**Prime PI:** Peter Daszak, Ph.D.

#### **ATTACHMENT A:** Scope of Work

**Project Description/Summary:** Southeast Asia is one of the world's highest-risk EID hotspots, the origin of the SARS pandemic, Nipah virus, and repeated outbreaks of influenza. This is driven by high diversity of wildlife and rapidly expanding demography that brings human and wildlife populations closer. This proposal will launch the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH), a collaboration among leaders in emerging disease research in the USA, Thailand, Singapore and the 3 major Malaysian administrative regions. These researchers have networks that span >50 clinics, laboratories and research institutions across almost all SE Asian countries and will use the EID-SEARCH as an early warning system for outbreaks involving exchange of information, reagents, samples and technology, and a collaborative power-house for fundamental and translational research. The EID-SEARCH will also act as a significant asset to scale-up and deploy resources in the case of an outbreak in the region. This EIDRC will conduct research to: 1) Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife, by analyzing previously-archived wildlife samples, conducting targeted wildlife surveillance, and using serology & PCR assays to identify novel viruses. These will be characterized to assess risk of spillover to people, and a series of in vitro (receptor binding, cell culture) and in vivo (humanized mouse and collaborative cross models) assays used to assess their potential to infect people and cause disease; 2) Collect samples and questionnaire data from human communities that live in EID hotspots and have high cultural and behavioral risk of animal exposure (e.g. wildlife hunting, bat guano collection). These will be tested with serological assays to identify evidence of novel virus spillover, and analyzed against metadata to identify key risk pathways for transmission; 3) Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts. We will conduct syndromic surveillance at clinics serving the populations in Aim 2, enroll patients with undiagnosed illness and symptoms consistent with emerging viral pathogens, and test samples with molecular and follow-up serological assays to identify causal links between these syndromes and novel viruses. This research will advance our understanding of the risk of novel viral emergence in a uniquely important region. It will also strengthen in-country research capacity by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. The large body of high impact collaborative research from this EIDRC leadership team provides proof-of-concept that EID-SEARCH has the background, collaborative network, experience, and skillset to act as a unique early warning system for novel EIDs of any etiology threatening to emerge in this hottest of the EID hotspots.

Under the supervision of Co-Investigators Dr. Christopher Broder and Dr. Eric Laing, working closely with the project coordinator Spencer Sterling, The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc. will conduct epidemiology research and characterization of a series of coronaviruses (CoVs), paramyxoviruses (PMVs – particularly Henipaviruses) and filoviruses (FVs) following Scope of Work:

**1. Continue to develop, validate, and refine serology platforms for laboratory analysis of collected human and animal samples.**

1.1 Develop and validate the regionally specific CoV/Henipavirus MMIA panel.

1.2 Refine MMIA tests for Marburg and Tai Forest viruses

**TITLE:** Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia

**Grant Number:** 5U01AI151797

Eric Laing, Ph.D., Site Principal Investigator,

Christopher Broder, Ph.D. Co-Investigators,

Spencer Sterling, MS, Scientific Project Coordinator

**Prime PI:** Peter Daszak, Ph.D.

- 1.3 Refine and produce antigens for MPOX assay in support of CREID network-wide activities.
- 1.4 Support the collaboration with PREMISE for PBMC studies in Thailand.
- 1.5 Provide on-site training to the project members from Conservation Medicine in Malaysia on serology testing.
- 1.6 Support data analysis in Thailand and Malaysia to ensure high-quality publications from EID-SEARCH
- 1.7 Support CREID Pilot Research Project proposals, as applicable.
- 1.8 Support CREID Pilot Proposal Research Project, “Expanding in-country surveillance capacity for bat-borne henipaviruses in Madagascar,” (PI, Dr. Hafaliana Christian Ranaivoson; Co-PI, Dr. Cara Brook), cross-Research Center collaboration with CREID-ESP
- 1.9 Support pilot study on blood-fed mosquitoes in collaboration with the NIAID vector research program (Dr. Lehmann).

## **2. Project management and coordination**

- 2.1 Ensure all permits and permissions are in place to conduct project activities.
- 2.2 Represent EID-SEARCH to present relevant research findings at conferences and other relevant meetings.
- 2.3 Collaborate with the EID-SEARCH partners for data cleaning, analysis, interpretation, and contributing to scientific publications as agreed.
- 2.4 The subrecipient will adhere to the applicable elements of resource and data management from the approved project proposal as described in Resource Sharing Plan in **ATTACHMENT D**.
- 2.5 Submit to the requirements of the Federal Funding Accountability and Transparency Act (FFATA) included as **ATTACHMENT C**, with the signed contract.

## **3. Project communication and reporting**

- 3.1 Participate in monthly meetings with project partners over video conference.
- 3.2 Attend CREID Network annual meeting and other in-person project meetings as applicable.
- 3.3 Present MPOX multiplex serology test development, and Marburg virus and fruit bat sero-surveillance in Madagascar (collaboration with Dr. Cara Brook, Co-PI of Pilot Award, CREID-ESP) at ASTHM 2023, Chicago, IL, USA.
- 3.4 Participate in calls with the EID-SEARCH partners and global team at EHA as requested.
- 3.5 Complete the following programmatic and financial reporting by the requested deadlines:
  - 3.5.1 Quarterly reporting to EcoHealth Alliance on programmatic activities due on the following dates:
    - 01 August 2023
    - 01 November 2023
    - 01 February 2024
    - 01 May 2024
  - 3.5.2 Semi-annual and annual reports to NIH/NIAID.
  - 3.5.3 Annual reports to the CREID Network and other reports requested by NIAID.
  - 3.5.4 Invoices and financial reports to EcoHealth Alliance every two months, including 1-page or longer programmatic update, copies of receipts and/or other supporting documents, and breakdown of the costs in each item as shown in

**ATTACHMENT C:** Federal Funding Accountability and Transparency Act (FFATA)

The Federal Funding Accountability and Transparency Act (FFATA) was signed on September 26, 2006 and requires information on federal awards (federal financial assistance and expenditures) be made available to the public via a single, searchable website, which is [www.USASpending.gov](http://www.USASpending.gov). All contractors receiving funds from EHA are required to provide the following information as a condition of receiving funds.

**Please answer the following questions Yes or No.**

a. In the previous tax year, was your company's gross income from all sources above \$300,000?

Yes  No

b. In Subrecipient's business or organization's preceding completed fiscal year, did its business or organization (the legal entity to which the UEI number it provided belongs) receive (1) 80 percent or more of its annual gross revenues in U.S. federal contracts, subcontracts, loans, grants, subgrants, and/or cooperative contracts; **and** (2) \$30,000 or more in annual gross revenues from U.S. federal contracts, subcontracts, loans, grants, subgrants, and/or cooperative contracts?

Yes  No

c. Does the public have access to information about the compensation of the executives in Subrecipient's business or organization (the legal entity to which the UEI number it provided belongs) through periodic reports filed under section 13(a) or 15(d) of the Securities Exchange Act of 1934 (15 U.S.C. 78m(a), 78o(d)) or section 6104 of the Internal Revenue Code of 1986?

Yes  No

d. Does your business or organization maintain an active registration in the System for Award Management ([www.SAM.gov](http://www.SAM.gov))?

Yes  No

#### **ATTACHMENT D:** Resource Sharing Plan

The following details are from this award's proposal.

To share resources with the academic research community, we will use the uniform Material Transfer Agreement (MTA), which acknowledges that the materials are proprietary to Institutions of the Cooperative Agreement and permitting their use in a manner that is consistent with the Bayh-Dole Act and NIH funding requirements. NIH research grants require that research be made available to the scientific community and public. The primary method of data sharing is through peer-reviewed publications in scientific journals and by presentation at scientific meetings. In addition, data and results created from NIH supported research will be submitted to NIH in annual progress reports per the terms and conditions of this award. Recombinant viruses, transgenic mouse models and experimental recombinant protein constructs will be made available upon request following a standard procedure (below). Several viruses isolated and studied in this program are select agents so these viruses will not be shipped unless appropriate documentation demonstrates the existence of approved BSL3/4 facilities, select agent licenses, and shipment using approved CDC and Department of Commerce procedures.

We already have established MTAs between most of our EID-SEARCH, consortium partners and will ensure these agreements are up to date and agreed upon by our consortium at the start of our project and then reviewed annually. Having these agreements in place will further reduce the time needed to share reagents and other resources in the event of an outbreak when time-sensitive sharing of biological resources and diagnostic reagents is most critical. **At the start of the project, we will work with the EIDRC – Coordinating Center to ensure these agreements and resource sharing plans are compliant and aligned with plans created for NIH's other EIDRCs.**

#### **Data Sharing Plan**

EcoHealth Alliance (EHA) will house the Data Management and Analysis (DMA) team for EIDRC SEARCH. EHA has served as the data and analysis hub for numerous multi-institutional, multi-sectoral, international disease research groups, including acting as the Modeling and Analytics lead institution for the USAID-PREDICT project, the Western Asia Bat Research Network lead by co-I Olival (1) and EHA's Rift Valley Fever Consortium (2). We will leverage our experience and infrastructure from those projects.

Project Database: We will create a dedicated, centralized EIDRC database to ingest, store, link, and provide for analysis all data associated with the proposed study and other expanded projects associated with the research network. The database will be SQL-based and use encrypted, secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations. The system will be designed to work with both with both paper- and tablet-based field data entry and with laboratory information management systems in place in individual partner labs. We will design and

**TITLE:** Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia

**Grant Number:** 5U01AI151797

Eric Laing, Ph.D., Site Principal Investigator,  
Christopher Broder, Ph.D. Co-Investigators,  
Spencer Sterling, MS, Scientific Project Coordinator

**Prime PI:** Peter Daszak, Ph.D.

engineer the systems to be compatible with other NIAID approved data management systems, including those utilized by the EIDRC-CC, by designing secure APIs, and matching data fields and data standards. The database will use existing metadata standards, including NCBI standards for genetic and molecular data and Ecological Metadata Language (EML) for field and wildlife data, as well as other standards and formats designated by the EIRDC CC. This will enable rapid publication and deposition of data. Granular security and privacy controls will be applied so that specific expansion projects undertaken in the network may be managed while maintaining data confidentiality as needed.

Data Identification and Privacy: For human clinical data and questionnaires, data will be identified by a unique identification code assigned to each individual and only this, de-identified code will be accessible in the project database. All questionnaire data and biological samples will be labeled with a unique alphanumeric identification code, assigned to each enrolled, sampled individual that does not identify the individual from whom data are collected. Participants' names and codes, along with other records with identifying information such as informed consent forms, will be stored in a separately secure system accessible to only essential project staff. If participants agree during the consent process, they may be contacted about having their samples or questionnaire data used for future separate studies about new animal infections discovered in the future, and factors that may affect their chances of getting these animal infections. No data will be released for other purposes without full consent from participants. Upon completion of the project, personal identifying information will be destroyed unless this protocol is extended.

Training: Members of the DMA team will team will develop documentation and provide training for field and laboratory teams at all partner institutions in data management, metadata standards and data hygiene best practices. The DMA team will act as trainers and consultants for partner institutions in experimental design, power analysis, data analysis, and computational and reproducibility issues. DMA trainers will visit each partner institution and/or field team base for training workshops and analysis consultations, and partner institution researchers and students will spend extended time at EHA for collaborative analysis, a model that has been successful in building and maintaining analytical capacity under our NSF EcoHealthNet and PREDICT programs.

Computing Resources: EHA operates a cluster of high-performance servers (System76 20- and 36-core Linux servers with NVIDIA deep-learning GPUs), for data analysis activities, as well as infrastructure to launch cloud-based computing environments of virtual machine with identical software infrastructure. Our servers provide a web-based analysis environment with all necessary software for statistical and bioinformatics work that is available to the DMA and partners anywhere in the world. We use a mixture of cloud services (AWS, Azure, Backblaze, GitHub) to provide redundancy, backup, version control, and rapid post-disaster recovery. The cluster is available to all project partners and can be used use for both high-performance and training-level work (under isolated environments for security and performance).

**TITLE:** Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia

**Grant Number:** 5U01AI151797

Eric Laing, Ph.D., Site Principal Investigator,  
Christopher Broder, Ph.D. Co-Investigators,  
Spencer Sterling, MS, Scientific Project Coordinator

**Prime PI:** Peter Daszak, Ph.D.

Data and Code Sharing: Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited for in long-term public scientific repositories. All sequence data will be made publicly available via GenBank. Additional ecological data collected in wildlife sampling will be deposited to the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestrictive MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

### **Sharing Model Organisms**

Within the program, we will utilize standard laboratory mice as well as different Collaborative Cross mouse strains as well as various transgenic mouse strains, several of which are already available at the NIH-supported Mutant Mouse Regional Resource Center (MMMRC) at UNC. The Collaborative Cross mice are already publicly available from the UNC Systems Genetics Core Facility and the Jackson laboratories, and as such available to the scientific community. All genotyping information generated on these populations will be deposited in the appropriate public repositories (e.g. GEO, ImmPort, ENA). Similarly, all phenotypic data generated within this program from studies with mice will be deposited in the Mouse Phenome Database upon publication, as well as ImmPort to ensure dissemination to the community at large.

In accordance with the NIH/NIAID data sharing and release guidelines, we will coordinate the rapid and unrestricted sharing of all data generated as part of this project.

1. Genotypes generated on the MUGA mouse array, including raw x- and y- intensity data and derived genotype calls will be made available for download from the Mutant Mouse Regional Resource Center at UNC's website (<https://www.med.unc.edu/mmrrc/genotypes/publications>) and at Zenodo (<https://zenodo.org/>).

### **Reagent Sharing**

For all other reagents/requests, we have established a consistent process for evaluating requests for samples and reagents from outside scientists. In order of priority, these include: 1) requests for reagents that have been published in peer-reviewed journals; 2) requests which enhance/promote a specific agenda of the program projects and faculty; 3) requests that promote scientifically valid collaborations between project faculty and outside scientists; and 4) overall research and public health needs. The general format involves: a) establishing a working knowledge of the research agenda and credentials of the requestor, b) group discussion and agreement, 3) MTA agreement with the appropriate institution, or license agreement with a commercial entity, and 4) inventory checking and sending out of reagents. We will work closely with the appropriate institutional Technology Transfer Office and individuals involved in

**TITLE:** Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia

**Grant Number:** 5U01AI151797

Eric Laing, Ph.D., Site Principal Investigator,

Christopher Broder, Ph.D. Co-Investigators,

Spencer Sterling, MS, Scientific Project Coordinator

**Prime PI:** Peter Daszak, Ph.D.

these transactions. The goal will be to provide reagents within a few months of receiving a request for traditional research purposes. In the event of an outbreak or emergency situation, we will communicate with the NIH and EIDRC-CC, and rapidly speed up resource sharing among our EID-SEARCH core partners and our extended network. As documented in the Research Strategy, EHA has successfully provided rapid technical assistance for testing and reagent needs during outbreaks under the USAID-PREDICT project, and has strong existing relationships and existing MTAs with our core EID-SEARCH partners to facilitate this. If needed, we will also acquire appropriate letters from the recipient institutions environmental health and safety officers and help coordinate CDC and/or USDA and Department of Commerce permits. The program faculty will not send reagents to individuals or institutions that do not have appropriate documentation of appropriate containment for the materials, might harbor ill-intentions, or are conducting irresponsible research.

### **Genomic Data Sharing**

We will ensure compliance with NIH's Genomic Data Sharing plans for all viral sequence data generated in this project. We anticipate obtaining genetic sequence data for 100s of novel virus genotypes, including RNA-dependent RNA polymerase (RdRp) sequences for all strains/genotypes and sequences of viral attachment glycoproteins. We will generate full viral genomes for a subset of the viruses and human virus strains that we identify. We will also generate host genetic sequence data for relevant cellular receptor genes of wildlife species. We will deposit all genetic sequences in the NIH data bank, NCBI GenBank as soon as possible after data are generated (including assurance of quality control), and no later than 6 months, so that they are readily available to the scientific community. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also submitted. We anticipate sequence generation will occur over the 5 year proposed project period.

All datasets and associated meta-data will be additionally submitted to Virus Pathogen Resource (ViPR, <http://www.viprbrc.org>). All computational models of biological processes will be made available on the BioModels Database (<http://www.ebi.ac.uk/biomodels-main/>).

### **Intellectual Property**

Intellectual property agreements, identified during the course of this project, will be accomplished by negotiation in good faith among the institutions and inventors. We will work with the inventors in the production of the necessary documents, working with the particular institutions, legal firms and commercial interests. It is anticipated that companies and institutions will have access to these reagents and viruses by MTA (for research purposes) or by a license agreement to be negotiated in good faith with a company.

Hi Eric and Kim,

If you want to reallocate funds within your budget for the travel to Malaysia meeting, please feel free to do it (We expect that Spencer could travel to Malaysia for training or troubleshooting in the draft scope of work we shared)

If you're concerned about the available fund for travel within your budget, let me know and we can see how to cover the cost from EHA's budget.

Best,  
Hongying

Hi Kim,

Thanks for the quick response and update. No problem, we can wait until Dr. Laing is back from vacation.

More changes will be shown in the **body of the contract** that NIH is reviewing now, we'll share them with you once NIH approves it. They are mostly about specifying everything in detail (e.g., we included general languages in the Y3 contract by referring to relevant policies, now we need to elaborate more in writing), and you can see we'll include the whole "NIH Grants Policy Statement" as Attachment F.

In the file I shared, most changes in Attachment A are on #2 and #3 to describe how we manage and oversee the project. So there will be more regular calls at least every month and more regular reporting, including quarterly reporting with specified deadlines (we'll further discuss with the team the most efficient formats for these reportings).

We also included the "Data and Resourcing Sharing Plan" from the originally submitted proposal as Attachment D to demonstrate what we will do for data sharing following the NIH policies.

Please feel free to email or call if anything I can further clarify. And once we get the approved contract template from NIH, it will be helpful if we can get on a Zoom meeting to go through the changes and explain everything as needed.

Thanks,  
Hongying

## **ATTACHMENT A: Scope of Work**

**Project Description/Summary:** Southeast Asia is one of the world's highest-risk EID hotspots, the origin of the SARS pandemic, Nipah virus, and repeated outbreaks of influenza. This is driven by high diversity of wildlife and rapidly expanding demography that brings human and wildlife populations closer. This proposal will launch the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH), a collaboration among leaders in emerging disease research in the USA, Thailand, Singapore and the 3 major Malaysian administrative regions. These researchers have networks that span >50 clinics, laboratories and research institutions across almost all SE Asian countries and will use the EID-SEARCH as an early warning system for outbreaks involving exchange of information, reagents, samples and technology, and a collaborative power-house for fundamental and translational research. The EID-SEARCH will also act as a significant asset to scale-up and deploy resources in the case of an outbreak in the region. This EIDRC will conduct research to: 1) Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife, by analyzing previously-archived wildlife samples, conducting targeted wildlife surveillance, and using serology & PCR assays to identify novel viruses. These will be characterized to assess risk of spillover to people, and a series of in vitro (receptor binding, cell culture) and in vivo (humanized mouse and collaborative cross models) assays used to assess their potential to infect people and cause disease; 2) Collect samples and questionnaire data from human communities that live in EID hotspots and have high cultural and behavioral risk of animal exposure (e.g. wildlife hunting, bat guano collection). These will be tested with serological assays to identify evidence of novel virus spillover, and analyzed against metadata to identify key risk pathways for transmission; 3) Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts. We will conduct syndromic surveillance at clinics serving the populations in Aim 2, enroll patients with undiagnosed illness and symptoms consistent with emerging viral pathogens, and test samples with molecular and follow-up serological assays to identify causal links between these syndromes and novel viruses. This research will advance our understanding of the risk of novel viral emergence in a uniquely important region. It will also strengthen in-country research capacity by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. The large body of high impact collaborative research from this EIDRC leadership team provides proof-of-concept that EID-SEARCH has the background, collaborative network, experience, and skillset to act as a unique early warning system for novel EIDs of any etiology threatening to emerge in this hottest of the EID hotspots.

Under the supervision of Co-Investigators Dr. Christopher Broder and Dr. Eric Laing, working closely with the project coordinator Spencer Sterling, The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc. will conduct epidemiology research and characterization of a series of coronaviruses (CoVs), paramyxoviruses (PMVs – particularly Henipaviruses) and filoviruses (FVs) following Scope of Work:

- 1. Continue to develop, validate, and refine serology platforms for laboratory analysis of collected human and animal samples.**
  - 1.1 Develop and validate the regionally specific CoV/Henipavirus MMIA panel.
  - 1.2 Refine MMIA tests for Marburg virus, filoviruses???
  - 1.3 Refine and produce antigens for MPOX assay in support of CREID network-wide activities.
  - 1.4 Support the collaboration with PREMISE for on PBMC study in Thailand.
  - 1.5 Provide on-site training to the project members from Conservation Medicine in Malaysia on serology testing.
  - 1.6 Support data analysis in Thailand and Malaysia to ensure high-quality publications from EID-

#### SEARCH

- 1.7 Support CREID Pilot Research Project applications as applicable.
- 1.8 Support pilot study on blood-fed mosquitoes in collaboration with the NIAID vector research program (Dr. Lehmann).

### 2. Project management and coordination

- 2.1 Ensure all permits and permissions are in place to conduct project activities.
- 2.2 Represent EID-SEARCH to present relevant research findings at conferences and other relevant meetings.
- 2.3 Collaborate with the EID-SEARCH partners for data cleaning, analysis, interpretation, and contributing to scientific publications as agreed.
- 2.4 The subrecipient will adhere to the applicable elements of resource and data management from the approved project proposal as described in Resource Sharing Plan in **ATTACHMENT D**.
- 2.5 Submit to the requirements of the Federal Funding Accountability and Transparency Act (FFATA) included as **ATTACHMENT C**, with the signed contract.

### 3. Project communication and reporting

- 3.1 Participate in monthly meetings with project partners over video conference.
- 3.2 Attend CREID Network annual meeting and other in-person project meetings as applicable.
- 3.3 Participate in calls with the EID-SEARCH partners and global team at EHA as requested.
- 3.4 Complete the following programmatic and financial reporting by the requested deadlines:
  - 3.4.1 Quarterly reporting to EcoHealth Alliance on programmatic activities due on the following dates:
    - 01 August 2023
    - 01 November 2023
    - 01 February 2024
    - 01 May 2024
  - 3.4.2 Semi-annual and annual reports to NIH/NIAID.
  - 3.4.3 Annual reports to the CREID Network and other reports requested by NIAID.
  - 3.4.4 Invoices and financial reports to EcoHealth Alliance every two months, including 1-page or longer programmatic update, copies of receipts and/or other supporting documents, and breakdown of the costs in each item as shown in **ATTACHMENT B** Project Budget.

**ATTACHMENT B: Project Budget**

Commented [HL1]: Please update.

**ATTACHMENT C: Federal Funding Accountability and Transparency Act (FFATA)**

The Federal Funding Accountability and Transparency Act (FFATA) was signed on September 26, 2006 and requires information on federal awards (federal financial assistance and expenditures) be made available to the public via a single, searchable website, which is [www.USASpending.gov](http://www.USASpending.gov). All contractors receiving funds from EHA are required to provide the following information as a condition of receiving funds.

**Please answer the following questions Yes or No.**

a. In the previous tax year, was your company's gross income from all sources above \$300,000?

Yes  No

b. In Subrecipient's business or organization's preceding completed fiscal year, did its business or organization (the legal entity to which the UEI number it provided belongs) receive (1) 80 percent or more of its annual gross revenues in U.S. federal contracts, subcontracts, loans, grants, subgrants, and/or cooperative contracts; **and** (2) \$30,000 or more in annual gross revenues from U.S. federal contracts, subcontracts, loans, grants, subgrants, and/or cooperative contracts?

Yes  No

c. Does the public have access to information about the compensation of the executives in Subrecipient's business or organization (the legal entity to which the UEI number it provided belongs) through periodic reports filed under section 13(a) or 15(d) of the Securities Exchange Act of 1934 (15 U.S.C. 78m(a), 78o(d)) or section 6104 of the Internal Revenue Code of 1986?

Yes  No

d. Does your business or organization maintain an active registration in the System for Award Management ([www.SAM.gov](http://www.SAM.gov))?

Yes  No

## ATTACHMENT D: Resource Sharing Plan

The following details are from this award's proposal.

To share resources with the academic research community, we will use the uniform Material Transfer Agreement (MTA), which acknowledges that the materials are proprietary to Institutions of the Cooperative Agreement and permitting their use in a manner that is consistent with the Bayh-Dole Act and NIH funding requirements. NIH research grants require that research be made available to the scientific community and public. The primary method of data sharing is through peer-reviewed publications in scientific journals and by presentation at scientific meetings. In addition, data and results created from NIH supported research will be submitted to NIH in annual progress reports per the terms and conditions of this award. Recombinant viruses, transgenic mouse models and experimental recombinant protein constructs will be made available upon request following a standard procedure (below). Several viruses isolated and studied in this program are select agents so these viruses will not be shipped unless appropriate documentation demonstrates the existence of approved BSL3/4 facilities, select agent licenses, and shipment using approved CDC and Department of Commerce procedures.

We already have established MTAs between most of our EID-SEARCH, consortium partners and will ensure these agreements are up to date and agreed upon by our consortium at the start of our project and then reviewed annually. Having these agreements in place will further reduce the time needed to share reagents and other resources in the event of an outbreak when time-sensitive sharing of biological resources and diagnostic reagents is most critical. **At the start of the project, we will work with the EIDRC – Coordinating Center to ensure these agreements and resource sharing plans are compliant and aligned with plans created for NIH's other EIDRCs.**

### **Data Sharing Plan**

EcoHealth Alliance (EHA) will house the Data Management and Analysis (DMA) team for EIDRC SEARCH. EHA has served as the data and analysis hub for numerous multi-institutional, multi-sectoral, international disease research groups, including acting as the Modeling and Analytics lead institution for the USAID-PREDICT project, the Western Asia Bat Research Network lead by co-I Olival (1) and EHA's Rift Valley Fever Consortium (2). We will leverage our experience and infrastructure from those projects.

Project Database: We will create a dedicated, centralized EIDRC database to ingest, store, link, and provide for analysis all data associated with the proposed study and other expanded projects associated with the research network. The database will be SQL-based and use encrypted, secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations. The system will be designed to work with both with both paper- and tablet-based field data entry and with laboratory information management systems in place in individual partner labs. We will design and engineer the systems to be compatible with other NIAID approved data management systems, including those utilized by the EIDRC-CC, by designing secure APIs, and matching data fields and data standards. The database will use existing metadata standards, including NCBI standards for genetic and molecular data and Ecological Metadata Language (EML) for field and wildlife data, as well as other standards and formats designated by the EIDRC CC. This will enable rapid publication and deposition of data. Granular

security and privacy controls will be applied so that specific expansion projects undertaken in the network may be managed while maintaining data confidentiality as needed.

Data Identification and Privacy: For human clinical data and questionnaires, data will be identified by a unique identification code assigned to each individual and only this, de-identified code will be accessible in the project database. All questionnaire data and biological samples will be labeled with a unique alphanumeric identification code, assigned to each enrolled, sampled individual that does not identify the individual from whom data are collected. Participants' names and codes, along with other records with identifying information such as informed consent forms, will be stored in a separately secure system accessible to only essential project staff. If participants agree during the consent process, they may be contacted about having their samples or questionnaire data used for future separate studies about new animal infections discovered in the future, and factors that may affect their chances of getting these animal infections. No data will be released for other purposes without full consent from participants. Upon completion of the project, personal identifying information will be destroyed unless this protocol is extended.

Training: Members of the DMA team will team will develop documentation and provide training for field and laboratory teams at all partner institutions in data management, metadata standards and data hygiene best practices. The DMA team will act as trainers and consultants for partner institutions in experimental design, power analysis, data analysis, and computational and reproducibility issues. DMA trainers will visit each partner institution and/or field team base for training workshops and analysis consultations, and partner institution researchers and students will spend extended time at EHA for collaborative analysis, a model that has been successful in building and maintaining analytical capacity under our NSF EcoHealthNet and PREDICT programs.

Computing Resources: EHA operates a cluster of high-performance servers (System76 20- and 36-core Linux servers with NVIDIA deep-learning GPUs), for data analysis activities, as well as infrastructure to launch cloud-based computing environments of virtual machine with identical software infrastructure. Our servers provide a web-based analysis environment with all necessary software for statistical and bioinformatics work that is available to the DMA and partners anywhere in the world. We use a mixture of cloud services (AWS, Azure, Backblaze, GitHub) to provide redundancy, backup, version control, and rapid post-disaster recovery. The cluster is available to all project partners and can be used for both high-performance and training-level work (under isolated environments for security and performance).

Data and Code Sharing: Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited for in long-term public scientific repositories. All sequence data will be made publicly available via GenBank. Additional ecological data collected in wildlife sampling will be deposited to the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestrictive MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

### **Sharing Model Organisms**

Within the program, we will utilize standard laboratory mice as well as different Collaborative Cross mouse strains as well as various transgenic mouse strains, several of which are already available at the NIH-supported Mutant Mouse Regional Resource Center (MMMRC) at UNC. The Collaborative Cross mice are already publicly available from the UNC Systems Genetics Core Facility and the Jackson laboratories, and as such available to the scientific community. All genotyping information generated on these populations will be deposited in the appropriate public repositories (e.g. GEO, ImmPort, ENA). Similarly, all phenotypic data generated within this program from studies with mice will be deposited in the Mouse Phenome Database upon publication, as well as ImmPort to ensure dissemination to the community at large.

In accordance with the NIH/NIAID data sharing and release guidelines, we will coordinate the rapid and unrestricted sharing of all data generated as part of this project.

1. Genotypes generated on the MUGA mouse array, including raw x- and y- intensity data and derived genotype calls will be made available for download from the Mutant Mouse Regional Resource Center at UNC's website (<https://www.med.unc.edu/mmrc/genotypes/publications>) and at Zenodo (<https://zenodo.org/>).

### **Reagent Sharing**

For all other reagents/requests, we have established a consistent process for evaluating requests for samples and reagents from outside scientists. In order of priority, these include: 1) requests for reagents that have been published in peer-reviewed journals; 2) requests which enhance/promote a specific agenda of the program projects and faculty; 3) requests that promote scientifically valid collaborations between project faculty and outside scientists; and 4) overall research and public health needs. The general format involves: a) establishing a working knowledge of the research agenda and credentials of the requestor, b) group discussion and agreement, 3) MTA agreement with the appropriate institution, or license agreement with a commercial entity, and 4) inventory checking and sending out of reagents. We will work closely with the appropriate institutional Technology Transfer Office and individuals involved in these transactions. The goal will be to provide reagents within a few months of receiving a request for traditional research purposes. In the event of an outbreak or emergency situation, we will communicate with the NIH and EIDRC-CC, and rapidly speed up resource sharing among our EID-SEARCH core partners and our extended network. As documented in the Research Strategy, EHA has successfully provided rapid technical assistance for testing and reagent needs during outbreaks under the USAID-PREDICT project, and has strong existing relationships and existing MTAs with our core EID-SEARCH partners to facilitate this. If needed, we will also acquire appropriate letters from the recipient institutions environmental health and safety officers and help coordinate CDC and/or USDA and Department of Commerce permits. The program faculty will not send reagents to individuals or institutions that do not have appropriate documentation of appropriate containment for the materials, might harbor ill-intentions, or are conducting irresponsible research.

### **Genomic Data Sharing**

We will ensure compliance with NIH's Genomic Data Sharing plans for all viral sequence data generated

in this project. We anticipate obtaining genetic sequence data for 100s of novel virus genotypes, including RNA-dependent RNA polymerase (RdRp) sequences for all strains/genotypes and sequences of viral attachment glycoproteins. We will generate full viral genomes for a subset of the viruses and human virus strains that we identify. We will also generate host genetic sequence data for relevant cellular receptor genes of wildlife species. We will deposit all genetic sequences in the NIH data bank, NCBI GenBank as soon as possible after data are generated (including ensurance of quality control), and no later than 6 months, so that they are readily available to the scientific community. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also submitted. We anticipate sequence generation will occur over the 5 year proposed project period.

All datasets and associated meta-data will be additionally submitted to Virus Pathogen Resource (ViPR, <http://www.viprbrc.org>). All computational models of biological processes will be made available on the BioModels Database (<http://www.ebi.ac.uk/biomodels-main/>).

#### **Intellectual Property**

Intellectual property agreements, identified during the course of this project, will be accomplished by negotiation in good faith among the institutions and inventors. We will work with the inventors in the production of the necessary documents, working with the particular institutions, legal firms and commercial interests. It is anticipated that companies and institutions will have access to these reagents and viruses by MTA (for research purposes) or by a license agreement to be negotiated in good faith with a company.

---

Dear Eric and Chris,

I hope you are doing well.

While we are waiting for the Year 4 Notice of Award (U01AI151797), we would like to start discussing with you the scope of work for Year 4.

Please take a look at the draft in the attached file, and **feel free to edit and add details to the planned research activities and update the budget accordingly.**

Please note that the funder specifically required information related to the reporting after they reviewed our Y3 contracts, so we have to include more details and adhere to them.

Please let Peter and me know if you have any questions. We can plan to discuss the work plan at the project all-partner meeting next Wednesday or set up a separate call. Thank you very much!

Best Regards,  
Hongying

**SECTION I – AWARD DATA – 5U01AI151797-03****Principal Investigator(s):**

Peter Daszak, PHD

**Award e-mailed to:** [chmura@ecohealthalliance.org](mailto:chmura@ecohealthalliance.org)

Dear Authorized Official:

The National Institutes of Health hereby awards a grant in the amount of \$1,504,400 (see “Award Calculation” in Section I and “Terms and Conditions” in Section III) to EcoHealth Alliance in support of the above referenced project. This award is pursuant to the authority of 42 USC 241 31 USC 6305 42 CFR 52 and is subject to the requirements of this statute and regulation and of other referenced, incorporated or attached terms and conditions.

Acceptance of this award, including the "Terms and Conditions," is acknowledged by the recipient when funds are drawn down or otherwise requested from the grant payment system.

Each publication, press release, or other document about research supported by an NIH award must include an acknowledgment of NIH award support and a disclaimer such as “Research reported in this publication was supported by the National Institute Of Allergy And Infectious Diseases of the National Institutes of Health under Award Number U01AI151797. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.” Prior to issuing a press release concerning the outcome of this research, please notify the NIH awarding IC in advance to allow for coordination.

Award recipients must promote objectivity in research by establishing standards that provide a reasonable expectation that the design, conduct and reporting of research funded under NIH awards will be free from bias resulting from an Investigator’s Financial Conflict of Interest (FCOI), in accordance with the 2011 revised regulation at 42 CFR Part 50 Subpart F. The Institution shall submit all FCOI reports to the NIH through the eRA Commons FCOI Module. The regulation does not apply to Phase I Small Business Innovative Research (SBIR) and Small Business Technology Transfer (STTR) awards. Consult the NIH website <http://grants.nih.gov/grants/policy/coi/> for a link to the regulation and additional important information.

If you have any questions about this award, please direct questions to the Federal Agency contacts.

Sincerely yours,

Vandhana Khurana  
Grants Management Officer  
NATIONAL INSTITUTE OF ALLERGY AND INFECTIOUS DISEASES

**SECTION II – PAYMENT/HOTLINE INFORMATION – 5U01AI151797-03**

For payment and HHS Office of Inspector General Hotline information, see the NIH Home Page at <http://grants.nih.gov/grants/policy/awardconditions.htm>

---

**SECTION III – STANDARD TERMS AND CONDITIONS – 5U01AI151797-03**

This award is based on the application submitted to, and as approved by, NIH on the above-titled project and is subject to the terms and conditions incorporated either directly or by reference in the following:

- a. The grant program legislation and program regulation cited in this Notice of Award.
- b. Conditions on activities and expenditure of funds in other statutory requirements, such as those included in appropriations acts.
- c. 45 CFR Part 75.
- d. National Policy Requirements and all other requirements described in the NIH Grants Policy Statement, including addenda in effect as of the beginning date of the budget period.
- e. Federal Award Performance Goals: As required by the periodic report in the RPPR or in the final progress report when applicable.
- f. This award notice, INCLUDING THE TERMS AND CONDITIONS CITED BELOW.

(See NIH Home Page at <http://grants.nih.gov/grants/policy/awardconditions.htm> for certain references cited above.)

**Research and Development (R&D):** All awards issued by the National Institutes of Health (NIH) meet the definition of "Research and Development" at 45 CFR Part§ 75.2. As such, auditees should identify NIH awards as part of the R&D cluster on the Schedule of Expenditures of Federal Awards (SEFA). The auditor should test NIH awards for compliance as instructed in Part V, Clusters of Programs. NIH recognizes that some awards may have another classification for purposes of indirect costs. The auditor is not required to report the disconnect (i.e., the award is classified as R&D for Federal Audit Requirement purposes but non-research for indirect cost rate purposes), unless the auditee is charging indirect costs at a rate other than the rate(s) specified in the award document(s).

Carry over of an unobligated balance into the next budget period requires Grants Management Officer prior approval.

This award is subject to the requirements of 2 CFR Part 25 for institutions to obtain a unique entity identifier (UEI) and maintain an active registration in the System for Award Management (SAM). Should a consortium/subaward be issued under this award, a UEI requirement must be included. See <http://grants.nih.gov/grants/policy/awardconditions.htm> for the full NIH award term implementing this requirement and other additional information.

