification occurred from veterinary reuse of needles in immunization programs to control JE, increasing outbreak severity and extent.
- Time from exposure to signs of infection averages ~2 weeks for humans and seroconversion occurs within a month of onset (dose / route dependent).
- Transmission directly to the vascular system could occur through bites from infected animals or broken skin exposed to secretions of infected animals.

- It is quite likely that an outbreak in animals would result in transmissions to humans.
- An outbreak of Nipah pneumonia or ARDs-like disease with human-to-human transmission as demonstrated in the Bangladesh outbreak could cause significant mortality. Nipah could cause more severe or different disease presentations in older or sick populations.

### **Viral Transmission**

- Deliberate release of virus in some manner is possible.
- Aerosol delivery might transmit the disease effectively to domestic animals, but the environmental requirements for maintaining virus stability are not well known.
- Transmission to humans through consumption of contaminated food has been documented.
- The veterinary reuse of needles in the Japanese Encephalitis immunization campaign and in artificial insemination may have been a factor in the near 100% infection level of Nipah in pigs observed on affected farms.
- Deliberate contamination of veterinary needles could initiate an outbreak in susceptible domestic animals.
- Human-to-human transmission through travel has not been documented, but is possible.
- Transport of infected pigs on trucks was a transmission route in the Malaysian outbreak. Generalizing-- transportation of infected humans on crowded airplanes, buses or trains could also transmit the disease. Human cases have been transported to highly populous cities (e.g. Dhaka) where risk of exposure and spread among the public is increased.

### **Summary**

- Nipah (henipaviruses) can be isolated from animal hosts.
- Several species of fruit bats, including *Pteropus spp.* widely distributed throughout Southeast Asia. The live animals are sold in food markets.
- A Nipah outbreak in swine producing areas can cause an economic crisis, even if human cases do not occur.
- Nipah virus can be amplified in permissive cell cultures (e.g., Vero cells) providing adequate laboratory facilities are available (Biosafety Level 4), although a bioterrorist group would not be restricted from growing the virus because of the lack of BSL-4 facilities.
- Effective aerosol delivery is likely possible but unpredictable on the basis of publicly available information. General unknowns are-- titers necessary for infection, virion stability in vitro, and how infectious the virus would be with this delivery.
- Effective surveillance programs, particularly in pig farming areas, are the best defense for early detection and containment of infection, whatever the source.

## **SUMMARY OF OBSTACLES TO PREVENTION AND CONTROL**

The 2017 gap analysis working group determined that the following countermeasures were important but several weaknesses were identified.

### **DIAGNOSIS**

NiV and HeV are zoonotic paramyxoviruses capable of causing severe disease in humans and animals. These viruses require biosafety level 4 (BSL-4) containment. The availability of safe laboratory diagnostic tests is limited. Sequence variation affects molecular diagnostics; both Clifton Beach (2007) and Redlands (2008) reported that Hendra virus strains failed in AAHL Hendra virus specific real-time PCR. Most published diagnostic PCRs only detect HeV or NiV, but not both. There is a need for a more general PCR to detect divergent and novel strains. Pan-paramyxovirus PCR assays exist and are in use to detect henipaviruses, but limitations in sensitivity limit diagnostic value. The USAID PREDICT program previously used its pan-paramyxovirus PCR assay for surveillance in more than 20 countries in Africa and Asia. Virus isolation and serum neutralization assays require live NiV. There is a need for diagnostics that can be used safely in the laboratory. There is a need for rapid nucleic acid-based assays that can detect all henipaviruses. There is also a critical need for improved antibody-based assays for disease outbreaks and disease surveillance. Importantly, there is a need to develop operator-safe diagnostic tests for which reagents can be produced without requiring high containment facilities.

Currently there is no expectation that validated tests will become available for livestock (or other species) in the near future. Nothing has been done in terms of test harmonization since 2009; however, a number of technology transfers have occurred: from AAHL to laboratories in Asia (Malaysia mainly); limited transfer from NCFAD to India (Bhopal High Containment Animal Health Laboratory); limited transfer from AAHL to the FLI and bilateral transfers between NCFAD and FLI.

### **VACCINATION**

There is currently a commercially available vaccine for horses but no vaccines for swine or human vaccines. The goal for a HeV vaccine for horses is to vaccinate horses in areas at risk for transmission from bats to horses in order to prevent bat to horse transmission and subsequent horse to human transmission. The goal for a NiV vaccine for swine is to have a large stockpile of vaccine available for rapid use in an outbreak situation to prevent swine to swine, swine to human, and perhaps human to swine transmission to control the outbreak. A large stockpile of NiV vaccine, or vaccine antigen concentrate, for rapid emergency use in swine to control a potential outbreak that spreads too quickly to be stamped out in swine dense areas is needed. The vaccine should be licensed in the U.S., E.U or Australia for stockpiling as well as in the countries where NiV is endemic in bats. The stockpile should be available for use internationally where ever it may be needed.

### **SURVEILLANCE**

Passive surveillance is the primary and most economical method used. Passive surveillance in commercial swine herds based on clinical signs has many weaknesses due to the difficulty of differentiating NiV from many common endemic infectious diseases of pigs; e.g., classical swine

fever, porcine reproductive and respiratory syndrome, pseudorabies, swine enzootic pneumoniae, and porcine pleuropneumonia.

In the case of infections in swine where recognition of Nipah symptoms is less likely, surveillance activities must be based on diagnostic testing to supplement surveillance based on clinical signs.

Active surveillance programs are expensive and would have to rely on direct diagnostic tests such as viral isolation and nucleic acid-based assays but available tests have significant weaknesses and have not been validated.

Rapid confirmation of cases is essential. Knowledge on serological cross-reactions with other henipaviruses and/or morbilliviruses in bats is improving. There is an urgent need to establish diagnostic capacity for Nipah virus in countries that are most likely to experience spillovers from the bat reservoirs.

## **DEPOPULATION**

Depopulation is the primary countermeasure to reduce virus shedding and stop the spread of Nipah virus in swine. Recent outbreaks have shown that the control of Nipah virus in pig populations through stamping out is complex due to the zoonotic nature of the agent and may be very expensive, particularly in areas with high pig densities. Because Nipah virus spreads rapidly and silently in pigs, a large number of animals would need to be pre-emptively culled if an outbreak occurred in the U.S, or in other swine dense countries in order to minimize the virus spread in the vicinity of infected herds. Thus, this method of control would have significant financial implications due to the culling of thousands or millions of animals.

# COUNTERMEASURES ASSESSMENT

## ASSUMPTIONS

The following captures assumptions made by the gap analysis working group to assess potential countermeasures to enhance our ability to contain and eradicate an outbreak of NiV.

### *Situation*

Countermeasures assessed for worst case scenario: A coordinated intentional distribution of NiV-contaminated material in a high density highly populated pig region of the United States.

### *Target Population*

Countermeasures assessed for target pig production segments in priority order:

1. Backyard pigs
2. Comprehensive commercial swine operations (farrowing, nursery, and finishing)
3. Commercial indoor farrowing operations
4. Large intensive indoor pig farms
5. Valuable commercial genetic swine stock

### *Scope of Outbreak*

Countermeasures assessed for multiple outbreaks occurring simultaneously in backyard pigs, three farrowing commercial operations, a finishing pig commercial operation, a sow replacement operation, and evidence of infection in feral swine.

## DECISION MODEL

The quantitative Kemper-Trego (KT) decision model was used to assess available vaccines and diagnostics. For the criteria and weights used to assess NiV vaccines and diagnostics (See Appendices II, III).

### *Criteria*

The following critical criteria were selected to enable the comparison of countermeasures using a pertinent and valid analysis, as follows:

#### Vaccines

- Efficacy
- Safety
- One dose
- Manufacturing safety
- DIVA compatible
- Manufacturing yield
- Rapid production
- Reasonable cost
- Short withdrawal period

- Long shelf life

#### Diagnostics

- Sensitivity
- Specificity
- DIVA detection
- Multispecies
- Validation to purpose
- Speed of scale-up
- Throughput
- Pen-side test
- Rapid result
- No need for a confirmatory test
- Easy to perform
- Safe to operate
- Availability
- Storage/Distribution
- Low cost to implement
- Perform at BSL-2
- Does not require use of live virus to prepare reagents

#### ***Weight***

Each criterion was weighted to allow a quantitative comparison of the impact of the selected interventions (See Appendices II and III).

#### ***Product profile***

To ensure a consistent and meaningful assessment, the desired product profile (i.e., the benchmark) was identified for each countermeasure:

#### Desired Vaccine Profile

1. Highly efficacious: prevent transmission; efficacy in all age animal target hosts, including maternal antibody override; cross protection across all henipavirus strains; quick onset of immunity; multiple animal target hosts; one year duration of immunity
2. Safe in all age animal target hosts; no reversion to virulence for live vaccines
3. One dose
4. Safe vaccine strain for manufacturing
4. DIVA compatible
5. Manufacturing method yields high number of doses
6. Rapid speed of production and scale-up
7. Reasonable cost
8. Short withdrawal period for food consumption
9. Long shelf life

#### Desired Diagnostic Test Profile

1. Detect all henipavirus
2. Identify Nipah virus specific strains
3. Direct tests for control and eradication
4. Indirect tests for post-control monitoring
5. Rapid test
6. >95% specificity
7. >95% sensitivity
8. Pen-side test
9. DIVA Compatible
10. Field validated
11. Easy to perform/easily train NAHML's personnel
12. Scalable
13. Reasonable cost
14. Operator safe
15. Reagents can be produced in low containment

### ***Values***

The values assigned for each of the interventions reflect the collective best judgment of members of the gap analysis working groups (See Appendices I and II)

## **VACCINES**

The human infections in the 1999 outbreak in Malaysia were linked to transmission of NiV from pigs. Accordingly, a swine vaccine able to prevent virus transmission would be an important tool to safeguard commercial swine operations and people at risk. In addition, since henipaviruses have a very broad host range, a vaccine that is efficacious in multiple susceptible animal species would be desirable. Although the 2017 gap analysis working group determined that there are still no NiV commercial vaccines available, there are several vaccine candidates that may be safe and effective in swine and other domestic animals that were recently reviewed in: (Weingartl H.M., 2015; Broder, C.C., *et al*, 2016; and Satterfield, B.A., *et al.*, 2016). After these reviews were published, a manuscript was published demonstrating the efficacy of a virus-like-particle (VLP) Nipah virus vaccine in hamsters for inducing virus neutralizing antibodies and protection from challenge (Walpita P., *et al.*, 2017). Another manuscript was published that concluded that an adjuvanted Hendra soluble G vaccine in pigs induced neutralizing antibody titers considered to be protective against Nipah virus without detectable T cell-mediated immunity to Nipah, which did not protect from challenge with Nipah virus. However, pigs that had been previously challenged with a low dose of NiV developed neutralizing antibodies and cell-mediated immune memory and were protected from a high challenge dose of NiV. The conclusion of this manuscript was that both virus neutralizing antibodies and cell-mediated immunity were necessary for protection from NiV challenge (Pickering B.S., *et al.*, 2016). Subsequent unpublished research demonstrated that a different adjuvant used with the soluble Hendra G vaccine caused the induction of both high titered virus neutralizing antibody and detectable T cell-mediated immunity in pigs to NiV. Challenge studies were not conducted (J.A. Roth, personal communication). All of these vaccine candidates would need further research and development to be licensed, and would need to be made available as a stockpile for rapid use in an emergency if an outbreak in swine were to occur that could not be effectively stamped out. A swine vaccine would

also be needed if the Nipah virus were to mutate to be efficiently transmitted between people and between people and pigs.