This award has been assigned the Federal Award Identification Number (FAIN) U01AI151797. Recipients must document the assigned FAIN on each consortium/subaward issued under this award.

Based on the project period start date of this project, this award is likely subject to the Transparency Act subaward and executive compensation reporting requirement of 2 CFR Part 170. There are conditions that may exclude this award; see <http://grants.nih.gov/grants/policy/awardconditions.htm> for additional award applicability information.

In accordance with P.L. 110-161, compliance with the NIH Public Access Policy is now mandatory. For more information, see NOT-OD-08-033 and the Public Access website: <http://publicaccess.nih.gov/>.

In accordance with the regulatory requirements provided at 45 CFR 75.113 and Appendix XII to 45 CFR Part 75, recipients that have currently active Federal grants, cooperative agreements, and procurement contracts with cumulative total value greater than \$10,000,000 must report and maintain information in the System for Award Management (SAM) about civil, criminal, and administrative proceedings in connection with the award or performance of a Federal award that reached final disposition within the most recent five-year period. The recipient must also make semiannual disclosures regarding such proceedings. Proceedings information will be made publicly available in the designated integrity and performance system (currently the Federal Awardee Performance and Integrity Information System

(FAPIIS)). Full reporting requirements and procedures are found in Appendix XII to 45 CFR Part 75. This term does not apply to NIH fellowships.

**Treatment of Program Income:**

Additional Costs

---

**SECTION IV – AI SPECIFIC AWARD CONDITIONS – 5U01AI151797-03**

Clinical Trial Indicator: No

This award does not support any NIH-defined Clinical Trials. See the NIH Grants Policy Statement Section 1.2 for NIH definition of Clinical Trial.

THIS AWARD CONTAINS GRANT SPECIFIC RESTRICTIONS. THESE RESTRICTIONS MAY ONLY BE LIFTED BY A REVISED NOTICE OF AWARD.

**SPECIFIC AWARD CONDITION:**

**Restriction:** This award is made based on the interinstitutional agreement (IIA) between the recipient and Tufts University, which has been approved by the Office of Laboratory Animal Welfare (OLAW) in accordance with the PHS Policy on Humane Care and Use of Laboratory Animals. If there are any changes to this IIA, the recipient must notify OLAW and NIAID within 15 days of the change and no further charges for research involving live vertebrate animals may be incurred on this award without prior approval by OLAW and by NIAID.

\*\*\*\*\*

The recipient must <sup>1</sup>conduct or arrange for the conduct of <sup>2</sup>onsite subrecipient facility inspections every 6 months to ensure that subaward activities are being properly executed. The recipient must provide certification in the Research Performance Progress Report that it is in compliance with this term and condition of award.

\*\*\*\*\*

The recipient must <sup>3</sup>provide NIAID with copies of FSRS reporting of all (existing and newly established) subaward agreements within 30 days of submitting to FSRS.

\*\*\*\*\*

The recipient must <sup>4</sup>provide NIH with copies of updated subaward agreements within 30 days of execution of any initial and subsequent subaward agreement(s). The subaward agreements must demonstrate compliance with the NIH Grants Policy Statement (NIH GPS) 15.2.1 Written Agreement. The subaward agreements must state the correct F&A rate which, for foreign subrecipients is 8% (see NIH GPS 16.6) and include descriptions of the biosafety monitoring plans for each project, where appropriate.

Failure to comply with this special condition can result in withholding of support, audit disallowances, suspension and/or termination of this award, and/or other appropriate enforcement actions. This award is subject to the Transparency Act subaward reporting requirement of 2 CFR Part 170, which <sup>5</sup>must be reported through the Federal Funding Accountability and Transparency Subaward Reporting System (FSRS).

\*\*\*\*\*

The recipient is required to <sup>6</sup>submit semi-annual progress reports, Research Performance Progress Report (RPPR), and Federal Financial Reports (FFR) to NIAID via the Request for Additional Materials module within eRA. The semi-annual reports for this budget period is <sup>7</sup>due on December 01, 2022. NIAID will initiate a RAM request within eRA at least 15 days prior to the due date of the semi-annual progress report, RPPR and FFR. Upon receipt of the RAM request, the recipient is required to upload the requested documents in Commons within RAM no later than the due date listed above.

\*\*\*\*\*

The authority for automatic no-cost extension has been removed for this award. The recipient <sup>1</sup> must request and receive written prior approval from NIAID before any extension of the final budget period.

++++++

This award includes a carryover of \$250,102. The carryover is approved for the purpose stated in the request dated <sup>2</sup> 8/31/2021 and will be subject to a downward adjustment should the available unobligated balance from the 01 year FFR be less than the cumulative carryover amount; no adjustments will be made to the "TOTAL FEDERAL AWARD AMOUNT" on the Notice of Award <sup>3</sup>

\*\*\*\*\*

This award is issued at the committed level for direct costs and facilities and administrative costs. The awardee must adhere to the applicable policies for rebudgeting costs as outlined in the NIH Grants Policy Statement.

\*\*\*\*\*

This award does not include funds to support research subject to the [Department of Health and Human Services Framework for Guiding Funding Decisions about Proposed Research Involving Enhanced Potential Pandemic Pathogens](#) (DHHS P3CO Framework) Therefore:

- For Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife, the building of chimeric SARS-like bat coronaviruses will be based on the SHC014 or the pangolin coronavirus molecular clones and the building of chimeric MERS-CoV will be based on the HKU5 strain. Prior to further altering the mutant viruses you must provide NIAID with a detailed description of the proposed alterations and supporting evidence for the anticipated phenotypic characteristics of each virus.
- Alternative approaches to those referenced above, including building chimeras based on SARS-CoV-1, SARS-CoV-2, and MERS-CoV, may be subject to the DHHS P3CO Framework and must be submitted to NIAID for review and approval prior to the work commencing.

If any of the experiments proposed for Aim 1 result in a virus with a phenotype of enhanced pathogenicity and/or transmissibility, enhanced growth by more than 10 fold when compared to wild type strains, or if the mice display significant increases in weight loss, viral titer, or mortality when compared to wild-type strains, the recipient must immediately stop the work and notify the NIAID Program Officer, Grants Management Specialist, and appropriate institutional biosafety committee. Policy changes regarding the classification of these experiments or components used in these experiments may be subject to immediate halting of experimentation. No NIH funding can be used to perform such experiments until these experiments have been approved by NIAID with a revised NOA.

\*\*\*\*\*

Dissemination of study data will be in accord with the Recipient's accepted genomic data sharing plan as stated on page(s) 373 of the application. Failure to adhere to the sharing plan as mutually agreed upon by the Recipient and the NIAID may result in Enforcement Actions as described in the NIH Grants Policy Statement.

\*\*\*\*\*

This award includes human subject research studies and must conform to the DHHS policies for the [Protection of Human Subjects](#) research, which are a term and condition of award. Human subjects research is covered by the 2018 Common Rule, and may not be initiated until the associated protocols have received IRB approval as specified in [45 CFR 46](#). Failure to comply with the terms and conditions of award may result in the disallowance of costs and/or additional enforcement actions as outlined in Section 8.5 of the NIH Grants Policy Statement.

The Research Performance Progress Report (RPPR), Section G.9 (Foreign component), includes reporting requirements for all research performed outside of the United States. Research conducted at the following site(s) must be reported in your RPPR:

**Jeppesen Field Consulting Australia - AUSTRALIA**  
**Conservation Medicine Ltd. - MALAYSIA**  
**Duke-NUS Medical School - SINGAPORE**  
**Chulalongkorn University - THAILAND**

\*\*\*\*\*

This Notice of Award (NoA) includes funds for activity with **Conservation Medicine Ltd. - MALAYSIA** in the amount of \$299,997 (including carryover)

\*\*\*\*\*

This Notice of Award (NoA) includes funds for activity with **Duke-NUS Medical School - SINGAPORE** in the amount of \$174,596 (including carryover)

\*\*\*\*\*

This Notice of Award (NoA) includes funds for activity with **Chulalongkorn University - THAILAND** in the amount of \$215,944

\*\*\*\*\*

This Notice of Award (NoA) includes funds for activity with **The University of North Carolina at Chapel Hill** in the amount of \$237,923 (including carryover)

\*\*\*\*\*

This Notice of Award (NoA) includes funds for activity **The Henry M. Jackson Fdn. for the Adv'mt. of Mil. Med., Inc.** in the amount of \$179,336 (including carryover)

\*\*\*\*\*

This award is issued as a Cooperative Agreement, a financial assistance mechanism in which substantial NIH scientific and/or programmatic involvement is anticipated in the performance of the activity. This award is subject to the Terms and Conditions of Award set forth in Section VI: Award Administrative Information of **RFA AI-19-028**, which are hereby incorporated by reference as special terms and conditions of award.

The RFA may be accessed at: <http://grants.nih.gov/grants/guide/index.html>

\*\*\*\*\*

This award is subject to the Clinical Terms of Award referenced in the NIH Guide for Grants and Contracts, July 8, 2002, NOT AI-02-032. These terms and conditions are hereby incorporated by reference, and can be accessed via the following World Wide Web address: <https://www.niaid.nih.gov/grants-contracts/niaid-clinical-terms-award> All submissions required by the NIAID Clinical Terms of Award must be forwarded electronically or by mail to the responsible NIAID Program Official identified on this Notice of Award.

\*\*\*\*\*

Highly Pathogenic Agents:

NIAID defines a Highly Pathogenic Agent as an infectious Agent or Toxin that may warrant a biocontainment safety level of BSL3 or higher according to the current edition of the CDC/NIH Biosafety in Microbiological and Biomedical Laboratories (BMBL) (<https://www.cdc.gov/labs/BMBL.html>). Research funded under this grant must adhere to the BMBL, including using the BMBL-recommended biocontainment level at a minimum. If the Institutional Biosafety Committee (IBC) (or equivalent body) or designated institutional biosafety official recommends a higher biocontainment level, the higher recommended containment level must be used.

When submitting future Progress Reports indicate at the beginning of the report:

If no research with a Select Agent (see 42 CFR 73 for the relevant human Select Agents and Toxins; and 7 CFR 331 and 9 CFR 121 for the relevant animal and plant Select Agents and Toxins at <https://www.selectagents.gov/regulations/> and <https://www.selectagents.gov/sat/list.htm>) and/or has been performed or is planned to be performed under this grant.

If the IBC or equivalent body or official has determined, for example, by conducting a risk assessment, that the work being planned or performed under this grant may be conducted at a biocontainment safety level that is lower than BSL3.

If the work involves Select Agents and/or Highly Pathogenic Agents, also address the following points:

Any NIAID pre-approved changes in the use of the Select Agents and/or Highly Pathogenic Agents including its restricted experiments that have resulted in a change in the required biocontainment level, and any resultant change in location, if applicable, as determined by the IBC or equivalent body or official.

If work with a new or additional Select Agents and/or Highly Pathogenic Agents is proposed in the upcoming project period, provide:

- A list of the new and/or additional Agent(s) that will be studied;
- A description of the work that will be done with the Agent(s), and whether or not the work is a restricted experiment;
- The title and location for each biocontainment resource/facility, including the name of the organization that operates the facility, and the biocontainment level at which the work will be conducted, with documentation of approval by the IBC or equivalent body or official. It is important to note if the work is being done in a new location;
- Any biosafety incidents that occurred and were reported to NIH/NIAID.

## B. ACCOMPLISHMENTS

### B.1 WHAT ARE THE MAJOR GOALS OF THE PROJECT?

Southeast Asia is one of the world's highest-risk EID hotspots, and the origin of the SARS pandemic, repeated outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as the Nipah virus. It is a wildlife 'megadiversity' region, where a rapidly expanding human population is increasing contact with wildlife, and increasing the risk of zoonotic disease outbreaks. The overarching goal of this proposal is to launch the Emerging Infectious Diseases - South East Asia Research Collaboration Hub (EID-SEARCH) to analyze the diversity of key viral pathogens in wildlife, the frequency and causes of their spillover, and to identify viral etiologies of undiagnosed 'cryptic' outbreaks in people. EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions, and in Thailand, Singapore, and the 3 major Malaysian administrative regions, whose collaborative networks span >50 clinics, laboratories, and research institutes across almost all SE Asian countries. This hub, and the network, will act as an early warning system for outbreaks - a way to exchange information, reagents, samples, and technology, and a collaborative power-house for translational research. The long-term collaboration among the key personnel and multidisciplinary skillsets from epidemiology, clinical management, lab analysis, through wildlife biology and data analysis will act as significant assets when deployed to help counter outbreaks in the region. The research goals of this EIDRC follow three specific aims:

Specific Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife. We will: 1) analyze some of the tens of thousands of archived wildlife samples at our disposal, conduct geographically- and taxonomically-targeted field surveillance in wild mammals (bats, rodents, primates), and use serological & PCR assays to identify known high-profile zoonotic pathogens, or close relatives with potential to infect people; 2) biologically characterize novel viruses that our analyses suggest have high spillover and pandemic potential; and 3) conduct in vitro receptor binding assays and cell culture experiments, and in vivo animal model infections using humanized mice and the collaborative cross mouse to assess their potential to infect people and cause disease.

Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays. Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities and approaches that can deal with the low statistical probability of identifying rare events. To achieve this, we will 1) conduct targeted cross-sectional serological surveys of human communities with extremely high geographic and cultural, occupational, and behavioral exposure to wildlife-origin viruses; 2) design and deploy novel serological assays to identify baseline spillover of known or novel CoVs, PMVs, and FVs in these populations; and 3) analyze and test hypotheses on the occupational, cultural and other risk factors for spillover (e.g. hunting wildlife).

Specific Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts. Our prior work provides substantial evidence of spillover leading to undiagnosed illness in people in the region. To test if these represent 'cryptic' outbreaks of novel viruses, we will conduct syndromic surveillance at regional clinics for the communities sampled in SA2. We will: 1) enroll and collect biological samples, and detailed survey data on risk factors, from patients presenting with influenza-like illness, severe respiratory illness, encephalitis, and other specific symptoms; 2) conduct molecular and follow-up serological diagnostic assays to test causal links between their syndromes and known and novel viral agents identified in SA1. Where viruses are identified, we will attempt to isolate and characterize them, then use the survey data, ecological and phylogenetic analyses to identify likely reservoir hosts/spillover pathways and inform intervention programs.

This research will advance our understanding of the risk of novel viral emergence in a uniquely important region. It will strengthen in-country research capacity by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. These include testing of tens of thousands of samples from wildlife, humans, and livestock in the region; discovery of hundreds of novel viruses from zoonotic viral families in wildlife; outbreak investigations in rural communities across SE Asia; discovery of the bat-origin of SARS-CoVs; discovery of a novel bat-origin SADS-CoV killing >25,000 pigs in S. China; and development of novel serological and molecular assays for high-impact viruses, and state-of-the-art in vitro and in vivo assays to characterize viral pathogenic potential. This body of collaborative research provides proof-of-concept that EID-SEARCH has the background, collaborative network, experience, and skillset to act as a unique early warning system for novel EIDs of any etiology threatening to emerge in this hottest of the EID

hotspots.

**B.1.a Have the major goals changed since the initial competing award or previous report?**

No

**B.2 WHAT WAS ACCOMPLISHED UNDER THESE GOALS?**

File Uploaded : B.2 Accomplishments final\_updated.pdf

**B.3 COMPETITIVE REVISIONS/ADMINISTRATIVE SUPPLEMENTS**

**For this reporting period, is there one or more Revision/Supplement associated with this award for which reporting is required?**

No

**B.4 WHAT OPPORTUNITIES FOR TRAINING AND PROFESSIONAL DEVELOPMENT HAS THE PROJECT PROVIDED?**

File Uploaded : B.4 Training and professional development\_final.pdf

**B.5 HOW HAVE THE RESULTS BEEN DISSEMINATED TO COMMUNITIES OF INTEREST?**

PI Daszak, and Co-investigators Wacharapluesadee, Hughes, Olival, Wang, Baric, Broder, Laing, and other key personnel from the EID-SEARCH were invited to give lectures, keynote speeches, government and inter-government briefings in Thailand, Malaysia, Southeast Asia, and internationally using EID-SEARCH work to demonstrate how disease ecology, lab virology, and social science approaches can provide a unique platform for a pandemic prediction and prevention, and share research strategies, technologies and results from this project.

Government and inter-government agency briefings

- Meeting with the Disease Control Checkpoint Officers, Field Epidemiology & Management Team (FEMT) program of the Ministry of Public Health, Thailand, for information sharing and capacity building purposes.
- Meeting with multi-sectoral stakeholders in the Philippines to share experience on approaches for One Health surveillance for Coronaviruses, Paramyxoviruses, and Filoviruses in the Philippines.
- Meeting with the Department of Wildlife and National Parks, Peninsular Malaysia
- Meetings with the Ministry of Health (MOH) of Malaysia, including the Zoonosis Sector, the Disease Control Division, the National Public Health Laboratory, infectious disease physicians, State Health Department staff from the States of Pahang, Perak, and Kelantan, Sabah State Health Department, the Kota Kinabalu Public Health Laboratory, and Jabatan Perlindungan Hidupan Liar dan Taman Negara (PERHILITAN) for project updates, results reporting, and research plan discussion.
- Meeting with the US Ambassador to Malaysia, the Economic Counsellor, the Economic Officer, and the Health Officer to discuss EID-SEARCH project progress, results, and plans.
- Meeting with Sabah Wildlife Department's Director, Deputy Director and Veterinarians to discuss EID-SEARCH project progress, molecular and serology testing results and work plans.
- Meeting with Sabah State Health Department (SSHHD) Director, Head of Sabah Centre for Disease Control, Director of the Kota Kinabalu Public Health Laboratory (KKPHL), staff from Public Health and Zoonotic Surveillance sections, the Director of the Borneo Medical Health Research Centre (BMHRC) at Universiti Malaysia Sabah (UMS) and staff from Hospital UMS, to discuss EID-SEARCH project progress, molecular and serology testing results, the strategy for syndromic surveillance and work plans.
- Meeting with the Director of the BMHRC and the Director of the KKPHL to discuss how to proceed with Syndromic Surveillance in Sabah, Malaysia.

Panel, workshop, training, webinar

- Workshop to design SBCC campaign to reduce illegal wild meat demand and prevent pandemics in Thailand, USAID Reducing Demand for Wildlife (USAID RDW) and WildAid, Thailand
- 41st Thailand Wildlife Seminar on wildlife surveillance, Kasetsart University, Thailand
- Strengthening surveillance of adverse events following immunization (AEFI) and laboratory identification of pathogenic viruses among network partners, Bureau of Epidemiology, Department of Disease Control, Thailand
- CEPI and NIAID panels for selecting coronaviruses with high pandemic risk.
- G20 webinar on Prevention and Preparedness based on the One Health Approach to Address Threats at The Human-Animal-Environment Interface. Contributed to policy brief via the T20 (Indonesia) in advance of the G20 meeting in Lombok, Indonesia in 2022.
- NSF-funded EcoHealthNet training program for One Health students. "Workshop Session 1: Future of Pandemics" One Health training for the Thailand One Health University Network (THOHUN) for their field epidemiology One Health training Southeast Asia One Health University Network (SEAOHUN) regional conference and helped moderate partnership meeting, Bangkok, Thailand.
- Panel discussion for the Food and Agriculture Organization (FAO) ONE HEALTH Dialogue Series No.6 "Environment and One Health"
- Technical Workshop on Bat Surveillance in the Mekong Region" hosted by King Chulalongkorn Memorial Hospital and the World Health Organization in Bangkok, Thailand.

Conference and university lectures

- Prince Mahidol Award Conference Side Meeting on "Addressing Ecosystem Change and Pandemic Emergence through Strengthening One Health Implementation", joint organized by EID-SEARCH and PICREID, Bangkok
- Joint International Tropical Medicine Meeting 2022, Bangkok on "Way Forward to Leverage Pandemic Prevention"
- 3rd International Symposium on Infectious Diseases of Bats, Ft. Collins, CO. on "Bat coronaviruses surveillance in Western Asia" and "A strategy to assess spillover risk of bat SARS-related coronaviruses in Southeast Asia."
- 19th International Bat Research Conference, organizer and chair of Symposium: "Advances in understanding bat health and disease dynamics" and Moderator for Panel discussion during symposium.
- 19th Ecology and Evolution of Infectious Diseases conference in Atlanta, GA on "Ecological correlates of coronavirus infection in wild bats"
- Presentation to the Responding to Epidemics and Crises in Health (REACH) Fellowship, Columbia University. ICAP on "One Health Approaches to Pandemic Prevention, Preparedness, and Response"
- ASTMH meeting Seattle, WA. Symposium on "Pandemic Surveillance and Pathogen Prediction: What's next and what will it take to keep us safe?"
- World One Health Congress, "Secondary health and ecological benefits of bat virus surveillance", "One Health 'Smart Surveillance' – using disease modeling to pinpoint high-risk spillover interfaces."
- Presentation and training on One Health Leadership for the One Health Young Leaders (OHYL) program of the Indonesia One Health University Network (INDOHUN) (virtual)
- Institute of Global Health, University of Geneva in Switzerland on "One Health and Ecological Approaches to Zoonotic Disease Prevention, Preparedness, and Response"
- Keynote panel on the Approaches to pandemic preparedness at the World Antiviral Congress in San Diego, CA.
- Keynote address for iSEE Congress 2023: Confronting Crises of Planetary Scale: Lessons from Pandemics and Climate Change, Urbana, IL
- Kasetsart University, Thailand on "Species distribution models/ecological niche models as a tool for disease risk assessment"
- Thai Red Cross Emerging Infectious Diseases Clinical Center EID Conference on "Next Generation Serology for Pathogen Discovery: Multiplex Immunoassays (MIA)"

- Asia Pacific Biorisk Conference on field biosafety
- Asia Society of Conservation Medicine on field biosafety

## Public outreach

- Field trip organizing for the SEAOHUN Competence Based Education Workshop led by research staff at TRC EIDCC on bat-human interface research under EID-SEARCH
- J&J on "Analytics to Support Pandemic Prevention".
- Field biosafety standards developed through the CREID/ EID-SEARCH project trained and implemented in various EHA-led projects in Vietnam, Liberia, Guinea
- Griffin Foundation

**B.6 WHAT DO YOU PLAN TO DO DURING THE NEXT REPORTING PERIOD TO ACCOMPLISH THE GOALS?**

In the next reporting period, we will follow the research plans laid out in our proposal with the specific actions as follows (no modifications of the scope of work):

Specific Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife

1.1 Wildlife (bats, rodents, non-human primates) sampling at selected sites.

1.1.1 Increase sampling efforts for rodents/tree shrews and non-human primates.

1.1.2 Conduct longitudinal sampling at a few selected sites to analyze viral shedding patterns and spillover risk.

1.1.3 Targeted surveillance to identify the animal host of the Mojiang-related virus.

1.2 Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 4-5 of the project.

1.3 Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses and paramyxoviruses.

(Filoviruses testing is suspended due to low detection rate in swabs)

1.4 Perform serology testing on the wildlife samples collected in Y1-4.

1.4.1 Perform serological testing for Coronaviruses, Filoviruses, and Henipaviruses.

1.4.2 Perform serological characterization of Sarbecovirus-positive samples using surrogate virus neutralization test (sVNT) RBD-based assay.

1.5 Conduct whole-genome and spike glycoprotein sequencing with newly identified viruses.

1.6 Continue research to further characterize a subset of novel viruses, including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies.

1.6.1 Rescue additional pangolin viruses that are genetically more distant from SARS-CoV-2 and the pangolin GD strain, as well as continue efforts to synthetically reconstruct and characterize the BANAL-52 isolate using in vitro and in vivo approaches.

1.6.2 Review novel bat sarbecovirus whole genomes identified in Y1-4 for synthetic recovery.

1.7 Develop zoonotic risk analyses for relevant viruses.

1.7.1 Analyze Spike and whole-genome sequences to predict host range using a variety of in silico approaches.

1.7.2 Model the host range, geographic distribution, extent of overlap with high-density human populations, etc., using existing apps/models to assess potential zoonotic disease risk.

1.7.3 Improve data workflow to integrate viral characterization results into zoonotic virus prediction models.

1.7.4 Conduct analysis to understand the diversity and evolution of SARS-CoV-2-related viruses.

1.7.5 Develop a risk assessment pipeline that determines the spillover risk, disease severity, and protective levels in individuals with pre-existing SARS-CoV-2 immunity.

Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays

2.1 Increase the number of sites and enrolled participants for community surveillance among at-risk populations to collect biological and behavioral data collection.

2.1.1 Enrolling human participants from additional community sites in Thailand where human-wildlife contact occurs.

2.1.2 Perform whole genome sequencing of identified CoVs from bat guano collectors.

2.1.3 Collect PBMCs from individuals with detectable antibodies against the Mojiang-related viruses for further characterization in Thailand.

2.1.4 Obtain MoA to enroll human participants at community sites in Malaysia.

2.2 Continue identifying community sites concurrent with animal surveillance sites (Specific Aim 1).

2.3 Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and Henipaviruses.

2.4 Continue epidemiological analyses of biological and behavioral data.

Specific Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts

3.1 Enrolling participants at selected hospital/clinic sites for syndromic surveillance.

3.1.1 Enroll human participants from additional hospital sites in Thailand.

3.1.2 Obtain MOA to start enrollment at hospital/clinic sites in Malaysia.

3.1.3 Perform PCR and serological tests with newly collected and archived samples if available.

3.2 Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.

3.3 Continue serological and molecular testing on collected human samples.

3.4 Perform viral characterization work if any novel viruses are identified.

Training and capacity-building activities to achieve project goals

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures, discussion, and hands-on guidance.

- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing

- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training.

- Continue training and troubleshooting on multiplex microsphere immunoassay (MMIA) data analysis and interpretation.

- Conduct refresher training on human research regarding survey design, interview skills, and data analysis.

- Conduct 2nd-round lab biosafety evaluation and regular research facilities inspection.

Additional activities

- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer review, publication, and broad distribution.

- Continue refining and sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government promptly.

- Organize meetings and workshops with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region.

- Continue supporting in-country outbreak research and response as requested.

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary research center with **specific objectives** to: 1) characterize diverse coronaviruses, paramyxoviruses, filoviruses, and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed 'cryptic' outbreaks. Here we report the **major activities** and **significant results** for the period of 06/01/2022 – 05/31/2023:

**Human and wildlife surveillance in Thailand and Malaysia**

	Year 1	Year 2	Year 3
<b>WILDLIFE</b>			
# Individual	100 NHPs <sup>1</sup> , 1,648 bats	2454 bats, 106 rodents, 6 NHPs	586 bats, 191 rodents, 168 NHPs, 2 carnivores
# Species	1 (NHP), 20 (bats)	~30 (bats), 4 (rodents), 2 (NHPs)	~20 (bats), ~24 (rodents/treeshrew), ~3 (NHPs), 1 (Malayan civet)
# Specimen <sup>2</sup>	12,694	20,747	6,261
# Site	6	12	8
# Individuals for PCR test	805 (NHPs, bats)	1,741 (rodents, bats, NHPs)	2,054 (bats, NHPs, rodents)
# PCR test	3,004 CoVs (two assays)	6,240 CoVs (two assays)	7,822 CoVs (two assays)
	1,502 PMVs	2,248 PMVs	2,878 PMVs
	1,502 FLVs	2,248 FLVs	2,479 FLVs
	200 for IFV-A	814 for IFV-A	306 for IFV-A
# Divergent viral PCR sequence (RdRp) detected <sup>3</sup>	5 novel CoVs from 107 bats (3 species)	7 novel CoV from 189 bats	CoV positive samples in 79 bats (8 species), analysis ongoing
	4 novel PMVs from 11 bats (3 species)	3 known PMVs from 4 rodents 7 novel PMVs from 14 bats	3 known PMVs from 3 bat (1 species) 4 novel PMVs from bats (2 species)
# Individuals for MMIA <sup>4</sup> test	0	1,225 bats (FLVs & Henipaviruses)	Archived samples of 392 bats, 64 rodents, 1 moonrat; 100 NHPs, 160 rodents
# Sero-positive <sup>5</sup>		Result analysis ongoing	1% (1/100 NHPs detectable level of antibodies reactive with the MERS-CoV)
			1% (1/100 NHPs detectable level of antibodies reactive with the Mojiang)
<b>HUMAN</b>			
# Enrollment	0	58	92
# Specimen	0	321	465
# Site	0	2	3
# PCR test	0	58 CoVs, 58 PMVs, 58 FVs, 58 IFV-A	146 CoVs, 146 PMVs
# PCR positive	0	0	CoVs positive in 9 participants (Quan) and 2 participants (Watanabe)
# Individuals for MMIA test	0	0	150 from this project and 1,590 archived samples from previous projects
# Specimen tested	0	0	407
# Sero-positive <sup>5</sup>	0	0	45/238 (18.91%) individuals with detected antibodies to FLVs
	0	0	38/214 (17.76%) individuals with detected antibodies to CoVs
	0	0	64/238 (26.89%) individuals with detected antibodies to henipaviruses
	0	0	264/265 (99.6%) individuals with detected antibodies to common human CoVs
<b>DOMESTIC ANIMAL AND LIVESTOCK</b>			
# Individuals for MMIA test	0	0	381 dogs, 15 goats, 7 wild boars, 7 NHPs, 4 rodents, 2 civets, 2 rabbits for CoVs (archived samples collected from at-risk community, wild boars, NHP, rodents and civets all wildlife kept as pet)
# Sero-positive <sup>5</sup>			7 were reactive to CoVs, result analysis ongoing

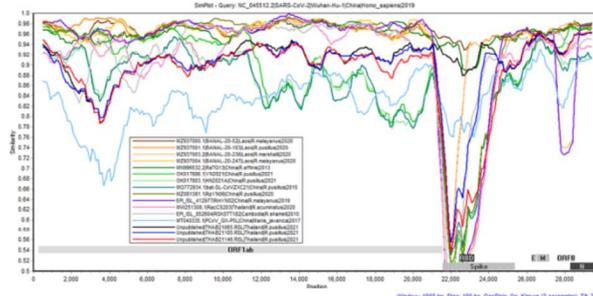

**Note:** <sup>1</sup>NHP: non-human primate; <sup>2</sup>Specimen include oral swabs, rectal swabs, urogenital swabs, and whole blood or serum, types of specimens may vary among individual animals and human participants; <sup>3</sup>Partial-gene phylogenetic trees suggest that these are potentially "novel viruses", further studies are underway to classify and characterize these divergent viral sequences; <sup>4</sup>MMIA: multiplex microsphere-based immunoassay; <sup>5</sup>Further analysis of serological results is ongoing.

**Characterization of bat coronaviruses**

Following our finding (Yr2) of SC2r-CoVs in *R. pusillus*, we continued sampling the same bat colony and obtained whole genome sequences (WGS) from 8 individual bats (**Table 1**). Three WGS were further analyzed using a similarity plot against SARS-CoV-2 isolate Wuhan-Hu-1 (**Fig. 1**) and show relatively similar overall genomic sequence except for the spike region. This indicates several SC2r-CoVs are circulating and evolving in the same bat population. Recombination analysis is ongoing. Genomes are being analyzed from 4 other CoVs from 4 different bat species (*R. pusillus*, *R. amplexicaudatus*, *C. plicatus*, *H. larvatus*).

**Table 2 (left).** Whole genome sequencing of SC2r-CoVs from bat specimen, collected from *R. pusillus* March and October 2021; **Fig. 1 (right).** Similarity plot against SARS-

Bat ID	Percent identity to SARS-CoV-2 isolate Wuhan-Hu-1 (NC_045512)	Percent identity to bat SARS-CoV-2	Percent genome completeness
THAB21028	74.30%	74.97% (BANAL20247)	81.26%
THAB21105	90.37%	90.86% (BANAL20236)	100%
THAB21114	88.96%	89.23% (BANAL20236)	97.92%
THAB21122	90.34%	90.96% (BANAL20236)	99.98%
THAB21135	54.84%	55.38% (BANAL20247)	60.24%
THAB21140	86.42%	86.68% (BANAL20236)	96.22%
THAB21146	89.77%	90.3% (BANAL20236)	100%
THAB21149	-	-	20.95%

CoV-2 plot showing the relative sequence similarity of each genome against SARS-CoV-2 calculated from a window size of 1000 bp, 100 bp step using Kimura (2-parameter).

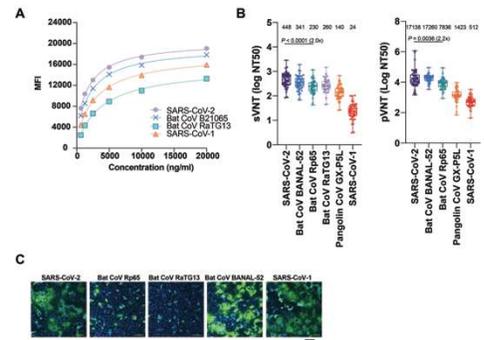

Meanwhile, further characterization of the previously identified bat CoV (Rp-65) were conducted, the results show this bat CoV binds to human ACE2 (**Fig 2A**). Using human serum samples collected from individuals vaccinated against SARS-CoV-2, we observed significant cross-neutralization activities to the bat CoV Rp-65 using sVNT and pseudovirus neutralization test (**Fig 2B**). Bat CoV Rp-65 is less fusogenic than SARS-CoV-2 and bat CoV BANAL-52 (**Fig 2C**). Considering the cross-reactivity of SARS-CoV-2 neutralizing antibodies and

U01AI151797

PI: Daszak, Peter

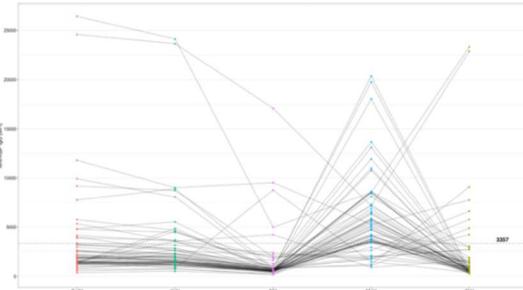

less fusogenic phenotype, individuals with pre-existing immunity to SARS-CoV-2 are likely protected against Bat CoV Rp-65.

**Fig 2. Characterization of the Bat CoV Rp-65 RBD. (A)** ACE2 binding SARS-CoV-2, Bat CoV Rp-6, Bat CoV- RaTG13 and SARS-CoV-1 RBD. **(B)** Neutralization titers determined by sVNT and pVNT for SARS-CoV-2 ancestral, Bat CoV BANAL-52, Bat CoV Rp-65, Pangolin CoV GX-P5L, and SARS-CoV-1. **(C)** Fusogenicity of SARS-CoV-2, Bat CoV Rp-65, Bat CoV RaTG13, Bat CoV BANAL-52, and SARS-CoV-1 spike protein

**Serological testing of human samples**

Serological testing was conducted on samples from rural community participants in Thailand, including bat guano collectors for henipavirus, filovirus, and wildlife and human associated CoV antigens. We found 99.62% (264/265) seroprevalence for HCoV-OC43 in pre- (n=215) and post-COVID-19 (n=50) individuals. All specimens in 2017 and 2018 were negative for SARS-CoV-2. We detected antibodies to

both filo-like viruses (18.91%, 45/238) and henipa-like viruses (26.89%, 64/238), including a high seroprevalence to the MojV RBP (21.85%, 52/238) (Fig 3). These results suggest possible exposure to novel MojV-related viruses within this population.

**Fig 3.** Median fluorescence intensities (MFI) values for henipavirus antigens of sera collected in 2017, 2018, 2021, and 2023 from the community site. Seropositivity is defined by seroreactivity to at least one of the antigens tested within the viral families and does not necessarily indicate the virus of exposure. Further characterization of the functional antibody responses such as neutralization tests would be required.

**Surrogate virus neutralization (sVNT) assay development**

At Duke NUS, the multiplex sVNT panel to detect neutralizing antibodies targeting multiple human and animal sarbecoviruses has been updated to include recent SARS-CoV-2 Omicron variants (e.g., BA.1, BA.2, BA.5, XBB.1 and XBB.1.5) and the bat CoV Rp-65 detected in Thailand. Apart from the sarbecovirus, the team has expanded the multiplex sVNT to detect neutralizing antibodies targeting members of merbecovirus, henipavirus, and ebolavirus, aiming to establish an all-in-one sVNT platform for viral pathogens with pandemic potential.

**Host range, transmissibility, and antigenicity of a pangolin coronavirus**

At Duke NUS, using a synthetically derived infectious cDNA clone, we recovered the Guangdong wildtype pangolin (Pg) CoV-GD and derivatives encoding indicator genes (nanoluc and GFP introduced into ORF7). We have further characterized it, and assessed its ability to infect human cells. Full details are given in the semi-annual report during Yr 3, and a paper is under 2<sup>nd</sup> round of review.

**Outbreak Research and Response**

Time Period	Aims	Funds Pivoted to this Project	Stakeholders/Partners Engaged for Project	Progress/Outcomes to Date
April-June 2022	Monkeypox outbreak preparedness	No direct funds were pivoted however, members from the EID-SEARCH assisted with laboratory testing and provided information to Thai government.	-Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC EIDCC) -Department of Disease Control, Thailand (DDC) -Division of High-Consequence Pathogens and Pathology, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, US	The first 5 cases of Mpox in Thailand were tested and confirmed at the TRC EIDCC laboratory. Whole-genome sequencing of Mpox was conducted and deposited in GISAID.
June 2021	Access to COVID vaccine in Malaysia	No direct funds were pivoted however, members from the EID-SEARCH assisted with facilitating the communication between US Embassy and the Ministry of Health Malaysia	-Conservation Medicine -Ministry of Health Malaysia -US Embassy in Malaysia	1 million Pfizer vaccines donated to Malaysia by the US government in July 2021
September 2020	Access to COVID testing supplies in Malaysia	No direct funds were pivoted however, members from the EID-SEARCH helped organise, source, and coordinate the delivery of supplies for testing 10,000 people	-Conservation Medicine -Ministry of Health Malaysia -US Embassy in Malaysia -Kota Kinabalu Public Health Laboratory	Supplies for testing 10,000 people were delivered to support the Ministry of Health in their impressive response to the COVID-19 outbreak.
August 2020	Wildlife testing for SARS-CoV-2	No direct funds were pivoted however, members from the EID-SEARCH assisted with laboratory testing and provided information to local government.	-Conservation Medicine -EcoHealth Alliance	1,254 archive animal samples in Malaysia from 1,207 animals, including 28 species considered potential reservoir or host species for SARS-CoV-2, were screened using a conventional PCR. SARS-CoV-2 was not detected in any of the samples.

**Publications** Full details in Section C.

During this reporting period, EID-SEARCH provided training sessions to individuals involved in the activities supported by the project that were focused on biosafety, the application of new technologies, and field and laboratory standard operating procedures to enhance in-country research capacity and improve information sharing. Training was conducted by EID-SEARCH project members and partners among in-country stakeholders in Thailand and Malaysia from local government, universities, research institutes, and NGOs. Some training activities are highlighted as follows:

**November-December 2022:** The Duke-NUS team provided continuous support for various training development opportunities with the other EID-SEARCH partners, including: Hosting 2 representatives from the Thai team (TRC-EID) during their visit to Singapore from 2 November to 12 November 2022. On-site training and technology transfer of the multiplex sVNT and pseudovirus neutralization assays developed by the Duke-NUS team were conducted for TRC-EID team members. Five research personnel from the Duke-NUS team including the co-Investigator Prof Wang visited TRC-EID lab from 6 December to 11 December 2022, as a follow up and also to assist with the establishment and optimization of the assays. The TRC-EID team also made arrangements to visit the bat caves in Thailand, where members of the Duke-NUS team were able to experience first-hand how the bats were caught in the wild and were taught procedures for processing bat tissues. EID-SEARCH members from Duke-NUS and TRC-EID attended the Joint International Tropical Medicine Meeting 2022 in person, where Prof Wang and Dr Supaporn presented results generated from this project in the session titled “*Way Forward to Leverage Pandemic Prevention*”.

**July 2022:** USU team provided instructional training to two laboratory members from TRC-EID on the serologic techniques used to detect binding antibodies. The training covers various topics of antigen design, assay techniques and testing strategies, and preliminary data analysis.

**24-25 April 2022:** Three Conservation Medicine (CM) staff completed a 2 day Outdoor First Aid course. This was not included in the last progress report, as this activity was completed after the report submission.

**25 April 2022:** Nine Conservation Medicine staff completed an annual 1-day Outdoor Refresher First Aid course. This was not included in the last progress report, as this activity was completed after the report submission.

**14 May 2022:** Conservation Medicine conducted a Biosafety in Field and Specimen Storage Training at Sabah Wildlife Department’s (SWD) - Sepilok Orangutan Rehabilitation Centre (SORC), Sandakan, Sabah. This one-day training included 10 participants from the Bornean Sun Bear Conservation Centre (BSBCC) and 11 participants from SORC – both organizations that have previously provided opportunities for wildlife sampling to EID-SEARCH. PPE donning and doffing, spill clean-up, and sample cold chain maintenance training were given. The objective of this training was to build capacity for those involved with the bio-surveillance of wildlife species at SORC and BSBCC. The training utilized lectures and PowerPoint presentations. After each presentation, post training quizzes were completed by all participants to assess their understanding of each session. Wet lab sessions including Mask Fit Test, PPE donning and doffing, and spill clean-up were conducted. Participants left the training knowing what type of N95 and N100 masks fitted them and the correct size of PPE that they need for lab and field work. This was not included in the last progress report, as this activity was completed after the report submission.

**30-31 July 2022:** Conservation Medicine Field Coordinator attended a workshop at Kota Kinabalu organized by Sabah Wildlife Department.

**04 September – 25 November 2022:** Conservation Medicine trained 6 staff from the Ministry of Health - National Public Health Laboratory on EID-SEARCH serology data analysis during the screening of archived human samples using the coronavirus multiplex immunoassay. This training was given over the course of 20 days by CM Laboratory Coordinator on the assay's theory, refresher training on the technique, and results analysis.

**16 March 2023:** 2 Conservation Medicine contract staff participated in EID-SEARCH lab related training. This training was given by CM Senior Laboratory Technician on Laboratory Safety, Biosafety and PPE, and TRIzol as a part of induction training for EID-SEARCH PCR testing.

**20-21 March 2023:** Conservation Medicine Field Coordinator and Senior Ranger attended the "Managing People and Macaques in shared spaces Workshop" organized by SWD. The workshop aimed to work towards solving the human-macaque conflict in Sabah, promote conservation for macaques and raise awareness about one health and the role macaques play in zoonosis in Sabah.

**Mentorship.** Through the CREID pilot research program, Dr. Cadhla Firth from EID-SEARCH has been mentoring pilot project awardees in 2022, Dr. Jurre Siegers and Vireak Heang, on research implementation in Cambodia and relevant data analysis. Dr. Firth continued providing mentorship support to Dr. Nguyen Van Cuong, awardee in 2021, on data analysis and manuscript development, as well as joint grant application. In addition, regular meetings were held among EID-SEARCH members and partners for collaborative laboratory results discussion, data analysis, and manuscript development, to support professional development of graduate students who work on this project.

EID-SEARCH members were able to participate training provided by the **CREID network** including the CREID Network Bioinformatics Training Workshop hosted by IRESSEF and CIGASS-UCAD in October 2022 and the CREID Biorepository Community of Practice (CoP) focuses on knowledge exchange through member presentations, invited seminars, and external stakeholder presentations.

Senior Field Veterinarian, Dr. Marc Valitutto, continued working with EID-SEARCH partners for collaborative advancement of **field biosafety standards** to develop specific field biosafety levels for a risk-based approach to practicing biosafety in the field.

## C. PRODUCTS

## C.1 PUBLICATIONS

Are there publications or manuscripts accepted for publication in a journal or other publication (e.g., book, one-time publication, monograph) during the reporting period resulting directly from this award?

Yes

**A. Personal Statement**

As a current employee with Dr. Eric Laing under his emerging infectious diseases research program. My academic training and research experience have provided me with a background in molecular biology, virology, and epidemiological techniques for zoonosis investigations. As part of my original post-baccalaureate work, I worked in a small team lead by Dr. Chris Border tasked with developing a serological binding assay for Coronaviruses, Filoviruses, and Henipaviruses. During this process, I worked closely with Dr. Laing and scientists from multiple Asian countries in developing and applying the multiplex techniques for rapid, high-throughput serological assays. Throughout this time, I have led technical and data analysis trainings in Cambodia, Bangladesh, and Thailand, and have assisted collaborators in Singapore, Malaysia, Australia, India, South Africa, and the United Kingdom in implementing these novel techniques. Currently, I am a visiting scientist with Dr. Supaporn Wacharapluesadee in the Emerging Infectious Diseases Clinical Center at King Chulalongkorn Medical Hospital as part of the CREID-EID SEARCH program.

**B. Positions, Scientific Appointments, and Honors**

05/22-present Visiting Scientist, King Chulalongkorn Medical Hospital, Bangkok, Thailand. Advisors: Dr. Supaporn Wacharapluesadee, Dr. Opass Putchaeron, and Dr. Eric D. Laing.

02/22-present Scientific Project Coordinator, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisors: Dr. Christopher C. Broder and Dr. Eric D. Laing

- 08/20-02/22 Research Associate 2, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 08/19-08/20 Senior Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 06/15 – 08/19 Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 01/14-08/14 Laboratory research internship, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder

### C. Contributions to Science

1. **Post-Baccalaureate:** My post-baccalaureate research works primarily targeted understanding the adaptive immune response to emerging zoonotic viruses as a tool for virus discovery. As part of the assay development team, I designed and expressed soluble, native-like filovirus and henipavirus attachment glycoproteins and developed the monoclonal antibodies and antisera used as standards in the assay. I have led technical training for international projects and assisted in data analysis
  - a. Laing ED, Mendenhall IH, Linster M, Low DHW, Chen Y, Yan L, **Sterling SL**, et al. “Serologic evidence of fruit bat exposure to filoviruses, Singapore, 2011–2016”. (2018). *Emerg Infect Dis.* 24(1):114-117. doi: 10.3201/eid2401.170401. PMID: 29260678.
  - b. Schulz JE, Seifert SN, Thompson JT, Avanzato V, **Sterling SL**, et al. “Serological evidence for henipavirus-like and filovirus-like viruses in Trinidad bats.” (2020) *J Infect Dis.* pii: jiz648. doi: 10.1093/infdis/jiz648. PMID: 32034942.

2. **Professional Studies:** While employed, I continued my studies by pursuing a Master’s in Public Health with a focus on Epidemiology. Immediately preceding my thesis work, COVID-19 was declared a pandemic, and I worked along side Dr. Eric Laing to develop and standardize a human coronavirus serological panel to track the serological response to SARS-CoV-2 infections and vaccinations among a military cohort. For my thesis, I evaluated the humoral immune response to SARS-CoV-2 patients as it related to the severity of the disease, where we observed significantly more robust antibody responses in people with more severe disease.

Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Putcharoen, Opass

eRA COMMONS USER NAME (credential, e.g., agency login): OPASS.P

POSITION TITLE: Assistant Professor, Division of Infectious Diseases, Department of Medicine, King Chulalongkorn Memorial Hospital, Chulalongkorn University

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Kon Kaen University, Thailand	M.D.	1995	Medicine
Chulalongkorn University, Thailand	M.Sc	2007	Medical Sciences

**A. Personal Statement**

I am the director of the Emerging Infectious Diseases Clinical Center, Thai Red Cross, and a senior lecturer of the division of infectious diseases, Department of Medicine, King Chulalongkorn Memorial Hospital, Chulalongkorn University, Bangkok, Thailand. I am also an assistant professor at the faculty of medicine, Chulalongkorn University. In 1998, I received a medical degree from Kon Kean University, Thailand, and then completed my residency and fellowship (infectious diseases) training at Chulalongkorn University. During 2008-2010, I received training grants from the Fogarty International Center at NIH, USA. From 2008-2011, I was a research fellow in HIV drug resistance at the department of immunology and infectious diseases, Harvard School of Public and a postdoctoral fellow at the section of retroviral therapeutics, division of infectious diseases, Brigham and Women's Hospital, Harvard School of Medicine, Boston, MA, USA. My current research focuses on long-term complications of antiretroviral therapy, HIV drug resistance, co-infections in resource-limited settings, and emerging infectious diseases.

**B. Positions, Scientific Appointments, and Honors****Positions**

1995-2001 General practitioner Panusnikom District Hospital, Chonburi, Thailand  
 2001-2005 Internist in Panusnikom District Hospital (200-bed community hospital), Chonburi, Thailand  
 2006-2008 Clinical fellow, Department of Infectious Diseases, Chulalongkorn Hospital, Bangkok, Thailand  
 2008-2010 Research fellow, Department of Immunology and Infectious Diseases, Harvard School of Public Health, Boston, MA  
 2010- Instructor in Medicine, Department of Medicine, Chulalongkorn University, Bangkok, Thailand  
 2017- Director, Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital

**Honors**

1994 Scholarship from Case Western Reserve University for short course training in "Introduction to Clinical Infectious Diseases"  
 2007 Award for selected high-quality abstracts in 17<sup>th</sup> European Congress of Clinical Microbiology and Infectious Diseases and 25<sup>th</sup> International Congress of Chemotherapy Munich/Germany

**E. IMPACT**

**E.1 WHAT IS THE IMPACT ON THE DEVELOPMENT OF HUMAN RESOURCES?**

Not Applicable

**E.2 WHAT IS THE IMPACT ON PHYSICAL, INSTITUTIONAL, OR INFORMATION RESOURCES THAT FORM INFRASTRUCTURE?**

EID-SEARCH project, in collaboration with Conservation Medicine in Malaysia, is committed to build in-country capacity for emerging infectious surveillance, the long-term collaboration with local government and institutions in Malaysia has led to significant infrastructure improvement as detailed below:

In January 2020, Conservation Medicine started the process of getting the Wildlife Health, Genetic and Forensic Laboratory (WHGFL) in Sabah, a BSL-2 laboratory certified to CDC and NIH laboratory standards, that Conservation Medicine designed and with support from EcoHealth Alliance established with Sabah Wildlife Department (SWD), ISO 17025 accredited. This accreditation will allow the laboratory to conduct forensic investigations for the Sabah Wildlife Department, an important development in combatting the illegal wildlife trade and its associated risks with the spread of zoonotic disease. The accreditation will also include the Disease Unit coordinated by Conservation Medicine and our CoV, PMV, and FLV testing. From 1st April 2020, we started the ISO 17025 training (16 people trained to date) and document preparations with guidance from our consultant. The document audit with Standards Malaysia was conducted on 28th July 2022, and we were found to be adequate. The pre-assessment on-site audit with Standards Malaysia was conducted on 12-13 January 2023. Addressing the few non-conformities identified during this audit is ongoing, and we are working closely with SWD with the hope of having the lab accredited before the end of 2023.

On 18 July 2022, the WHGFL in Sabah was certified for the ninth year in a row as a BSL- 2 laboratory, in accordance with the Biosafety in Microbiological and Biomedical Laboratories (BMBL) 5th Edition (December 2009), which is the US standard for laboratory specifications.

On 3 October 2022, the Molecular Zoonosis Laboratory at PERHILITAN’s National Wildlife Forensic Laboratory was certified for the sixth year in a row as a BSL-2 laboratory in accordance with the Biosafety in Microbiological and Biomedical Laboratories (BMBL) 5th Edition (December 2009).

On 27 February 2023, with approved funding, EID-SEARCH/Conservation Medicine purchased the MAGPIX Multiplex System for serology work in Sabah. This will be located at the Borneo Medical and Health Research Centre (BMHRC) and Universiti Malaysia Sabah (UMS). It will be used to screen human and wildlife samples for EID-SEARCH as agreed with Sabah State Health Department, SWD, and UMS. Conservation Medicine are working with BMHRC to get the lab ready, so that the wildlife serology screening can start in June 2023, followed by human serology once all approvals are in place. The laboratory and work will be managed according to internationally recognized BioSafety standards.

Additional resources were kindly provided by the NIAID Office of Global Research (OGR) via the CREID network, which helped to improve the molecular viral screening and characterization capacity in Thailand and Malaysia.

**E.3 WHAT IS THE IMPACT ON TECHNOLOGY TRANSFER?**

**E.4 WHAT DOLLAR AMOUNT OF THE AWARD'S BUDGET IS BEING SPENT IN FOREIGN COUNTRY(IES)?**

Dollar Amount	Country
---------------	---------

\$431,551	MALAYSIA
\$108,006	SINGAPORE
\$215,944	THAILAND

## F. CHANGES

### F.1 CHANGES IN APPROACH AND REASONS FOR CHANGE

Not Applicable

### F.2 ACTUAL OR ANTICIPATED CHALLENGES OR DELAYS AND ACTIONS OR PLANS TO RESOLVE THEM

The biggest challenge we have encountered during this reporting period goes back to the large number of hospitalized patients in local hospitals due to COVID-19. Patient influx delayed human participant enrollment at targeted hospital sites and the subsequent laboratory analysis we anticipated in Year 2. During Year 3, we have worked hard to address this challenge and will increase human enrollment at both hospital and community sites in Malaysia and Thailand as we move into Year 4. To address these issues, we have 1) added additional hospitals, including both larger hospitals and community clinics; 2) refined the study tools and provided refresher training to hospital staff to improve the enrollment and data collection procedures to allow faster processing. Meanwhile, we have included 3) archived samples with the undiagnosed causes of infection or death cases of encephalitis from the local surveillance program into this program.

In Malaysia, while waiting for government approval for human surveillance, we have continued working on archived human samples and are already getting exciting results, which will be reported to NIAID after they are validated and approved in the coming weeks.

Are there personnel on this project who are newly involved in the design or conduct of human subjects research?

No

### G.6 HUMAN EMBRYONIC STEM CELLS (HESCS)

Does this project involve human embryonic stem cells (only hESC lines listed as approved in the NIH Registry may be used in NIH funded research)?

No

### G.7 VERTEBRATE ANIMALS

Does this project involve vertebrate animals?

Yes

**G.8 PROJECT/PERFORMANCE SITES**

Organization Name	UEI	Congressional District	Address

**G.9 FOREIGN COMPONENT****Organization Name:** Chulalongkorn University**Country:** THAILAND**Description of Foreign Component:**

The site will 1) collect biological specimens from target animal and human populations; 2) collect questionnaire survey data from target human populations; 3) conduct laboratory RT-PCR testing, sequencing, and serological testing with collected specimens; 4) conduct viral isolation, full genome sequencing and initial data analysis; and 5) share data and samples with US collaborator.

**Organization Name:** Conservation Medicine**Country:** MALAYSIA**Description of Foreign Component:**

The site will 1) collect biological specimens from target animal and human populations; 2) collect questionnaire survey data from target human populations; 3) conduct laboratory RT-PCR testing, sequencing, and serological testing with collected specimens; 4) conduct viral isolation, full genome sequencing, and initial data analysis; and 5) share data and samples with US collaborators.

**Organization Name:** Duke-NUS Medical School**Country:** SINGAPORE

**Description of Foreign Component:**

The site will 1) develop serological platforms for the human biological sample testing; 2) provide the serological assays to project collaborators in Thailand and Malaysia; and 3) provide lab technical support and consultation regarding any specific pathogens that are identified as high interest to the CREID and NIH.

**G.10 ESTIMATED UNOBLIGATED BALANCE**

**G.10.a Is it anticipated that an estimated unobligated balance (including prior year carryover) will be greater than 25% of the current year's total approved budget?**

No

**G.11 PROGRAM INCOME**

**Is program income anticipated during the next budget period? No**

**G.12 F&A COSTS**

**Is there a change in performance sites that will affect F&A costs?**

No

All special reporting requirements specified in the award terms and conditions in the Notice of Award (NoA) have been addressed and reported to the Grants Management Specialist and Program Office.

EcoHealth Alliance certifies that during the current reporting period, onsite subrecipient facility inspections were conducted as required in our NoA to ensure that subaward activities are being properly executed.

**Section 1 - Basic Information (Study 293221)**

1.1. Study Title \*

Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia

1.2. Is this study exempt from Federal Regulations \*

Yes  No

1.3. Exemption Number

1  2  3  4  5  6  7  8

1.4. Clinical Trial Questionnaire \*

1.4.a. Does the study involve human participants?

Yes  No

1.4.b. Are the participants prospectively assigned to an intervention?

Yes  No

1.4.c. Is the study designed to evaluate the effect of the intervention on the participants?

Yes  No

1.4.d. Is the effect that will be evaluated a health-related biomedical or behavioral outcome?

Yes  No

1.5. Provide the ClinicalTrials.gov Identifier (e.g. NCT87654321) for this trial, if applicable

## Section 2 - Study Population Characteristics (Study 293221)

### 2.1. Conditions or Focus of Study

- Humans living in geographic hotspot areas/close contact with wild animals

### 2.2. Eligibility Criteria

#### ELIGIBILITY CRITERIA

Participants to be enrolled in this study will be individuals from Thailand (Ratchaburi and Chonburi provinces), Peninsular Malaysia, Sabah Malaysia, or Sarawak # 12 years old living or working around wildlife habitats (e.g. bat caves/roosts), those who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife or visiting or working in high-risk sites (e.g. wildlife markets) who meet the inclusion criteria outlined below. Study sites are prioritized based on the hotspot geographic areas described in Aim 1, according to ecological and epidemiological conditions associated with a high risk for the coronaviruses, henipaviruses, filoviruses spillover.

Research participants will be enrolled in two settings:

1. Community - We aim to enroll and collect biological samples and survey responses individuals' living, working, or visiting targeted high-risk communities (as defined above) who have close contact with wildlife, specifically bats, rodents, non-human primates, with a range of exposures to these animals. Enrolled research participants will be asked to provide biological samples and complete a questionnaire that is designed to obtain detailed information into wildlife contact frequency and exposures related to: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house and other livestock animals (e.g. farming, butchering, slaughtering); 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported symptoms relating to a) severe/acute respiratory illness (SARI/ARI); b) Influenza-like illness (ILI); c) fever of unknown origin (FUO); d) encephalitis; or e) hemorrhagic fever; or f) diarrhea in combination with any of the previously mentioned illnesses within the 12 months and lifetime.

Additional inclusion criteria:

- Adults (18 years of age or older) who provide informed consent
- Children aged 12-17 years of age who provide assent along with an accompanying parent or guardian who is able to provide informed consent and
- Pregnant women will be considered eligible for inclusion

Exclusion criteria:

- Adults (18 years of age or older) who are unable to provide informed consent, including individuals with physiologically or medically induced cognitive impairments
- Individuals under 12 years of age
- Children without an accompanying parent or guardian who is able to provide informed consent, or a child 12-17 years old unable or unwilling to provide assent or children who are wards of the state
- Prisoners

2. Hospital - Both out-patients and in-patients at clinics or hospitals presenting with clinically defined symptoms of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever; or 6) diarrhea in combination with any of the previously mentioned illnesses of unknown etiology. Biological samples will be collected from the patients and the patient, will complete a questionnaire. We will follow up with these participants 35 days after enrollment to collect another biological sample to assess the development of IgG/IgM and collect additional data on the course of symptoms in the interim period.

Additional inclusion criteria:

- Adults (18 years of age or greater) who provide informed consent
- Children aged 12-17 years of age who provide assent along with an accompanying parent or guardian who is able to provide informed consent and
- Pregnant women will be considered eligible for inclusion

Exclusion criteria:

- Individuals over the age of 12 years who refuse to provide informed consent
- Adults unable to provide informed consent, including individuals with physiologically or medically induced cognitive impairments
- Children, aged 12-17 years, without an accompanying parent or guardian who is able to provide informed consent, or a child aged 12 to 17 who is unable or unwilling to provide assent
- Children < 12 years of age or children who are wards of the state
- Prisoners

### 2.3. Age Limits

Min Age: 12 Years

Max Age: N/A (No limit)

#### 2.3.a. Inclusion of Individuals Across the Lifespan

2.4. Inclusion of Women and Minorities	Inclusion_of_Women_Min_Children_FINAL.pdf
2.5. Recruitment and Retention Plan	Section_2_Attmt_Recruitment_Retention_Plan_FINAL.pdf
2.6. Recruitment Status	Not yet recruiting
2.7. Study Timeline	Section_2_Attmt_Study_Timeline_FINAL.pdf
2.8. Enrollment of First Participant (SEE SECTION 6.3)	

## INCLUSION OF WOMEN AND MINORITIES:

This study will enroll men and women, including pregnant women, as study participants. Subjects will be enrolled in this study without regard to ethnicity.

Women who volunteer to participate are not at an increased risk based on pregnancy status and are at the same exposure risk as non-pregnant women. Every effort will be made to protect the privacy, dignity, and well-being of all study participants especially special populations who participate in this study.

Individuals in sub-sites in selected geographic hotspot regions will be the primary mechanism for identifying subjects. We will make every effort to have men and women equally represented in this study and no individuals will be excluded based on ethnicity.

- **At community sites**, living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be the primary criteria for identifying participants in community.
- **At clinic sites**, only patients who present at the healthcare facility who meet the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever; or 6) diarrhea in combination with any of the previously mentioned illnesses of unknown etiology will be recruited for this study, and no patients will be excluded based on ethnicity or gender.

## INCLUSION OF CHILDREN:

Children aged 12–17 years will be included in this study, and there will be no maximum age restriction for adults, at both community and clinical sites

- Previous clinic-based studies have shown that children are one of the major populations who present to healthcare facilities with severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), or fever of unknown origin (FUO). Our behavioral study in Thailand and Malaysia also suggested the close contact with wild animals among children in the study regions via activities of animal hunting, trade, or butchering.
- Children aged 12 years or older are post-primary school in Thailand and Malaysia and are able to comprehend and respond to the questionnaire autonomously which increases the reliability of responses. We will not enroll children aged 12-17 years without an accompanying parent or guardian who is able to provide informed consent, or a child aged 12-17 who is unable to or unwilling to provide assent.
- Children under age 12 in target communities are mainly school children who have very limited exposures to wild animals under the scenarios of interest to the study, and ethically we do not want to collect or enroll participants without strong scientific need for inclusion. We will not enroll children who are wards of the state
- Every effort will be made to protect the privacy, dignity, and well-being of children who participate in this study. Our in-country human research team are well-trained medical doctors and researchers who have extensive experience working with children, as well as their parents, at both community and clinical settings. Prior to the start of human subject research activities, all research staff will be CITI-trained and further trained on conducting ethical human subject research training including a module on the special considerations for working with children

Program Director/Principal Investigator: Daszak, Peter  
regarding risk and coercion. Enrollment of children will be monitored and annually reported to the IRB.

## RECRUITMENT AND RETENTION PLAN

In order to improve recruitment within target communities, introductory visits will be made by project staff to each of the selected sub-sites. These visits will be advertised through word of mouth and a project description letter to village/town/city leaders and letters that can be posted or shared in a central community location. The letter will inform the community that a team will be coming on a particular day(s) to enroll voluntary participants and after discuss health issues related to animal contact. This letter will be for informational sharing not be used for recruitment purposes. It will only be used to inform the community of the research visits. The project description letter will be written in the local language with a Flesch–Kincaid readability score equivalent to a 7th grade reading level or below (primary school in Thailand and Malaysia), to assure that community leaders and potential community participants understand the study purpose, eligibility, and inclusion guidelines.

Community visits will begin with discussions and meetings with local authorities and community leaders to introduce ourselves and our project, and when appropriate following approval from local authorities, the study team will post flyers to inform the community when the team will be speaking about enrollment and later coming back to enroll interested individuals. Attending this “town hall” style meeting will be completely voluntary and based on our experience, those interested are likely to attend. Although local authorities may be present to introduce the study team members, they will not be involved in the recruitment and/or consent of the participants for the study. Individuals will be clearly informed during the recruitment process that their participation in the study is voluntary. If research visits or recruitment events are held at a workplace individuals choice of involvement will not impact their employment, nor will information discussed be shared with employers. With local permissions and accompanied by local community leaders, district health officers, or authorities the study team members will engage in community town halls and ‘walkabouts’ during which they will discuss study details, dates, times, and locations for enrollment and participation in the study.

Participation in the study will be strictly voluntary and will require signed informed consent for all participants and signed assent for participants aged 12-17 along with parent or guardian consent. During the enrollment process interested individuals will be given a consent form and research staff will read the consent form to potential participants. Together they will review the consent form and study staff will explain details of the study including: why they were selected, what the study procedures are and what will be expected from them, potential risks and benefits of their participation, that their participation is completely voluntary, and that they can withdraw their participation at any time. After reviewing the consent form individuals will be given as much time as needed to ask questions. At that time if individuals wish to participate they will sign two copies of the consent form and it will be countersigned by the research staff, with a copy given to the participant for their records. Included in the consent form is the contact information for local research staff and a local IRB contact for participants if they have questions in the future. Responses will be kept strictly confidential. Measures will be taken to assure the privacy, dignity, and respect of each participant. Ethical human subjects research methods will be a focus in all training of research staff, we will emphasize the importance of avoiding coercion during enrollment and protecting the privacy of participants.

**Community-based recruitment:** Participants from the community will be recruited through town hall meetings and community ‘walkabouts’ as described above. Meeting dates, times, and locations for enrollment and participation will be shared during these activities, and individuals who wish to enroll can volunteer to participate at these times and locations.

**Clinic-based recruitment:** Patients eligible for enrollment will be identified during standard intake procedures or from overnight intake logs, or in the emergency room, ward, or intensive care unit of each participating clinic or hospital by collaborating clinic staff. Employed staff at each location will identify potential participants meeting the clinical case definition of 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever; or 6) diarrhea in combination with any of the previously mentioned illnesses of unknown etiology. Patients will be screened for eligibility according to the inclusion/exclusion criteria based on available clinical information and clinical presentation.

We have set a minimum target enrollment sample size to detect live virus in patients at each hospital assuming a population prevalence of 1% with a 95% probability. We will work with the local institution review board to determine the maximum enrollment of patients without undue burden on the population. However, in larger

Program Director/Principal Investigator: Daszak, Peter

tertiary healthcare centers where many cases fitting study inclusion are expected or are being enrolled we will regularly evaluate enrollment logs to be sure we are prepared to collect samples throughout the length of the sample collection timeline as to not miss a change in circulating virus. If we need to control the number of patients being enrolled at a hospital interval sampling will be implemented by selecting every Nth case of those individuals who meet enrollment criteria. The interval will be determined in collaboration with the local research staff and implementing partners based on an evaluation of the enrolled participants to date and expected number of cases presenting at the site within a given year in order to best meet study design and sample size criteria and stay IRB compliant. In terms of retention, we will express our gratitude to subjects for their participation and discuss the research importance of the follow-up data collection. Nonetheless, we expect to have an approximate 40% loss to follow up and have included this in our sample size calculations.

## STUDY TIMELINE

At each sampling time point, patients/participants will be asked to volunteer approximately 1 hour of their time for participation in the study, including providing biological samples and completing the questionnaire.

This will be an ongoing five-year project from the time of award.

- We anticipate obtaining all required IRB approvals and local permissions in the first 6 months of projects;
- We will start human subject enrollment at community and clinical sites in Year 0.5 at the earliest, and enrollment will continue through Year 5, to be completed by the conclusion of the project;
- Human sample testing will start in Year 0.5 at the earliest, with completion of analyses by the end of the award.

## 2.9. Inclusion Enrollment Reports

3.3. Data and Safety Monitoring Plan

3.4. Will a Data and Safety Monitoring Board be appointed for this study?

Yes     No

3.5. Overall structure of the study team

## PROTECTION OF HUMAN SUBJECTS:

### 1. Risks to Human Subjects

#### 1.1 Human Subjects Involvement, Characteristics, and Design

This project is a study of human spillover and exposure to animal coronaviruses, henipaviruses, and filoviruses in Southeast Asia, with active sample collection in Thailand and Malaysia and testing of archived samples in Singapore. As there is substantial evidence that these viruses likely spillover regularly to people, are often unreported or misdiagnosed and thus underestimated; and this targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. Subjects will be enrolled on a voluntary basis and informed consent will be obtained from all participants and assent from all participants aged 12-17. Consenting participants will provide biological samples for PCR or serological testing and complete a questionnaire to collect information on wildlife exposures and frequency. Subjects will be individuals: 1) who are highly exposed to wildlife, specifically bats, rodents, and non-human primates, in community settings, through hunting, butchering, or general handling within the context of their living or working environments ( $\geq 18$  years old); and 2) patients admitted to hospitals and clinics presenting with disease symptoms of clinically-defined 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever; or 6) diarrhea in combination with any of the previously mentioned illnesses of unknown etiology.

The study population will be selected from the subnational geographic hotspot regions listed in Aim 1. We will enroll participants from: 1) communities at 4 sub-sites from each of the regions of interest in Ratchaburi (Thailand), Chonburi (Thailand), Peninsular Malaysia, Sabah Malaysia, and Sarawak, 175 individuals from each of sub-site in the 5 regions will be collected and pooled across the region for a total of 700 participants per region, allowing us to make region-level comparisons of differing effects, enrolling a total of 3,500 participants; and 2) patients from the selected 2 town-level level clinics and 2 provincial-level hospitals in each of the geographic regions of Thailand, Peninsular Malaysia, Sabah and Sarawak, we will enroll a minimum of 300 participants per clinic or hospital, for a total of 16 healthcare facilities and 4,800 total clinical participants. This will yield 2,880 participants that will be available for follow-up blood sampling assuming for an estimated 40% loss from follow-up. The community and clinical sites are further defined in Specific Aims 2 and 3.

There are no data to suggest a gender or ethnic bias for coronaviruses, henipaviruses, and filoviruses exposure or infection, therefore individuals will be enrolled based on exposure criteria alone and individuals will not be excluded based on ethnicity or gender. We will also monitor sampling enrollment to ensure equal representation of sex, demographic, and socio-economic factors in each community site.

#### 1.2 Sources of Materials

Biological samples to be collected and tested for coronaviruses, henipaviruses, and filoviruses include whole blood, serum, and nasal/oropharyngeal swabs. Samples will be collected by locally trained medical personnel and a questionnaire will be administered by research or collaborating staff from the local hospitals and clinics.

In community sites, whole blood samples will be collected from participants one time during the data collection period during Years 2-5 of the study. The whole blood samples will be aliquoted into at least one max. 500  $\mu$ L whole blood and two 500  $\mu$ L serum samples. Samples will be tested for coronaviruses, henipaviruses, and filoviruses using developed ELISA by consortium partners. For participants who report the symptoms relating to 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever; or 6) diarrhea in combination with any of the previously mentioned illnesses of unknown etiology within the last 10 days, an additional sample type will be collected, nasal or oropharyngeal swabs (2x). These samples will be marked for additional PCR-based assays to identify presence of known and novel coronaviruses, henipaviruses and

Program Director/Principal Investigator: Daszak, Peter

filoviruses, and for isolation and biological characterization of potential pathogens if PCR results are positive.

In clinic sites, both whole blood samples and nasal/oropharyngeal swabs will be collected at enrollment, whole blood samples will be aliquoted into at least one max. 500 µL whole blood and two 500 µL serum samples. Samples will be tested for coronaviruses, henipaviruses, and filoviruses using consensus PCR (cPCR). We will follow up 35 days after enrollment to collect an additional blood sample of 5mL to be separated and aliquoted into a minimum of two 500 µL serum samples that will be serological tested with the developed ELISA assay.

All blood samples will be kept frozen for future harvesting of Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive for emerging viral pathogens. These will be used for harvesting polyclonal and monoclonal antibodies as potential therapeutics.

During data collection a standardized questionnaire will be administered to both community and clinic participants. This survey will collect data on exposure type and frequency with wildlife focusing on: 1) occupation and occupational exposures; 2) observed or reported interactions with wildlife, especially bats, rodents, and non-human primates, in/around house; 3) proximity of residence or workplace to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12 months. During the follow-up with clinic participants a standardized questionnaire supplement will be administered to collect additional data on the course of symptoms in the interim period. All electronic data will be password protected, and all hardcopy files and biological samples will be stored in secure storage facilities. All consent forms and participant logs will be stored separately from research data in locked filing cabinets.

### 1.3 Potential Risks

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions, however, administration will be conducted privately and confidentially to protect individuals' personal health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

## 2. Adequacy of Protection against Risks

### 2.1 Recruitment and Informed Consent

Potential study participants at each site will be recruited after obtaining local permissions and support from local community leaders, district health officers, and/or authorities the study team members will engage in community town hall meetings and 'walkabouts' during which they will discuss study details, dates, times, and locations for enrollment and participation in the study for individuals who wish volunteer to participate. The team will be trained on conducting ethical human subjects research before the commencement of data collection and enrollment of participants. This will include the importance of avoiding coercion during enrollment, protecting the privacy of participants, how to effectively communicate the research objectives, what is being asked of participants, any risks or benefits to participation, with sufficient support to be able to address any questions that potential participants may have. Training will also include a module on special populations for advanced training on working with minors during human subjects research. During the enrollment process interested individuals will be given a consent form in the local language and research staff will read the consent form to potential participants, via an interpreter in local dialects if necessary. Together they will review the consent form and study staff will explain details of the study including: why they were selected, what the study procedures are and what will be expected from them, potential risks and benefits of their participation, that their participation is completely voluntary, and that they can withdraw their participation at any time. After reviewing the consent form individuals will be given as much time as needed to

Program Director/Principal Investigator: Daszak, Peter

ask questions. At that time if individuals wish to participate they will sign two copies of the consent form and it will be countersigned by the research staff, with a copy given to the participant for their records. Contact details for local research staff member, a local IRB contact, and project PI will be provided to all subjects in the consent form to answer any future questions or requests for withdrawal participants may have.

## 2.2 Protection against Risks

**Biological sample collection:** collection of whole blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. The potential complications associated with whole blood draw include pain and/or hematoma at the site of venipuncture. Nasal or oropharyngeal swab sample collection may cause minor irritation at the time of collection. To protect against and minimize potential complications, all biological sampling will be done by a locally trained and certified healthcare professional and/or clinic staff, and the sample collection sites will be monitored according to existing health facility protocols.