### Summary

- Vaccination against NiV has been successfully demonstrated
- Experimental henipavirus vaccines can prevent clinical disease
- Experimental henipavirus vaccines elicit systemic and mucosal immunity
- Experimental henipavirus vaccines prevent viral replication in target tissues
- HeV commercial vaccine Equivac® HeV does not cross protect against NiV infection in swine
- Henipavirus vaccines appear to be effective in several mammalian animal species

### Assessment of Commercial Vaccines

A commercial vaccine (Equivac® HeV) against Hendra virus approved for use in horses (Middleton D.J. *et al.*, 2014) was registered by Zoetis in Australia in 2015. A six month booster dose is required for full protection, followed by annual vaccination. The vaccine is also approved for pregnant mares. There is currently no Nipah virus vaccine approved for swine. Likewise, there is no vaccine against Hendra virus (or Nipah virus) approved for human use.

### Assessment of Experimental Vaccines

The working group felt that limited information was available to assess and contrast experimental vaccines that have been reported in the literature. Experimental animal vaccines under investigation are summarized in Table I. Experimental vaccines for humans are summarized in Table II. Several of the working group members have directly or indirectly been involved in the research associated with these vaccines so that an assessment could be made (See Appendix I). The following describes some of the most promising experimental vaccine technologies.

#### *1) Canarypox-vectored NiV Vaccines*

The ALVAC canarypox virus-based recombinant vaccine vector (Taylor *et al.*, 1994) was used to construct two experimental NiV vaccines (Weingartl *et al.*, 2006). These experimental vaccines were engineered by Merial.

The first construct carries the gene for NiV attachment glycoprotein G (ALVAC-G). The second construct carries the NiV fusion protein F (ALVAC-F).

The efficacy of both the ALVAC-G and ALVAC-F were tested in pigs either as monovalent vaccine or in combination (ALVAC-G/F). The vaccine dose used was 10(8) PFU. The vaccine regimen was two doses administered 14 days apart. Both non-vaccinated controls and vaccinated pigs were challenged with 2.5 x 10(5) PFU of NiV two weeks later.

The combined ALVAC-F/G vaccine induced the highest levels of neutralization antibodies. Despite the low neutralizing antibody levels induced by ALVAC-F all vaccinated animals were protected against challenge. Virus was not isolated from the tissues of any of the vaccinated pigs post-challenge, and a real-time reverse transcription (RT)-PCR assay detected only small amounts of viral

RNA in several samples. In challenge control pigs, virus was isolated from a number of tissues or detected by real-time RT-PCR. Vaccination of pigs with the ALVAC-F/G stimulated both type 1 and type 2 cytokine responses. No virus shedding was detected in vaccinated animals, in contrast to challenge control pigs, from which virus was isolated from the throat and nose.

Based on the data generated in this one study, both the ALVAC-G or the combined ALVAC-F/G vaccine appears to be a very promising vaccine candidate for swine.

## 2) *Soluble G Henipavirus Vaccine*

HeV and NiV infect cells by a pH-independent membrane fusion event mediated by their attachment (G) and fusion (F) glycoproteins. Scientists at the Uniformed Services University of the Health Sciences in Bethesda, Maryland, in collaboration with the Australian Animal Health Laboratory characterized HeV- and NiV-mediated fusion activities and detailed their host-cell tropism characteristics. These studies suggested that a common cell surface receptor was utilized by both viruses. To further characterize the G glycoprotein and its unknown receptor, soluble forms of HeV G (sG) were constructed by replacing its cytoplasmic tail and transmembrane domains with an immunoglobulin kappa leader sequence coupled with an S-peptide tag (sG) to facilitate purification and detection. Expression of sG was verified in cell lysates and culture supernatants by specific affinity precipitation. Analysis of sG by size exclusion chromatography and sucrose gradient centrifugation demonstrated tetrameric, dimeric, and monomeric species, with the majority of the sG released as a disulfide-linked dimer. Immunofluorescence staining revealed that sG specifically bound to HeV and NiV infection-permissive cells. The scientists further reported that administration of sG to rabbits can elicit a potent cross-reactive neutralizing antibody response against infectious HeV and NiV (Bossart *et al.* 2005).

Experimental subunit vaccine formulation containing either HeV sG or NiV sG were evaluated as potential NiV vaccines in the cat model. Two cats were immunized with HeV sG and two cats were immunized with NiV sG. Immunized animals and two additional naïve controls were then challenged subcutaneously with 500 TCID<sub>50</sub> of NiV. Naive animals developed clinical disease 6 to 13 days post-infection, whereas none of the immunized animals showed any sign of disease (Mungall *et al.*, 2006).

In a subsequent experiment, an experimental subunit formulation containing HeV sG and CpG adjuvant was evaluated as a potential NiV vaccine in the cat model. Vaccinated animals demonstrated varying levels of NiV-specific Ig systemically and importantly, all vaccinated cats possessed antigen-specific IgA on the mucosa. Upon oronasal challenge with NiV (50,000 TCID<sub>50</sub>), all vaccinated animals were protected from disease although virus was detected on day 21 post-challenge in one animal. (McEachern *et al.*, 2008).

A recent publication demonstrated that an adjuvanted Hendra soluble G vaccine in pigs induced SN antibody titers considered to be protective against Nipah virus without detectable T cell-mediated immunity to Nipah which did not protect from challenge with Nipah virus. Pigs which had been previously challenged with a low dose of Nipah developed SN antibodies and cell-mediated immune memory and were protected from a high challenge dose of Nipah virus. The conclusion of this manuscript was that both SN antibodies and cell-mediated immunity were necessary for protection from Nipah virus challenge (Protection against henipaviruses in swine requires both, cell-mediated and

humoral immune response, B.S. Pickering, J.M. Hardham, G. Smith, E.T. Weingartl, P.J. Dominowski, D.L. Foss, D. Mwangi, C.C. Broder, J.A. Roth, H.M. Weingartl, *Vaccine* 34(40): 4777-4786, 2016). Subsequent unpublished research demonstrated that a different adjuvant used with the soluble Hendra G vaccine caused the induction of both high titered SN antibody and detectable T cell-mediated immunity in pigs to Nipah virus. Challenge studies were not conducted (J.A. Roth, personal communication).

### 3) *Vaccinia-vectored NiV Vaccine*

The NYVAC vaccinia virus-based recombinant vaccine vector (Tartaglia *et al.*, 1992) was used to construct an experimental NiV vaccine where the vaccinia virus expresses both the NiV glycoproteins G and F (Guillaume *et al.*, 2004). This experimental vaccine was engineered by the Pasteur Institute.

Scientists at the Pasteur Institute in collaboration with University of Malaysia scientists showed that both of the NiV glycoproteins G and F when expressed as vaccinia virus recombinants induced an immune response in hamsters that protected against a lethal challenge with NiV. Furthermore, this team of scientists demonstrated passive transfer of antibody induced by either of the glycoproteins protected the animals.

## DIAGNOSTICS

The gap analysis working group determined that the availability of validated diagnostic tests for surveillance, early detection, and recovery during a NiV outbreak were critical to minimize the spread of disease and reduce the economic and public impact.

Currently the diagnosis of NiV infection is by virus isolation, detection of viral RNA, or demonstration of viral antigen in tissue collected at necropsy. Specific antibody detection can also be useful, particularly in pigs where NiV infection may go unnoticed. Demonstration of specific antibody to NiV in either animals or humans is of diagnostic significance because of the rarity of infection and the serious zoonotic implication of NiV transmission.

### Summary

- Antibody response to NiV take at least 14 days and therefore early diagnosis based on serology will be less reliable than antigen or molecular tests
- Recombinant N-ELISA will likely not pick up all infected pigs
- The concept of a pen-side test is attractive, but the development and regulation of such a test will be extremely challenging

### Assessment of Laboratory Diagnostic Tests (See Appendix II)

Details in the OIE Manual of Diagnostic Tests and Vaccines for Terrestrial Animals 2015, Chapter 2.1.14 Hendra and Nipah Virus Diseases, provides recommendations for the following tests.

### **Identification of the agent**

1. Virus isolation and characterization
  - 1.1. sampling and submission of specimens
  - 1.2. isolation in cultured cells
  - 1.3. Identification: immunostaining and Immuno EM

2. Viral identification: differentiation of HeV and NiV
  - 2.1 comparative immunostaining
  - 2.2. immunofluorescence
  - 2.3. microtiter neutralization
3. Molecular methods
  - 3.1. real-time RT-PCR
  - 3.2. Conventional RT-PCR and Sanger sequencing
4. Immunohistochemistry

### **Serological tests**

1. Virus neutralization tests
2. Enzyme-linked immunosorbent assay
3. Bead-based assays

### **Histopathology**

1. Veterinary diagnostic labs might use histopathology to make the first diagnosis
2. NiV does not produce pathognomonic lesions, but a generalized vasculitis with fibrinoid necrosis in several tissues (e.g. lung and kidneys) is characteristic; NiV might be considered in the initial differential diagnosis by experienced veterinary pathologists.

### Assessment of Available Diagnostic Tests

Australia, Canada, and Germany have diagnostic capability for henipaviruses in livestock; India (e.g. NIHSAD) is building its veterinary diagnostic capability; U.S. veterinary diagnostic laboratories do not have diagnostic capability to detect NiV in livestock, although the Center for Disease Control (CDC) in Atlanta, Georgia, is an OIE collaborating center for NiV.

Currently, there are no expectations of validated tests for livestock (or other species). Nothing has been done in terms of test harmonization for serological, antigen, or nucleic acid detection assays; however, successful technology transfers have taken place, as follows: from AAHL to laboratories in Asia (Malaysia mainly); limited transfer from NCFAD to India (Bhopal High Containment Animal Health Laboratory); limited transfer from AAHL to FLI and bilateral transfers between NCFAD and FLI.

Serologic testing plays an important role in the diagnosis and detection of NiV infections. Serologic tests are the most straightforward and practical means to confirm acute cases of disease and serologic evidence of infection is used in screening programs for reservoir hosts and domestic animals. However, serological assays are limited in their ability to differentiate between known and unknown henipaviruses, as cross-reactivity to one or more known viruses is possible. Both serum neutralization and Luminex assays have shown positive reactivity to both NiV and HeV in bats where the presence of a yet-to-be characterized henipavirus could not be ruled out.