**Risk factor questionnaire survey:** potential risks associated with the administration of the questionnaire may be discomfort or concern providing responses related to wild animal contact or consumption if practices are taboo or prohibited by local laws. To minimize this risk, questionnaire data will be collected in a strictly confidential manner. The questionnaire will be conducted in private, ensuring that others cannot overhear participant responses and a barrier will be used or created so that no other individuals can view the participants. Depending on the location, this could be a private room, behind a building or fence, or behind a line of trees, obstructing view so that confidentiality may be maintained. The interview team will take care to pair interviewers and participants by sex to the best of their ability to increase the level of comfort of the participant and the team will ensure the privacy and confidentiality of response data. Children aged 12-17 will not be interviewed in the absence of a parent or guardian. Every effort will be made to ensure the privacy, dignity, and well-being of children and adults who participate in this study. In addition, identifying information will not be linked to responses, and data will be stored in secure, password protected files or locked secure storage facilities.

Participants may feel some stress or discomfort if informed that they have been exposed to a known or novel zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals. Additionally, we will provide participating hospitals, clinicians, and community leaders with information and background data on relevant zoonotic viruses.

## 3. Potential Benefits to Subjects and Others

There are no measurable benefits to the individual study participants enrolled in this study. There may be secondary benefits including receiving a physical exam/health check from a medical officer at the time of enrollment or advanced non-diagnostic testing assays that add clarity medical history for clinic participants. There are also benefits to the community and regional healthcare providers understand the risk of zoonotic infections among high-risk populations. At the conclusion of the study, we will deliver an educational workshop reporting study findings that will be open to both study and non-study participants, describing the health benefits of using PPE and hand-washing during animal handling activities throughout the day, as well as to share other prevention interventions that emerge from the research data.

## 4. The Importance of Knowledge to be Gained

There are valuable potential benefits to the general public from the knowledge to be gained from this study. One key benefit of this study to the community an understanding the risk of zoonotic spillover events among high-risk populations. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. As well as share information with communities on practices that could reduce exposure and related health risks such as the avoidance of particular animals or the need for PPE and extra care when handling wildlife may substantially reduce the risk zoonotic pathogen transmission.

Program Director/Principal Investigator: Daszak, Peter

Knowledge gained will also increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

**SINGLE INSTITUTIONAL REVIEW BOARD (sIRB)**

In compliance with the NIH Policy on the use of a single IRB of record for multi-site research EcoHealth Alliance will prepare, submit, and work the institutional review board that follows the ethical standards set forth by the HHS regulations at 45 CFR 46. Once this single IRB is approved in the US it will function as the IRB of record and will be relied on at all planned sites and any future sites.

We are currently anticipating working with HummingbirdIRB to serve as the IRB of record for all study sites. All of our local research partners, partner institutions, and study staff will rely on the IRB protocol that is approved at the IRB of record for all planned and future sites where data collection will occur. All data collection (biological and questionnaire) procedures and protocols and consent processes will be conducted using the same protocols outlined in the approved IRB of record and consistent for all location sites. The approved protocol at IRB of record will serve as the foundation for all locally submitted IRB packages in all partner countries, Thailand, Malaysia, and potential Singapore for inclusion of archived samples for testing.

EcoHealth Alliance will submit for IRB approval and maintain all records, and annually manage and submit for continuing review approvals at the IRB of record. Additionally, EcoHealth Alliance will manage the authorization and reliance agreements between partners and implement the communication plan. Each partner implementing human subjects research in Thailand, Malaysia, and Singapore will maintain regular communication with scheduled updates to the EcoHealth Alliance point of contact on enrollment and recruitment numbers, breakdown of enrollment of special populations and report any adverse events within 8 hours if not sooner.

Prior to commencing study enrollment or sample testing, the partner organization that is managing human subjects enrollment in Thailand, Malaysia, and Singapore will sign a reliance agreement that will acknowledge the role of the IRB of record and responsibilities of the participating institutional partners.

**Section 4 - Protocol Synopsis (Study 293221)**

4.1. Study Design

4.1.a. Detailed Description

4.1.b. Primary Purpose

4.1.c. Interventions

Type	Name	Description
------	------	-------------

4.1.d. Study Phase

Is this an NIH-defined Phase III Clinical Trial?  Yes  No

4.1.e. Intervention Model

4.1.f. Masking  Yes  No

Participant  Care Provider  Investigator  Outcomes Assessor

4.1.g. Allocation

4.2. Outcome Measures

Type	Name	Time Frame	Brief Description
------	------	------------	-------------------

4.3. Statistical Design and Power

4.4. Subject Participation Duration

4.5. Will the study use an FDA-regulated intervention?  Yes  No

4.5.a. If yes, describe the availability of Investigational Product (IP) and Investigational New Drug (IND)/ Investigational Device Exemption (IDE) status

4.6. Is this an applicable clinical trial under FDAAA? (SEE SECTION 6.6)

4.7. Dissemination Plan

---

Dear All,

Thank you for the call yesterday!

As discussed, I am sharing the Year 3 Notice of Award (NoA) of the EID-SEARCH project and the Year 3 Research Performance Progress Report (RPPR) report as submitted.

The NoA is issued annually, and this Y3 NoA has been attached to the Y3 contracts we signed. You can see these special requirements as highlighted on Pages 6-7.

In addition to the annual RPPR report (due April 1 every year), we are also required to submit a semi-annual report. The semi-annual report is less structured compared to the RPPR, focusing on research activities mainly without needing to fill in different sections.

In the attached RPPR report, Page 27 G.1 Section is where we report about the special reporting requirements as described in the NoA.

Please feel free to let Peter, Aleksei, and me know if you have any questions about these documents. And thank you very much for your understanding to help the project comply with these requirements.

Sincerely,  
Hongying

Dear All,

Reminder of our EID-SEARCH all partner meeting coming up tomorrow (Wednesday night US time, Thursday morning SE Asian time).

We're going to be doing these every month, with the key goals of 1) identifying important issues from EID-SEARCH HQ, e.g. requests from NIAID etc.; 2) to help each partner to find out what the other partners are doing; 3) brainstorm solutions to problems, and ways to increase efficiency of sampling, testing, characterization, surveys and paper publishing.

At this first meeting, I'll start off with a quick round up of overall EID-SEARCH updates, then we'll just go round the table and get an update from each partner.

Please make sure that at least one or two people from your team will be joining, and get ready to be put on the spot to give a quick update...

Look forward to talking and to having these regularly!

Cheers,

Peter

**Subject:** EID-SEARCH All-partner calls every month, starting April 12th (April 13th in

Asia)

**Importance:** High

Hello EID-SEARCH team!

Now that we're near the end of Year 3, and with work really cranking up now in our project, and multiple groups doing all forms of testing and analyses, I'm canceling the 'lab meetings' and setting up a monthly ALL-PARTNER meeting. The first will be on April 12<sup>th</sup> at 8:30pm Eastern time which is April 13<sup>th</sup> in the morning in Asia. These will be on the second Wednesday/Thursday of each month and you will receive an automatic calendar invite with Zoom information from Alison Andre.

It's very important for each partner to have staff on this call every month. The goal of the meeting is to keep everyone updated on news from NIAID and EcoHealth Alliance re. the project, get updates from each of the partners and brainstorm together to maximize our outputs (science, papers, talks, outreach) towards the grant renewal. So please take one hour per month to join the meeting, and feel free to send me and Hongying any discussion items you have.

I won't be sending out agendas, these meetings are intended to be updates from each of us so that all partners can hear what we're all up to.

Also, please note that this all-partner meeting is in addition to the monthly calls we have with each of the partners individually.

Look forward to seeing you on the 12<sup>th</sup>...

Cheers,

Peter

**Reporting Period: 06/01/2022 – 05/31/2023**

## **B.2 What was accomplished under these goals (by Aims)? \*required**

### **Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.**

In Year 3, we provided henipavirus, filovirus, and coronavirus reagents for testing 92 rodent, 100 non-human primate (NHP), and 700 bat serum samples in Thailand and coronavirus reagents for testing over 3,000 bat serum samples in Malaysia.

In Thailand, there was no seroprevalence of henipavirus, filovirus, or coronavirus antibodies in the rodents that were tested. One NHP (1/100, 1%) had detectable antibodies against the MERS-CoV spike glycoprotein, and three additional NHPs (3/100, 3%) had elevated (but not positive) levels of MERS-CoV reactive antibodies. Additionally, one NHP (1/100, 1%) had positive levels of antibodies reactive with the Mojiang (MojV) receptor binding protein (RBP) and six additional NHPs (6/100, 6%) had elevated (but not positive) levels of anti-MojV antibodies. There were no filovirus antibodies detected within this cohort of NHPs. The proposed bat samples have not been tested during this study period due to troubleshooting optimization of the binding and neutralization assays for the coronavirus proteins.

### **Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.**

The testing of samples from humans was prioritized in Thailand. We supplied reagents for the serological testing of 457 community samples from 288 individual participants, including 84 samples from a bat guano collection operation, and 100 samples from a human cohort without wildlife contact residing within Bangkok against protein antigens from henipavirus, filovirus, and wildlife and human-associated coronaviruses. We identified a 99.62% (264/265) seroprevalence for HCoV-OC43 in pre- and post-COVID-19 samples. Interestingly, there was minimal wildlife-associated coronavirus seroprevalence in samples collected prior to the COVID-19 pandemic. We observed in this SARS-CoV-2 seroprevalence after the start of the COVID-19 pandemic, likely induced by SARS-CoV-2 infections and COVID-19 vaccinations. Within the community surveillance cohort, we detected antibodies to both filoviruses (18.91%, 45/238) and henipaviruses (26.89%, 64/238), including a high seroprevalence to the MojV RBP (21.85%, 52/238). These results suggest there is infection by novel MojV-like viruses within this population.

### **Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts.**

#### **Network Collaboration**

Our group at USU has been setting up a material transfer agreement with WAC-EID via UTMB investigator, Dr. Robert Cross. Materials and protocols for henipavirus and filovirus serological testing will be transferred to Dr. Cross and assays will be established at partner labs within WAC-EID.

We also continue to develop a multiplex serology test for MPOX and are awaiting a transfer of convalescent sera from the CDC. In Year 4 we aim to further qualify and optimize a multiplex serology

<b>Divergent viral PCR sequences (RdRp) detected<sup>2</sup></b>	3 novel CoVs from 11 bats (in 1 species) 3 known PMVs from 4 rodents (in 2 species) 4 novel PMVs from 11 bats (in 1 species)	5 novel CoVs from 112 bats (in 3 species) 4 novel PMVs from 10 bats (in 2 species) 2 known PMVs from 2 bats (in 1 species)
<b># Specimens for MMIA testing (FLVs, CoV, Henipaviruses)</b>	100 (macaques), 1 CoV positive, 1 HNV positive 92 (rodents), 0 positive	1,225 (bats)
<b>Human</b>		
<b># Enrollment</b>	93 enrollment	
<b># Samples</b>		
<b># Sites</b>		
<b># PCR tests (for CoVs, PMVs, FLVs)</b>		
<b># PCR positive (for CoVs, PMVs, FLVs, respectively)</b>		
<b># MMIA tests (FLVs, CoV, Henipaviruses)</b>	357 samples in duplicate	
<b># Sero-positive (for FLVs, CoV, Henipaviruses, respectively)</b>	36 FLV positive, 77 HNV positive	

<sup>2</sup>Specimens include oral swabs, rectal swabs, urogenital swabs, and whole blood, types of specimens may vary among individual animals.

### B.4 What opportunities for training and professional development has the project provided? *\*required*

For each relevant activity, please include information about the topic, time (month/month), number of attendees (gender if available), organizations, if possible.

In July 2022, Mr. Spencer Sterling (USU) provided instructional training on the serologic techniques used to detect binding antibodies. Participants of the training included Dr. Krongkan Srimuang (KCMH-EIDcc) and Ms. Sasiprapa Ninwattana (KCMH-EIDcc). Included in the training were the topics of antigen design, assay techniques and testing strategies, and preliminary data analysis.

Christopher Broder, Ph.D., Site Investigator  
Eric Laing, Ph.D., Co-Investigator  
Spencer Sterling, MS, Scientific Project Coordinator  
Uniformed Services University of the Health Sciences  
The Henry M. Jackson Foundation

From October 20-21, 2022, Mr. Sterling participated in the “Technical Workshop – Bat Surveillance in the Mekong Region” hosted by King Chulalongkorn Memorial Hospital and the World Health Organization in Bangkok, Thailand. Mr. Sterling presented research work and participated as a rapporteur.

From November 7-10, 2022, Mr. Sterling attended the World One Health Congress in Singapore. He presented a poster and participated in project meetings.

On November 15, 2022, Dr. Laing was invited to present a seminar, “*Antibody durability, vaccine-related symptoms, and omicron neutralization after BNT162b2 mRNA COVID-19 vaccination in the Prospective Assessment of SARS-CoV-2 Seroconversion (PASS) Study*” to the Department of Medicine, Chulalongkorn University, Bangkok, Thailand.

On January 24, 2023, Mr. Sterling participated as a rapporteur in the Prince Mahidol Award Ceremony – School of Global Health Side Meeting on “Addressing Ecosystem Change and Pandemic Emergence through Strengthening One Health Implementation” in Bangkok, Thailand.

On March 23, 2023, Mr. Sterling presented “Next Generation Serology for Pathogen Discovery: Multiplex Immunoassays (MIA)” at the Thai Red Cross Emerging Infectious Diseases Clinical Center EID Conference 2023 in Bangkok, Thailand

#### **B.5 How have the results been disseminated to communities of interest ? \*required**

- Government and inter-government agency briefings
- Panels, workshop, webinars
- Conference and university lectures
- Public outreach

#### **B.6 What do you plan to do during the next reporting period to accomplish the goals (by Aims)? \*required**

**Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.**

**Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.**

**Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts.**

#### **C.1 Publications \*required**

**Subject:** [EXTERNAL] NIH EID-SEARCH Year 3 Progress Report\_by March 24, 2023

**ATTENTION: This email originated from outside of the organization.  
Do not open attachments or click on links unless you recognize the  
sender and know the content is safe.**

Dear EID-SEARCH Members,

The NIH Research Performance Progress Report (reporting period **06/01/2022-05/31/2023**) for EID-SEARCH (U01AI151797) is due on **April 1, 2023**.

I've attached a template with the different sections we would like to get updates from you as part of the report. All relevant work for any section is welcomed (the more detailed, the better, don't worry about the languages or word limits); I also labeled some sections as *\*required* where are the most important to concentrate.

And as part of the CREID Network, we also need to highlight the cross-Research Center activities, which are now KPIs to evaluate each Research Center's performance by the funder. So if you have anything relevant to report, please provide information on the Word document and fill in the *Excel file* I've attached.

The information required for this report is majorly focused on the research findings and plans and very minimal on administration/finance unless you have any significant changes on project key/senior personnel or budget.

We would greatly appreciate it if you could send us updates by **Friday, March 24, 2023**, so we can have a few days to consolidate everything to submit.

Please do not hesitate to let me know if you have any questions. Thank you very much!

Sincerely,  
Hongying

**Abstract:** Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles and little circulation but lower seroprevalence amongst adults. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

**Keywords:** bats; Nipah virus; filovirus; Rubulavirus; *Pteropus medius*; Bangladesh; serology; disease dynamics; generalized additive models

## Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics<sup>1-3</sup>. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses<sup>4,5</sup> including close relatives of SARS-CoV-2<sup>6</sup>, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses<sup>1,2,7</sup>.

Bat species can carry diverse viruses which circulate simultaneously within single populations<sup>8-11</sup>. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire virus have also been detected in this bat in Central Africa, suggesting that it may play a role in

- Number: 9 Author: Steve Luby Date: 9/2/2022 9:36:00 AM  
True, but since the new data presented here don't address this issue, I don't see this as central to the introduction, i.e. Error 3.12
-

45 the circulation of multiple filoviruses<sup>12,13</sup>. In addition to these filoviruses, a novel zoonotic and  
46 pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations<sup>14</sup>.  
47 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to  
48 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity<sup>15</sup>. Various  
49 surveillance efforts have found diverse viruses from within the same viral family in various bat  
50 species<sup>5,16,17</sup>, and other studies have used metagenomic approaches to look broadly at viral diversity  
51 within individual bat species<sup>9,11,18-21</sup>.

52 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of  
53 viruses and their relationships to specific hosts<sup>6,22</sup> and inform public health strategies<sup>23</sup>. However,  
54 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated  
55 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or  
56 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other  
57 species, including domestic animals and humans<sup>24</sup>. For these, more detailed demographic and  
58 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect  
59 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics<sup>25-27</sup>.  
60 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral  
61 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been  
62 observed to have annual shedding patterns<sup>28</sup>, whereas Hendra virus, which is closely related to Nipah  
63 virus and is carried by multiple pteropodid bat species in Australia, has asynchronous and non-periodic  
64 cycles which appear to be influenced by localized factors such as specific bat species abundance and  
65 climatic factors<sup>29</sup>. Bi-annual pulses of Marburg virus shedding were observed in Uganda, coinciding  
66 with synchronous birth pulses in *R. aegyptiacus*<sup>30</sup>. Serological data is often valuable in understanding  
67 disease dynamics and transmission<sup>31-33</sup>, especially in cases where direct detection and incidence rates  
68 of viruses are low<sup>34</sup>.

69 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, lethal<sup>5</sup> neurotropic  
70 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus<sup>35-37</sup>. In Bangladesh and India,  
71 *P. medius* is a reservoir of Nipah virus, which has spilled over to human populations repeatedly<sup>38</sup>.  
72 Viruses from eight other viral families have been detected in *P. medius* in Bangladesh<sup>9</sup>. The  
73 epidemiology of these other viruses is far less characterized, and little is known about their  
74 interactions or zoonotic potential.

75 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,  
76 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in  
77 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-  
78 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of  
79 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral  
80 circulation. We found that Nipah virus circulates primarily among adults without distinct seasonality,  
81 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by  
82 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also  
83 circulated in juveniles but exhibited distinct patterns antibody waning and limited maternal  
84 inheritance.

## 85 2. Results

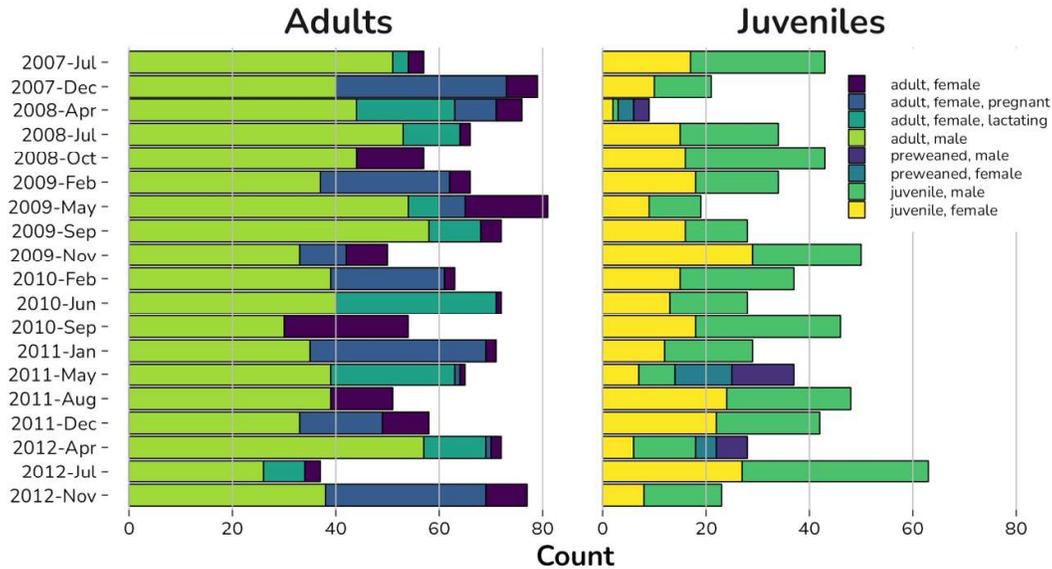

### 86 *Bat Dynamics and Demographics*<sup>7</sup>

87 We conducted a five<sup>8</sup>-year longitudinal study<sup>9</sup> sampling *P. medius* bats quarterly from a roost  
88 complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies sampling bats  
89 monthly from roosts in Chatoria<sup>10</sup> and Ramnagar of Faridpur district, Bangladesh. In the five-year  
90 study, we sampled and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39  
91 weaning juveniles (captured attached to adult females) over 19 sampling events (Figure 1). During  
92 the one-year studies, 919 bats were sampled: 435 in Chatoria<sup>11</sup> (251 adults, 144 free-flying juveniles  
93 and 40 weaning juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning  
94 juveniles (Figure S1). Nearly all juveniles (as determined by examination of maturation of sex organs)

it would be helpful to clarify how far apart these places are, as you have a considerable section exploring spatial comparisons.

95 were 14 months old or less and could be assigned to a birth cohort based on size. Pregnant and  
 96 juvenile bats were captured more frequently during the late spring and summer months. Mother-  
 97 pup pairs were all captured during April and May in the five-year study whilst in the one-year-  
 98 studies a small number were also captured in June and July. Pregnant females were captured between  
 99 November and April/May. Lactating females were found between April and July.  
 100

101 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured  
 102 in months from November to June, lactating females were captured in months from April to July.  
 103 Females with pre-weaning juveniles attached were found from April to May.

104 *Patterns of Immunity and Co-immunity*

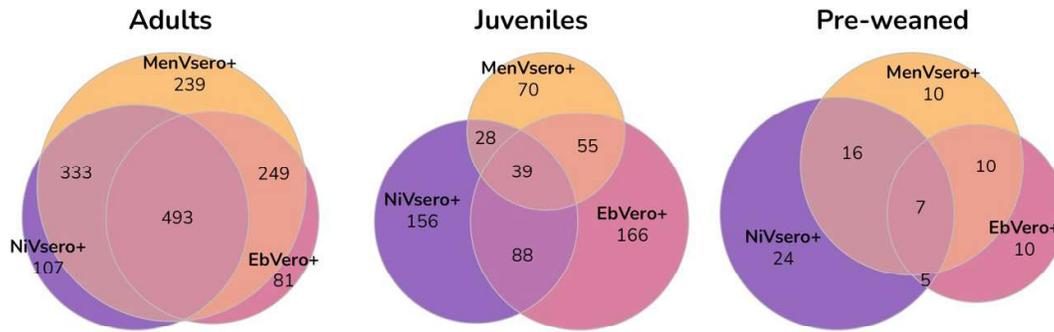

105 We found bats were seropositive for antibodies against the henipavirus (HenipVsero+), a  
 106 filovirus (EbVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the  
 107 rubulavirus were common; 1,314 of 1752 adult bats were MenVsero+. Antibodies against Nipah virus  
 108 or filovirus were less common – 1,031 were NiVsero+ and 921 were EbVsero+. Among the 921  
 109 juveniles, 192 were MenVsero+, 311 were NiVsero+ and 348 were EbVsero+. Of the 122 pre-weaned  
 110 juveniles, 43 were MenVsero+, 52 were NiVsero+, and 32 were EbVsero+.

111 Co-exposure to multiple viruses was common (Figure 2). Over half (1,173) of the 1752 adults had  
 112 antibodies against more than one of the three viruses, and 493 had antibodies against all three.  
 113 Among the 921 juveniles, 210 had antibodies against more than one, and 39 had antibodies all three.  
 114 38 of 122 pre-weaned juveniles had more than one of the three antibodies, with seven having all three.

115 We found correlations between serostatus between all three pairs of viruses in a model  
 116 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other  
 117 more than would be expected than if they were distributed independently among bats. Nipah virus  
 118 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).  
 119 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of  
 120 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had a covariance of 0.23 (0.17-0.29).

4

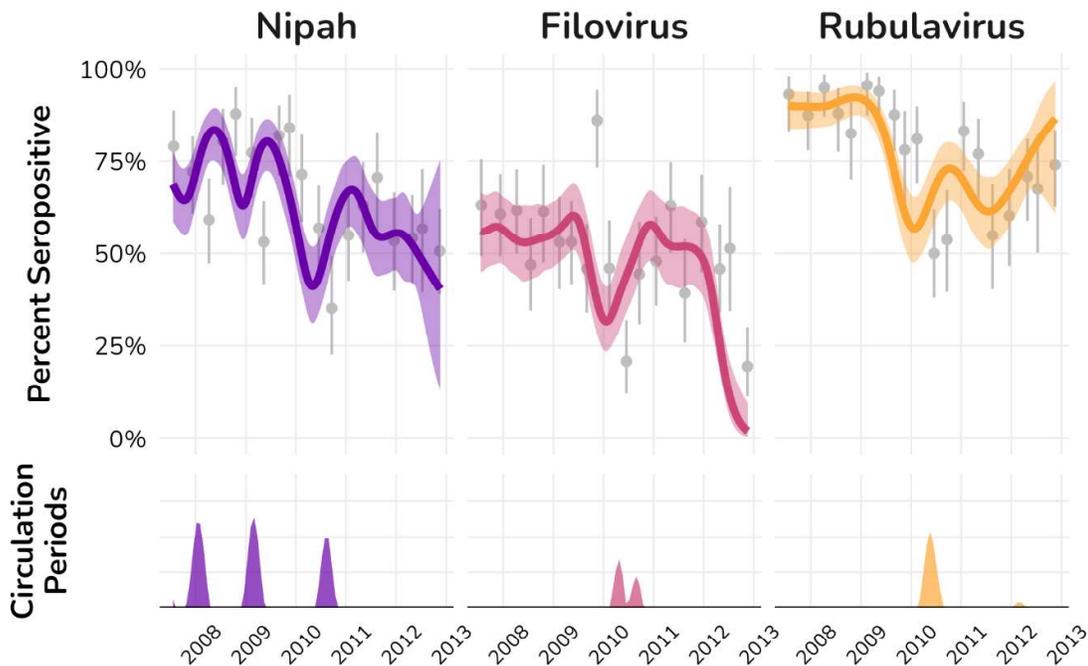

- 
- Number: 1 Author: Wang Linfa Date: 8/21/2022 10:48:00 AM  
I think it is better to treat the three group of viruses equally as you have done for the title. It makes no difference whether we use NiV or Henipavirus in the context of the current study. Luminex-based assays targeting binding antibodies will in theory detect cross-RX antibodies in all three cases. See also comments in Methods
- 
- Number: 2 Author: Steve Luby Date: 9/2/2022 10:01:00 AM  
Include percentages for all of these comparisons.
- 
- Number: 3 Author: Emily Gurley Date: 9/9/2022 7:36:00 PM  
Agree with Linfa - unclear how many viruses, better to treat as groups
- 
- Number: 4 Author: Steve Luby Date: 9/2/2022 10:03:00 AM  
Again, including percentages for all of these comparisons would make this much easier to understand.
- 
- Number: 5 Author: Emily Gurley Date: 9/9/2022 7:37:00 PM  
Some kind of general cross-reactivity, non-specificity of the assay?
- 
- Number: 6 Author: Steve Luby Date: 9/2/2022 10:03:00 AM  
I did not see this described in the methods section.

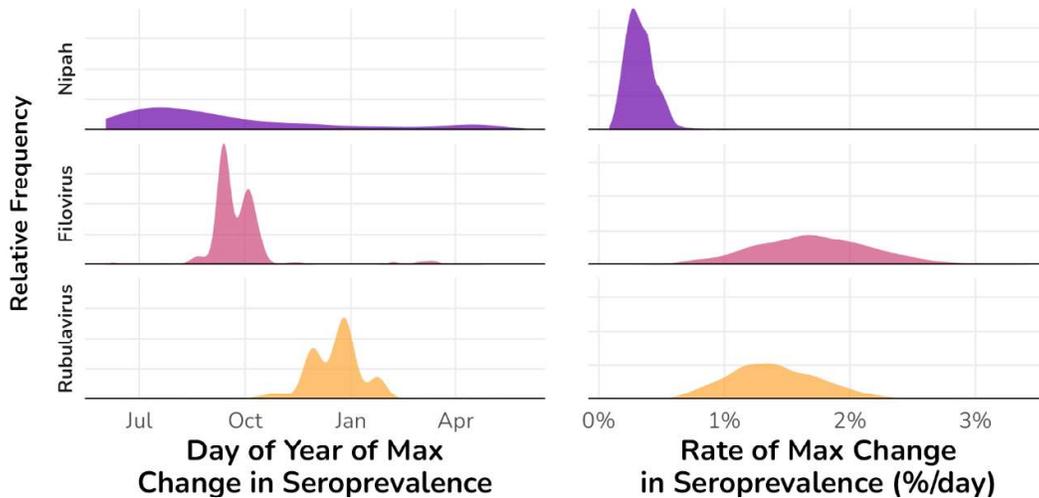

121 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn  
 122 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,  
 123 filovirus, and Rubulavirus. Numbers under labels are counts of bats with only those viruses, numbers  
 124 in overlapping areas represent number of bats detected with multiple viruses.

125 *Serodynamics*

126 Dynamics of population seroprevalence were different across the viral types. In adults,  
 127 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)  
 128 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-  
 129 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very  
 130 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in [Epstein, et al. 34](#)).  
 131

132  
 133 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population  
 134 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey  
 135 points and bars represent measured population seroprevalence from individual sampling events on  
 136 and 95% exact binomial confidence intervals. Thick lines and shaded areas represent the inter-annual  
 137 (non-seasonal) spline component of a generalized additive mixed model (GAMM) of serodynamics  
 138 and 95% confidence intervals for the mean pattern over time. Bottom: Circulation periods, when  
 139 modeled slopes of the [GAMM splines](#) are positive for >95% of 1000 draws from the model posterior.

Timing and strength of seasonality of viral circulation in adults.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left), and the rate of increase (right), for adult bats, drawn from GAMM models of seasonality. Densities are of these quantities derived from 1000 samples of model posteriors.

145

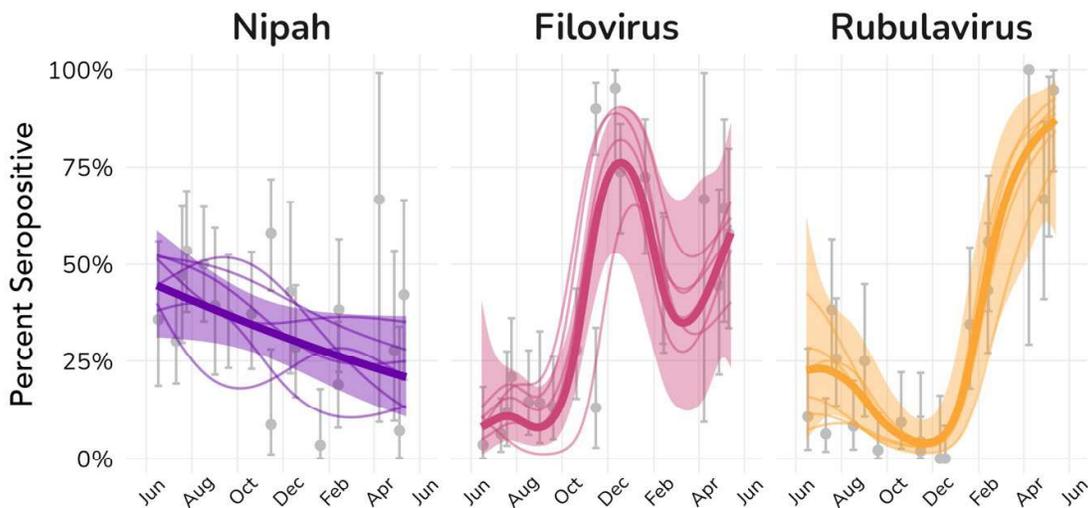

146

147

148

149

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

150

151

152

What is the y axis for these curves?

---

 Number: 2 Author: Emily Gurley Date: 9/9/2022 8:45:00 PM  
Also from the last paper, right? Or are these new data?

---

159

160 **Fig 6. Timing and strength of seasonality of viral circulation in juveniles over the five-year**  
 161 **study.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left),  
 162 and the rate of increase (right), for juvenile bats. Densities are of these quantities derived from 1000  
 163 samples of model posteriors.

164 Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against  
 165 filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus  
 166 seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had  
 167 periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah  
 168 virus) (Fig. 3). filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

169 Among juveniles within the average year, filovirus seroprevalence started very low in June at  
 170 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age  
 171 before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it  
 172 consistently occurred in December or January. The average date with the greatest rate of  
 173 seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day  
 174 (4.5%/day-9.9%/day).

175 Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus  
 176 seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74%  
 177 (62%-84%), though there were some temporary periods of decline. There were distinct periods of  
 178 increasing circulation in early 2010 and <sup>2</sup>early 2012. Only for the rubulavirus did adult seroprevalence  
 179 exhibit patterns of seasonality. Periods of increasing seroprevalence in adults exhibited strong  
 180 seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean peak date  
 181 occurring on Dec 15 (Oct 15-Feb 1)

182 In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in  
 183 the youngest bats in June, though in individual years this could range from 7%-43%. In all years  
 184 juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec  
 185 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%) The  
 186 peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and occurred  
 187 Jan 9 (Dec 21-Mar 16).

188 *Spatial Comparisons*

189 Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria  
 190 and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2).  
 191 In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of  
 192 April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

## Page: 6

---

Number: 3 Author: Steve Luby Date: 9/2/2022 10:24:00 AM  
Consider including a figure in the appendix that illustrates this.

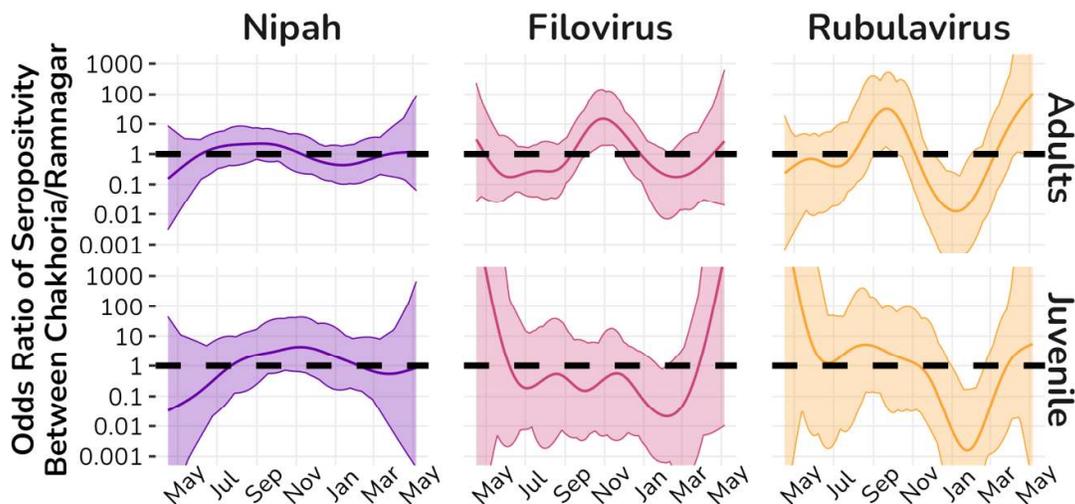

---

193 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-51%) in April 2010, rising to  
 194 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over  
 195 the same period. The trend in juveniles was as described for the five-year study.

196 For the filovirus, the seroprevalence in the one-year studies was higher than the reported  
 197 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-  
 198 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of  
 199 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the  
 200 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the  
 201 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,  
 202 there were two periods of increasing seroprevalence in adults over the course of the year. The first of  
 203 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August  
 204 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the  
 205 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)  
 206 between early March 2011 to late April 2011.

207 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from  
 208 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in  
 209 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December 2010/January 2011  
 210 in Chakhoria. These decreases were followed by rapid increases back to high seroprevalence, coincident  
 211 with increasing levels in juveniles. The pattern in juveniles was as described in the five-year study,  
 212 with seroprevalence estimates in yearlings in April 2011 of 80% (28%-99%) in both locations.

214 Comparison of the seroprevalence trends within each age group and virus between the two one-  
 215 year study locations did not support spatial differences in the timing of changes in seroprevalence  
 216 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between  
 217 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at  
 218 the end of 2010.

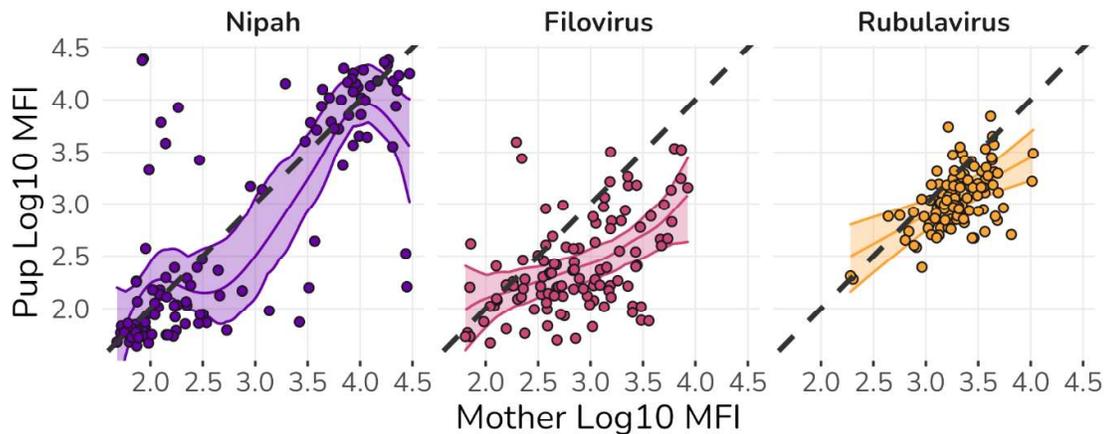

219  
 220 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**  
 221 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference  
 222 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.  
 223 Where the confidence interval excludes zero, there is evidence for a significant difference in the  
 224 serodynamics between the Ramnagar and Chakhoria populations over that period.

225 *Maternal Inheritance of antibodies*

226 We examined the relationship between mother and pup antibody titers, as measured by our  
 227 Luminex assays (see Methods). This relationship varied between viruses (Figure 7). For Nipah virus,

228 the relationship was nonlinear due to clustering at high and low values, but largely followed a 1:1  
229 relationship between mother and pup antibody titers. For the rubulavirus the relationship was near-  
230 linear and near 1:1. For the filovirus, though, the relationship between MFI values measured in  
231 mothers and their pups fell well below the 1:1 line, indicating pups having low inheritance of  
232 antibodies against the filovirus relative to the other two viruses.

233

234 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for  
235 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the  
236 predicted mean relationship between the two and their associated 95% confidence intervals.

### 237 3. Discussion

238 We found serological evidence for regular circulation of multiple viruses in *P. medius*  
239 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to  
240 humans in the region, as well as a filovirus and a rubulavirus. It was common for bats to have  
241 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity  
242 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance  
243 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types  
244 being positively correlated within bats.

245 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The  
246 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations  
247 inherit maternal antibodies against the rubulavirus, which wane over the first six months of their life,  
248 after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in  
249 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the  
250 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence  
251 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating  
252 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of  
253 the rubulavirus to be strongest in the late winter and early spring months in these populations.  
254 Mortlock et al.<sup>39</sup> found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via  
255 PCR detection in pooled urine samples), including a peak during a period of presumed antibody  
256 waning, though only within a one-year study.

257 An outstanding question is how the rubulavirus is maintained in the population despite high  
258 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent  
259 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*<sup>40</sup>, Hendra virus in  
260 *P. alecto* and *P. poliocephalus*<sup>41</sup>, and Lagos bat lyssavirus and African henipavirus in *Eidolon helvum*<sup>42</sup>.  
261 Another possibility is re-importation. In concurrent work with this study, we found that bat home

Something about individual bat risk or strange bat immune responses?

---

262 ranges overlapped with nearby colonies so as to form a meta-population<sup>34</sup>, allowing occasional  
263 infection from outside bats, as has been shown to maintain Hendra virus in *Pteropus* populations<sup>43,44</sup>.

264 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle  
265 virus, which has been found in multiple *Pteropus* species in Australia<sup>45,46</sup>. At least 11 distinct  
266 Paramyxoviruses have been found in *P. medius* in Bangladesh alone: Nipah virus and ten  
267 uncharacterized species, including six Rubulaviruses closely related to Menangle virus and the  
268 Tioman virus<sup>9,47</sup>. It is possible that the serological patterns observed represent antibodies against a  
269 complex of multiple Rubulaviruses, though the regular interannual patterns in seroprevalence would  
270 indicate that they are operating similarly.

271 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with  
272 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some  
273 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup  
274 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults  
275 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,  
276 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah  
277 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by  
278 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years<sup>28</sup>.  
279 Human Nipah virus outbreaks in Bangladesh, on the other hand, exhibit seasonality associated with  
280 the palm-sap consumption, the most frequently implicated spillover pathway<sup>48</sup>.

281 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-Zaire  
282 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have  
283 been found in *R. leschenaultii* in the country<sup>49</sup>. This could be one of several known filoviruses or an  
284 unknown species. There have been several recent findings of new Ebola-like filoviruses in bats  
285 extending across Africa and Asia. These include Bombali virus in Sierra Leone<sup>50</sup>, and Mënglà virus  
286 in *Rousettus* bats in China<sup>51</sup>. Ebola-Reston virus was found in multiple bat species (*M. australis*, *C.*  
287 *brachyotis* and *Ch. plicata*) in the Philippines<sup>52</sup>. Marburg virus and Ebola-Zaire virus may have been  
288 detected in Sierra Leone and Liberia (unpublished,<sup>53,54</sup>). Serological evidence of filoviruses in bats has  
289 been found in multiple bat species in Central<sup>12,55</sup> and Western<sup>56</sup> African countries, Singapore<sup>57</sup>,  
290 China<sup>58</sup>, as well as Trinidad<sup>59</sup>. Our finding here adds to the evidence of broad host and geographic  
291 host ranges for filoviruses.

292 Several components of the serological patterns of filovirus antibodies are of interest. Young  
293 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months  
294 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite  
295 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult  
296 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period  
297 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase  
298 among juveniles. One possible hypothesis explaining this pattern is that the filovirus may exhibit low  
299 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.  
300 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain  
301 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was  
302 found to be rapid, but bats retained protective immunity even with very low antibody titers<sup>60,61</sup>. If a  
303 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite  
304 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles  
305 following the peak is consistent with this explanation.

306 However, if adults remain immune to the filovirus despite low antibody titers, this immunity  
307 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and  
308 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the  
309 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly  
310 differential maternally derived immunity. If pups derive weaker immunity from dams than for other  
311 viruses, this may provide another mechanism for maintenance of the virus. It possible that patterns  
312 in filovirus antibody detection are an artifact of our test, specific to Ebola-Zaire virus, and that  
313 temporal trends are in part reflective of differential cross-reaction with viruses in this bat population.

Number: 1 Author: Hume Field Date: 8/24/2022 9:59:00 AM

And recently in Australia.

Barr et al. J Gen Virol. 2022 Aug;103(8).

doi: 10.1099/jgv.0.001785.

314 However, while this may modify estimates of overall seroprevalence, the differential pup/dam MFI  
315 relationship, and consistent rise in seroprevalence among young juveniles, would require the test to  
316 exhibit differential sensitivity by age.

317 Serodynamics in our two one-year studies were broadly similar to those found in the five-year  
318 study. We found weak evidence for differences in serodynamics between sites for the filovirus in  
319 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the  
320 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study<sup>34</sup>,  
321 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their  
322 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are <sup>1</sup>approximately 225  
323 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible  
324 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or  
325 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple  
326 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

327 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-  
328 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from  
329 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or  
330 transmission, via competition for host nutritional or cellular resources, or via immune-mediation  
331 involving cross-immunity or antibody-dependent enhancement, and these interactions structure  
332 viral communities<sup>26</sup>. These interactions can have complex, even opposite effects when scaled to the  
333 population<sup>27</sup>. Here, we found positive correlations between serostatus against different viruses.  
334 External factors may also affect these relationships. For instance, all three viruses appear to have  
335 circulated in adults in mid-2010. It is possible that common factors like population density and/or  
336 nutrition availability<sup>62</sup> affected transmission of multiple viruses.

337 While rich observational serological data reveal these patterns, greater study is required to  
338 characterize these viruses and their effects on the host population and potential for spillover, as well  
339 as the degree and mechanisms of interactions. Our inferred periods of viral circulation point to  
340 optimal sub-populations and times to sample this population to detect viral shedding and isolate  
341 these viruses, and potentially capture co-infected hosts.

342 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term  
343 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and  
344 shedding, but establishing patterns or variation in seasonality requires extended, multi-year  
345 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was  
346 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The  
347 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.  
348 Similarly, we were able to understand these patterns far better by separating juvenile and adult  
349 patterns, which we would be unable to distinguish in pooled samples. <sup>2</sup>

350 While such extended individual-capture longitudinal studies are resource-intensive,  
351 understanding the joint circulation of multiple viruses can be accomplished via multiplex  
352 immunoassays such as those used here. The continuous measures from these assays also have the  
353 potential to identify key patterns such as the differential inheritance of filovirus antibodies we  
354 identified here. Interpretation of these values is challenging and the relationship between immune  
355 status, antibody titer, and measured fluorescence is complex<sup>32</sup>, but they have much potential to shed  
356 light on mechanistic drivers of disease circulation.

## 357 **Methods**

### 358 *Field collection*

359 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-  
360 year studies in different locations, sampling monthly. All capture and sampling methods were  
361 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol  
362 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as  
363 previously described in Epstein, et al. <sup>34</sup> The area of the roost complex consists of patchy forest

---

Number: 1 Author: Steve Luby Date: 9/2/2022 10:41:00 AM

As noted above, this important detail needs to be mentioned sooner.

---

Number: 2 Author: Steve Luby Date: 9/2/2022 10:44:00 AM

In addition to uncertainty over which specific viruses these assays are detecting antibodies against, which is addressed earlier in the discussion, other limitations to scientific inference that seem to me important to discuss include:  
there were only two sites to assess spatial heterogeneity. A more robust assessment would require more sites.  
Although five years is longer than usually studied, it is too short of a time for measuring temporal dynamics that might play out over longer time periods.

---

Number: 3 Author: Emily Gurley Date: 9/9/2022 9:07:00 PM

Agree

---

Number: 4 Author: Steve Luby Date: 9/2/2022 10:43:00 AM

Seems a weak concluding statement. I recommend a stronger statement of implications and way forward. To my mind, identification of the specific viruses that are driving these antibody responses would be the highest priority.

---

Number: 5 Author: Steve Luby Date: 9/2/2022 9:47:00 AM

I recommend listing the local IRB first.

364 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July  
365 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst  
366 roosts within the 80km<sup>2</sup> roost complex over the period of the study. Sampling occurred at the largest  
367 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex  
368 across consecutive sampling nights if required to capture a sufficient number of individuals.

369 Approximately 100 bats were captured at each sampling event, over 7-10 days. We captured bats<sup>[1]</sup>  
370 with a 10x15m mist net between 11pm and 5am each night as bats returned from foraging until the  
371 count of 100 was reached.

372 In the one-year longitudinal studies, sampling was undertaken in two roost complexes in  
373 Ramnagar and Chakhoria, Bangladesh between April 2010 and May 2011. Monthly sampling of  
374 approximately 40 bats in each location was performed to obtain data at a finer temporal scale. Details  
375 of collection are otherwise as described for the five-year study.

376 For each study, we recorded each bat's age class, reproductive status, weight, size, and body  
377 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with  
378 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box  
379 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and  
380 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton  
381 Cryogenics, NJ, USA).

382 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal  
383 swabs and pooled urine samples from under colonies. Further details can be found in [Epstein, et al.](#)  
384 <sup>34</sup>

### 385 *Serological Assays*

386 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and  
387 gamma irradiated upon receipt. We used a bead-based microsphere assay that specifically detects  
388 antibodies to the soluble attachment glycoproteins<sup>57,63,64</sup> for a panel of viruses. Beads coated with each  
389 protein were mixed with sera at a dilution of 1:100. Biotinylated Protein A/G and Streptavidin-PE  
390 were then used to detect bound antibody. Beads were interrogated by lasers in a BioRad BioPlex  
391 machine and the results recorded as the Median Fluorescent Intensity (MFI) of 100 beads. We report  
392 here results for Nipah, Ebola-Zaire, and Menangle, the only three for which we established regular  
393 positive results.

394 While the Nipah virus has been detected in this population<sup>65</sup> and the specificity of the Nipah test  
395 is well-established<sup>66</sup>, the Ebola-Zaire and Menangle virus tests are cross-reactive with other Ebola  
396 and rubulavirus species<sup>67,68</sup>. Thus we refer to these as tests for filovirus and Rubulavirus.

### 397 *Data Analysis*

398 We determined individual bat serostatus using Bayesian mixture models<sup>69</sup> fit on pooled data  
399 across all three longitudinal studies, calculating a cutoff of log-MFI as the point of equal probability<sup>[4]</sup>  
400 between the smallest and second-smallest cluster of equal distributions for each assay.

401 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian  
402 multivariate probit model<sup>70,71</sup> which allows estimation of the joint outcomes (serostatus against each  
403 virus) and the correlation between the outcomes. We included age and sex variables to account for  
404 these effects on serostatus.

405 To examine time-varying changes in population seroprevalence, we fit binomial generalized  
406 additive mixed models (GAMMs)<sup>72,73</sup> to the time-series of serostatus measurements. For the five-year  
407 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit  
408 a model for seroprevalence dynamics over the course of the whole study. This treats the adult  
409 population as a single unit, though individuals within the population may turn over via migration,  
410 death and recruitment. We included both long-term and annual cyclic components for the multi-year  
411 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate  
412 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile  
413 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles

---

Number: 1 Author: Steve Luby Date: 9/2/2022 9:49:00 AM  
Error 5.4

---

Number: 2 Author: Emily Gurley Date: 9/9/2022 8:54:00 PM  
If data from this aren't included here, does it need to be in the methods?

---

Number: 3 Author: Wang Linfa Date: 8/21/2022 10:50:00 AM  
I am not 100% sure about this. All serological tests (the NiV test included) will detect cross-RX antibodies from related viruses. For NiV, you can argue that longitudinal surveillance has NOT detected any related viruses in the study populations, but we can't say that the Ab test is specific to NiV.

---

Number: 4 Author: Emily Gurley Date: 9/9/2022 8:56:00 PM  
How has it been done in other similar studies? Using the beads from USU now, we see more than one cluster of MFI values below what we're considering positive.

---

Number: 5 Author: Steve Luby Date: 9/2/2022 9:53:00 AM  
Why should we assume that the second smallest cluster is associated with the genuine presence or absence of antibody?

---

414 over their first year. To estimate periods of peak viral circulation within the population, we calculated  
415 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior  
416 distributions and classified periods with >95% of samples with positive derivatives - that is,  
417 increasing population seroprevalence - as periods of viral circulation. We also calculated strength  
418 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date  
419 at which this maximum occurred, again sampling these values from the model posterior, and  
420 calculating mean and high-density posterior interval (HDPI) values.

421 For the one-year studies, we fit models primarily to detect differences in time-varying changes  
422 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus  
423 measurements with separate models for each immunoassay. We included a separate, fixed-term  
424 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in  
425 serodynamics for each virus in each age group were compared between locations to test for spatial  
426 differences<sup>74</sup>. Juveniles identified as being from the previous year's cohort were excluded from the  
427 analysis.

428 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI  
429 between adult lactating females and their attached pups for each viral assay. We limited these to data  
430 from the five-year longitudinal study.

**Abstract:** Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles and little circulation but lower seroprevalence amongst adults. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

**Keywords:** bats; Nipah virus; filovirus; Rubulavirus; *Pteropus medius*; Bangladesh; serology; disease dynamics; generalized additive models

## Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics<sup>1-3</sup>. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses<sup>4,5</sup> including close relatives of SARS-CoV-2<sup>6</sup>, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses<sup>1,2,7</sup>.

Bat species can carry diverse viruses which circulate simultaneously within single populations<sup>8-11</sup>. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire virus have also been detected in this bat in Central Africa, suggesting that it may play a role in the circulation of multiple filoviruses<sup>12,13</sup>. In addition to these filoviruses, a novel zoonotic and pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations<sup>14</sup>.

Evidence that this is just one virus?			
	Number: 8	Author: Steve Luby	Date: 9/2/2022 9:33:00 AM
This seems an odd sentence to close with. The last sentence is usually a conclusion, but I can't see how the data presented in the abstract supports this conclusion.			
	Number: 9	Author: Steve Luby	Date: 9/2/2022 9:36:00 AM
True, but since the new data presented here don't address this issue, I don't see this as central to the introduction, i.e. Error 3.12			

46 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to  
47 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity<sup>15</sup>. Various  
48 surveillance efforts have found diverse viruses from with the same viral family in various bat  
49 species<sup>5,16,17</sup>, and other studies have used metagenomic approaches to look broadly at viral diversity  
50 within individual bat species<sup>9,11,18-21</sup>.

51 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of  
52 viruses and their relationships to specific hosts<sup>5,22</sup> and inform public health strategies<sup>23</sup>. However,  
53 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated  
54 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or  
55 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other  
56 species, including domestic animals and humans<sup>24</sup>. For these, more detailed demographic and  
57 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect  
58 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics<sup>25-27</sup>.  
59 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral  
60 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been  
61 observed to have annual shedding patterns<sup>28</sup>, whereas Hendra virus, which is closely related to Nipah  
62 virus and is carried by multiple pteropodid bat species in Australia, has asynchronous and non-periodic  
63 cycles which appear to be influenced by localized factors such as specific bat species abundance and  
64 climatic factors<sup>29</sup>. Bi-annual pulses of Marburg virus shedding were observed in Uganda, coinciding  
65 with synchronous birth pulses in *R. aegyptiacus*<sup>30</sup>. Serological data is often valuable in understanding  
66 disease dynamics and transmission<sup>31-33</sup>, especially in cases where direct detection and incidence rates  
67 of viruses are low<sup>34</sup>.

68 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, lethal<sup>5</sup> neurotropic  
69 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus<sup>35-37</sup>. In Bangladesh and India,  
70 *P. medius* is a reservoir of Nipah virus, which has spilled over to human populations repeatedly<sup>38</sup>.  
71 Viruses from eight other viral families have been detected in *P. medius* in Bangladesh<sup>9</sup>. The  
72 epidemiology of these other viruses is far less characterized, and little is known about their  
73 interactions or zoonotic potential.

74 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,  
75 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in  
76 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-  
77 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of  
78 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral  
79 circulation. We find that Nipah virus circulates primarily among adults without distinct seasonality,  
80 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by  
81 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also  
82 circulated in juveniles but exhibited distinct patterns antibody waning and limited maternal  
83 inheritance.

## 84 2. Results

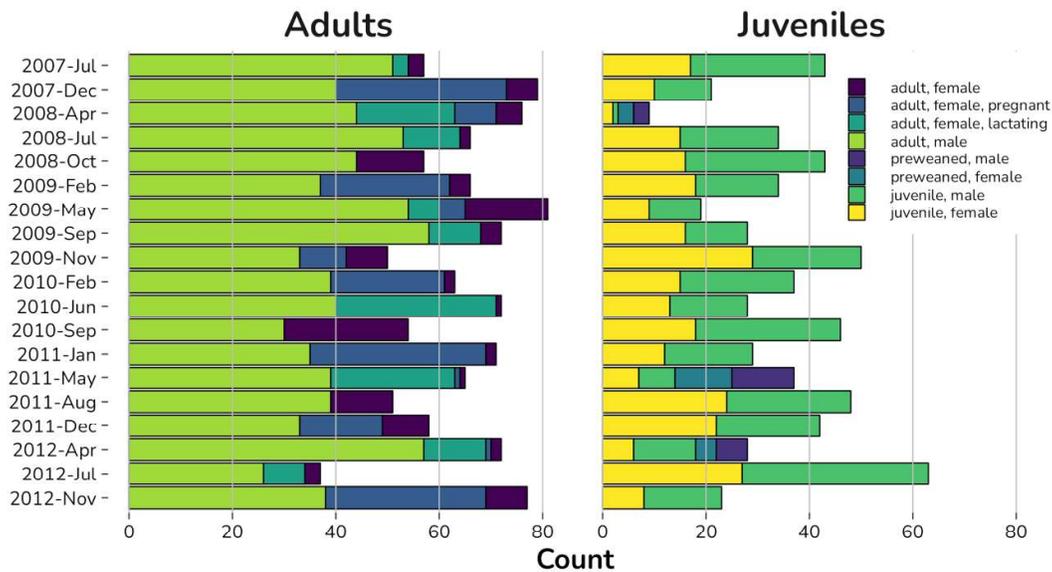

### 85 *Bat Dynamics and Demographics*<sup>7</sup>

86 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly from a roost  
87 complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies sampling bats  
88 monthly from roosts in Chakhoria and Ramnagar, Bangladesh. In the five-year study, we sampled  
89 and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39 weaning juveniles  
90 (captured attached to adult females) over 19 sampling events (Figure 1). During the one-year studies,  
91 919 bats were sampled: 435 in Chakhoria (251 adults, 144 free-flying juveniles and 40 weaning  
92 juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning juveniles (Figure  
93 S1). Nearly all juveniles (as determined by examination of maturation of sex organs) were 14 months  
94 old or less and could be assigned to a birth cohort based on size. Pregnant and juvenile bats were  
95 captured more frequently during the late spring and summer months. Mother-pup pairs were all

96 captured during April and May in the five-year study whilst in the one-year-studies a small number  
 97 were also captured in June and July. Pregnant females were captured between November and  
 98 April/May. Lactating females were found between April and July.  
 99

100 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured  
 101 in months from November to June, lactating females were captured in months from April to July.  
 102 Females with pre-weaning juveniles attached were found from April to May.

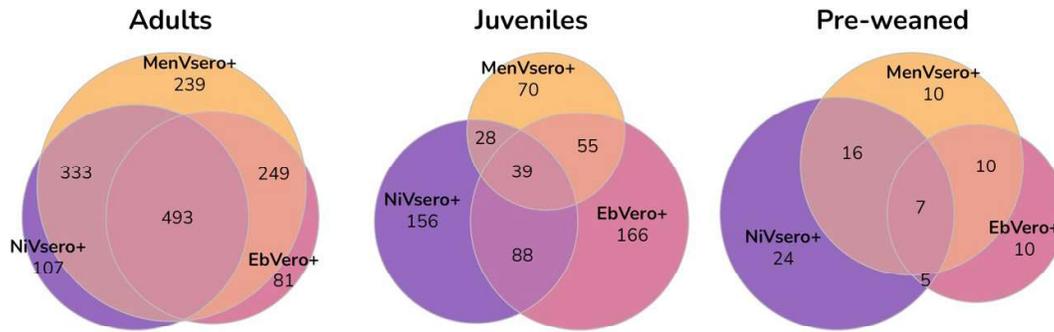

103 *Patterns of Immunity and Co-immunity*

104 We found bats were seropositive for antibodies against the henipavirus (HenipVsero+), a  
 105 filovirus (EbVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the  
 106 rubulavirus were common; 1,314 of 1752 adult bats were MenVsero+. Antibodies against Nipah virus  
 107 or filovirus were less common – 1,031 were NiVsero+ and 921 were EbVsero+. Among the 921  
 108 juveniles, 192 were MenVsero+, 311 were NiVsero+ and 348 were EbVsero+. Of the 122 pre-weaned  
 109 juveniles, 43 were MenVsero+, 52 were NiVsero+, and 32 were EbVsero+.

110 Co-exposure to multiple viruses was common (Figure 2). Over half (1,173) of the 1752 adults had  
 111 antibodies against more than one of the three viruses, and 493 had antibodies against all three.  
 112 Among the 921 juveniles, 210 had antibodies against more than one, and 39 had antibodies all three.  
 113 38 of 122 pre-weaned juveniles had more than one of the three antibodies, with seven having all three.

114 We found correlations between serostatus between all three pairs of viruses in a model  
 115 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other  
 116 more than would be expected than if they were distributed independently among bats. Nipah virus  
 117 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).  
 118 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of  
 119 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had a covariance of 0.23 (0.17-0.29).

-  Number: 1 Author: Wang Linfa Date: 8/21/2022 10:48:00 AM  
I think it is better to treat the three group of viruses equally as you have done for the title. It makes no difference whether we use NIV or Henipavirus in the context of the current study. Luminex-based assays targeting binding antibodies will in theory detect cross-RX antibodies in all three cases. See also comments in Methods

I did not see this described in the methods section.

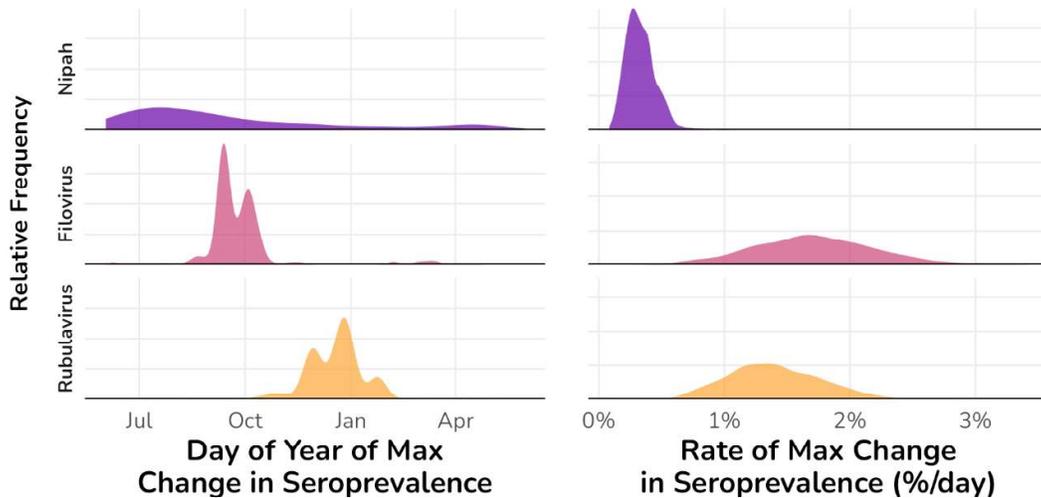

120 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn  
 121 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,  
 122 filovirus, and Rubulavirus. Numbers under labels are counts of bats with only those viruses, numbers  
 123 in overlapping areas represent number of bats detected with multiple viruses.

124 *Serodynamics*

125 Dynamics of population seroprevalence were different across the viral types. In adults,  
 126 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)  
 127 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-  
 128 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very  
 129 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in [Epstein, et al. 34](#)).  
 130

131  
 132 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population  
 133 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey  
 134 points and bars represent measured population seroprevalence from individual sampling events on  
 135 and 95% exact binomial confidence intervals. Thick lines and shaded areas represent the inter-annual  
 136 (non-seasonal) spline component of a generalized additive mixed model (GAMM) of serodynamics  
 137 and 95% confidence intervals for the mean pattern over time. Bottom: Circulation periods, when  
 138 modeled slopes of the [GAMM splines](#) are positive for >95% of 1000 draws from the model posterior.

148

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

Also from the last paper, right? Or are these new data?

158

159 **Figure 6. Timing and strength of seasonality of viral circulation in juveniles over the five-year**  
 160 **study.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left),  
 161 and the rate of increase (right), for juvenile bats. Densities are of these quantities derived from 1000  
 162 samples of model posteriors.

163 Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against  
 164 filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus  
 165 seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had  
 166 periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah  
 167 virus) (Fig. 3). filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

168 Among juveniles within the average year, filovirus seroprevalence started very low in June at  
 169 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age  
 170 before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it  
 171 consistently occurred in December or January. The average date with the greatest rate of  
 172 seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day  
 173 (4.5%/day-9.9%/day).

174 Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus  
 175 seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74%  
 176 (62%-84%), though there were some temporary periods of decline. There were distinct periods of  
 177 increasing circulation in early 2010 and early 2012. Only for the rubulavirus did adult seroprevalence  
 178 exhibit patterns of seasonality. Periods of increasing seroprevalence in adults exhibited strong  
 179 seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean peak date  
 180 occurring on Dec 15 (Oct 15-Feb 1)

181 In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in  
 182 the youngest bats in June, though in individual years this could range from 7%-43%. In all years  
 183 juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec  
 184 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%) The  
 185 peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and occurred  
 186 Jan 9 (Dec 21-Mar 16).

187 *Spatial Comparisons*

188 Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria  
 189 and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2).  
 190 In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of  
 191 April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

Consider including a figure in the appendix that illustrates this.			

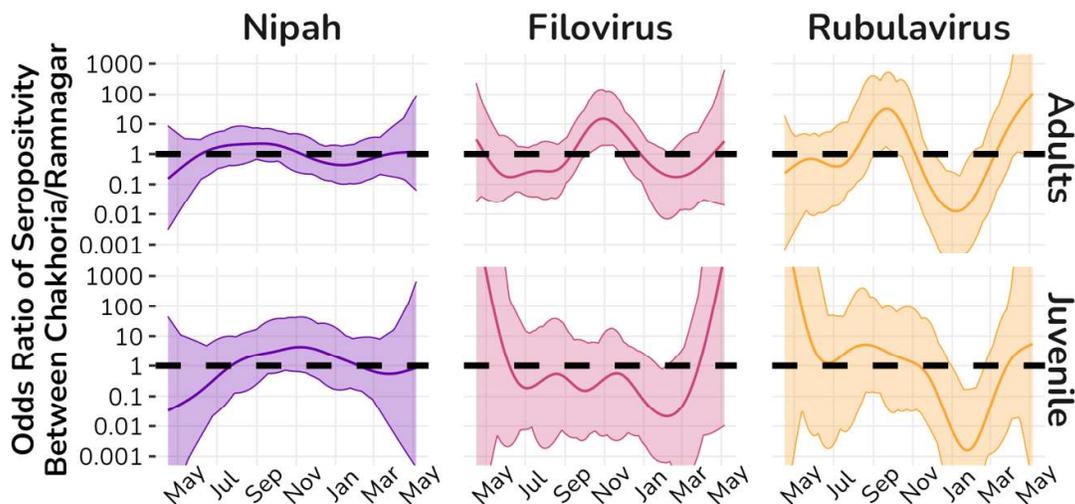

---

192 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-61%) in April 2010, rising to  
193 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over  
194 the same period. The trend in juveniles was as described for the five-year study.

195 For the filovirus, the seroprevalence in the one-year studies was higher than the reported  
196 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-  
197 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of  
198 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the  
199 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the  
200 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,  
201 there were two periods of increasing seroprevalence in adults over the course of the year. The first of  
202 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August  
203 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the  
204 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)  
205 between early March 2011 to late April 2011.

206 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from  
207 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in  
208 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December  
209 2010/January 2011 in Chakhoria. These decreases were followed by rapid increases back to high  
210 seroprevalence, coincident with increasing levels in juveniles. The pattern in juveniles was as  
211 described in the five-year study, with seroprevalence estimates in yearlings in April 2011 of 80%  
212 (28%-99%) in both locations.

213 Comparison of the seroprevalence trends within each age group and virus between the two one-  
214 year study locations did not support spatial differences in the timing of changes in seroprevalence  
215 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between  
216 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at  
217 the end of 2010.

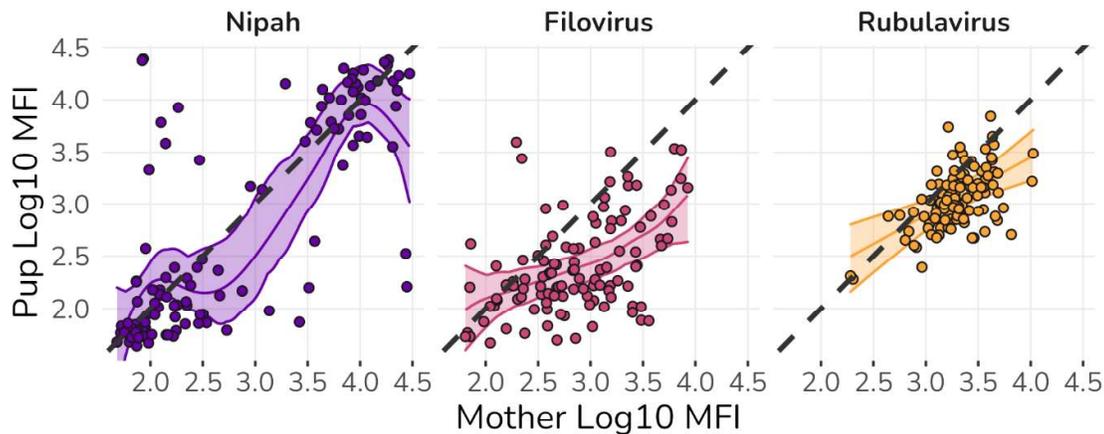

218  
219 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**  
220 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference  
221 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.  
222 Where the confidence interval excludes zero, there is evidence for a significant difference in the  
223 serodynamics between the Ramnagar and Chakhoria populations over that period.

#### 224 *Maternal Inheritance of antibodies*

225 We examined the relationship between mother and pup antibody titers, as measured by our  
226 Luminex assays (see Methods). This relationship varied between viruses (Figure 7). For Nipah virus,

227 the relationship was nonlinear due to clustering at high and low values, but largely followed a 1:1  
228 relationship between mother and pup antibody titers. For the rubulavirus the relationship was near-  
229 linear and near 1:1. For the filovirus, though, the relationship between MFI values measured in  
230 mothers and their pups fell well below the 1:1 line, indicating pups having low inheritance of  
231 antibodies against the filovirus relative to the other two viruses.

232

233 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for  
234 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the  
235 predicted mean relationship between the two and their associated 95% confidence intervals.

### 236 3. Discussion

237 We found serological evidence for regular circulation of multiple viruses in *P. medius*  
238 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to  
239 humans in the region, as well as a filovirus and a rubulavirus. It was common for bats to have  
240 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity  
241 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance  
242 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types  
243 being positively correlated within bats.

244 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The  
245 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations  
246 inherit maternal antibodies against the rubulavirus, which wane over the first six months of their life,  
247 after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in  
248 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the  
249 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence  
250 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating  
251 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of  
252 the rubulavirus to be strongest in the late winter and early spring months in these populations.  
253 Mortlock et al.<sup>39</sup> found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via  
254 PCR detection in pooled urine samples), including a peak during a period of presumed antibody  
255 waning, though only within a one-year study.

256 An outstanding question is how the rubulavirus is maintained in the population despite high  
257 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent  
258 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*<sup>40</sup>, Hendra virus in  
259 *P. alecto* and *P. poliocephalus*<sup>41</sup>, and Lagos bat lyssavirus and African henipavirus in *Eidolon helvum*<sup>42</sup>.  
260 Another possibility is re-importation. In concurrent work with this study, we found that bat home

---

 Number: 1 Author: Emily Gurley Date: 9/9/2022 8:59:00 PM  
I thought maybe not with the filos?

---

 Number: 2 Author: Emily Gurley Date: 9/9/2022 9:00:00 PM  
Something about individual bat risk or strange bat immune responses?

261 ranges overlapped with nearby colonies so as to form a meta-population<sup>34</sup>, allowing occasional  
262 infection from outside bats, as has been shown to maintain Hendra virus in *Pteropus* populations<sup>43,44</sup>.

263 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle  
264 virus, which has been found in multiple *Pteropus* species in Australia<sup>45,46</sup>. At least 11 distinct  
265 Paramyxoviruses have been found in *P. medius* in Bangladesh alone: Nipah virus and ten  
266 uncharacterized species, including six Rubulaviruses closely related to Menangle virus and the  
267 Tioman virus<sup>9,47</sup>. It is possible that the serological patterns observed represent antibodies against a  
268 complex of multiple Rubulaviruses, though the regular interannual patterns in seroprevalence would  
269 indicate that they are operating similarly.

270 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with  
271 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some  
272 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup  
273 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults  
274 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,  
275 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah  
276 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by  
277 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years<sup>28</sup>.  
278 Human Nipah virus outbreaks in Bangladesh, on the other hand, exhibit seasonality associated with  
279 the palm-sap consumption, the most frequently implicated spillover pathway<sup>48</sup>.

280 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-Zaire  
281 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have  
282 been found in *R. leschenaultii* in the country<sup>49</sup>. This could be one of several known filoviruses or an  
283 unknown species. There have been several recent findings of new Ebola-like filoviruses in bats  
284 extending across Africa and Asia. These include Bombali virus in Sierra Leone<sup>50</sup>, and Mënglà virus  
285 in *Rousettus* bats in China<sup>51</sup>. Ebola-Reston virus was found in multiple bat species (*M. australis*, *C.*  
286 *brachyotis* and *Ch. plicata*) in the Philippines<sup>52</sup>. Marburg virus and Ebola-Zaire virus may have been  
287 detected in Sierra Leone and Liberia (unpublished,<sup>53,54</sup>). Serological evidence of filoviruses in bats has  
288 been found in multiple bat species in Central<sup>12,55</sup> and Western<sup>56</sup> African countries, Singapore<sup>57</sup>,  
289 China<sup>58</sup>, as well as Trinidad<sup>59</sup>. Our finding here adds to the evidence of broad host and geographic  
290 host ranges for filoviruses.

291 Several components of the serological patterns of filovirus antibodies are of interest. Young  
292 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months  
293 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite  
294 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult  
295 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period  
296 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase  
297 among juveniles. One possible hypothesis explaining this pattern is that the filovirus may exhibit low  
298 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.  
299 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain  
300 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was  
301 found to be rapid, but bats retained protective immunity even with very low antibody titers<sup>60,61</sup>. If a  
302 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite  
303 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles  
304 following the peak is consistent with this explanation.

305 However, if adults remain immune to the filovirus despite low antibody titers, this immunity  
306 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and  
307 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the  
308 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly  
309 differential maternally derived immunity. If pups derive weaker immunity from dams than for other  
310 viruses, this may provide another mechanism for maintenance of the virus. It possible that patterns  
311 in filovirus antibody detection are an artifact of our test, specific to Ebola-Zaire virus, and that  
312 temporal trends are in part reflective of differential cross-reaction with viruses in this bat population.

 And recently in Australia.  
Barr et al. J Gen Virol. 2022 Aug;103(8).  
doi: 10.1099/jgv.0.001785.

313 However, while this may modify estimates of overall seroprevalence, the differential pup/dam MFI  
314 relationship, and consistent rise in seroprevalence among young juveniles, would require the test to  
315 exhibit differential sensitivity by age.