Several standard and new experimental technologies that are currently being used or considered for the detection of NiV in the laboratory or as pen-side tests for field use. Shedding of NiV in oral fluids starts early post-infection and rope sampling could prove convenient for collecting samples that could be used to test larger numbers (i.e., pen tests) of pigs. Suitability of oral fluid samples for various test

platforms should be investigated. There is a need to develop a formalized worldwide structure for test validation and ring trials (i.e., inter-laboratory comparisons).

The following describes some of the most promising diagnostic platforms with potential application for NiV detection.

### 1) *Quantitative (q) real-time PCR*

Real-time PCR is a sensitive and useful approach to the detection of henipavirus genome in specimens. Due to its nature, rRT-PCR may not be able to detect all divergent and novel henipavirus strains, although adaptation of molecular tests to new virus variants could be rapid. Test methods and primers used depend on the technology platform and associated chemistry being used in individual laboratories. Test procedures have been described by different laboratories (Mungall *et al.*, 2006; Wacharapluesadee and Hemachudha, 2007; Guillaume *et al.*, 2004; Chang *et al.*, 2006; Feldman *et al.*, 2009).

The AAHL has developed a quantitative real-time PCR to detect NiV or HeV RNA synthesis. The most commonly targeted amplification regions are directed against the N gene (Feldman *et al.*, 2009).

RT-PCR targeting the N gene of NiV will detect both, NiV-M and NiV-B, with somewhat lower sensitivity for NiV-B. Confirmatory RT-PCR targeting the F gene specific only for NiV-B has therefore been developed (publication in preparation; H.M. Weingartl, personal communication).

### 2) *Conventional PCR*

Classical RT-PCR followed by sequencing may be more successful in detecting novel henipavirus strains. Combination of both approaches may need to be considered. Genomic RNA detection can be performed on blood or serum samples collected from live animals as well as tissues from dead animals. RNA is extracted using an RNA extraction kit [e.g., RNeasy mini kit (Qiagen)]. Extracted total cellular RNA is first subjected to first-stand cDNA synthesis using a reverse transcriptase kit [e.g., SensiScript (Qiagen)] and a reverse transcriptase primer. The resulting cDNA is amplified using a Master Mix PCR kit (Qiagen) and primers that are designed to target HeV and NiV positive-sense mRNA from the N, M and G genes and negative-sense genomic viral RNA (vRNA) at the N/P, M/F and F/G gene junctions.

### 3) *Field PCR*

Not available. Isothermal real-time RT-PCR is promising as a field deployable assay.

While this will be costly and not be practical to have in large numbers, it is worth considering having the capabilities to establish in several strategically located regions across the nation to respond rapidly in an emergency situation. Technically it will not be difficult to achieve if there is the will and financial support.

#### 4) *Virus isolation (VI)*

Virus isolation in permissive cell culture is considered the “gold standard” for isolating all strains of henipaviruses. Virus isolation greatly facilitates identification procedures and definitive diagnosis should be undertaken where operator safety can be guaranteed. Isolation is especially relevant in any new case or outbreak, particularly in countries or geographical areas where infection by NiV or HeV has not been previously documented. Implication of wildlife species as natural hosts of the viruses requires positive serology, PCR or virus isolation from wild-caught animals (Daniels *et al.*, 2007). The range of tissues yielding virus in natural and experimental cases include the brain, lung, kidney and spleen (Crameri G., *et al.* 2002).

Henipaviruses grow rapidly to high titers in a large number of cell lines. African green monkey kidney (Vero) and rabbit kidney (RK-13) cells have been found to be particularly susceptible. A CPE usually develops within 3 days, but two 5-day passages are recommended before judging the attempt unsuccessful. After low multiplicity of infection, the CPE is characterised by formation of syncytia that may, after 24–48 hours, contain over 60 or more nuclei. Syncytia formed by NiV in Vero cell monolayers are significantly larger than those created by HeV in the same time period. Although the distribution of nuclei in NiV-induced syncytia early in infection resembles that induced by HeV, with nuclei aggregated in the middle of the syncytia, nuclei in mature NiV-induced syncytia are distributed around the outside of the giant cell (Hyatt *et al.*, 2001).

Very low virus load in bats makes isolation very difficult. Linfa Wang and colleagues at the AAHL have increased sensitivity of cell lines by “rational engineering,” consisting of a single point mutation in ephrinB2 resulting in enhanced affinity for NiV.

#### 5) *Pen-side test*

Not yet developed.

While the concept is attractive, it is a huge challenge technically and in regulatory sense, especially considering how presumable false positive results would be handled.

#### 6) *N and G ELISA*

Indirect recombinant N- ELISA and G-ELISA have been developed, and are now in the stage of diagnostic evaluation (Fisher K., *et al.*, 2018). The N-ELISA protocol was transferred to HSADDL (India) and validated and used for surveillance (Kulkarni *et al.*, 2016).

Problems with specificity (i.e., false positives) could arise. For example, swine sero-surveillance in West Bengal, India, appears to be negative; however, 8/328 samples tested positive (i.e., presumably false positive) using the anti-N antigen ELISA antibody detection test. Evaluation of the indirect IgG ELISA based on the recombinant NiV-N antigen using swine samples from Canada yielded similar results, including an indirect IgG ELISA based on the G glycoprotein. In Canadian context, the problem is the diagnostic specificity, with 5% false positives, resulting in the decision to complement with the G-ELISA. Only sera positive on both tests are considered

positive. Confirmatory testing may be required, if this was to be the first case reported in non-endemic area.

A diagnostic test for differentiating infected from vaccinated animals (DIVA) would have to most likely target the N antigen, or alternatively P gene coded products depending on the level of expression and antigenicity in animals, and the number of reactors in non-endemic areas.

The N ELISA assay could fulfill DIVA requirements if the canarypox vectored NiV-G-NiV-F vaccine is used because antibodies to N would only occur after NiV infection.

#### 7) *IgM ELISA*

The U.S Center for Disease Control and Prevention (CDC) developed an IgM ELISA for human serology. Detection of IgM was used to confirm recent infection with NiV in both Malaysia and Bangladesh. NiV-infected cells that have been inactivated by gamma irradiation are used as antigens.

In theory the same can be done for different animal species as long as we have the right anti-species antibodies. For bats, that is still a challenge.

#### 8) *Virus neutralization test (VNT)*

VNT serves as the traditional gold standard of serological investigations. The VNT requires live virus and thus BSL-4 containment facilities are required (Crameri *et al.*, 2002). It has proven to be a very valuable specific and sensitive tool in the diagnosis of NiV.

VNT rely on quantification methods. Three different procedures are available to titer HeV and NiV. In the traditional plaque and microtiter assay procedures, the titer is calculated as plaque forming units (PFU) or the tissue culture infectious dose capable of causing CPE in 50% of replicate wells (TCID<sub>50</sub>), respectively.

In an alternative procedure, the viruses are titrated on Vero cell monolayers in 96-well plates and after 18–24 hours, foci of infection are detected immunologically in acetone-fixed cells using anti-viral antiserum (Crameri G., *et al.* 2002). The virus titre is expressed as focus-forming units (FFU)/ml.

Neutralisation assays using these three methods are described in the OIE Manuel of Diagnostic Tests and Vaccines for Terrestrial Animals.

Virus quantification procedures should be conducted at BSL4. A new version of the differential neutralisation test has been recently described, which avoids the use of infectious virus by the use of ephrin-B2-bound biospheres (Bossart *et al.*, 2007). Although the test has yet to be formally validated, it appears to have the potential to be a screening tool for use in countries without BSL4 facilities.

9) *Pseudotype virus plaque reduction neutralization test (PRNT)*

The standard plaque reduction neutralization assay (PRNT) used to detect NiV and HeV must be performed in BSL-4 containment and takes several days to complete. The CDC and the AAHL have modified the PRNT by using recombinant Vesicular Stomatitis Virus (VSV) derived from the cDNA of VSV Indiana to construct pseudotype particles expressing the F and G proteins of NiV (pVSV-NiV-F/G) as target antigens (Chang *et al.*, 2006; Tamin *et al.*, 2009; Kaku *et al.*, 2009). This rapid assay can be performed at BSL-2. The PRNT was evaluated using serum samples from outbreak investigations and more than 300 serum samples from an experimental NiV vaccination study in swine. The results of the neutralization assays with pVSV-NiV-F/G as antigen showed a good correlation with those of standard PRNT. The PRNT titers give an indication of protective immunity. Therefore, this new method has the potential to be a rapid and cost-effective diagnostic method, especially in locations that lack high containment facilities, and will provide a valuable tool for basic research and vaccine development. A similar assay has been developed by the Japanese-Australian group (Kaku *et al.*, 2009), which proved to be as specific as the VNT and much more sensitive than VNT.

10) *Binding Luminex Assay*

Sera are tested for antibodies binding to recombinant soluble G (sG) proteins in a Luminex® multiplexed microsphere binding assay. The sG proteins retain their ability to bind the cellular receptor molecule, indicating their native conformation is maintained, which is important for the detection of neutralizing antibodies. For bat sera, median fluorescence intensities (MFI) readings of  $\geq 200$  are considered positive. Three times the average background reading of negative sera is used as a cut-off for the binding assay.

11) *Luminex® multiplexed nucleic acid detection assay*

Foord *et al.*, 2012, reported microsphere suspension array systems enable the simultaneous fluorescent identification of multiple separate nucleotide targets in a single reaction using commercially available oligo-tagged microspheres (Luminex® MagPlex-TAG) to construct and evaluate multiplexed assays for the detection and differentiation of HeV and NiV. Assays were developed to target multiple sites within the nucleoprotein (N) and phosphoprotein (P) encoding genes. The relative specificities and sensitivities of the assays were determined using reference isolates of each virus type, samples from experimentally infected horses, and archival veterinary diagnostic submissions. Results were assessed in direct comparison with an established qPCR. Foord reported the microsphere array assays achieved unequivocal differentiation of HeV and NiV and the sensitivity of HeV detection was comparable to qPCR, indicating high analytical and diagnostic specificity and sensitivity.

12) *Luminex® proprietary multiplex bead-based immunoassay*

Currently, the Luminex® proprietary multiplex bead-based immunoassay testing platform for the detection of anti-G antibodies is used for bat surveillance at the AAHL, and by other research investigators. Luminex® technology detects antibodies to recombinant soluble G (sG) proteins from NiV and HeV in a multiplexed microsphere binding assay. Since the glycoprotein specific

antibody response to both NiV and HeV can be measured simultaneously, this assay can differentiate between the serologic responses to NiV and HeV.

### *13) Blocking Luminex® Assay*

This is an extension of the Binding Luminex Assay, developed as a surrogate VNT in the sense that it measures antibodies that block the binding of the soluble henipavirus G protein to the ephrin-B2 receptor molecule. It is highly specific, but needs further validation with field samples.