316 Serodynamics in our two one-year studies were broadly similar to those found in the five-year  
317 study. We found weak evidence for differences in serodynamics between sites for the filovirus in  
318 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the  
319 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study<sup>34</sup>,  
320 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their  
321 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are approximately 225  
322 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible  
323 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or  
324 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple  
325 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

326 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-  
327 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from  
328 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or  
329 transmission, via competition for host nutritional or cellular resources, or via immune-mediation  
330 involving cross-immunity or antibody-dependent enhancement, and these interactions structure  
331 viral communities<sup>26</sup>. These interactions can have complex, even opposite effects when scaled to the  
332 population<sup>27</sup>. Here, we found positive correlations between serostatus against different viruses.  
333 External factors may also affect these relationships. For instance, all three viruses appear to have  
334 circulated in adults in mid-2010. It is possible that common factors like population density and/or  
335 nutrition availability<sup>62</sup> affected transmission of multiple viruses.

336 While rich observational serological data reveal these patterns, greater study is required to  
337 characterize these viruses and their effects on the host population and potential for spillover, as well  
338 as the degree and mechanisms of interactions. Our inferred periods of viral circulation point to  
339 optimal sub-populations and times to sample this population to detect viral shedding and isolate  
340 these viruses, and potentially capture co-infected hosts.

341 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term  
342 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and  
343 shedding, but establishing patterns or variation in seasonality requires extended, multi-year  
344 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was  
345 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The  
346 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.  
347 Similarly, we were able to understand these patterns far better by separating juvenile and adult  
348 patterns, which we would be unable to distinguish in pooled samples.

349 While such extended individual-capture longitudinal studies are resource-intensive,  
350 understanding the joint circulation of multiple viruses can be accomplished via multiplex  
351 immunoassays such as those used here. The continuous measures from these assays also have the  
352 potential to identify key patterns such as the differential inheritance of filovirus antibodies we  
353 identified here. Interpretation of these values is challenging and the relationship between immune  
354 status, antibody titer, and measured fluorescence is complex<sup>32</sup>, but they have much potential to shed  
355 light on mechanistic drivers of disease circulation.

## 356 **Methods**

### 357 *Field collection*

358 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-  
359 year studies in different locations, sampling monthly. All capture and sampling methods were  
360 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol  
361 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as  
362 previously described in Epstein, et al.<sup>34</sup> The area of the roost complex consists of patchy forest

- 
-  Number: 1 Author: Steve Luby Date: 9/2/2022 10:41:00 AM  
As noted above, this important detail needs to be mentioned sooner.
- 
-  Number: 2 Author: Steve Luby Date: 9/2/2022 10:44:00 AM  
In addition to uncertainty over which specific viruses these assays are detecting antibodies against, which is addressed earlier in the discussion, other limitations to scientific inference that seem to me important to discuss include: there were only two sites to assess spatial heterogeneity. A more robust assessment would require more sites. Although five years is longer than usually studied, it is too short of a time for measuring temporal dynamics that might play out over longer time periods.
- 
-  Number: 3 Author: Emily Gurley Date: 9/9/2022 9:07:00 PM  
Agree
- 
-  Number: 4 Author: Steve Luby Date: 9/2/2022 10:43:00 AM  
Seems a weak concluding statement. I recommend a stronger statement of implications and way forward. To my mind, identification of the specific viruses that are driving these antibody responses would be the highest priority.
- 
-  Number: 5 Author: Steve Luby Date: 9/2/2022 9:47:00 AM  
I recommend listing the local IRB first.

363 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July  
364 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst  
365 roosts within the 80km<sup>2</sup> roost complex over the period of the study. Sampling occurred at the largest  
366 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex  
367 across consecutive sampling nights if required to capture a sufficient number of individuals.

368 Approximately 100 bats were captured at each sampling event, over 7-10 days. We captured bats<sup>61</sup>  
369 with a 10x15m mist net between 11pm and 5am each night as bats returned from foraging until the  
370 count of 100 was reached.

371 In the one-year longitudinal studies, sampling was undertaken in two roost complexes in  
372 Ramnagar and Chakhoria, Bangladesh between April 2010 and May 2011. Monthly sampling of  
373 approximately 40 bats in each location was performed to obtain data at a finer temporal scale. Details  
374 of collection are otherwise as described for the five-year study.

375 For each study, we recorded each bat's age class, reproductive status, weight, size, and body  
376 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with  
377 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box  
378 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and  
379 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton  
380 Cryogenics, NJ, USA).

381 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal  
382 swabs and pooled urine samples from under colonies. Further details can be found in [Epstein, et al.](#)  
383 <sup>34</sup>

#### 384 *Serological Assays*

385 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and  
386 gamma irradiated upon receipt. We used a bead-based microsphere assay that specifically detects  
387 antibodies to the soluble attachment glycoproteins<sup>57,63,64</sup> for a panel of viruses. Beads coated with each  
388 protein were mixed with sera at a dilution of 1:100. Biotinylated Protein A/G and Streptavidin-PE  
389 were then used to detect bound antibody. Beads were interrogated by lasers in a BioRad BioPlex  
390 machine and the results recorded as the Median Fluorescent Intensity (MFI) of 100 beads. We report  
391 here results for Nipah, Ebola-Zaire, and Menangle, the only three for which we established regular  
392 positive results.

393 While the Nipah virus has been detected in this population<sup>65</sup> and the specificity of the Nipah test  
394 is well-established<sup>66</sup>, the Ebola-Zaire and Menangle virus tests are cross-reactive with other Ebola  
395 and rubulavirus species<sup>67,68</sup>. Thus we refer to these as tests for filovirus and Rubulavirus.

#### 396 *Data Analysis*

397 We determined individual bat serostatus using Bayesian mixture models<sup>69</sup> fit on pooled data  
398 across all three longitudinal studies, calculating a cutoff of log-MFI as the point of equal probability  
399 between the smallest and second-smallest cluster of equal distributions for each assay.

400 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian  
401 multivariate probit model<sup>70,71</sup> which allows estimation of the joint outcomes (serostatus against each  
402 virus) and the correlation between the outcomes. We included age and sex variables to account for  
403 these effects on serostatus.

404 To examine time-varying changes in population seroprevalence, we fit binomial generalized  
405 additive mixed models (GAMMs)<sup>72,73</sup> to the time-series of serostatus measurements. For the five-year  
406 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit  
407 a model for seroprevalence dynamics over the course of the whole study. This treats the adult  
408 population as a single unit, though individuals within the population may turn over via migration,  
409 death and recruitment. We included both long-term and annual cyclic components for the multi-year  
410 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate  
411 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile  
412 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles

Error 5.4			
	Number: 2	Author: Emily Gurley	Date: 9/9/2022 8:54:00 PM
If data from this aren't included here, does it need to be in the methods?			
	Number: 3	Author: Wang Linfa	Date: 8/21/2022 10:50:00 AM
I am not 100% sure about this. All serological tests (the NIV test included) will detect cross-RX antibodies from related viruses. For NIV, you can argue that longitudinal surveillance has NOT detected any related viruses in the study populations, but we can't say that the Ab test is specific to NIV.			
	Number: 4	Author: Emily Gurley	Date: 9/9/2022 8:56:00 PM
How has it been done in other similar studies? Using the beads from USU now, we see more than one cluster of MFI values below what we're considering positive.			
	Number: 5	Author: Steve Luby	Date: 9/2/2022 9:53:00 AM
Why should we assume that the second smallest cluster is associated with the genuine presence or absence of antibody?			

413 over their first year. To estimate periods of peak viral circulation within the population, we calculated  
414 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior  
415 distributions and classified periods with >95% of samples with positive derivatives - that is,  
416 increasing population seroprevalence - as periods of viral circulation. We also calculated strength  
417 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date  
418 at which this maximum occurred, again sampling these values from the model posterior, and  
419 calculating mean and high-density posterior interval (HDPI) values.

420 For the one-year studies, we fit models primarily to detect differences in time-varying changes  
421 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus  
422 measurements with separate models for each immunoassay. We included a separate, fixed-term  
423 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in  
424 serodynamics for each virus in each age group were compared between locations to test for spatial  
425 differences<sup>74</sup>. Juveniles identified as being from the previous year's cohort were excluded from the  
426 analysis.

427 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI  
428 between adult lactating females and their attached pups for each viral assay. We limited these to data  
429 from the five-year longitudinal study.

430 **Data Availability:** Raw data from this study and reproducible code used to perform analyses is available at the  
431 Zenodo Scientific Archive [Zenodo DOI to be generated] and also on GitHub at  
432 <https://github.com/ecohealthalliance/bangladesh-bat-serodynamics>

**Abstract:** Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles with a lower seroprevalence amongst adults suggesting limited circulation or immunity despite low antibody titers. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

**Keywords:** Chiroptera; Nipah virus; Ebola Zaire; Menangle virus; flying fox; Bangladesh; serology; longitudinal surveillance; disease dynamics; generalized additive models

## Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics<sup>1-3</sup>. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses<sup>4,5</sup> including close relatives of SARS-CoV-2<sup>6</sup>, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses<sup>1,2,7</sup>.

Bat species can carry diverse viruses which circulate simultaneously within single populations<sup>8-11</sup>. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire virus have also been detected in this bat in Central Africa, suggesting that it may play a role in the circulation of multiple filoviruses<sup>12,13</sup>. In addition to these filoviruses, a novel zoonotic and

Per comments from Linfa and Hume, I think we may want to change the way we describe these throughout given the potential for cross-reactivity with all assays (in fact most serological assays!). At the moment, it's really only when you get to the methods or later in the discussion that it's clear the assays are for Menangle virus and Ebola Zaire viruses specifically. Also, weren't there other Filos in the panel? If so, curious about cross reactivity with any other Filos, e.g. Reston?

How about instead of "a rubulavirus" or "a filovirus" we just go with: Nipah-like, Meangle-like and Ebola-Zaire-like? OR Nipah-related, Menangle-related, and Ebola-Zaire-related viruses? Or we just use the nomenclature you have below, e.g. MenVsero+, EbVsero+... and then later in the discussion have a section about the implications of cross reactivity, i.e. that these may be novel viruses or even multiple related viruses, and not exactly EboV or MenV.

The Letko et al. 2020 Nature Review Microb. is a good one to cite too. Also check out the section on adaptive immunity for some relevant discussion about filoviruses vs henipaviruses, etc. <https://doi.org/10.1038/s41579-020-0394-z>

46 pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations<sup>14</sup>.  
47 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to  
48 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity<sup>15</sup>. Various  
49 surveillance efforts have found diverse viruses from with the same viral family in various bat  
50 species<sup>5,16,17</sup>, and other studies have used metagenomic approaches to look broadly at viral diversity  
51 within individual bat species<sup>9,11,18-21</sup>.

52 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of  
53 viruses and their relationships to specific hosts<sup>5,22</sup> and inform public health strategies<sup>23</sup>. However,  
54 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated  
55 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or  
56 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other  
57 species, including domestic animals and humans<sup>24</sup>. For these, more detailed demographic and  
58 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect  
59 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics<sup>25-27</sup>.  
60 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral  
61 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been  
62 observed to have annual shedding patterns<sup>28</sup>, whereas Hendra virus, which is closely related to  
63 Nipah virus and is carried by multiple pteropid bat species in Australia, has asynchronous and non-  
64 periodic cycles which appear to be influenced by localized factors such as specific bat species  
65 abundance and climatic factors<sup>29</sup>. Bi-annual pulses of Marburg virus shedding were observed in  
66 Uganda, coinciding with synchronous birth pulses in *R. aegyptiacus*<sup>30</sup>. Serological data is often  
67 valuable in understanding disease dynamics and transmission<sup>31-33</sup>, especially in cases where direct  
68 detection and incidence rates of viruses are low<sup>34</sup>.

69 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, lethal neurotropic  
70 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus<sup>35-37</sup>. In Bangladesh and India,  
71 *P. medius* is a reservoir of Nipah virus, which has spilled over to human populations repeatedly<sup>38</sup>.  
72 Viruses from eight other viral families have been detected in *P. medius* in Bangladesh<sup>9</sup>. The  
73 epidemiology of these other viruses is far less characterized, and little is known about their  
74 interactions or zoonotic potential.

75 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,  
76 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in  
77 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-  
78 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of  
79 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral  
80 circulation. We find that Nipah virus circulates primarily among adults without distinct seasonality,  
81 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by  
82 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also  
83 circulated in juveniles but exhibited distinct patterns antibody waning and limited maternal  
84 inheritance.

## 85 2. Results

### 86 *Bat Dynamics and Demographics*<sup>3</sup>

87 We conducted a five-year longitudinal study (2007-2012) sampling *P. medius* bats quarterly from  
88 a roost complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies (2010-  
89 2011) sampling bats monthly from roosts in Chakhoria and Ramnagar, Bangladesh. In the five-year  
90 study, we sampled and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39  
91 weaning juveniles (captured attached to adult females) over 19 sampling events (Figure 1). During  
92 the one-year studies, 919 bats were sampled: 435 in Chakhoria (251 adults, 144 free-flying juveniles  
93 and 40 weaning juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning  
94 juveniles (Figure S1). Nearly all juveniles (as determined by examination of maturation of sex organs)  
95 were 14 months old or less and could be assigned to a birth cohort based on size. Pregnant and

---

96 juvenile bats were captured more frequently during the late spring and summer months. Mother-  
 97 pup pairs were all captured during April and May in the five-year study whilst in the one-year-  
 98 studies a small number were also captured in June and July. Pregnant females were captured between  
 99 November and April/May. Lactating females were found between April and July.  
 100

101 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured  
 102 in months from November to June, lactating females were captured in months from April to July.  
 103 Females with pre-weaning juveniles attached were found from April to May.

104 *Patterns of Immunity and Co-immunity*

105 We found bats were seropositive for antibodies against the henipavirus (HenipVsero+), a  
 106 filovirus (EbVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the  
 107 rubulavirus were common; 1,314 of 1752 adult bats were MenVsero+. Antibodies against Nipah virus  
 108 or filovirus were less common – 1,031 were NiVsero+ and 921 were EbVsero+. Among the 921  
 109 juveniles, 192 were MenVsero+, 311 were NiVsero+ and 348 were EbVsero+. Of the 122 pre-weaned  
 110 juveniles, 43 were MenVsero+, 52 were NiVsero+, and 32 were EbVsero+.

111 Co-exposure to multiple viruses was common (Figure 2). Two-thirds (1,173) of the 1752 adults  
 112 had antibodies against more than one of the three viruses, and 493 (28%) had antibodies against all  
 113 three. Among the 921 juveniles, 210 (23%) had antibodies against more than one, and 39 had  
 114 antibodies all three. Almost a third, 38 of 122 pre-weaned juveniles, had more than one of the three  
 115 antibodies, with seven having all three.

116 We found correlations *between* serostatus between all three pairs of viruses in a model  
 117 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other  
 118 more than would be expected than if they were distributed independently among bats. Nipah virus  
 119 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).  
 120 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of  
 121 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had the highest covariance of 0.23 (0.17-0.29).

## Page: 3

Minor: but consider separating out figure legend, one for adult panel and one key for the juv panel, as colors repeat and a little confusing.

---

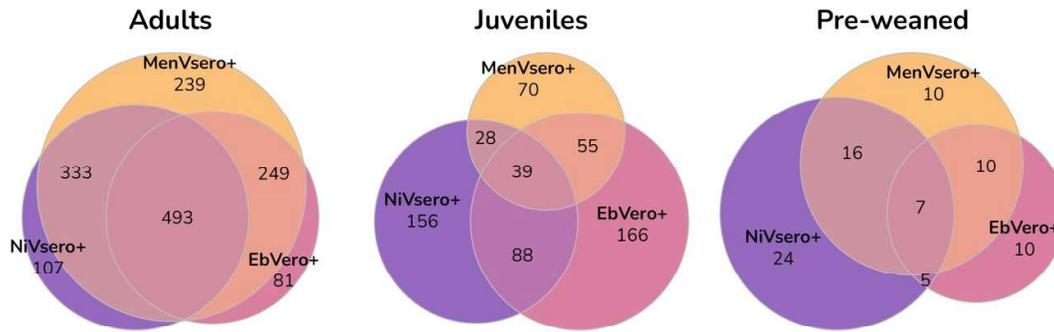

Number: 2 Author: Kevin Olival Date: 9/6/2022 12:05:00 AM

Just flagging as we aren't consistent with using these "sero+" nomenclatures on seropositivity later, as we keep referring generically to rubula and filo throughout.

---

Number: 3 Author: Wang Linfa Date: 8/21/2022 10:48:00 AM

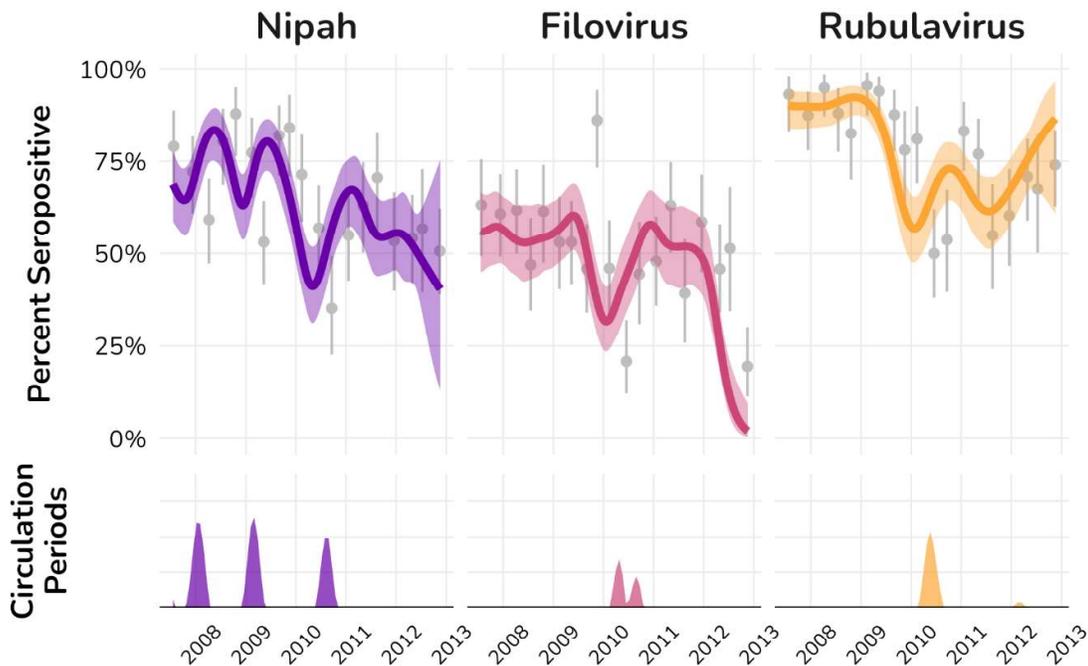

I think it is better to treat the three group of viruses equally as you have done for the title. It makes no difference whether we use NiV or Henipavirus in the context of the current study. Luminex-based assays targeting binding antibodies will in theory detect cross-RX antibodies in all three cases. See also comments in Methods

122 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn  
 123 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,  
 124 filovirus, and Rubulavirus. Numbers under labels are counts of bats with only those viruses, numbers  
 125 in overlapping areas represent number of bats detected with multiple viruses.

126 *Serodynamics*

127 Dynamics of population seroprevalence were different across the viral types. In adults,  
 128 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)  
 129 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-  
 130 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very  
 131 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in [Epstein, et al. 34](#)).  
 132

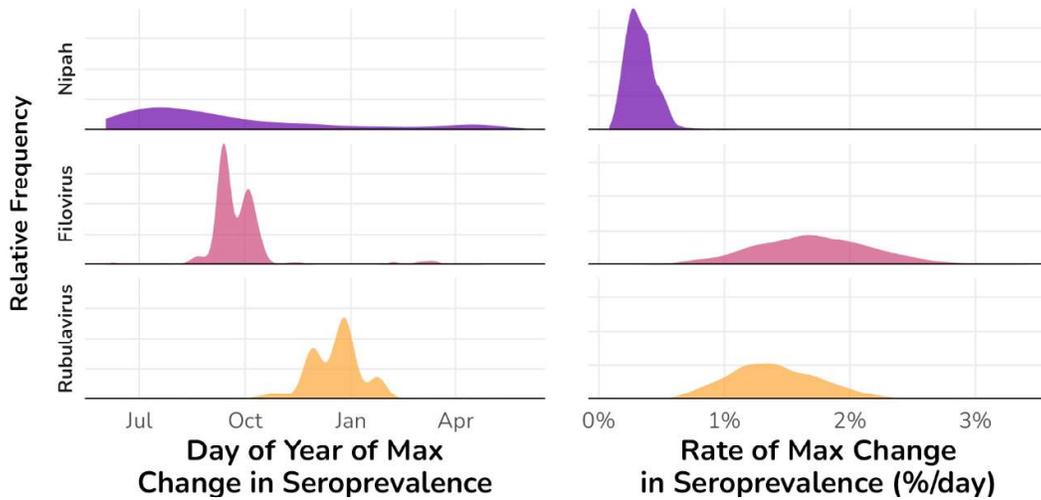

133  
 134 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population  
 135 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey  
 136 points and bars represent measured population seroprevalence from individual sampling events on  
 137 and 95% exact binomial confidence intervals. Thick lines and shaded areas represent the inter-annual  
 138 (non-seasonal) spline component of a generalized additive mixed model (GAMM) of serodynamics  
 139 and 95% confidence intervals for the mean pattern over time. Bottom: Circulation periods, when  
 140 modeled slopes of the [GAMM splines](#) are positive for >95% of 1000 draws from the model posterior.

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

**Figure 5. Serodynamics in juvenile bats in five-year study.** Measured and modeled population seroprevalence in juvenile bats caught over their first year of life. Sampling events from multiple years are transposed onto a single year starting June (the earliest month free-flying young-of-the-year juveniles were captured). X-axis ticks mark the first day of each month. Grey points and bars represent measured population seroprevalence from individual sampling events on and 95% exact binomial confidence intervals. Thick lines and shaded areas represent GAMM-modeled average serodynamics across all years and 95% confidence intervals for the mean effect. Thin lines represent individual-year deviations from the average year pattern.

160

161

162 **Figure 6. Timing and strength of seasonality of viral circulation in juveniles over the five-year**  
 163 **study.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left),  
 164 and the rate of increase (right), for juvenile bats. Densities are of these quantities derived from 1000  
 165 samples of model posteriors.

166 Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against  
 167 filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus  
 168 seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had  
 169 periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah  
 170 virus) (Fig. 3). Filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

171 Among juveniles within the average year, filovirus seroprevalence started very low in June at  
 172 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age  
 173 before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it  
 174 consistently occurred in December or January. The average date with the greatest rate of  
 175 seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day  
 176 (4.5%/day-9.9%/day).

177 Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus  
 178 seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74%  
 179 (62%-84%), though there were some temporary periods of decline (Fig 3). There were distinct periods  
 180 of increasing circulation in early 2010 and early 2012 (Fig 3). Only for the rubulavirus did adult  
 181 seroprevalence exhibit patterns of seasonality. Periods of increasing seroprevalence in adults  
 182 exhibited strong seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean  
 183 peak date occurring on Dec 15 (Oct 15-Feb 1) (Fig 4).

184 In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in  
 185 the youngest bats in June, though in individual years this could range from 7%-43%. In all years  
 186 juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec  
 187 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%).  
 188 The peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and  
 189 occurred Jan 9 (Dec 21-Mar 16) (Fig 5).

190 *Spatial Comparisons*

191 Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria  
 192 and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2).  
 193 In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of  
 194 April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

---

 Number: 1 Author: Kevin Olival Date: 9/10/2022 4:48:00 AM  
Didn't see this one in the file. Also, seems there's no Supp Figure 1?

195 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-61%) in April 2010, rising to  
196 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over  
197 the same period. The trend in juveniles was as described for the five-year study.

198 For the filovirus, the seroprevalence in the one-year studies was higher than the reported  
199 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-  
200 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of  
201 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the  
202 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the  
203 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,  
204 there were two periods of increasing seroprevalence in adults over the course of the year. The first of  
205 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August  
206 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the  
207 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)  
208 between early March 2011 to late April 2011.

209 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from  
210 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in  
211 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December  
212 2010/January 2011 in Chakhoria. These decreases were followed by rapid increases back to high  
213 seroprevalence, coincident with increasing levels in juveniles. The pattern in juveniles was as  
214 described in the five-year study, with seroprevalence estimates in yearlings in April 2011 of 80%  
215 (28%-99%) in both locations.

216 Comparison of the seroprevalence trends within each age group and virus between the two one-  
217 year study locations did not support spatial differences in the timing of changes in seroprevalence  
218 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between  
219 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at  
220 the end of 2010.

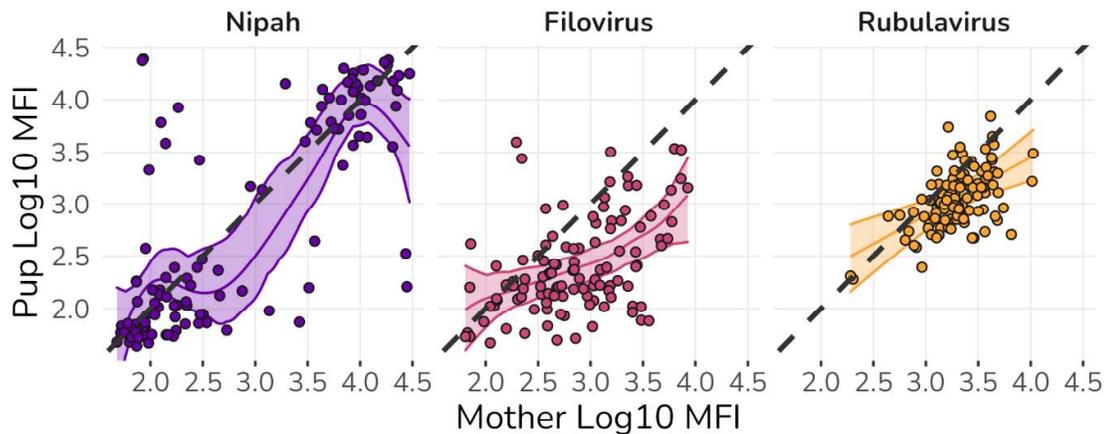

221

222 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**  
223 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference  
224 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.  
225 Where the confidence interval excludes zero, there is evidence for a significant difference in the  
226 serodynamics between the Ramnagar and Chakhoria populations over that period.

### 227 *Maternal Inheritance of antibodies*

228 We examined the relationship between mother and pup antibody titers, as measured by our  
229 Luminex assays (see Methods). This relationship varied between viruses (Figure 7). For Nipah virus,

230 the relationship was nonlinear due to clustering at high and low values, but largely followed a 1:1  
231 relationship between mother and pup antibody titers. For the rubulavirus the relationship was near-  
232 linear and near 1:1. For the filovirus, though, the relationship between MFI values measured in  
233 mothers and their pups fell well below the 1:1 line, indicating pups having low inheritance of  
234 antibodies against the filovirus relative to the other two viruses.

235

236 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for  
237 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the  
238 predicted mean relationship between the two and their associated 95% confidence intervals.

### 239 3. Discussion

240 We found serological evidence for regular circulation of multiple viruses in *P. medius*  
241 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to  
242 humans in the region, as well as a filovirus and a rubulavirus. It was common for bats to have  
243 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity  
244 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance  
245 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types  
246 being positively correlated within bats.

247 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The  
248 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations  
249 inherit maternal antibodies against the rubulavirus, which wane over the first six months of their life,  
250 after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in  
251 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the  
252 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence  
253 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating  
254 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of  
255 the rubulavirus to be strongest in the late winter and early spring months in these populations.  
256 Mortlock et al.<sup>39</sup> found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via  
257 PCR detection in pooled urine samples), including a peak during a period of presumed antibody  
258 waning, though only within a one-year study.

259 An outstanding question is how the rubulavirus is maintained in the population despite high  
260 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent  
261 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*<sup>40</sup>, Hendra virus in  
262 *P. alecto* and *P. poliocephalus*<sup>41</sup>, and Lagos bat lyssavirus and African henipavirus in *Eidolon helvum*<sup>42</sup>.  
263 Another possibility is the re-introduction of virus, or distinct viral strains, from outside bat  
264 populations. We have previously shown that bat home ranges overlapped with nearby colonies so as

## Page: 8

Just as example if we're changing nomenclature, this would be "how Menangle-related viruses are maintained"...

---

Number: 2 Author: Kevin Olival Date: 9/10/2022 4:51:00 AM

Not clear what this means?

265 to form a meta-population<sup>34</sup>, findings further supported by population genetic studies of *P. medius* in  
266 Bangladesh [REF]. These metapopulation dynamics may allow for occasional infection of viruses or  
267 novel viral strains from outside bats, as has been shown to maintain Hendra virus in *Pteropus*  
268 populations<sup>43,44</sup>.

269 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle  
270 virus, which has been found in multiple *Pteropus* species in Australia<sup>45,46</sup>. At least 11 distinct  
271 Paramyxoviruses have been found in *P. medius* in Bangladesh alone: Nipah virus and ten  
272 uncharacterized species, including six Rubulaviruses closely related to Menangle virus and the  
273 Tioman virus<sup>9,47</sup>. It is possible that the serological patterns observed represent antibodies against a  
274 complex of multiple Rubulaviruses, though the regular interannual patterns in seroprevalence would  
275 indicate that they are operating similarly. The development of more specific serological assays for the  
276 six known rubulaviruses found in this species would help to further disentangle these patterns.

277 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with  
278 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some  
279 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup  
280 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults  
281 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,  
282 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah  
283 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by  
284 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years<sup>28</sup>.  
285 Human Nipah virus outbreaks in Bangladesh, on the other hand, exhibit seasonality associated with  
286 the palm-sap consumption, the most likely spillover mechanism<sup>48</sup>.

287 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-Zaire  
288 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have  
289 been found in *R. leschenaultii* in the country<sup>49</sup>. Interestingly, *P. medius* and *R. leschenaultii* have been  
290 observed sharing a common food resources, i.e. date palm sap [REF<sup>2</sup>] which represents a pathway for  
291 cross-species EboV transmission and also a potential route of exposure to humans. There have been  
292 several recent findings of new Ebola-like filoviruses in bats extending across Africa and Asia, and it's  
293 likely the virus we are detecting is not Ebola-Zaire but rather a novel and related virus. New bat  
294 filovirus discoveries include Bombali virus in Sierra Leone<sup>50</sup>, and Měnglà virus in *Rousettus* bats in  
295 China<sup>51</sup>. Ebola-Reston virus was found in multiple bat species (*M. australis*, *C. brachyotis* and *Ch.*  
296 *plicata*) in the Philippines<sup>52</sup>. Marburg virus and Ebola-Zaire virus may have been detected in Sierra  
297 Leone and Liberia<sup>3</sup> (unpublished<sup>53,54</sup>). Serological evidence of filoviruses in bats has been found in  
298 multiple bat species in Central<sup>12,55</sup> and Western<sup>56</sup> African countries, Singapore<sup>57</sup>, China<sup>58</sup>, as well as  
299 Trinidad<sup>59</sup>. Our finding here adds to the evidence of broad host and geographic host ranges for  
300 filoviruses.

301 Several components of the serological patterns of filovirus antibodies are of interest. You<sup>5</sup>g  
302 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months  
303 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite  
304 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult  
305 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period  
306 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase  
307 among juveniles. One p<sup>2</sup>ossible hypothesis explaining this pattern is that the filovirus may exhibit low  
308 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.  
309 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain  
310 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was  
311 found to be rapid, but bats retained protective immunity even with very low antibody titers<sup>60,61</sup>. If a  
312 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite  
313 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles  
314 following the peak is consistent with this explanation.

315 However, if adults remain immune to the filovirus despite low antibody titers, this immunity  
316 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and

Random thought, and pretty speculative, but could expression of some endogenous viral elements cause a pattern like this (or any of the juvenile patterns we observed, as opposed to a strictly maternal antibody inheritance model)? I guess if so, all individuals would show antibodies.
- 
- Number: 6 Author: Kevin Olival Date: 9/10/2022 5:16:00 AM  
I think this 2010 finding is an interesting and understated finding of ours... namely that all 3 viruses showed significant viral circulation during this period. What inter-annual dyanmics could have led to this? Food shortage (ala some of Raina's work (a new paper coming out soon on this), other environmental or physiological stressors?
- 
- Number: 7 Author: Kevin Olival Date: 9/10/2022 5:18:00 AM  
We don't know much about this in bats I guess (maybe for Marburg) but Filos in people aren't spread very easily, so some intrinsically lower Rt for filoviruses over other bat viruses?

317 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the  
318 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly  
319 differential maternally derived immunity. If pups derive weaker immunity from dams than for other  
320 viruses, this may provide another mechanism for maintenance of the virus. It's also possible that  
321 patterns in filovirus antibody detection are an artifact of our test, specific to Ebola-Zaire virus, and  
322 that temporal trends are in part reflective of differential cross-reaction with viruses in this bat  
323 population. However, while this may modify estimates of overall seroprevalence, the differential  
324 pup/dam MFI relationship, and consistent rise in seroprevalence among young juveniles, would  
325 require the test to exhibit differential sensitivity by age which we believe is unlikely.

326 Serodynamics in our two one-year studies were broadly similar to those found in the five-year  
327 study. We found weak evidence for differences in serodynamics between sites for the filovirus in  
328 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the  
329 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study<sup>34</sup>,  
330 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their  
331 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are approximately 225  
332 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible  
333 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or  
334 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple  
335 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

336 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-  
337 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from  
338 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or  
339 transmission, via competition for host nutritional or cellular resources, or via immune-mediation  
340 involving cross-immunity or antibody-dependent enhancement, and these interactions structure  
341 viral communities<sup>26</sup>. These interactions can have complex, even opposite effects when scaled to the  
342 population<sup>27</sup>. Here, we found positive correlations between serostatus against three different viruses.  
343 Notably, all three viruses had a significant increase in viral circulation in adults in mid-2010.  
344 External factors may explain these inter-annual viral circulation patterns, for example changes in  
345 population density and/or physiological stress due to climate or nutrition availability<sup>62</sup> could  
346 simultaneously affected transmission of multiple viruses.

347 While rich observational serological data reveal these patterns, further studies are required to  
348 characterize these viruses and their effects on the host population and potential for spillover, as well  
349 as the degree and mechanisms of interactions. Our model of longitudinal, serological data was able  
350 to infer periods of increased viral circulation – providing a tool to more precisely target optimal sub-  
351 populations and times to sample bats or other wildlife reservoirs to detect viral shedding, isolate  
352 viruses, and potentially capture co-infected hosts.

353 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term  
354 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and  
355 shedding, but establishing patterns or variation in seasonality requires extended, multi-year  
356 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was  
357 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The  
358 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.  
359 Similarly, we were able to understand these patterns far better by separating juvenile and adult  
360 patterns, which we would be unable to distinguish in pooled samples. Future work should examine  
361 these inter-annual patterns in viral dynamics with ecological correlates and intrinsic health  
362 parameters for bats in the population

363 While such extended individual-capture longitudinal studies are resource-intensive,  
364 understanding the joint circulation of multiple viruses can be accomplished via multiplex  
365 immunoassays such as those used here. The continuous measures from these assays also have the  
366 potential to identify key patterns such as the differential inheritance of filovirus antibodies we  
367 identified here. Interpretation of these values is challenging and the relationship between immune

368 status, antibody titer, and measured fluorescence is complex<sup>32</sup>, but they have much potential to shed  
369 light on mechanistic drivers of disease circulation.

## 370 **Methods**

### 371 *Field collection*

372 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-  
373 year studies in different locations, sampling monthly. All capture and sampling methods were  
374 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol  
375 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as  
376 previously described in Epstein, et al.<sup>34</sup> The area of the roost complex consists of patchy forest  
377 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July  
378 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst  
379 roosts within the 80km<sup>2</sup> roost complex over the period of the study. Sampling occurred at the largest  
380 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex  
381 across consecutive sampling nights if required to capture a sufficient number of individuals.

382 Approximately 100 bats were captured at each sampling event, which lasted 7-10 days. We  
383 captured bats with a 10x15m mist net between 11pm and 5am each night as bats returned from  
384 foraging until the count of 100 was reached.

385 In the one-year longitudinal studies, sampling was undertaken in two roost complexes  
386 approximately 225km apart in Ramnagar and Chakhoria, Bangladesh between April 2010 and May  
387 2011. Monthly sampling of approximately 40 bats in each location was performed to obtain data at a  
388 finer temporal scale. Details of collection are otherwise as described for the five-year study.

389 For each study, we recorded each bat's age class, reproductive status, weight, size, and body  
390 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with  
391 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box  
392 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and  
393 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton  
394 Cryogenics, NJ, USA).

395 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal  
396 swabs and pooled urine samples from under colonies. Further details can be found in Epstein, et al.  
397 <sup>34</sup>

### 398 *Serological Assays*

399 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and  
400 gamma irradiated upon receipt. We used a bead-based microsphere assay that specifically detects  
401 antibodies to the soluble attachment glycoproteins<sup>57,63,64</sup> for a panel of viruses. Beads coated with each  
402 protein were mixed with sera at a dilution of 1:100. Biotinylated Protein A/G and Streptavidin-PE  
403 were then used to detect bound antibody. Beads were interrogated by lasers in a BioRad BioPlex  
404 machine and the results recorded as the Median Fluorescent Intensity (MFI) of 100 beads. We report  
405 here results for Nipah, Ebola-Zaire, and Menangle, the only three for which we established regular  
406 positive results.