## **DEPOPULATION**

Preemptive culling of herds in the neighborhood of an infected herd is an effective and even indispensable measure in the control of a NiV epidemic in areas with high pig densities. The purpose of this measure is to prevent infection of new herds, which would generate massive infectious virus production, and thus to reduce the virus infection load in an area. This reduced infection load subsequently results in a reduction of the between-herd virus transmission. However, recent outbreaks have shown that the control of Nipah virus in pig populations through stamping out is complex due to the zoonotic nature of the agent. In addition, depopulation may be logistically difficult and very expensive in swine dense area, and would not be effective if the Nipah virus mutates to become easily transmitted between people and from people to pigs. Depopulation will not be possible in situation like those that occurred in Bangladesh in which NiV was transmitted from bats to humans without an amplifying host. Depopulation of swine may be impossible in a rapidly spreading outbreak in a pig dense region with hundreds of millions of swine, such as in southeast China (Vergne T. *et. al.* 2017).

## **SURVEILLANCE**

The initial expression of NiV in U.S swine would be variable and unpredictable due to the myriad of host factors and the broad diversity of virulence among strains of henipaviruses. Different surveillance strategies will be required to detect the different clinical manifestations.

For acute infection, surveillance activities can be based on clinical signs, but signs are unlikely to be noticed by producers and practitioners. It would be prudent to develop surveillance activities based on diagnostic testing to supplement surveillance based on clinical signs.

The following surveillance programs are in place to meet the objective of rapid detection of henipaviruses in Malaysia and Australia:

1. Population-based passive reporting of suspicious NiV cases. Efforts to enhance reporting will be focused on high risk areas.
2. Laboratory-based surveillance of serum and tissue submitted from sick pigs.

There is no diagnostic capability for henipaviruses in United States veterinary diagnostic laboratories due to the lack of BSL-4 laboratory space. The only diagnostic capability for henipaviruses in the U.S is the Center for Disease Control and Prevention (CDC). There are no active or passive surveillance programs. Henipavirus suspect samples would be sent to the CDC, the OIE reference laboratory at the

Australian Animal Health Laboratory, or the National Canadian Foreign Animal Disease Center, in Winnipeg, Canada.

### **DRUGS**

There are no licensed anti-viral drugs available to treat people or animals against Henipaviruses.

### **DISINFECTANTS**

People: Soaps and detergents.

Fomite disinfection: Sodium hypochlorite to supply 10,000 ppm chlorine or Virkon.

### **PERSONAL PROTECTIVE EQUIPMENT (PPE)**

PPE should be suitable to prevent farm-to-farm virus spread by diagnostic or vaccination teams.

# RECOMMENDATIONS

## RESEARCH

The 2017 gap analysis working group recommends the implementation of the following research priorities.

### **Viral Pathogenesis**

- Determine early events of NiV infection, immune evasion and identify determinants for virulence and host susceptibility

### **Immunology**

- Characterize the antibody and cell-mediated immune response to NiV infection and vaccination
- Develop the basic knowledge of the mechanisms NiV uses to evade the innate immune response
- Characterize the ability of interferons to inhibit virus replication and shedding early in infection.

### **Vaccine Discovery and Development Research.**

- Implement comprehensive vaccine research program to deliver next generation NiV vaccines and specifically design strategies for control in priority susceptible hosts
- Investment in Nipah vaccine development needs to include conducting studies to demonstrate safety and efficacy necessary for licensure by authorities in countries that may have an emergency need for vaccine in swine.

### **Diagnostics**

- Develop a panel of reference standards for both molecular and serologic tests that can be made available to all of the laboratories performing diagnostic tests for henipaviruses. This panel should also include monoclonal antibodies and recombinant antigens that would be readily available as low biosecurity BSL-2 reagents.
- Develop a formalized structured worldwide network for reference panel development and assay validation and harmonization.
- Develop and validate broadly reactive PCR assays targeting highly conserved genetic targets within the henipaviruses. Evaluate the relative sensitivity and specificity of the currently used PCR assays.
- Develop and validate field tests (both protein- and nucleic acid-based) to detect henipaviruses.
- Explore new antigen detection assays, including antigen capture, Loop Mediated Isothermal Amplification Protocol (LAMP) suitable for resource limited situations, and nanotechnology.
- Develop species specific reagents to improve the quality of serologic assays.
- Evaluate the relative sensitivity and specificity of molecular and serologic tests, especially new serologic tests that could replace serum neutralization titers (SNT) and meet DIVA (differentiate infected from vaccinated animals) requirements.
- Explore the use of serological assays based on recombinant antigens that could be produced at BSL-2. Classical serological tests using low biosecurity (recombinant) reagents produced at BSL-2 facilities could be developed reasonably quickly and at a reasonable cost.
- Develop species independent serologic assays using recombinant antigens.

## **Epidemiology**

- The epidemiology of NiV in disease outbreaks needs to be assessed and modeled on the level of the individual pig, the herd, and the demographics of the region.
- Epidemiological investigations should be performed on the implementation of emergency vaccination and the use of ‘DIVA’ and other diagnostic tests to detect infected pigs in vaccinated populations
- Risk assessments need to be performed with regard to control or spread of henipaviruses
- The epidemiological evaluation of wildlife needs to be carried out in order to improve the risk estimates of outbreaks in domestic animal and human populations

## **PREPAREDNESS**

Many of the countermeasures discussed in this report will require preparation and integration in a coordinated disease control program and funding for a stockpile for use in an emergency response plan for an outbreak of NiV infection. The Henipavirus gap analysis working group recommends investing in the implementation of the following preparedness plan to ensure the effective use of the countermeasures in the NVS:

- See the Ausvetplan:  
<https://www.animalhealthaustralia.com.au/our-publications/ausvetplan-manuals-and-documents/>  
Assessed July 22, 2018
- See Guidelines for Veterinarians Handling potential Hendra Virus infection in Horses (QDPI):  
[https://www.daf.qld.gov.au/\\_data/assets/pdf\\_file/0005/126770/2913\\_-\\_Guidelines-for-veterinarians-handling-potential-Hendra-virus-infection-in-horses-V5.1.pdf](https://www.daf.qld.gov.au/_data/assets/pdf_file/0005/126770/2913_-_Guidelines-for-veterinarians-handling-potential-Hendra-virus-infection-in-horses-V5.1.pdf)  
Accessed July 22, 2018

## **Surveillance**

Routine surveillance for NiV is now limited to serologic screening of pigs in several Southeast Asian countries.

- Develop a regional surveillance strategy, including laboratory, to detect spillovers of NiV into domestic and agricultural animals.
- Determine the optimal surveillance strategy to detect circulation of NiV in the bats reservoirs and other wild life.
- Improve surveillance capacity to detect henipaviruses in high risk countries.
- Establish a formal laboratory network for henipavirus surveillance that includes standardized specimen collection, laboratory testing scheme, quality control, specimen referral and accreditation.

## **Biosecurity**

Design NiV-specific on-farm biosecurity programs to implement in a disease outbreak situation.

## **Personal Protective Equipment and Decontamination**

- See Australian procedures  
[https://www.dpi.nsw.gov.au/\\_data/assets/pdf\\_file/0003/494202/Hendra-virus-ppe-procedures.pdf](https://www.dpi.nsw.gov.au/_data/assets/pdf_file/0003/494202/Hendra-virus-ppe-procedures.pdf)

Chapter 2: Working safely with Nipah Virus  
<http://www.fao.org/docrep/005/AC449E/ac449e05.htm#bm05>  
Assessed July 22, 2018

### **Depopulation and Disposal**

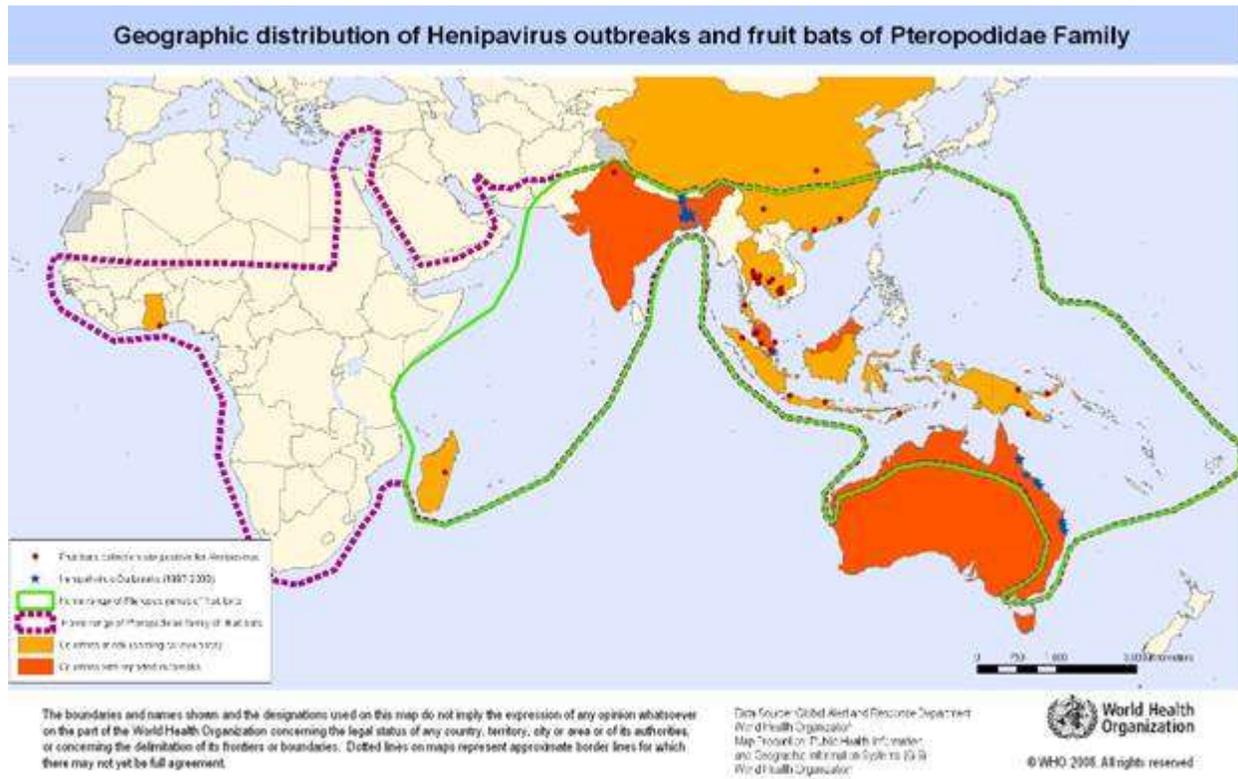

Develop plans for handling disposal of animals infected with a zoonotic agent, including an emergency plan to dispose of infected swine and decontaminate facilities and equipment determined to be infected.