407 While the Nipah virus has been detected in this population<sup>65</sup> and the specificity of the Nipah test  
408 is well-established<sup>66</sup>, the Ebola-Zaire and Menangle virus tests are cross-reactive with other Ebola  
409 and rubulavirus species<sup>67,68</sup>. Thus we refer to these as tests for filovirus and Rubulavirus.

### 410 *Data Analysis*

411 We determined individual bat serostatus using Bayesian mixture models<sup>69</sup> fit on pooled data  
412 across all three longitudinal studies, calculating a cutoff of log-MFI as the point of equal probability  
413 between the smallest and second-smallest cluster of equal distributions for each assay.

414 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian  
415 multivariate probit model<sup>70,71</sup> which allows estimation of the joint outcomes (serostatus against each

Do we give GPS lat/long anywhere, even if rounded up some decimal points?

---

Number: 2 Author: Wang Linfa Date: 8/21/2022 10:50:00 AM

I am not 100% sure about this. All serological tests (the NiV test included) will detect cross-RX antibodies from related viruses. For NiV, you can argue that longitudinal surveillance has NOT detected any related viruses in the study populations, but we can't say that the Ab test is specific to NiV.

416 virus) and the correlation between the outcomes. We included age and sex variables to account for  
417 these effects on serostatus.

418 To examine time-varying changes in population seroprevalence, we fit binomial generalized  
419 additive mixed models (GAMMs)<sup>72,73</sup> to the time-series of serostatus measurements. For the five-year  
420 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit  
421 a model for seroprevalence dynamics over the course of the whole study. This treats the adult  
422 population as a single unit, though individuals within the population may turn over via migration,  
423 death and recruitment. We included both long-term and annual cyclic components for the multi-year  
424 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate  
425 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile  
426 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles  
427 over their first year. To estimate periods of peak viral circulation within the population, we calculated  
428 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior  
429 distributions and classified periods with >95% of samples with positive derivatives - that is,  
430 increasing population seroprevalence - as periods of viral circulation. We also calculated strength  
431 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date  
432 at which this maximum occurred, again sampling these values from the model posterior, and  
433 calculating mean and high-density posterior interval (HDPI) values.

434 For the one-year studies, we fit models primarily to detect differences in time-varying changes  
435 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus  
436 measurements with separate models for each immunoassay. We included a separate, fixed-term  
437 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in  
438 serodynamics for each virus in each age group were compared between locations to test for spatial  
439 differences<sup>74</sup>. Juveniles identified as being from the previous year's cohort were excluded from the  
440 analysis.

441 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI  
442 between adult lactating females and their attached pups for each viral assay. We limited these to data  
443 from the five-year longitudinal study.

444 **Data Availability:** Raw data from this study and reproducible code used to perform analyses is available at the  
445 Zenodo Scientific Archive [Zenodo DOI to be generated] and also on GitHub at  
446 <https://github.com/ecohealthalliance/bangladesh-bat-serodynamics>

**Abstract:** Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles and little circulation but lower seroprevalence amongst adults. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

**Keywords:** bats; Nipah virus; filovirus; Rubulavirus; *Pteropus medius*; Bangladesh; serology; disease dynamics; generalized additive models

---

## Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics<sup>1-3</sup>. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses<sup>4,5</sup> including close relatives of SARS-CoV-2<sup>6</sup>, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses<sup>1,2,7</sup>.

Bat species can carry diverse viruses which circulate simultaneously within single populations<sup>8-11</sup>. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire virus have also been detected in this bat in Central Africa, suggesting that it may play a role in the circulation of multiple filoviruses<sup>12,13</sup>. In addition to these filoviruses, a novel zoonotic and pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations<sup>14</sup>.

46 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to  
47 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity<sup>15</sup>. Various  
48 surveillance efforts have found diverse viruses from with the same viral family in various bat  
49 species<sup>5,16,17</sup>, and other studies have used metagenomic approaches to look broadly at viral diversity  
50 within individual bat species<sup>9,11,18-21</sup>.

51 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of  
52 viruses and their relationships to specific hosts<sup>5,22</sup> and inform public health strategies<sup>23</sup>. However,  
53 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated  
54 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or  
55 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other  
56 species, including domestic animals and humans<sup>24</sup>. For these, more detailed demographic and  
57 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect  
58 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics<sup>25-27</sup>.  
59 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral  
60 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been  
61 observed to have annual shedding patterns<sup>28</sup>, whereas Hendra virus, which is closely related to  
62 Nipah virus and is carried by multiple pteropodid bat species in Australia, has asynchronous and non-  
63 periodic cycles which appear to be influenced by localized factors such as specific bat species  
64 abundance and climatic factors<sup>29</sup>. Bi-annual pulses of Marburg virus shedding were observed in  
65 Uganda, coinciding with synchronous birth pulses in *R. aegyptiacus*<sup>30</sup>. Serological data is often  
66 valuable in understanding disease dynamics and transmission<sup>31-33</sup>, especially in cases where direct  
67 detection and incidence rates of viruses are low<sup>34</sup>.

68 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, lethal neurotropic  
69 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus<sup>35-37</sup>. In Bangladesh and India,  
70 *P. medius* is a reservoir of Nipah virus, which has spilled over to human populations repeatedly<sup>38</sup>.  
71 Viruses from eight other viral families have been detected in *P. medius* in Bangladesh<sup>9</sup>. The  
72 epidemiology of these other viruses is far less characterized, and little is known about their  
73 interactions or zoonotic potential.

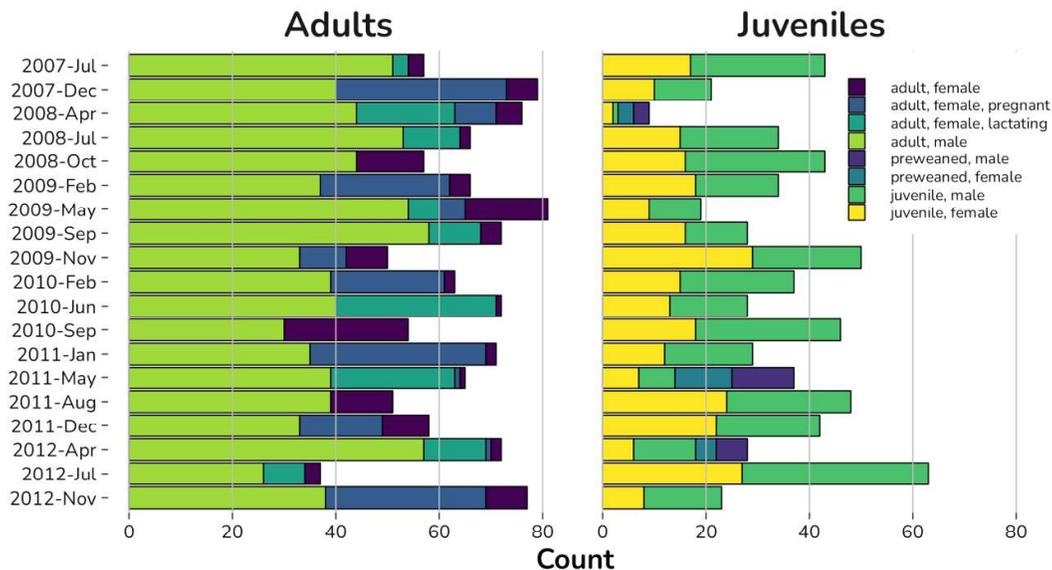

74 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,  
75 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in  
76 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-  
77 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of  
78 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral  
79 circulation. We find that Nipah virus circulates primarily among adults without distinct seasonality,  
80 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by  
81 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also  
82 circulated in juveniles but exhibited distinct patterns antibody waning and limited maternal  
83 inheritance.

## 84 **2. Results**

### 85 *Bat dynamics and demographics*

86 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly from a roost  
87 complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies sampling bats  
88 monthly from roosts in Chakhoria and Ramnagar, Bangladesh. In the five-year study, we sampled  
89 and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39 weaning juveniles  
90 (captured attached to adult females) over 19 sampling events (Figure 1). During the one-year studies,  
91 919 bats were sampled: 435 in Chakhoria (251 adults, 144 free-flying juveniles and 40 weaning  
92 juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning juveniles (Figure  
93 S1). Nearly all juveniles (as determined by examination of maturation of sex organs) were 14 months  
94 old or less and could be assigned to a birth cohort based on size. Pregnant and juvenile bats were  
95 captured more frequently during the late spring and summer months. Mother-pup pairs were all

96 captured during April and May in the five-year study whilst in the one-year-studies a small number  
 97 were also captured in June and July. Pregnant females were captured between November and  
 98 April/May. Lactating females were found between April and July.  
 99

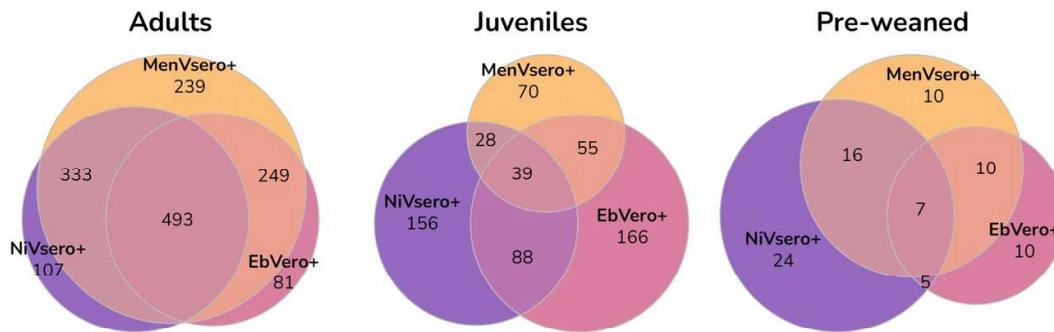

100 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured  
 101 in months from November to June, lactating females were captured in months from April to July.  
 102 Females with pre-weaning juveniles attached were found from April to May.

103 *Patterns of Immunity and Co-immunity*

104 We found bats were seropositive for antibodies against the Nipah virus (NiVsero+), a filovirus  
 105 (EbVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the rubulavirus  
 106 were common; 1,314 of 1752 adult bats were MenVsero+. Antibodies against Nipah virus or filovirus  
 107 were less common – 1,031 were NiVsero+ and 921 were EbVsero+. Among the 921 juveniles, 192 were  
 108 MenVsero+, 311 were NiVsero+ and 348 were EbVsero+. Of the 122 pre-weaned juveniles, 43 were  
 109 MenVsero+, 52 were NiVsero+, and 32 were EbVsero+.

110 Co-exposure to multiple viruses was common (Figure 2). Over half (1,173) of the 1752 adults had  
 111 antibodies against more than one of the three viruses, and 493 had antibodies against all three.  
 112 Among the 921 juveniles, 210 had antibodies against more than one, and 39 had antibodies all three.  
 113 38 of 122 pre-weaned juveniles had more than one of the three antibodies, with seven having all three.

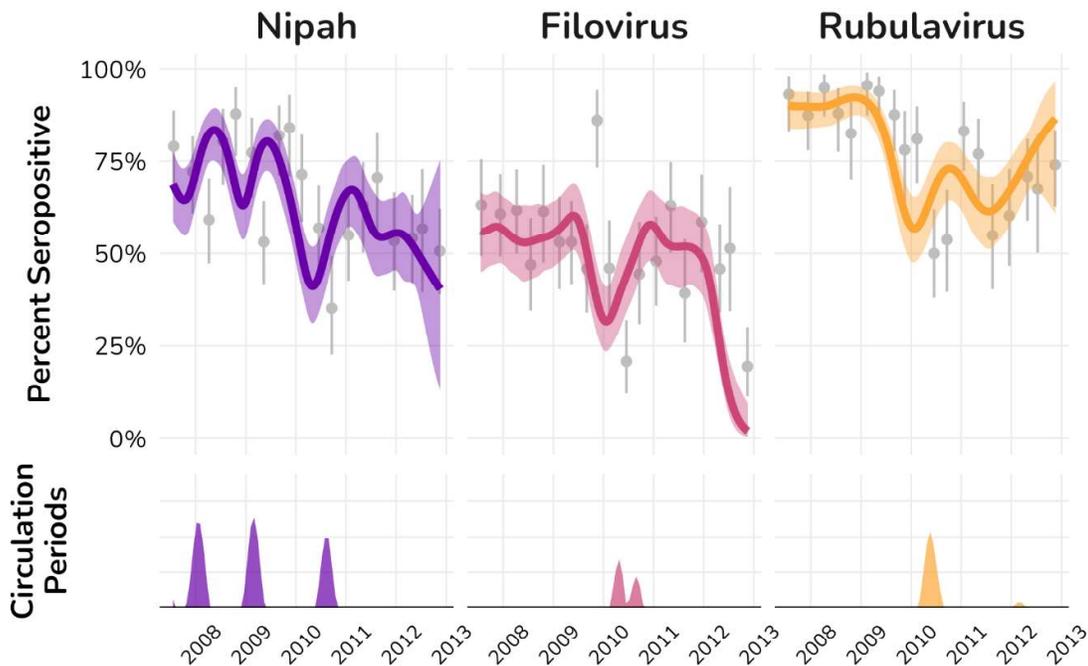

114 We found correlations **between** serostatus between all three pairs of viruses in a model  
 115 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other  
 116 more than would be expected than if they were distributed independently among bats. Nipah virus  
 117 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).  
 118 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of  
 119 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had a covariance of 0.23 (0.17-0.29).

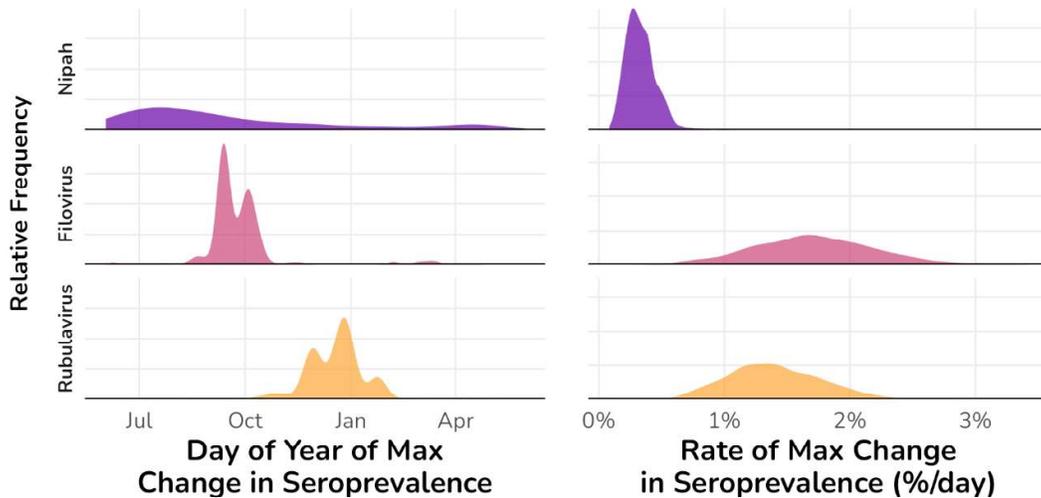

120 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn  
 121 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,  
 122 filovirus, and Rubulavirus. Numbers under labels are counts of bats with only those viruses, numbers  
 123 in overlapping areas represent number of bats detected with multiple viruses.

124 *Serodynamics*

125 Dynamics of population seroprevalence were different across the viral types. In adults,  
 126 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)  
 127 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-  
 128 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very  
 129 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in in [Epstein, et al. 34](#)).  
 130

131  
 132 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population  
 133 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey  
 134 points and bars represent measured population seroprevalence from individual sampling events on  
 135 and 95% exact binomial confidence intervals. Thick lines and shaded areas represent the inter-annual  
 136 (non-seasonal) spline component of a generalized additive mixed model (GAMM) of serodynamics  
 137 and 95% confidence intervals for the mean pattern over time. Bottom: Circulation periods, when  
 138 modeled slopes of the [GAMM splines](#) are positive for >95% of 1000 draws from the model posterior.

139

140

143

**Figure 4. Timing and strength of seasonality of viral circulation in adults.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left), and the rate of increase (right), for adult bats, drawn from GAMM models of seasonality. Densities are of these quantities derived from 1000 samples of model posteriors.

144

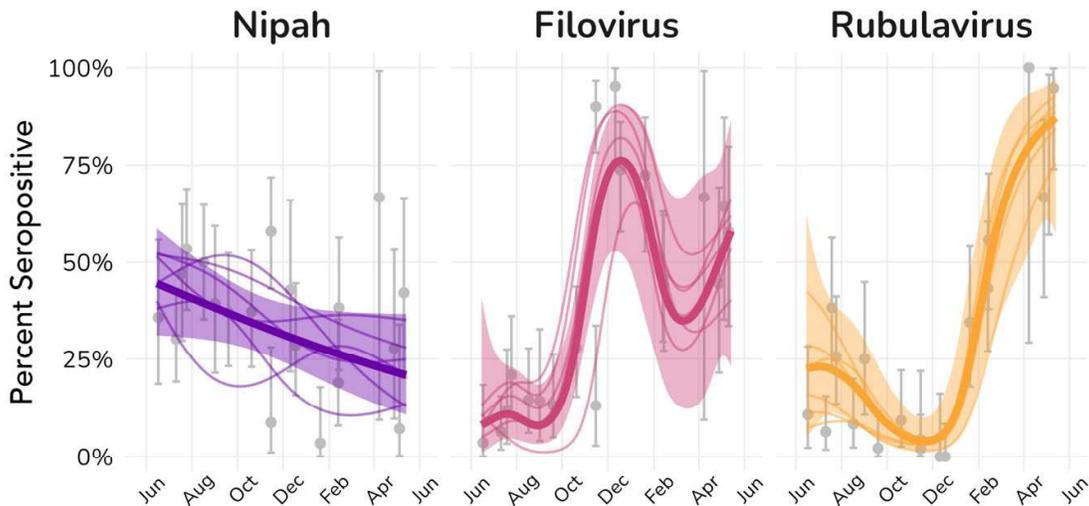

145

146

147

148

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

149

150

151

152

153

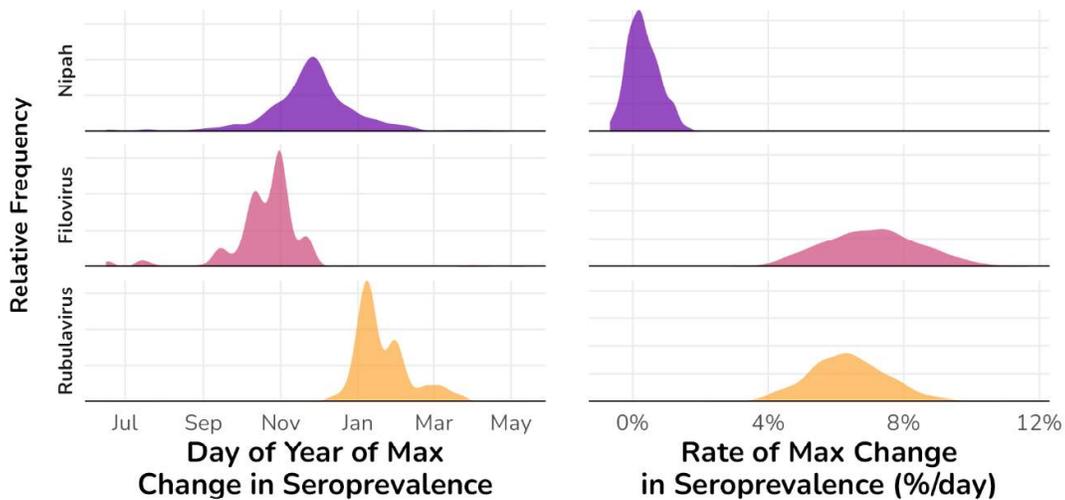

154

155

156

157

**Figure 5. Serodynamics in juvenile bats in five-year study.** Measured and modeled population seroprevalence in juvenile bats caught over their first year of life. Sampling events from multiple years are transposed onto a single year starting June (the earliest month free-flying young-of-the-year juveniles were captured). X-axis ticks mark the first day of each month. Grey points and bars represent measured population seroprevalence from individual sampling events on and 95% exact binomial confidence intervals. Thick lines and shaded areas represent GAMM-modeled average serodynamics across all years and 95% confidence intervals for the mean effect. Thin lines represent individual-year deviations from the average year pattern.

158

159 **Figure 6. Timing and strength of seasonality of viral circulation in juveniles over the five-year**  
 160 **study.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left),  
 161 and the rate of increase (right), for juvenile bats. Densities are of these quantities derived from 1000  
 162 samples of model posteriors.

163 Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against  
 164 filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus  
 165 seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had  
 166 periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah  
 167 virus) (Fig. 3). filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

168 Among juveniles within the average year, filovirus seroprevalence started very low in June at  
 169 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age  
 170 before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it  
 171 consistently occurred in December or January. The average date with the greatest rate of  
 172 seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day  
 173 (4.5%/day-9.9%/day).

174 Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus  
 175 seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74%  
 176 (62%-84%), though there were some temporary periods of decline. There were distinct periods of  
 177 increasing circulation in early 2010 and early 2012. Only for the rubulavirus did adult seroprevalence  
 178 exhibit patterns of seasonality. Periods of increasing seroprevalence in adults exhibited strong  
 179 seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean peak date  
 180 occurring on Dec 15 (Oct 15-Feb 1)

181 In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in  
 182 the youngest bats in June, though in individual years this could range from 7%-43%. In all years  
 183 juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec  
 184 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%) The  
 185 peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and occurred  
 186 Jan 9 (Dec 21-Mar 16).

187 *Spatial Comparisons*

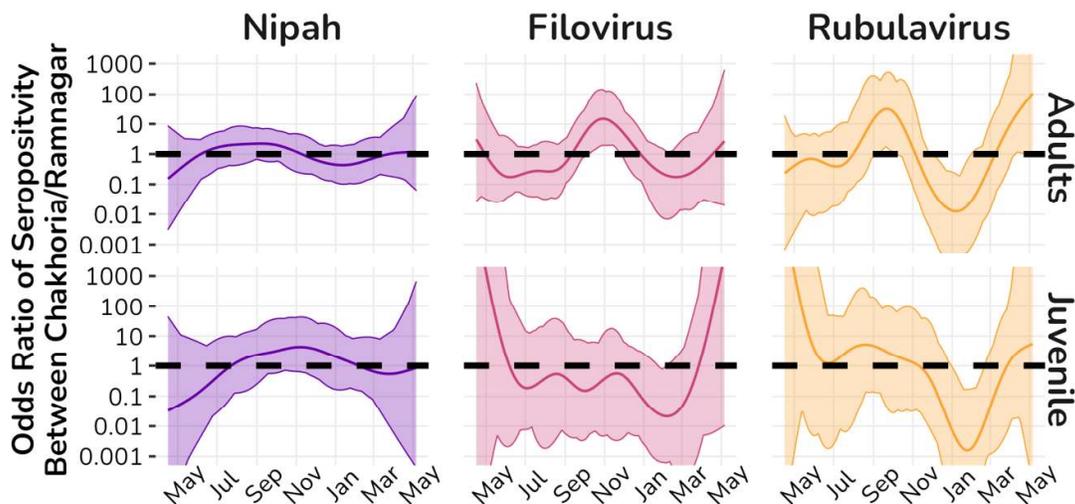

188 Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria  
 189 and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2).  
 190 In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of  
 191 April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

192 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-61%) in April 2010, rising to  
193 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over  
194 the same period. The trend in juveniles was as described for the five-year study.

195 For the filovirus, the seroprevalence in the one-year studies was higher than the reported  
196 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-  
197 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of  
198 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the  
199 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the  
200 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,  
201 there were two periods of increasing seroprevalence in adults over the course of the year. The first of  
202 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August  
203 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the  
204 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)  
205 between early March 2011 to late April 2011.

206 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from  
207 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in  
208 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December  
209 2010/January 2011 in Chakhoria. These decreases were followed by rapid increases back to high  
210 seroprevalence, coincident with increasing levels in juveniles. The pattern in juveniles was as  
211 described in the five-year study, with seroprevalence estimates in yearlings in April 2011 of 80%  
212 (28%-99%) in both locations.

213 Comparison of the seroprevalence trends within each age group and virus between the two one-  
214 year study locations did not support spatial differences in the timing of changes in seroprevalence  
215 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between  
216 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at  
217 the end of 2010.

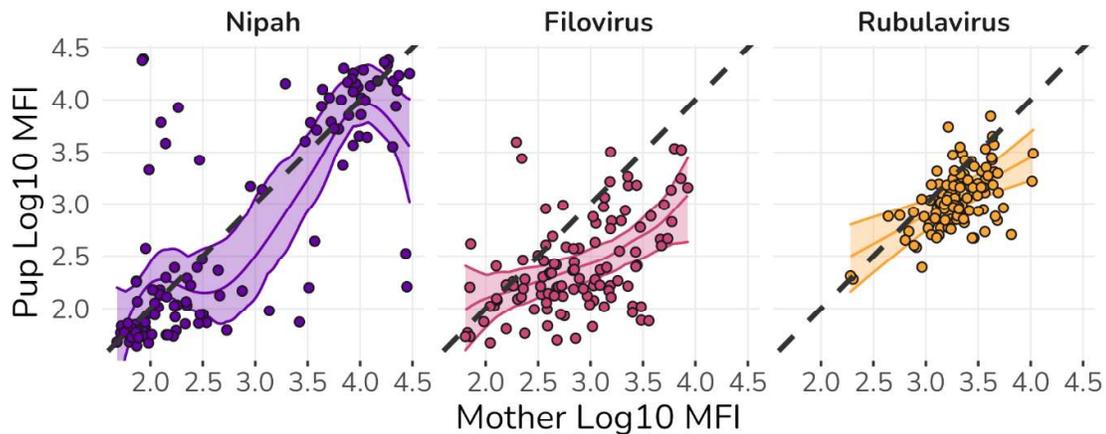

218  
219 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**  
220 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference  
221 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.  
222 Where the confidence interval excludes zero, there is evidence for a significant difference in the  
223 serodynamics between the Ramnagar and Chakhoria populations over that period.

#### 224 *Maternal Inheritance of antibodies*

225 We examined the relationship between mother and pup antibody titers, as measured by our  
226 Luminex assays (see Methods). This relationship varied between viruses (Figure 7). For Nipah virus,

227 the relationship was nonlinear due to clustering at high and low values, but largely followed a 1:1  
228 relationship between mother and pup antibody titers. For the rubulavirus the relationship was near-  
229 linear and near 1:1. For the filovirus, though, the relationship between MFI values measured in  
230 mothers and their pups fell well below the 1:1 line, indicating pups having low inheritance of  
231 antibodies against the filovirus relative to the other two viruses.

232

233 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for  
234 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the  
235 predicted mean relationship between the two and their associated 95% confidence intervals.

### 236 3. Discussion

237 We found serological evidence for regular circulation of multiple viruses in *P. medius*  
238 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to  
239 humans in the region, as well as a filovirus and a Rubulavirus. It was common for bats to have  
240 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity  
241 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance  
242 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types  
243 being positively correlated within bats.

244 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The  
245 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations  
246 inherit maternal antibodies against the Rubulavirus, which wane over the first six months of their  
247 life, after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in  
248 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the  
249 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence  
250 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating  
251 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of  
252 the rubulavirus to be strongest in the late winter and early spring months in these populations.  
253 Mortlock et al.<sup>39</sup> found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via  
254 PCR detection in pooled urine samples), including a peak during a period of presumed antibody  
255 waning, though only within a one-year study.

256 An outstanding question is how the rubulavirus is maintained in the population despite high  
257 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent  
258 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*<sup>40</sup>, Hendra virus in  
259 *P. Medius*<sup>41</sup>, and Lagos bat lyssavirus and African henipavirus in *Eidolon helvum*<sup>42</sup>. Another possibility  
260 is re-importation. In concurrent work with this study, we found that bat home ranges overlapped

261 with nearby colonies so as to form a meta-population<sup>34</sup>, allowing occasional infection from outside  
262 bats, as has been shown to maintain Hendra virus in *Pteropus* populations<sup>43,44</sup>.

263 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle  
264 virus, which has been found in *P. medius* in Australia<sup>45,46</sup>. At least 11 distinct Paramyxoviruses have  
265 been found in *P. medius* in Bangladesh alone: Nipah virus and ten uncharacterized species, including  
266 six Rubulaviruses closely related to Menangle virus and the Tioman virus<sup>9,47</sup>. It is possible that the  
267 serological patterns observed represent antibodies against a complex of multiple Rubulaviruses,  
268 though the regular interannual patterns in seroprevalence would indicate that they are operating  
269 similarly.

270 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with  
271 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some  
272 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup  
273 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults  
274 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,  
275 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah  
276 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by  
277 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years<sup>28</sup>.  
278 Human Nipah virus outbreaks in Bangladesh, on the other hand, exhibit seasonality associated with  
279 the palm-sap consumption, the most likely spillover mechanism<sup>48</sup>.

280 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-Zaire  
281 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have  
282 been found in *R. leschenaultii* in the country<sup>49</sup>. This could be one of several known filoviruses or an  
283 unknown species. There have been several recent findings of new Ebola-like filoviruses in bats  
284 extending across Africa and Asia. These include Bombali virus in Sierra Leone<sup>50</sup>, and Mënglà virus  
285 in *Rousettus* bats in China<sup>51</sup>. Ebola-Reston virus was found in multiple bat species (*M. australis*, *C.*  
286 *brachyotis* and *Ch. plicata*) in the Philippines<sup>52</sup>. Marburg virus and Ebola-Zaire virus may have been  
287 detected in Sierra Leone and Liberia (unpublished,<sup>53,54</sup>). Serological evidence of filoviruses in bats has  
288 been found in multiple bat species in Central<sup>12,55</sup> and Western<sup>56</sup> African countries, Singapore<sup>57</sup>,  
289 China<sup>58</sup>, as well as Trinidad<sup>59</sup>. Our finding here adds to the evidence of broad host and geographic  
290 host ranges for filoviruses.

291 Several components of the serological patterns of filovirus antibodies are of interest. Young  
292 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months  
293 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite  
294 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult  
295 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period  
296 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase  
297 among juveniles. One possible hypothesis explaining this pattern is that the filovirus may exhibit low  
298 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.  
299 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain  
300 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was  
301 found to be rapid, but bats retained protective immunity even with very low antibody titers<sup>60,61</sup>. If a  
302 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite  
303 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles  
304 following the peak is consistent with this explanation.

305 However, if adults remain immune to the filovirus despite low antibody titers, this immunity  
306 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and  
307 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the  
308 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly  
309 differential maternally derived immunity. If pups derive weaker immunity from dams than for other  
310 viruses, this may provide another mechanism for maintenance of the virus. It possible that patterns  
311 in filovirus antibody detection are an artifact of our test, specific to Ebola-Zaire virus, and that  
312 temporal trends are in part reflective of differential cross-reaction with viruses in this bat population.

313 However, while this may modify estimates of overall seroprevalence, the differential pup/dam MFI  
314 relationship, and consistent rise in seroprevalence among young juveniles, would require the test to  
315 exhibit differential sensitivity by age.

316 Serodynamics in our two one-year studies were broadly similar to those found in the five-year  
317 study. We found weak evidence for differences in serodynamics between sites for the filovirus in  
318 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the  
319 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study<sup>34</sup>,  
320 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their  
321 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are approximately 225  
322 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible  
323 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or  
324 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple  
325 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

326 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-  
327 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from  
328 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or  
329 transmission, via competition for host nutritional or cellular resources, or via immune-mediation  
330 involving cross-immunity or antibody-dependent enhancement, and these interactions structure  
331 viral communities<sup>26</sup>. These interactions can have complex, even opposite effects when scaled to the  
332 population<sup>27</sup>. Here, we found positive correlations between serostatus against different viruses.  
333 External factors may also affect these relationships. For instance, all three viruses appear to have  
334 circulated in adults in mid-2010. It is possible that common factors like population density and/or  
335 nutrition availability<sup>62</sup> affected transmission of multiple viruses.

336 While rich observational serological data reveal these patterns, greater study is required to  
337 characterize these viruses and their effects on the host population and potential for spillover, as well  
338 as the degree and mechanisms of interactions. Our inferred periods of viral circulation point to  
339 optimal sub-populations and times to sample this population to detect viral shedding and isolate  
340 these viruses, and potentially capture co-infected hosts.

341 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term  
342 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and  
343 shedding, but establishing patterns or variation in seasonality requires extended, multi-year  
344 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was  
345 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The  
346 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.  
347 Similarly, we were able to understand these patterns far better by separating juvenile and adult  
348 patterns, which we would be unable to distinguish in pooled samples.

349 While such extended individual-capture longitudinal studies are resource-intensive,  
350 understanding the joint circulation of multiple viruses can be accomplished via multiplex  
351 immunoassays such as those used here. The continuous measures from these assays also have the  
352 potential to identify key patterns such as the differential inheritance of filovirus antibodies we  
353 identified here. Interpretation of these values is challenging and the relationship between immune  
354 status, antibody titer, and measured fluorescence is complex<sup>32</sup>, but they have much potential to shed  
355 light on mechanistic drivers of disease circulation.

## 356 **Methods**

### 357 *Field collection*

358 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-  
359 year studies in different locations, sampling monthly. All capture and sampling methods were  
360 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol  
361 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as  
362 previously described in Epstein, et al.<sup>34</sup> The area of the roost complex consists of patchy forest

363 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July  
364 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst  
365 roosts within the 80km<sup>2</sup> roost complex over the period of the study. Sampling occurred at the largest  
366 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex  
367 across consecutive sampling nights if required to capture a sufficient number of individuals.

368 Approximately 100 bats were captured at each sampling event, which lasted 7-10 days. We  
369 captured bats with a 10x15m mist net between 11pm and 5am each night as bats returned from  
370 foraging until the count of 100 was reached.

371 In the one-year longitudinal studies, sampling was undertaken in two roost complexes in  
372 Ramnagar and Chakhoria, Bangladesh between April 2010 and May 2011. Monthly sampling of  
373 approximately 40 bats in each location was performed to obtain data at a finer temporal scale. Details  
374 of collection are otherwise as described for the five-year study.

375 For each study, we recorded each bat's age class, reproductive status, weight, size, and body  
376 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with  
377 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box  
378 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and  
379 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton  
380 Cryogenics, NJ, USA).

381 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal  
382 swabs and pooled urine samples from under colonies. Further details can be found in [Epstein, et al.](#)  
383 [34](#)

#### 384 *Serological Assays*

385 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and  
386 gamma irradiated upon receipt. We used a bead-based microsphere assay that specifically detects  
387 antibodies to the soluble attachment glycoproteins<sup>57,63,64</sup> for a panel of viruses. Beads coated with each  
388 protein were mixed with sera at a dilution of 1:100. Biotinylated Protein A/G and Streptavidin-PE  
389 were then used to detect bound antibody. Beads were interrogated by lasers in a BioRad BioPlex  
390 machine and the results recorded as the Median Fluorescent Intensity (MFI) of 100 beads. We report  
391 here results for Nipah, Ebola-Zaire, and Menangle, the only three for which we established regular  
392 positive results.

393 While the Nipah virus has been detected in this population<sup>65</sup> and the specificity of the Nipah test  
394 is well-established<sup>66</sup>, the Ebola-Zaire and Menangle virus tests are cross-reactive with other Ebola  
395 and rubulavirus species<sup>67,68</sup>. Thus we refer to these as tests for filovirus and Rubulavirus.

#### 396 *Data Analysis*

397 We determined individual bat serostatus using Bayesian mixture models<sup>69</sup> fit on pooled data  
398 across all three longitudinal studies, calculating a cutoff of log-MFI as the point of equal probability  
399 between the smallest and second-smallest cluster of equal distributions for each assay.

400 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian  
401 multivariate probit model<sup>70,71</sup> which allows estimation of the joint outcomes (serostatus against each  
402 virus) and the correlation between the outcomes. We included age and sex variables to account for  
403 these effects on serostatus.

404 To examine time-varying changes in population seroprevalence, we fit binomial generalized  
405 additive mixed models (GAMMs)<sup>72,73</sup> to the time-series of serostatus measurements. For the five-year  
406 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit  
407 a model for seroprevalence dynamics over the course of the whole study. This treats the adult  
408 population as a single unit, though individuals within the population may turn over via migration,  
409 death and recruitment. We included both long-term and annual cyclic components for the multi-year  
410 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate  
411 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile  
412 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles

413 over their first year. To estimate periods of peak viral circulation within the population, we calculated  
414 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior  
415 distributions and classified periods with >95% of samples with positive derivatives - that is,  
416 increasing population seroprevalence - as periods of viral circulation. We also calculated strength  
417 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date  
418 at which this maximum occurred, again sampling these values from the model posterior, and  
419 calculating mean and high-density posterior interval (HDPI) values.