- FAO (Food and Agriculture Organization) – Manual on the Diagnosis of Nipah Virus in Animals:  
Chapter 5: Control and eradication  
<http://www.fao.org/docrep/005/AC449E/ac449e08.htm#bm08>

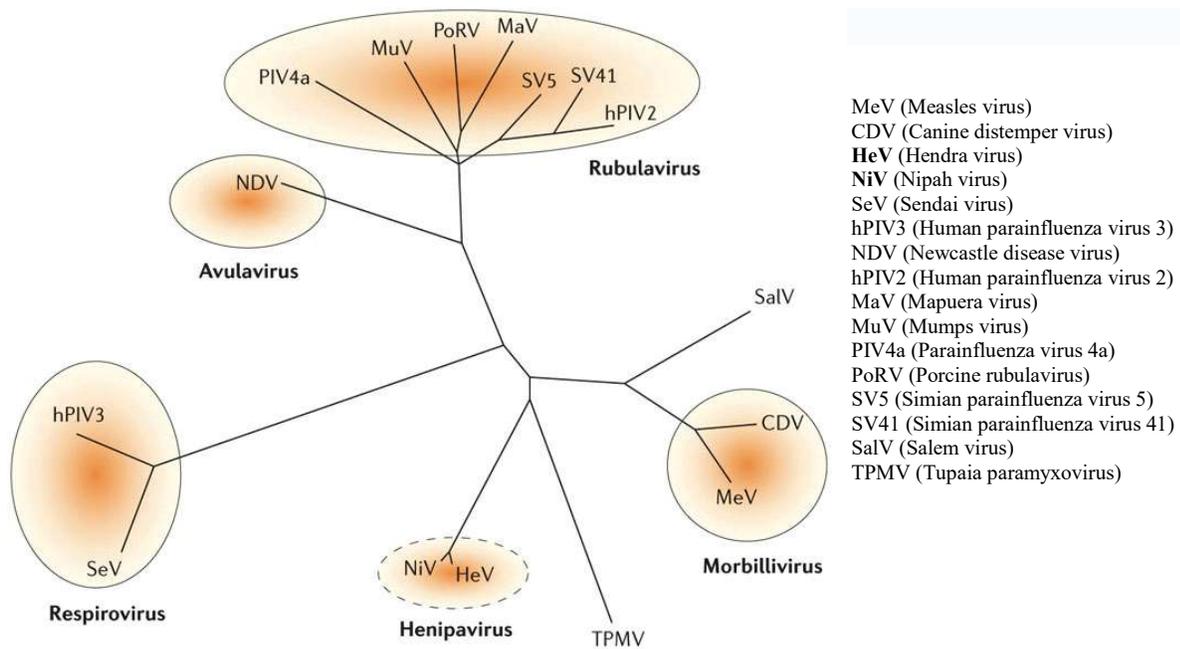

## CONCLUSION

The threat of an outbreak with a henipavirus in the United States due to a natural transmission from a reservoir host is very low since the reservoirs are known to be bats in South East Asia, South Asia, and Asia. However, an outbreak that is not controlled in swine or in people in Asia could result in infection being introduced accidentally into North America or Europe. There is considerable concern that henipaviruses could be used as a weapon of mass destruction (WMD) because they have many of the characteristics of the ideal biological weapon, including causing one of the highest mortality rate in people known for an infectious disease. The possibility of an intentional criminal spread at least in short clusters of terrorist attacks is a distinct possibility, for example by aerosolization in confined public spaces, or through infection of pigs. Surveillance brings challenges and weaknesses of diagnostic methods may impede the early detection of an outbreak in the United States. There are no commercially available diagnostic tests and although laboratory tests are available they have not been field validated. Depopulation is the primary method to eradicate NiV but present very high risks since henipaviruses are BSL-4 zoonotic agents. There are commercially available vaccines for horses, but none for swine and people. Accordingly, the gap analysis working group recommends investing in the research and development of countermeasures and ensure their use and integration in planning for preparedness and future control campaigns. Priority should be given to funding research to improve surveillance, diagnostics, and vaccines. Specific goals include 1) improving diagnostic tests to rapidly identify new disease outbreaks; 2) epidemiological research to better understand virus transmission in wildlife and maintain a passive surveillance program in high risk commercial livestock operations; and 3) develop safe and effective vaccines specifically designed for control and eradication. The United States should stockpile NiV vaccines when they become available for use in contact herds to create a buffer zone as an additional control measure to prevent the spread of henipaviruses should an outbreak ever occur.

## TABLE III – VACCINE PLATFORMS

C.C. Broder et al. / Vaccine 34 (2016) 3525–353

**Table 1**

Advanced active vaccination and passive immunization platforms tested in Hendra virus and/or Nipah virus animal challenge models.

Platform	Viral antigen target or immunogen	Animal challenge model
Active vaccination		
Recombinant vaccinia virus	Nipah F and/or G glycoprotein	Hamster <sup>a</sup> (NiV)
Recombinant canarypox virus	Nipah F and/or G glycoprotein	Pig <sup>b</sup> (NiV)
Recombinant VSV	Nipah F and/or G glycoprotein	Ferret <sup>c</sup> (NiV), Hamster <sup>d</sup> (NiV), nonhuman primate <sup>e</sup> (NiV)
Recombinant AAV	Nipah G glycoprotein	Hamster <sup>f</sup> (NiV, HeV)
Recombinant measles virus	Nipah G glycoprotein	Hamster and nonhuman primate <sup>g</sup> (NiV)
Recombinant subunit	Hendra soluble G glycoprotein	Cat <sup>h</sup> (NiV), Ferret <sup>i</sup> (HeV, NiV), nonhuman primate <sup>j</sup> (HeV, NiV), horse <sup>k</sup> (HeV)
Passive immunization		
Human monoclonal antibody m102.4	Hendra/Nipah G glycoprotein	Ferret <sup>l</sup> (NiV) Nonhuman primate <sup>m</sup> (HeV, NiV)

<sup>a</sup> Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vaccinia viruses were protected against disease following intraperitoneal challenge with  $10^3$  PFU of NiV [137].

<sup>b</sup> Pigs immunized with NiV F and/or G glycoprotein encoding recombinant canarypox viruses were protected against intranasal challenge with  $2.5 \times 10^5$  PFU of NiV [138].

<sup>c</sup> Ferrets immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intranasal challenge with  $5 \times 10^3$  PFU of NiV [141].

<sup>d</sup> Hamsters immunized with NiV F and/or G glycoprotein encoding recombinant vesicular stomatitis virus (VSV) vectors were protected against lethal intraperitoneal challenge with  $10^5$  TCID<sub>50</sub> of NiV [143]; or  $6.8 \times 10^4$  TCID<sub>50</sub> of NiV [142].

<sup>e</sup> African green monkeys immunized with a NiV G encoding recombinant VSV vector were protected against lethal intratracheal challenge with  $10^5$  TCID<sub>50</sub> of NiV [156].

<sup>f</sup> Hamsters immunized with a NiV G encoding recombinant adeno-associated virus (AAV) vector were protected against lethal intraperitoneal with  $10^4$  PFU of NiV [139].

<sup>g</sup> Hamsters and African green monkeys immunized with a NiV G encoding recombinant measles virus vector were protected against lethal intraperitoneal challenge with  $10^3$  TCID<sub>50</sub> of NiV (hamsters) or  $10^5$  TCID<sub>50</sub> of NiV (monkeys) [140].

<sup>h</sup> Hendra virus soluble G glycoprotein (HeV-sG) used to immunize cats protects against lethal subcutaneous ( $500$  TCID<sub>50</sub>) [120] or oronasal ( $5 \times 10^4$  TCID<sub>50</sub>) NiV challenge [145].

<sup>i</sup> HeV-sG used to immunize ferrets protects against lethal oronasal challenge with  $5 \times 10^3$  TCID<sub>50</sub> of HeV [124] or  $5 \times 10^3$  TCID<sub>50</sub> of NiV challenge [146].

<sup>j</sup> HeV-sG used to immunize African green monkeys protects against lethal intratracheal challenge with  $10^5$  TCID<sub>50</sub> of NiV [157] or  $5 \times 10^5$  PFU of HeV [147].

<sup>k</sup> HeV-sG used to immunize horses protects against lethal oronasal challenge with  $2 \times 10^6$  TCID<sub>50</sub> of HeV [15].

<sup>l</sup> A NiV and HeV cross-reactive G glycoprotein specific neutralizing human mAb (m102.4) protects ferrets against lethal oronasal challenge with  $5 \times 10^3$  TCID<sub>50</sub> of NiV [125] or  $5 \times 10^3$  TCID<sub>50</sub> of HeV (J. Pallister and C. Broder, unpublished) by post-exposure infusion.

<sup>m</sup> Human mAb m102.4 protects African green monkeys by post-exposure infusion following lethal intratracheal challenge with  $4 \times 10^5$  TCID<sub>50</sub> of HeV [153] or lethal intratracheal challenge with  $5 \times 10^5$  PFU of NiV [154].

## TABLE IV – CURRENT VACCINE CANDIDATES

## APPENDIX III - CONTRIBUTORS

### **Christopher C. Broder, Ph.D (2009 and 2017)**

Professor and Director, F. Edward Hebert School of Medicine  
Department of Microbiology  
Uniformed Services University *of the Health Services*  
4301 Jones Bridge Rd, Bethesda, MD 20814-4799  
Tel (301) 295-3401  
Fax (301) 295-1545/3773  
Email: [christopher.broder@usuhs.edu](mailto:christopher.broder@usuhs.edu)

### **Anne Balkema-Buschman, Ph.D (2017)**

Friedrich-Loeffler-Institut - Federal Research Institute for Animal Health  
Institute of Novel and Emerging Infectious Diseases  
Greifswald - Insel Riems, Germany  
Email: [Anne.Balkema-Buschmann@fli.de](mailto:Anne.Balkema-Buschmann@fli.de)

### **Bruce A. Carter, DVM (2017)**

Global Vaccine Manager  
Animal and Plant Health Inspection Service  
Veterinary Services  
Center for Veterinary Biologics  
1920 Dayton Ave.  
Ames, Iowa 50010  
Tel 515 337 6610  
Fax 515 337 6120  
Email: [bruce.a.carter@aphis.usda.gov](mailto:bruce.a.carter@aphis.usda.gov)

### **Dr. Paul Chua (2009)**

National Public Health Laboratory  
Ministry of Health Malaysia  
Email: [chuakawbing@yahoo.com.sg](mailto:chuakawbing@yahoo.com.sg)

### **Gary Crameri (2009)**

New & Emerging Zoonotic Diseases  
Australian Biosecurity CRC  
CSIRO Australian Animal Health Laboratory Geelong, Australia.  
Tel (03) 5227 5305  
Fax (03) 5227 5555  
Email: [gary.crameri@csiro.au](mailto:gary.crameri@csiro.au)

### **Dr. Peter Daniels (2009 and 2017)**

OIE Biological Standards Commission, OFFLU  
Email: [Danielpeter19@gmail.com](mailto:Danielpeter19@gmail.com)

**Dr. Sandra Diederich (2017)**

Friedrich-Loeffler-Institut - Federal Research Institute for Animal Health  
Greifswald - Insel Riems  
Germany  
Email: [Sandra.diederich@fli.de](mailto:Sandra.diederich@fli.de)

**Jon Epstein, DVM, Ph.D (2017)**

EcoHealth Alliance  
New York, NY  
Email: [epstein@ecohealthalliance.org](mailto:epstein@ecohealthalliance.org)

**Dr. Hume Field (2009)**

Principle Veterinary Epidemiologist (Emerging Diseases)  
Biosecurity Sciences Laboratory  
Animal Research Institute  
Department of Primary Industries and Fisheries  
Queensland Government  
665 Fairfield Road, Yeerongpilly Qld 4105  
LMB4 Moorooka Queensland 4105  
Australia  
Tel: +61 (0) 3362 9566  
Fax: +61 (0) 7 3362 9457  
E-mail: [hume.field@dpi.qld.gov.au](mailto:hume.field@dpi.qld.gov.au)  
Website : [www.dpi.qld.gov.au](http://www.dpi.qld.gov.au)

**Pierre B. H. Formenty, DVM (2009)**

Epidemic and Pandemic Alert and Response Department (HSE/EPR)  
World Health Organization (WHO)  
20 Avenue Appia  
CH-1211 Geneva 27 - SWITZERLAND  
Tel: +41 22 791 25 50

**Cyril Gerard Gay, DVM, Ph.D (2009 and 2017, Chair 2009)**

Senior National Program Leader  
Animal Production and Protection  
Office of National Programs, ARS, REE, USDA  
5601 Sunnyside Avenue  
Beltsville, MD 20705  
Tel (301) 504-4786  
Fax (301) 504-5467  
Email: [cyril.gay@ars.usda.gov](mailto:cyril.gay@ars.usda.gov)

**Dr. Glenn Marsh (2009 and 2017)**

CSIRO Livestock Industries  
Australian Animal Health Laboratory  
5 Portarlinton Rd, East Geelong, VIC 3220  
Australia  
Tel: (03) 5227 5125  
Email: [glenn.marsh@csiro.au](mailto:glenn.marsh@csiro.au)

**Steve Luby, MD (2009)**

Agency Head  
Centers for Disease Control and Prevention  
US Embassy, Bangladesh  
Head, Programme on Infectious Diseases and Vaccine Sciences  
ICDDR, B  
GPO Box 128  
Dhaka – 1000, Bangladesh  
68, Shaheed Tajuddin Ahmed  
Sarani, Mohakhali, Dhaka 1212  
Tel: 880-2-9881761 (Direct)  
880-2-8860523-32 Ext. 2502  
Fax: 880-2-8823963  
E-mail: [sluby@icddr.org](mailto:sluby@icddr.org)  
Website : [www.icddr.org](http://www.icddr.org)

**Professor John S. Mackenzie (2009)**

Australian Biosecurity CRC  
Curtin University of Technology  
GPO Box U1987  
Perth, WA6845  
Australia  
Tel +61-3-9822 6223  
Fax +61-8-9266 1650  
Email: [J.MacKenzie@curtin.edu.au](mailto:J.MacKenzie@curtin.edu.au)

**Jenn McEachern BSc (2009)**

Research Assistant  
CSIRO Livestock Industries  
Australian Animal Health Laboratory  
5 Portarlinton Rd, East Geelong, VIC 3220  
Tel: (03) 5227 5094  
Email: [jennifer.meachern@csiro.au](mailto:jennifer.meachern@csiro.au)

**Deborah Middleton, DVM, Ph.D (2009)**

Transforming Animal Biosecurity  
Australian Animal Health Laboratory  
Common Wealth Scientific and Industrial Research Organisation (CSIRO)  
Geelong, Australia  
Email: [Deborah.middleton@csiro.au](mailto:Deborah.middleton@csiro.au)

**Samia Metwally, DVM, Ph.D (2009)**

Animal Health Officer (Virologist)  
AGAH, AGA Division  
Food and Agriculture Organization of UN  
Viale delle Terme di Caracalla, 00153 Rome, Italy  
Tel: +39 06 570 55838  
Email: [Samia.Metwally@fao.org](mailto:Samia.Metwally@fao.org)  
EMPRES-i: <http://empres-i.fao.org/empres-i/home>  
GLEWS: <http://www.glews.net>

**Dr. Jackie Pallister (2009)**

New & Emerging Zoonotic Diseases  
Australian Biosecurity CRC  
CSIRO Australian Animal Health Laboratory, Geelong, Australia.  
Email: [Jackie.Pallister@csiro.au](mailto:Jackie.Pallister@csiro.au)

**Dr. Brad Pickering (2017)**

National Center for Foreign Animal Disease; Canadian Food Inspection Agency  
Winnipeg, MB, Canada  
Email: [Bradley.Pickering@inspeciton.gc.ca](mailto:Bradley.Pickering@inspeciton.gc.ca)

**Dr. Ashwin A. Raut (2017)**

ICAR-National Institute of High Security Animal Diseases  
OIE Reference Laboratory for Avian Influenza  
Anandnagar, Bhopal, India  
Email: [ashwin.hsadl@gmail.com](mailto:ashwin.hsadl@gmail.com)

**Paul A. Rota, Ph.D (2009)**

Lead Scientist, Measles Team  
Measles, Mumps, Rubella and Herpesviruses Laboratory Branch  
Division of Viral and Rickettsial Diseases  
Centers for Disease Control and Prevention  
MS-C-22, 1600 Clifton Rd  
Atlanta, GA, USA 30333  
Tel 1-404-639-4181 (voicemail)  
Fax 1-404-639-4187  
Email: [parl@cdc.gov](mailto:parl@cdc.gov)

**James A. Roth, DVM, PhD (2009 and 2017)**

Director, Center for Food Security and Public Health  
Executive Director, Institute for International Cooperation in Animal Biologics  
College of Veterinary Medicine Iowa State University Ames, Iowa 50010  
Phone: 515-294-8459  
Fax: 515-294-8259  
Email: [jaroth@iastate.edu](mailto:jaroth@iastate.edu)

**Dr. Ellie Virtue (2009)**

New & Emerging Zoonotic Diseases  
Australian Biosecurity CRC  
CSIRO Australian Animal Health Laboratory, Geelong, Australia.  
Email: [Elena.Virtue@csiro.au](mailto:Elena.Virtue@csiro.au)

**Linfa Wang, Ph.D (2009)**

Senior Principal Research Scientist  
CEO Science Leader  
CSIRO Livestock Industries  
Australian Animal Health Laboratory  
PO Bag 24, Geelong, VIC 3220  
Australia  
Tel (61-3)-52275121  
Fax (61-3)-52275555  
Email: [Linfa.Wang@csiro.au](mailto:Linfa.Wang@csiro.au)

**Hana M. Weingartl, Ph.D (2009 and 2017, Chair 2017)**

Head, Special Pathogens Unit  
National Centre for Foreign Animal Disease  
Canadian Food Inspection Agency  
1015 Arlington St.  
Winnipeg, Manitoba  
R3J 0C2  
Canada  
Tel 204 789 2027

---

Dear Colleagues,

Thanks to Hana for helping update Section 6 of the diagnostic section. I'm attaching here the report one more time for those of you that have not had a chance to look at it yet. I plan on posting the report on the USDA website next week so please take a quick look as indicated in my message below.

Thank you.

Cyril

**Subject:** Henipavirus Gap Analysis Report

Dear Colleagues,

Please find attached the subject report for your review and input. It's taken me a while to update the gap analysis report, but really appreciated the help received from Jim Roth, Jon Epstein, Bruce Carter, and Hanna Weingartl. I would like to post the report on the USDA website as soon as possible (a lot of people have been asking me for the report), so I would really appreciate if you could take a quick look in the sections that interest you and edit and supplement with new information and references where needed.

At a minimum, there are three areas that definitely need your attention.

- 1) The Recommendation section on "Preparedness" on Page 40 is weak as I had to delete all the reference materials previously provided by Peter Daniels because they have all been "deleted" from the AAHL website. I tried finding other relevant information on the internet, unsuccessfully. Perhaps this section should be deleted? Or you may be able to improve it?

- 2) The one area that requires special technical attention for sure is the diagnostic section, especially “6) *N and G ELISA*” on Page 34. I think this section needs to clearly differentiate antibody detection versus antigen detection ELISAs, which is not clear as currently written. I think we also need to add information on assays that have recently been developed that can differentiate NiV and HeV; e.g., publications from Chiang et al (2013), and Fisher et al (2018).
  
- 3) Lastly, I think the research recommendations on Page 39 could be improved with additional research priorities to fill the many gaps identified in the report.

As previously mentioned when we were all in Canada, this report will be distributed to stakeholders and funders of research (globally), as well as industry, and government agencies that have interest in stockpiling veterinary medical countermeasures – so your critical view of the report is essential as it reflects our collective expert opinion.

Thank you so much for your help and contributions.

Best regards,

Cyril

## **EcoHealth Alliance BEP proposal 2018.**

**Activity #1 Project Title:** Serological Biosurveillance for Henipaviruses and Filoviruses in Uttar Pradesh, India

**Activity #1 Project Summary:** EcoHealth Alliance (EHA) proposes to enhance early detection and surveillance capacity in India by: 1) transferring Luminex-based Bio-Plex technology and validated reagents to detect IgG antibodies against all henipaviruses (e.g. Nipah virus) and filoviruses (e.g. Ebola virus) to the premiere UP medical laboratory – Sanjay Gandhi Institute of Postgraduate Medical Sciences; 2) training laboratory personnel to develop and utilize Bio-Plex assays; 3) conducting biological surveillance in bats, domestic animals and people in rural communities where there are high levels of contact among people and animals. Activities will be coordinated with, and complementary to the USAID Emerging Pandemic Threats: PREDICT program and the Global Health Security Agenda, and surveillance data will be shared with the Government of India (GoI). Henipaviruses and filoviruses are highly pathogenic zoonotic viruses and select agents capable of causing public health emergencies of international concern. Henipaviruses are associated with acute encephalitis and filoviruses are associated with hemorrhagic fever in people. A disproportionate number of cases of acute encephalitis occur in Uttar Pradesh (UP), India, and most remain undiagnosed. Hemorrhagic fever has also recently been reported in UP. Bats are reservoirs for henipaviruses and filoviruses and zoonotic transmission of these viruses directly and via livestock has occurred in Asia.

**Country of Impact:** India

**Nonproliferation Objective and the Project's Role in Meeting this Objective:** In conjunction with activities included in this proposal for Indonesia, Jordan, and Malaysia, EcoHealth Alliance (EHA) will leverage its global expertise in biological threat reduction across the wildlife-livestock-human interface and existing relationships in India to strengthen the country's capacity to test, diagnose, and respond to natural and manmade threats from viral zoonoses and other dangerous pathogens. The proposed activities meet the outlined nonproliferation objectives as follows: promoting biorisk management practices through training workshops with partners from Ministries of Health, Agriculture, Environment, and Defense; securing life science institutions and dangerous pathogens in BEP second-highest priority countries through biosecurity, biosafety, and rapid agent/pathogen detection capacity-building; decreasing the risk that scientists with dual-use expertise will misuse pathogens through biosecurity/biosafety training workshops and introducing surveillance and detection duties that foster positive US relations; promoting the detection, disruption, mitigation, and investigation of biological terrorism plots through increased capacity for rapid agent detection and regular communication among government partners; promoting the adoption of and compliance with comprehensive international frameworks that advance U.S. biological nonproliferation objectives through training workshops.

**Scope of Work:** The Luminex-based Bio-Plex assay is a quantitative, multiplex, bead-based technology that allows the user to screen for antibodies against viruses using a relatively small volume of serum per test (~1 µL) compared to ELISA (~20 µL) and avoids the need for working with live viruses. *This is ideal*

*as reservoir species for select agents can be tiny and provide only a few  $\mu\text{L}$  of serum.* Our group has developed and validated Bio-Plex reagents that will detect antibodies for each of the known henipavirus and filovirus species and we have previously screened bat and livestock sera using these reagents.

EHA will leverage its long-standing relationships with Indian government and non-governmental sector partners supported by current USAID and DoD DTRA CBEP projects to implement and scale up rapid and efficient diagnostic capacity for antibodies against any filovirus or henipavirus using BioPlex systems, which can be updated as more reagents become available. Through a series of training workshops and transfer of the Bio-plex technology and reagents, EHA and partners will conduct surveillance in animal reservoirs and at-risk human populations for these zoonotic viruses. Placing this technology in India’s hotspot for acute encephalitis syndrome will provide significant benefit to India’s public health system. EHA and local implementing partners will communicate with GoI stakeholders to ensure dissemination of information.

EHA has a long history of collaboration with the **Uniformed Services University of the Health Sciences**, which has developed the full panel of henipavirus and filovirus antigens and multiplexed platform using the Biorad Bio-plex technology. The lab will provide these reagents and deliver training to our implementing partner lab at **Sanjay Gandhi Institute of Postgraduate Medical Sciences (SGIPGMS)** in Lucknow, UP. Human and animal sample testing will be conducted at SGIPGMS. We will also partner with **DUVASU veterinary college** in UP for trainings and sample collection. SGIPGMS, DUVASU, and EHA are partners under the USAID PREDICT India project and the proposed activities will also allow PREDICT to screen sera that would not otherwise be tested.

**Deliverables: EHA will complete the following tasks:**

- A. Procure all necessary Biorad Bio-Plex machines and transfer reagents;
- B. Conduct two training workshops: Biosecurity, biosafety and One Health surveillance; and Bio-training workshop for core lab staff
- C. Hold monthly webinars and check-ins with partners
- D. Perform 3 quality control assessments of deliverables F, G, H
- E. Distribute training curriculum to participants and train future trainers to ensure sustainability.

**Demonstrated ability of partner labs to:**

- F. Conduct human & animal surveillance with safe specimen collection and transfer to partner lab
- G. Screen serum using Bio-plex technologies & data analysis
- H. Disseminate laboratory results to stakeholders

**Schedule/Timeline:** The project will be 12 months, beginning the month funding is received.

Month	1	2	3	4	5	6	7	8	9	10	11	12
Deliverable	AC	ACF	ABC	CDFG	BC	CF	CF	CDG	CG	CG	CG	CDEFGH

**Sustainability:** This project will provide enhanced capacity to detect exposure to biothreats in a BEP priority country. Labs will learn how to produce reagents for the Bio-Plex machine so work can continue beyond the performance period. This will allow our partner lab to serve a wider network of diagnostic labs and conduct enhanced serological detection of the aforementioned agents in an area of high risk for zoonotic disease emergence. The surveillance and training activities will be conducted by EHA and in-country partners who are established medical and veterinary teaching institutions, providing credibility and sustainability. Our partners have direct lines of communication to federal health agencies which will maximize this project’s impact. Participants will include government officers from animal and human health sectors, who will be trained in enhanced biosecurity, biosafety, and biosurveillance, which will promote sustainable practices beyond the project period. Partner labs will be sufficiently trained to sustainably conduct frontline detection of biothreats, addressing nonproliferation objectives after the project’s conclusion.

---

Hey Eric,

Thanks, sorry things have been crazy and I haven't gotten much in way of writing done yet.

The general plan for the Liberia/CIV project is to screen human and bat sera for Filos and Henipas only. Wondering if the assays will capture this one too? <http://punchng.com/new-ebola-virus-found-in-sierra-leone-govt-says/>  
<https://twitter.com/EcoHealthNYC/status/1022567864656699392> Late breaker, more to come.

As we discussed, we're hoping to use your existing Bio-plex panels, and to export samples to USU for analysis. Still a lot to figure out - e.g. if we should have any capacity building piece to this, and also adding in some "predictive risk mapping" with the results, but by tomorrow afternoon should have this scoped out more. Can you guys advise on the cost per specimen and labor costs, so I can think about the number of specimens and sampling design a little more?

Also, attached is the language I have from one of our previous (unfunded) BEP proposals that I'll modify. Please feel free to track changes and flesh out the methods a little more or change them if needed.

Cheers,  
Kevin

Partner labs will be sufficiently trained to sustainably conduct frontline detection of biothreats, addressing nonproliferation objectives after the project’s conclusion.

## **Activity #2 Project Title:** Enhancing Serological Biosurveillance for Select Agents in Indonesia

**Activity #2 Project Summary:** EcoHealth Alliance (EHA) will leverage its global expertise in biological threat reduction across the wildlife-livestock-human interface and long-standing relationships with government and non-governmental sector partners in Indonesia to strengthen the country's capacity to test, diagnose, and respond to natural and manmade threats from dangerous pathogens known to occur in the region. We will establish affordable and efficient Bio-Plex (e.g. Luminex-based) technologies for serological biosurveillance, and implement wildlife and human testing for Henipaviruses (Nipah, Hendra, Cedar viruses) and Filoviruses (Ebola viruses and Marburg). EHA will train staff from academic and government partner organizations to optimize the technology, enhance biosecurity and biosafety practices, and conduct frontline detection of dangerous pathogens in humans and animals. We will leverage specimens collected under USAID PREDICT-2 for initial screening. Additional resources will support ongoing specimen collection and optimization of additional locally-relevant assays (e.g. melioidosis) to ensure sustainable and continued use of the platform for pre-emptive zoonotic biosurveillance. At project conclusion, local partners will have demonstrated ability to rapidly and accurately detect and differentiate exposure to select agents; implement One Health surveillance; respond to frontline dangerous pathogen detection requests and facilitate specimen collection and transfer; and rapidly disseminate laboratory results to government partners.

### **Country of Impact:** Indonesia

**Nonproliferation Objective and the Project's Role in Meeting this Objective:** In conjunction with projects included in this proposal for India, Jordan, and Malaysia, the proposed activities meet the outlined nonproliferation objectives as follows: promoting biorisk management practices through training workshops for partners from academia and Ministries of Health, Agriculture, Environment, and Defense; securing life science institutions and dangerous pathogens in BEP second-highest priority countries through biosecurity, biosafety, and rapid agent/pathogen detection capacity-building; decreasing the risk that scientists with dual-use expertise will misuse pathogens through biosecurity/biosafety training workshops and introducing surveillance and detection duties that foster positive US relations; promoting the detection, disruption, mitigation, and investigation of biological terrorism plots through increased capacity for rapid agent detection and regular communication among government partners; promote biorisk management through training workshops inclusive of government partners; promoting the adoption of and compliance with frameworks that advance U.S. biological nonproliferation objectives through training workshops.

**Scope of Work:** EHA will leverage its existing disease surveillance and laboratory partners in Indonesia and experts in the US to implement and scale up rapid diagnostic capacity using bio-plex technologies to screen human and animal specimens for exposure to select agents (Filo- and Henipaviruses initially, and begin developing melioidosis (*Burkholderia pseudomallei*) assays. We will enhance biosecurity and biosafety at partner labs and institutions that handle high risk biological specimens through training events. We will procure and transfer Bio-Plex technology, equipment and reagents to **Institut Pertanian Bogor, Primate Research Center (IPB-PRC)**, and prepare staff from IPB-PRC and **Eijkman Institut** (where Bio-Plex technology already exists) to conduct frontline detection of bioweapons and dangerous pathogens. Multiplex PCR Bio-Plex platforms will be used to detect potential bioweapons and dangerous pathogens from specimens collected from surveillance of wildlife populations and hospitalized patients with fevers of unknown origin, hemorrhagic fevers of unknown origin, severe acute respiratory illnesses of unknown origin, as well as from outbreaks, suspicious substances, and emergency scenarios reported to the team by government partners. EHA and local implementing partners will regularly communicate with Ministries of Health, Agriculture, Environment, and Defense to facilitate this collaboration. EHA has a long history of collaboration with the **Uniformed Services University of the Health Sciences (USUHS)**, which has developed the full panel of henipavirus and filovirus antigens and multiplexed platform using

the Biorad Bio-plex technology. USUHS will produce these reagents, serve as experts in trainings, and participate in QA/QC and data analysis. EHA will strengthen local capacity with partners from the USAID PREDICT project including IPB-PRC for wildlife surveillance; Eijkman Institut for human surveillance; and personnel from the Ministry of Agriculture’s Disease Investigation Centers for training.

**Deliverables:**

**EHA will complete the following tasks:**

- A. Procure all necessary Biorad Bio-Plex machines and produce or procure reagents
- B. Host two training workshops. 1 workshop on biosecurity and biosafety and One Health outbreak response for local partners; 1 Bio-Plex training workshop for lab staff from IPB-PRC and Eijkman
- C. Hold monthly webinars and check-ins for partners
- D. Perform 3 quality control assessments of deliverables F, G, H
- E. Distribute training curriculum to participants for each workshop and train future trainers to ensure sustainable transfer of knowledge

**Demonstrated ability of partner labs to:**

- F. Conduct One Health surveillance and facilitate specimen collection and transfer to reference labs
- G. Screen wildlife and human serum using Bio-Plex technologies
- H. Disseminate laboratory results to appropriate partner(s)

**Schedule/Timeline:** The project will be 12 months, beginning the month funding is received.

Month	1	2	3	4	5	6	7	8	9	10	11	12
Deliverable	AC	ABC	ACF	BCD	C	CF	C	CD	CF	C	C	CDEFGH

**Sustainability:** This project will result in sustainable frontline detection of bioweapons and dangerous pathogens in a BEP second-highest priority country. Partner labs will be fitted with Bio-Plex technologies for rapid detection of the aforementioned agents, and the work will be conducted by in-country scientists working at government institutions and universities. The project involves close collaboration among government ministries and research institutions, and promotes regional collaboration and skills sharing between nations. In-country personnel will be trained in enhanced biosecurity, biosafety, and rapid agent detection, so the work will continue past the 12-month performance period but under the leadership of in-country staff and government partners. Training workshops will be conducted such that they will be reproducible by in-country scientists for future training of scientists/partners following the completion of the project. Country staff at government labs and research facilities will be sufficiently trained to sustainably conduct frontline surveillance and detection of bioweapons and dangerous pathogens addressing nonproliferation objectives after the project’s conclusion.

**Activity #3 Project Title:** Enhancing Serological Biosurveillance for Henipaviruses, Filoviruses, and MERS-CoV in Jordan

**Activity #3 Project Summary:** In conjunction with projects included in this proposal for India, Indonesia, and Malaysia, EcoHealth Alliance (EHA) will leverage its global expertise in biological threat reduction across the wildlife-livestock-human interface and long-standing relationships with the Jordanian government and non-governmental sector to strengthen the country's capacity to test, diagnose, and respond to natural and manmade threats from viral zoonoses and other dangerous pathogens. We will establish affordable and efficient Luminex-based technologies (Biorad Inc., Bio-Plex) for serological surveillance and implement rapid diagnostic capacity for Henipaviruses (e.g., Nipah virus) and Filoviruses (e.g., Ebola virus), and likewise serological surveillance for Middle East Respiratory Syndrome Coronavirus (MERS-CoV) through a commercially-available ELISA. EHA will train staff at existing partner organizations to utilize the technology and optimize assays, enhance biosecurity and biosafety practices, and conduct frontline detection of dangerous pathogens in humans and animals. We will leverage specimens collected under USAID PREDICT-2 from humans, livestock and wildlife for initial screening. At project conclusion, local partners will have demonstrated ability to rapidly and accurately detect and differentiate exposure to select agents; implement One Health surveillance; respond to dangerous pathogen detection requests and facilitate specimen collection and transfer; and rapidly disseminate laboratory results to government partners.

**Country of Impact:** Jordan

**Nonproliferation Objective and the Project's Role in Meeting this Objective:** The proposed activities meet the outlined nonproliferation objectives as follows: promoting biorisk management practices through training workshops partners from Ministries of Health, Agriculture, Environment, and Defense; securing life science institutions and dangerous pathogens in BEP second-highest priority countries through biosecurity, biosafety, and rapid agent/pathogen detection capacity-building; decreasing the risk that scientists with dual-use expertise will misuse pathogens through biosecurity/biosafety training workshops and introducing surveillance and detection duties that foster positive US relations; promoting the detection, disruption, mitigation, and investigation of biological terrorism plots through increased capacity for rapid agent detection and regular communication among government partners; partnering with non-scientific interlocutors such as policymakers, law enforcement, military, and diplomatic audiences to promote biorisk management through training workshops inclusive of government partners; promoting the adoption of and compliance with comprehensive international frameworks that advance U.S. biological nonproliferation objectives through training workshops.

**Scope of Work:** EHA will leverage its existing relationships supported by current USAID and DoD DTRA CBEP projects to implement and scale up rapid diagnostic capacity for Henipaviruses and Filoviruses (using Luminex-based technologies), and likewise for MERS-CoV using ELISA, in addition to enhancing biosecurity and biosafety at partner labs that handle high risk biological specimens.

Through a series of training workshops and transfer of the Bio-Plex technology and reagents assays and required laboratory equipment, EHA will prepare staff to conduct frontline detection of dangerous pathogens. Multiplex PCR Bio-Plex platforms will be used to detect exposure to these zoonotic viruses from specimens collected from surveillance in animal reservoirs and at-risk human populations for these zoonotic viruses. EHA and local implementing partners will regularly communicate with Ministries of Health, Agriculture, Environment, and Defense to facilitate this collaboration.

EHA has a long history of collaboration with the **Uniformed Services University of the Health Sciences (USUHS)**, which has developed the full panel of henipavirus and filovirus antigens and multiplexed platform using the Biorad Bio-Plex technology. The lab will produce these reagents and deliver training

to each partner lab in country. They will also participate in QA/QC and data analysis. In Jordan, we will continue our partnerships with **Jordan University for Science and Technology** and the **Princess Haya Biotechnology Center**, to focus on Henipaviruses, Filoviruses, and MERS.

**Deliverables:**

**EHA will complete the following tasks:**

- A. Procure all necessary Biorad Bio-Plex machines and produce or procure reagents
- B. Host two training workshops. 1 workshop on biosecurity and biosafety and One Health outbreak response for local partners; 1 Bio-Plex training workshop for core lab staff
- C. Hold monthly webinars and check-ins for partners
- D. Perform 3 quality control assessments of deliverables F, G, H
- E. Distribute training curriculum to participants and train future trainers to ensure sustainable transfer of knowledge.

**Demonstrated ability of partner labs to:**

- F. Conduct One Health surveillance and facilitate specimen collection and transfer to reference labs
- G. Screen serum using Bio-Plex technologies
- H. Disseminate laboratory results to appropriate partner(s)

**Schedule/Timeline:** The project will be 12 months, beginning the month funding is received.

Month	1	2	3	4	5	6	7	8	9	10	11	12
Deliverable	AC	ABC	ACF	BCD	C	CF	C	CD	CF	C	C	CDEFGH

**Sustainability:** This project will result in sustainable frontline detection of dangerous pathogens in multiple BEP second-highest priority countries. Partner labs will be fitted with Bio-Plex technologies for rapid detection of the aforementioned agents, and the work will be conducted by in-country scientists working at government institutions and universities, trained by EHA scientists. The project involves close collaboration among government ministries and research institutions, and promotes regional collaboration and skills sharing between nations. In-country personnel will be trained in enhanced biosecurity, biosafety, and rapid agent detection, so the work will continue past the 12-month performance period but under the leadership of in-country staff and government partners. Training workshops will be conducted such that they will be reproducible by in-country scientists for future training of scientists/partners following the completion of the project. Country staff at government labs and research facilities will be sufficiently trained to sustainably conduct frontline detection of dangerous pathogens addressing nonproliferation objectives after the project’s conclusion.

**Activity #4 Project Title:** Serological Biosurveillance for Henipaviruses and Filoviruses in Sabah, Malaysia

**Activity #4 Project Summary:** EcoHealth Alliance (EHA) proposes to build on our earlier work in Malaysia to enhance early detection and surveillance capacity by: 1) transferring Luminex-based Bio-Plex technology and validated reagents to detect IgG antibodies against all henipaviruses and filoviruses to the PREDICT lab at the Sabah Wildlife Department; 2) training laboratory personnel to develop and utilize Bio-Plex assays; 3) conducting biological surveillance in bats, rodents and primates in rural communities and ecotourism sites where there are high levels of contact among people and animals. Activities will be coordinated with, and complementary to USAID's Emerging Pandemic Threats: PREDICT program, the Global Health Security Agenda, and DTRA supported activities. Surveillance data will be shared with the Government of Sabah. Henipaviruses (e.g. Nipah virus) and filoviruses (e.g. Ebola virus) are highly pathogenic zoonotic viruses and select agents capable of causing public health emergencies of international concern. Bats in Malaysia are reservoirs for Nipah virus and possibly filoviruses. Zoonotic transmission of Nipah virus via livestock has previously occurred in Malaysia. Sabah, located in Borneo, has a large diversity of bats and areas where human contact is common.

**Country of Impact:** Malaysia

**Nonproliferation Objective and the Project's Role in Meeting this Objective:** In conjunction with projects included in this proposal for India, Jordan, and Indonesia, the proposed activities meet the outlined nonproliferation objectives as follows: promoting surveillance and biorisk management practices through training workshops with participants from departments of Health, livestock, and wildlife, and the University of Malaysia, Sabah Medical college in a BEP priority country. Activities under this project will also enhance the semi-autonomous state of Sabah's capabilities to detect spillover or exposure to select agents in animals and people. These activities support current priorities and One Health surveillance activities conducted by the PREDICT project in partnership with the government of Sabah. Sharing findings with state government policymakers will advance U.S. biological nonproliferation objectives through training workshops.

**Scope of Work:** EHA will leverage its long-standing relationships with Malaysian government and non-governmental sector partners supported by current USAID and DoD DTRA CBEP projects to implement and scale up rapid and efficient diagnostic capacity for antibodies against any filovirus or henipavirus using Bio-Plex systems, which can be updated as more reagents become available. The Luminex-based Bio-Plex assay is a quantitative, multiplex, bead-based technology that allows the user to screen for antibodies against viruses using a relatively small volume of serum per test (~1µL) compared to ELISA (~20 µL) and avoids the need for working with live viruses. *This is ideal as reservoir species for special agents are tiny and provide only a few µL of serum.* Our group has developed and validated Bio-Plex reagents that will detect antibodies for each of the known henipavirus and filovirus species and we have previously screened bat and livestock sera using these reagents. Through a series of training workshops and transfer of the Bio-plex technology and reagents, EHA and partners will conduct surveillance in animal reservoirs and at-risk human populations for these zoonotic viruses. As part of ongoing DTRA and PREDICT work BioPlex has been successfully installed and implemented in Peninsular Malaysia partner labs; this activity will leverage this partnership and expand this technology to Sabah, Malaysia (which is geographically and administratively distinct from Peninsular Malaysia), enhancing Malaysia's overall capacity to rapidly detect and respond to zoonotic viruses. This project will also strengthen collaboration and skills sharing between Peninsular Malaysia and Sabah through One Health biosecurity and biosafety trainings. EHA and local implementing partners will regularly communicate with state and federal stakeholders to ensure sharing of information and capacities.

EHA has a long history of collaboration with the Broder lab at the **Uniformed Services University of the Health Sciences (USUHS)**, which has developed the full panel of henipavirus and filovirus antigens and multiplexed platform using the Biorad Bio-Plex technology. The lab will produce these reagents and deliver training to each partner lab in country. In Malaysia, we will continue our existing partnerships under USAID and DoD DTRA CBEP support with **Conservation Medicine, Ltd.**, and the **Sabah Wildlife Department** (a state government agency). We will focus on screening wildlife sera for antibodies against henipaviruses and filoviruses at the PREDICT lab shared with Sabah Wildlife Department, with the potential to expand this capability to Sabah State Health Department labs in the future.

**Deliverables:**

**EHA will complete the following tasks:**

- A. Procure all necessary Biorad Bio-Plex machines and produce or procure reagents
- B. Host two training workshops. 1 workshop on biosecurity and biosafety and One Health outbreak response for local partners; 1 Bio-Plex training workshop for core lab staff
- C. Hold monthly webinars and check-ins for partners
- D. Perform 3 quality control assessments of deliverables F, G, H
- E. Distribute training curriculum to participants and train future trainers to ensure sustainable transfer of knowledge.

**Demonstrated ability of partner labs to:**

- F. Conduct One Health surveillance and facilitate specimen collection and transfer to reference labs
- G. Screen serum using Bio-plex technologies
- H. Disseminate laboratory results to appropriate partner(s)

**Schedule/Timeline:** The project will be 12 months, beginning the month funding is received.

Month	1	2	3	4	5	6	7	8	9	10	11	12
<b>Deliverable</b>	AC	ACF	ABC	CDFG	BC	CF	CF	CDG	CG	CG	CG	CDEGH

**Sustainability:** This project will result in sustainable frontline detection of bioweapons and dangerous pathogens in a BEP second-highest priority country. Partner labs will be fitted with Bio-Plex technologies for rapid detection of the aforementioned agents, and the work will be conducted by in-country scientists working at government institutions and universities, trained by EHA scientists. The project involves close collaboration among government ministries and research institutions, and promotes regional collaboration and skills sharing between nations. Hi Chris,

Please find the Project Summary from the submission. Please let me know if you need anything else.

Thanks,  
Emma

hi Emma

Could you please send me the info from the state dept grant that went in last week?

title, dates, number?

thanks  
CB