420 For the one-year studies, we fit models primarily to detect differences in time-varying changes  
421 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus  
422 measurements with separate models for each immunoassay. We included a separate, fixed-term  
423 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in  
424 serodynamics for each virus in each age group were compared between locations to test for spatial  
425 differences<sup>74</sup>. Juveniles identified as being from the previous year's cohort were excluded from the  
426 analysis.

427 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI  
428 between adult lactating females and their attached pups for each viral assay. We limited these to data  
429 from the five-year longitudinal study.

430 **Data Availability:** Raw data from this study and reproducible code used to perform analyses is available at the  
431 Zenodo Scientific Archive [Zenodo DOI to be generated] and also on GitHub at  
432 <https://github.com/ecohealthalliance/bangladesh-bat-serodynamics>

Sorry to be late to the party – a few more comments attached to add to the insightful suggestions you've already received.

Jon – still think it would be great to link up so we can describe antibody dynamics over time in our recaptures!

Have a great weekend,  
Emily

Noam and Jon,

Attached are my edits and comments. I started working on this using the version from Hume and Linfa, so my version here does not include Steve's valuable comments.

Great paper.

Cheers,  
Kevin

Hi Jon,

Thanks for sharing this interesting work. Kudos to Noam and the team for pulling all of this together.

Attached are my comments.

To reduce the amount of my time and improve the thoroughness of my review, I use error codes when I identify common errors within a scientific document. A full description of the error and strategies for addressing it can be found in a scientific writing guide written by Dorothy Southern and I (Pathway to Publishing-A Guide to Quantitative Writing in the Health Sciences) published as an Open Access ebook through Springer. It can be downloaded from here: <https://link.springer.com/book/10.1007/978-3-030-98175-4>

Colleagues,

I hope you're all doing well. I'm excited to share a draft manuscript, led by Noam, that details the serodynamics of henipaviruses, filoviruses and rubulaviruses in a population of *Pteropus medius*. We plan to submit this to *Nature Communications* in September. Please send Noam and I your comments by **September 10th**.

Cheers,  
Jon

**Abstract:** Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles and little circulation but lower seroprevalence amongst adults. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

**Keywords:** bats; Nipah virus; filovirus; Rubulavirus; *Pteropus medius*; Bangladesh; serology; disease dynamics; generalized additive models

## Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics<sup>1-3</sup>. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses<sup>4,5</sup> including close relatives of SARS-CoV-2<sup>6</sup>, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses<sup>1,2,7</sup>.

Bat species can carry diverse viruses which circulate simultaneously within single populations<sup>8-11</sup>. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire virus have also been detected in this bat in Central Africa, suggesting that it may play a role in the circulation of multiple filoviruses<sup>12,13</sup>. In addition to these filoviruses, a novel zoonotic and pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations<sup>14</sup>.

This seems an odd sentence to close with. The last sentence is usually a conclusion, but I can't see how the data presented in the abstract supports this conclusion.

---

Number: 5 Author: Steve Luby Date: 9/2/2022 9:36:00 AM  
True, but since the new data presented here don't address this issue, I don't see this as central to the introduction, i.e. Error 3.12

---

46 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to  
47 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity<sup>15</sup>. Various  
48 surveillance efforts have found diverse viruses from within the same viral family in various bat  
49 species<sup>5,16,17</sup>, and other studies have used metagenomic approaches to look broadly at viral diversity  
50 within individual bat species<sup>9,11,18-21</sup>.

51 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of  
52 viruses and their relationships to specific hosts<sup>5,22</sup> and inform public health strategies<sup>23</sup>. However,  
53 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated  
54 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or  
55 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other  
56 species, including domestic animals and humans<sup>24</sup>. For these, more detailed demographic and  
57 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect  
58 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics<sup>25-27</sup>.  
59 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral  
60 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been  
61 observed to have annual shedding patterns<sup>28</sup>, whereas Hendra virus, which is closely related to Nipah  
62 virus and is carried by multiple pteropodid bat species in Australia, has asynchronous and non-periodic  
63 cycles which appear to be influenced by localized factors such as specific bat species abundance and  
64 climatic factors<sup>29</sup>. Bi-annual pulses of Marburg virus shedding were observed in Uganda, coinciding  
65 with synchronous birth pulses in *R. aegyptiacus*<sup>30</sup>. Serological data is often valuable in understanding  
66 disease dynamics and transmission<sup>31-33</sup>, especially in cases where direct detection and incidence rates  
67 of viruses are low<sup>34</sup>.

68 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, lethal<sup>1</sup> neurotropic  
69 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus<sup>35-37</sup>. In Bangladesh and India,  
70 *P. medius* is a reservoir of Nipah virus, which has spilled over to human populations repeatedly<sup>38</sup>.  
71 Viruses from eight other viral families have been detected in *P. medius* in Bangladesh<sup>9</sup>. The  
72 epidemiology of these other viruses is far less characterized, and little is known about their  
73 interactions or zoonotic potential.

74 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,  
75 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in  
76 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-  
77 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of  
78 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral  
79 circulation. We<sup>2</sup> find that Nipah virus circulates primarily among adults without distinct seasonality,  
80 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by  
81 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also  
82 circulated in juveniles but exhibited distinct patterns of antibody waning and limited maternal  
83 inheritance.

## 84 2. Results

### 85 *Bat Dynamics and Demographics*<sup>3</sup>

86 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly from a roost  
87 complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies sampling bats  
88 monthly from roosts in Chakhoria and Ramnagar, Bangladesh. In the five-year study, we sampled  
89 and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39 weaning juveniles  
90 (captured attached to adult females) over 19 sampling events (Figure 1). During the one-year studies,  
91 919 bats were sampled: 435 in Chakhoria (251 adults, 144 free-flying juveniles and 40 weaning  
92 juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning juveniles (Figure  
93 S1). Nearly all juveniles (as determined by examination of maturation of sex organs) were 14 months  
94 old or less and could be assigned to a birth cohort based on size. Pregnant and juvenile bats were  
95 captured more frequently during the late spring and summer months. Mother-pup pairs were all

it would be helpful to clarify how far apart these places are, as you have a considerable section exploring spatial comparisons.

---

96 captured during April and May in the five-year study whilst in the one-year-studies a small number  
 97 were also captured in June and July. Pregnant females were captured between November and  
 98 April/May. Lactating females were found between April and July.  
 99

100 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured  
 101 in months from November to June, lactating females were captured in months from April to July.  
 102 Females with pre-weaning juveniles attached were found from April to May.

103 *Patterns of Immunity and Co-immunity*

104 We found bats were seropositive for antibodies against the henipavirus (HenipVsero+), a  
 105 filovirus (EbVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the  
 106 rubulavirus were common; 1,314 of 1752 adult bats were MenVsero+. Antibodies against Nipah virus  
 107 or filovirus were less common – 1,031 were NiVsero+ and 921 were EbVsero+. Among the 921  
 108 juveniles, 192 were MenVsero+, 311 were NiVsero+ and 348 were EbVsero+. Of the 122 pre-weaned  
 109 juveniles, 43 were MenVsero+, 52 were NiVsero+, and 32 were EbVsero+.

110 Co-exposure to multiple viruses was common (Figure 2). Over half (1,173) of the 1752 adults had  
 111 antibodies against more than one of the three viruses, and 493 had antibodies against all three.  
 112 Among the 921 juveniles, 210 had antibodies against more than one, and 39 had antibodies all three.  
 113 38 of 122 pre-weaned juveniles had more than one of the three antibodies, with seven having all three.

114 We found correlations between serostatus between all three pairs of viruses in a model  
 115 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other  
 116 more than would be expected than if they were distributed independently among bats. Nipah virus  
 117 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).  
 118 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of  
 119 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had a covariance of 0.23 (0.17-0.29).

---

Number: 1 Author: Wang Linfa Date: 8/21/2022 10:48:00 AM

I think it is better to treat the three group of viruses equally as you have done for the title. It makes no difference whether we use NiV or Henipavirus in the context of the current study. Luminex-based assays targeting binding antibodies will in theory detect cross-RX antibodies in all three cases. See also comments in Methods

Include percentages for all of these comparisons.

---

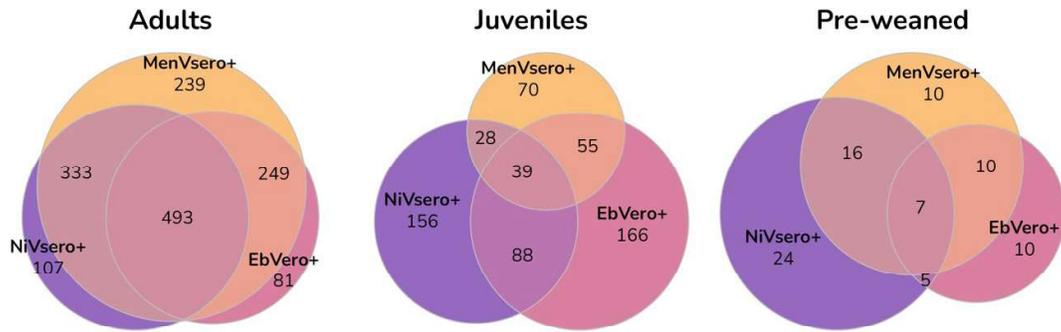

Number: 3 Author: Steve Luby Date: 9/2/2022 10:03:00 AM

Again, including percentages for all of these comparisons would make this much easier to understand.

---

Number: 4 Author: Steve Luby Date: 9/2/2022 10:03:00 AM

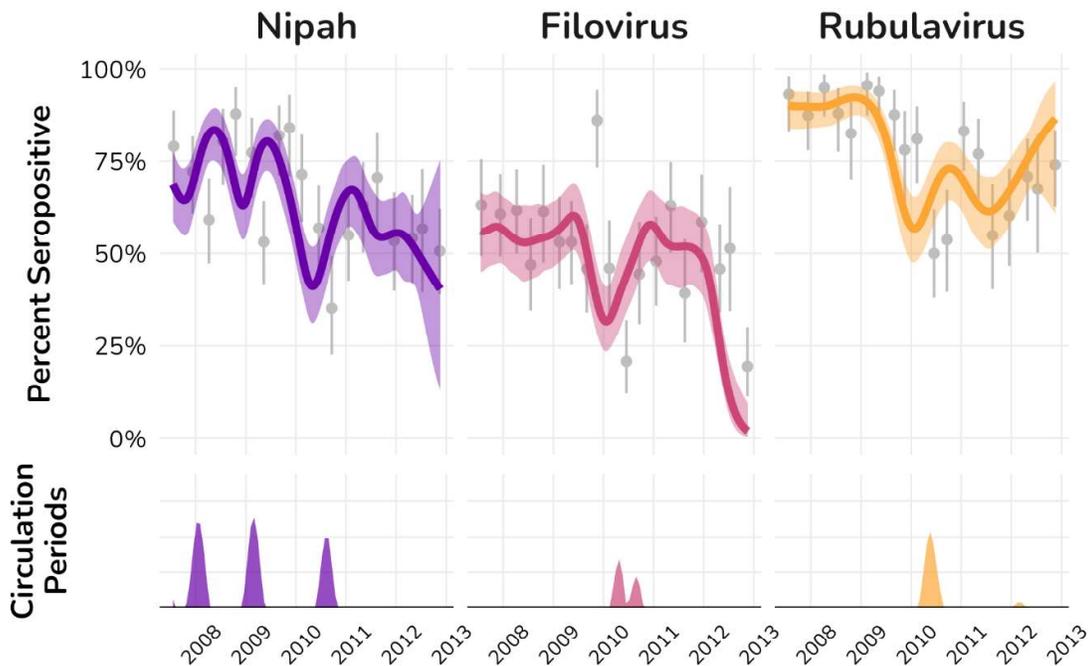

I did not see this described in the methods section.

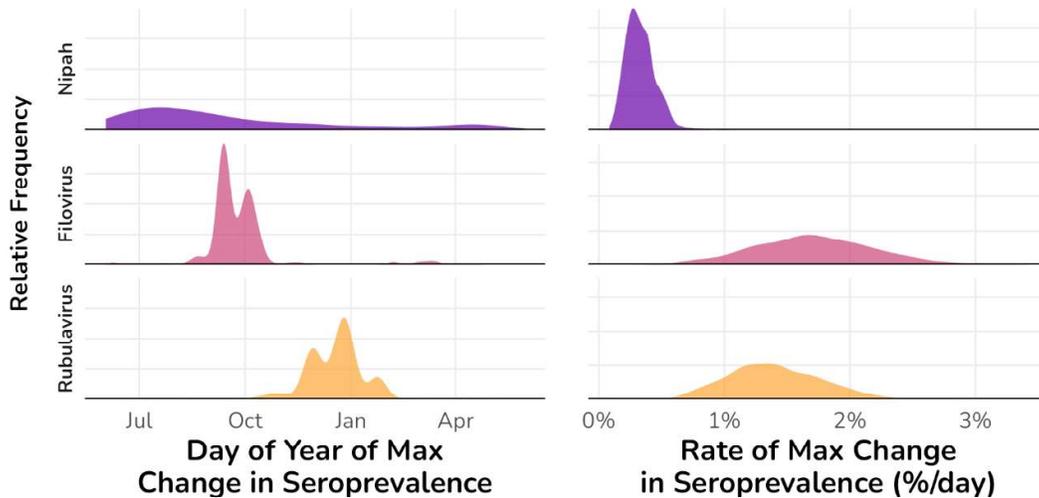

120 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn  
 121 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,  
 122 filovirus, and Rubulavirus. Numbers under labels are counts of bats with only those viruses, numbers  
 123 in overlapping areas represent number of bats detected with multiple viruses.

124 *Serodynamics*

125 Dynamics of population seroprevalence were different across the viral types. In adults,  
 126 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)  
 127 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-  
 128 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very  
 129 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in [Epstein, et al. 34](#)).  
 130

131  
 132 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population  
 133 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey  
 134 points and bars represent measured population seroprevalence from individual sampling events on  
 135 and 95% exact binomial confidence intervals. Thick lines and shaded areas represent the inter-annual  
 136 (non-seasonal) spline component of a generalized additive mixed model (GAMM) of serodynamics  
 137 and 95% confidence intervals for the mean pattern over time. Bottom: Circulation periods, when  
 138 modeled slopes of the [GAMM splines](#) are positive for >95% of 1000 draws from the model posterior.

147

148

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

 Number: 1      Author: Steve Luby      Date: 9/2/2022 10:18:00 AM  
What is the y axis for these curves?

158

159 **Fig 6. Timing and strength of seasonality of viral circulation in juveniles over the five-year**  
 160 **study.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left),  
 161 and the rate of increase (right), for juvenile bats. Densities are of these quantities derived from 1000  
 162 samples of model posteriors.

163 Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against  
 164 filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus  
 165 seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had  
 166 periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah  
 167 virus) (Fig. 3). filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

168 Among juveniles within the average year, filovirus seroprevalence started very low in June at  
 169 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age  
 170 before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it  
 171 consistently occurred in December or January. The average date with the greatest rate of  
 172 seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day  
 173 (4.5%/day-9.9%/day).

174 Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus  
 175 seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74%  
 176 (62%-84%), though there were some temporary periods of decline. There were distinct periods of  
 177 increasing circulation in early 2010 and <sup>2</sup>early 2012. Only for the rubulavirus did adult seroprevalence  
 178 exhibit patterns of seasonality. Periods of increasing seroprevalence in adults exhibited strong  
 179 seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean peak date  
 180 occurring on Dec 15 (Oct 15-Feb 1)

181 In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in  
 182 the youngest bats in June, though in individual years this could range from 7%-43%. In all years  
 183 juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec  
 184 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%) The  
 185 peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and occurred  
 186 Jan 9 (Dec 21-Mar 16).

187 *Spatial Comparisons*

188 Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria  
 189 and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2).  
 190 In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of  
 191 April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

## Page: 6

As above. What is the y axis?

---

Number: 2 Author: Steve Luby Date: 9/2/2022 10:22:00 AM  
Is this appropriate to call out when it is not identified by the GAMM splines?

---

Number: 3 Author: Steve Luby Date: 9/2/2022 10:24:00 AM  
Consider including a figure in the appendix that illustrates this.

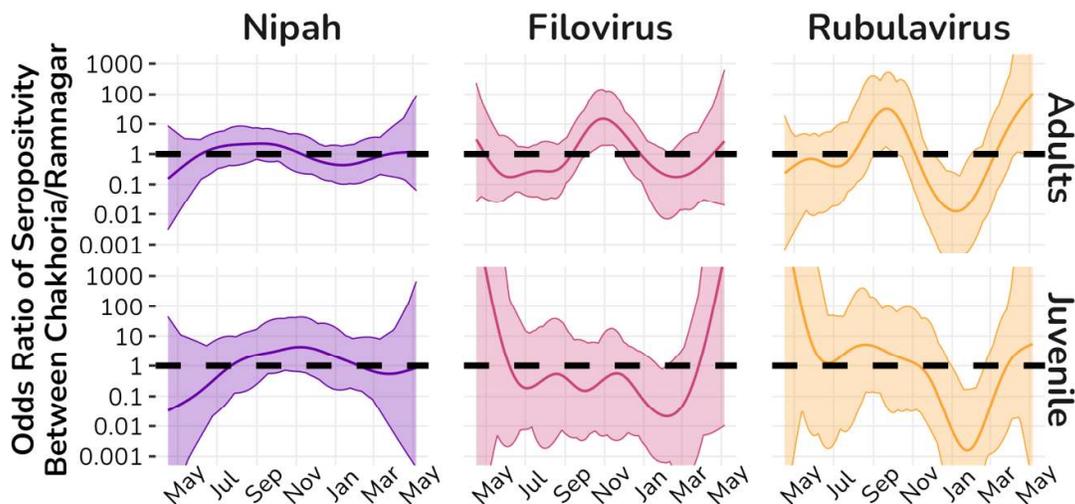

---

192 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-61%) in April 2010, rising to  
193 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over  
194 the same period. The trend in juveniles was as described for the five-year study.

195 For the filovirus, the seroprevalence in the one-year studies was higher than the reported  
196 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-  
197 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of  
198 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the  
199 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the  
200 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,  
201 there were two periods of increasing seroprevalence in adults over the course of the year. The first of  
202 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August  
203 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the  
204 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)  
205 between early March 2011 to late April 2011.

206 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from  
207 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in  
208 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December  
209 2010/January 2011 in Chakhoria. These decreases were followed by rapid increases back to high  
210 seroprevalence, coincident with increasing levels in juveniles. The pattern in juveniles was as  
211 described in the five-year study, with seroprevalence estimates in yearlings in April 2011 of 80%  
212 (28%-99%) in both locations.

213 Comparison of the seroprevalence trends within each age group and virus between the two one-  
214 year study locations did not support spatial differences in the timing of changes in seroprevalence  
215 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between  
216 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at  
217 the end of 2010.

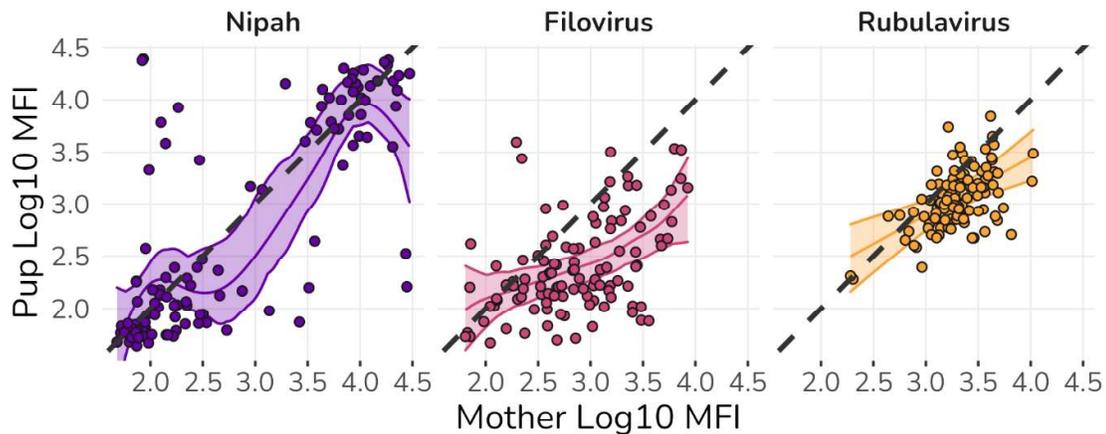

218  
219 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**  
220 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference  
221 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.  
222 Where the confidence interval excludes zero, there is evidence for a significant difference in the  
223 serodynamics between the Ramnagar and Chakhoria populations over that period.

#### 224 *Maternal Inheritance of antibodies*

225 We examined the relationship between mother and pup antibody titers, as measured by our  
226 Luminex assays (see Methods). This relationship varied between viruses (Figure 7). For Nipah virus,

227 the relationship was nonlinear due to clustering at high and low values, but largely followed a 1:1  
228 relationship between mother and pup antibody titers. For the rubulavirus the relationship was near-  
229 linear and near 1:1. For the filovirus, though, the relationship between MFI values measured in  
230 mothers and their pups fell well below the 1:1 line, indicating pups having low inheritance of  
231 antibodies against the filovirus relative to the other two viruses.

232

233 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for  
234 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the  
235 predicted mean relationship between the two and their associated 95% confidence intervals.

### 236 3. Discussion

237 We found serological evidence for regular circulation of multiple viruses in *P. medius*  
238 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to  
239 humans in the region, as well as a filovirus and a rubulavirus. It was common for bats to have  
240 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity  
241 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance  
242 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types  
243 being positively correlated within bats.

244 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The  
245 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations  
246 inherit maternal antibodies against the rubulavirus, which wane over the first six months of their life,  
247 after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in  
248 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the  
249 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence  
250 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating  
251 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of  
252 the rubulavirus to be strongest in the late winter and early spring months in these populations.  
253 Mortlock et al.<sup>39</sup> found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via  
254 PCR detection in pooled urine samples), including a peak during a period of presumed antibody  
255 waning, though only within a one-year study.

256 An outstanding question is how the rubulavirus is maintained in the population despite high  
257 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent  
258 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*<sup>40</sup>, Hendra virus in  
259 *P. alecto* and *P. poliocephalus*<sup>41</sup>, and Lagos bat lyssavirus and African henipavirus in *Eidolon helvum*<sup>42</sup>.  
260 Another possibility is re-importation. In concurrent work with this study, we found that bat home

261 ranges overlapped with nearby colonies so as to form a meta-population<sup>34</sup>, allowing occasional  
262 infection from outside bats, as has been shown to maintain Hendra virus in *Pteropus* populations<sup>43,44</sup>.

263 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle  
264 virus, which has been found in multiple *Pteropus* species in Australia<sup>45,46</sup>. At least 11 distinct  
265 Paramyxoviruses have been found in *P. medius* in Bangladesh alone: Nipah virus and ten  
266 uncharacterized species, including six Rubulaviruses closely related to Menangle virus and the  
267 Tioman virus<sup>9,47</sup>. It is possible that the serological patterns observed represent antibodies against a  
268 complex of multiple Rubulaviruses, though the regular interannual patterns in seroprevalence would  
269 indicate that they are operating similarly.

270 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with  
271 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some  
272 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup  
273 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults  
274 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,  
275 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah  
276 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by  
277 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years<sup>28</sup>.  
278 Human Nipah virus outbreaks in Bangladesh, on the other hand, exhibit seasonality associated with  
279 the palm-sap consumption, the most frequently implicated spillover pathway<sup>48</sup>.

280 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-Zaire  
281 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have  
282 been found in *R. leschenaultii* in the country<sup>49</sup>. This could be one of several known filoviruses or an  
283 unknown species. There have been several recent findings of new Ebola-like filoviruses in bats  
284 extending across Africa and Asia. These include Bombali virus in Sierra Leone<sup>50</sup>, and Mënglà virus  
285 in *Rousettus* bats in China<sup>51</sup>. Ebola-Reston virus was found in multiple bat species (*M. australis*, *C.*  
286 *brachyotis* and *Ch. plicata*) in the Philippines<sup>52</sup>. Marburg virus and Ebola-Zaire virus may have been  
287 detected in Sierra Leone and Liberia (unpublished,<sup>53,54</sup>). Serological evidence of filoviruses in bats has  
288 been found in multiple bat species in Central<sup>12,55</sup> and Western<sup>56</sup> African countries, Singapore<sup>57</sup>,  
289 China<sup>58</sup>, as well as Trinidad<sup>59</sup>. Our finding here adds to the evidence of broad host and geographic  
290 host ranges for filoviruses.

291 Several components of the serological patterns of filovirus antibodies are of interest. Young  
292 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months  
293 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite  
294 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult  
295 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period  
296 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase  
297 among juveniles. One possible hypothesis explaining this pattern is that the filovirus may exhibit low  
298 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.  
299 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain  
300 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was  
301 found to be rapid, but bats retained protective immunity even with very low antibody titers<sup>60,61</sup>. If a  
302 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite  
303 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles  
304 following the peak is consistent with this explanation.

305 However, if adults remain immune to the filovirus despite low antibody titers, this immunity  
306 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and  
307 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the  
308 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly  
309 differential maternally derived immunity. If pups derive weaker immunity from dams than for other  
310 viruses, this may provide another mechanism for maintenance of the virus. It possible that patterns  
311 in filovirus antibody detection are an artifact of our test, specific to Ebola-Zaire virus, and that  
312 temporal trends are in part reflective of differential cross-reaction with viruses in this bat population.

---

Number: 1 Author: Hume Field Date: 8/24/2022 9:59:00 AM

And recently in Australia.  
Barr et al. J Gen Virol. 2022 Aug;103(8).  
doi: 10.1099/jgv.0.001785.

313 However, while this may modify estimates of overall seroprevalence, the differential pup/dam MFI  
314 relationship, and consistent rise in seroprevalence among young juveniles, would require the test to  
315 exhibit differential sensitivity by age.

316 Serodynamics in our two one-year studies were broadly similar to those found in the five-year  
317 study. We found weak evidence for differences in serodynamics between sites for the filovirus in  
318 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the  
319 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study<sup>34</sup>,  
320 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their  
321 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are <sup>1</sup>approximately 225  
322 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible  
323 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or  
324 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple  
325 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

326 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-  
327 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from  
328 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or  
329 transmission, via competition for host nutritional or cellular resources, or via immune-mediation  
330 involving cross-immunity or antibody-dependent enhancement, and these interactions structure  
331 viral communities<sup>26</sup>. These interactions can have complex, even opposite effects when scaled to the  
332 population<sup>27</sup>. Here, we found positive correlations between serostatus against different viruses.  
333 External factors may also affect these relationships. For instance, all three viruses appear to have  
334 circulated in adults in mid-2010. It is possible that common factors like population density and/or  
335 nutrition availability<sup>62</sup> affected transmission of multiple viruses.

336 While rich observational serological data reveal these patterns, greater study is required to  
337 characterize these viruses and their effects on the host population and potential for spillover, as well  
338 as the degree and mechanisms of interactions. Our inferred periods of viral circulation point to  
339 optimal sub-populations and times to sample this population to detect viral shedding and isolate  
340 these viruses, and potentially capture co-infected hosts.

341 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term  
342 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and  
343 shedding, but establishing patterns or variation in seasonality requires extended, multi-year  
344 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was  
345 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The  
346 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.  
347 Similarly, we were able to understand these patterns far better by separating juvenile and adult  
348 patterns, which we would be unable to distinguish in pooled samples. <sup>2</sup>

349 While such extended individual-capture longitudinal studies are resource-intensive,  
350 understanding the joint circulation of multiple viruses can be accomplished via multiplex  
351 immunoassays such as those used here. The continuous measures from these assays also have the  
352 potential to identify key patterns such as the differential inheritance of filovirus antibodies we  
353 identified here. Interpretation of these values is challenging and the relationship between immune  
354 status, antibody titer, and measured fluorescence is complex<sup>32</sup>, but they have much potential to shed  
355 light on mechanistic drivers of disease circulation.

## 356 **Methods**

### 357 *Field collection*

358 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-  
359 year studies in different locations, sampling monthly. All capture and sampling methods were  
360 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol  
361 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as  
362 previously described in Epstein, et al. <sup>34</sup> The area of the roost complex consists of patchy forest

---

Number: 1 Author: Steve Luby Date: 9/2/2022 10:41:00 AM

As noted above, this important detail needs to be mentioned sooner.

---

Number: 2 Author: Steve Luby Date: 9/2/2022 10:44:00 AM

In addition to uncertainty over which specific viruses these assays are detecting antibodies against, which is addressed earlier in the discussion, other limitations to scientific inference that seem to me important to discuss include:

there were only two sites to assess spatial heterogeneity. A more robust assessment would require more sites.

Although five years is longer than usually studied, it is too short of a time for measuring temporal dynamics that might play out over longer time periods.

---

Number: 3 Author: Steve Luby Date: 9/2/2022 10:43:00 AM

Seems a weak concluding statement. I recommend a stronger statement of implications and way forward. To my mind, identification of the specific viruses that are driving these antibody responses would be the highest priority.

---

Number: 4 Author: Steve Luby Date: 9/2/2022 9:47:00 AM

I recommend listing the local IRB first.

363 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July  
364 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst  
365 roosts within the 80km<sup>2</sup> roost complex over the period of the study. Sampling occurred at the largest  
366 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex  
367 across consecutive sampling nights if required to capture a sufficient number of individuals.

368 Approximately 100 bats were captured at each sampling event, over 7-10 days. We captured bats<sup>1</sup>  
369 with a 10x15m mist net between 11pm and 5am each night as bats returned from foraging until the  
370 count of 100 was reached.

371 In the one-year longitudinal studies, sampling was undertaken in two roost complexes in  
372 Ramnagar and Chakhoria, Bangladesh between April 2010 and May 2011. Monthly sampling of  
373 approximately 40 bats in each location was performed to obtain data at a finer temporal scale. Details  
374 of collection are otherwise as described for the five-year study.

375 For each study, we recorded each bat's age class, reproductive status, weight, size, and body  
376 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with  
377 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box  
378 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and  
379 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton  
380 Cryogenics, NJ, USA).

381 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal  
382 swabs and pooled urine samples from under colonies. Further details can be found in [Epstein, et al.](#)  
383 <sup>34</sup>

#### 384 *Serological Assays*

385 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and  
386 gamma irradiated upon receipt. We used a bead-based microsphere assay that specifically detects  
387 antibodies to the soluble attachment glycoproteins<sup>57,63,64</sup> for a panel of viruses. Beads coated with each  
388 protein were mixed with sera at a dilution of 1:100. Biotinylated Protein A/G and Streptavidin-PE  
389 were then used to detect bound antibody. Beads were interrogated by lasers in a BioRad BioPlex  
390 machine and the results recorded as the Median Fluorescent Intensity (MFI) of 100 beads. We report  
391 here results for Nipah, Ebola-Zaire, and Menangle, the only three for which we established regular  
392 positive results.

393 While<sup>2</sup> the Nipah virus has been detected in this population<sup>65</sup> and the specificity of the Nipah test  
394 is well-established<sup>66</sup>, the Ebola-Zaire and Menangle virus tests are cross-reactive with other Ebola  
395 and rubulavirus species<sup>67,68</sup>. Thus we refer to these as tests for filovirus and Rubulavirus.

#### 396 *Data Analysis*

397 We determined individual bat serostatus using Bayesian mixture models<sup>69</sup> fit on pooled data  
398 across all three longitudinal studies, calculating a cutoff of log-MFI as the<sup>3</sup> point of equal probability  
399 between the smallest and second-smallest cluster of equal distributions for each assay.

400 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian  
401 multivariate probit model<sup>70,71</sup> which allows estimation of the joint outcomes (serostatus against each  
402 virus) and the correlation between the outcomes. We included age and sex variables to account for  
403 these effects on serostatus.

404 To examine time-varying changes in population seroprevalence, we fit binomial generalized  
405 additive mixed models (GAMMs)<sup>72,73</sup> to the time-series of serostatus measurements. For the five-year  
406 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit  
407 a model for seroprevalence dynamics over the course of the whole study. This treats the adult  
408 population as a single unit, though individuals within the population may turn over via migration,  
409 death and recruitment. We included both long-term and annual cyclic components for the multi-year  
410 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate  
411 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile  
412 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles

Error 5.4

---

Number: 2 Author: Wang Linfa Date: 8/21/2022 10:50:00 AM

I am not 100% sure about this. All serological tests (the NiV test included) will detect cross-RX antibodies from related viruses. For NiV, you can argue that longitudinal surveillance has NOT detected any related viruses in the study populations, but we can't say that the Ab test is specific to NiV.

---

Number: 3 Author: Steve Luby Date: 9/2/2022 9:53:00 AM

Why should we assume that the second smallest cluster is associated with the genuine presence or absence of antibody?

413 over their first year. To estimate periods of peak viral circulation within the population, we calculated  
414 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior  
415 distributions and classified periods with >95% of samples with positive derivatives - that is,  
416 increasing population seroprevalence - as periods of viral circulation. We also calculated strength  
417 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date  
418 at which this maximum occurred, again sampling these values from the model posterior, and  
419 calculating mean and high-density posterior interval (HDPI) values.

420 For the one-year studies, we fit models primarily to detect differences in time-varying changes  
421 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus  
422 measurements with separate models for each immunoassay. We included a separate, fixed-term  
423 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in  
424 serodynamics for each virus in each age group were compared between locations to test for spatial  
425 differences<sup>74</sup>. Juveniles identified as being from the previous year's cohort were excluded from the  
426 analysis.

427 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI  
428 between adult lactating females and their attached pups for each viral assay. We limited these to data  
429 from the five-year longitudinal study.

430 **Data Availability:** Raw data from this study and reproducible code used to perform analyses is available at the  
431 Zenodo Scientific Archive [Zenodo DOI to be generated] and also on GitHub at

**Abstract:** Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles and little circulation but lower seroprevalence amongst adults. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

**Keywords:** bats; Nipah virus; filovirus; Rubulavirus; *Pteropus medius*; Bangladesh; serology; disease dynamics; generalized additive models

---

## Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics<sup>1-3</sup>. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses<sup>4,5</sup> including close relatives of SARS-CoV-2<sup>6</sup>, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses<sup>1,2,7</sup>.

Bat species can carry diverse viruses which circulate simultaneously within single populations<sup>8-11</sup>. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire virus have also been detected in this bat in Central Africa, suggesting that it may play a role in the circulation of multiple filoviruses<sup>12,13</sup>. In addition to these filoviruses, a novel zoonotic and pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations<sup>14</sup>.

46 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to  
47 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity<sup>15</sup>. Various  
48 surveillance efforts have found diverse viruses from with the same viral family in various bat  
49 species<sup>5,16,17</sup>, and other studies have used metagenomic approaches to look broadly at viral diversity  
50 within individual bat species<sup>9,11,18-21</sup>.

51 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of  
52 viruses and their relationships to specific hosts<sup>6,22</sup> and inform public health strategies<sup>23</sup>. However,  
53 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated  
54 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or  
55 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other  
56 species, including domestic animals and humans<sup>24</sup>. For these, more detailed demographic and  
57 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect  
58 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics<sup>25-27</sup>.  
59 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral  
60 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been  
61 observed to have annual shedding patterns<sup>28</sup>, whereas Hendra virus, which is closely related to  
62 Nipah virus and is carried by multiple pteropodid bat species in Australia, has asynchronous and non-  
63 periodic cycles which appear to be influenced by localized factors such as specific bat species  
64 abundance and climatic factors<sup>29</sup>. Bi-annual pulses of Marburg virus shedding were observed in  
65 Uganda, coinciding with synchronous birth pulses in *R. aegyptiacus*<sup>30</sup>. Serological data is often  
66 valuable in understanding disease dynamics and transmission<sup>31-33</sup>, especially in cases where direct  
67 detection and incidence rates of viruses are low<sup>34</sup>.

68 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, lethal neurotropic  
69 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus<sup>35-37</sup>. In Bangladesh and India,  
70 *P. medius* is a reservoir of Nipah virus, which has spilled over to human populations repeatedly<sup>38</sup>.  
71 Viruses from eight other viral families have been detected in *P. medius* in Bangladesh<sup>9</sup>. The  
72 epidemiology of these other viruses is far less characterized, and little is known about their  
73 interactions or zoonotic potential.

74 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,  
75 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in  
76 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-  
77 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of  
78 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral  
79 circulation. We find that Nipah virus circulates primarily among adults without distinct seasonality,  
80 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by  
81 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also  
82 circulated in juveniles but exhibited distinct patterns antibody waning and limited maternal  
83 inheritance.

## 84 2. Results

### 85 *Bat Dynamics and Demographics*<sup>2</sup>

86 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly from a roost  
87 complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies sampling bats  
88 monthly from roosts in Chakhoria and Ramnagar, Bangladesh. In the five-year study, we sampled  
89 and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39 weaning juveniles  
90 (captured attached to adult females) over 19 sampling events (Figure 1). During the one-year studies,  
91 919 bats were sampled: 435 in Chakhoria (251 adults, 144 free-flying juveniles and 40 weaning  
92 juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning juveniles (Figure  
93 S1). Nearly all juveniles (as determined by examination of maturation of sex organs) were 14 months  
94 old or less and could be assigned to a birth cohort based on size. Pregnant and juvenile bats were  
95 captured more frequently during the late spring and summer months. Mother-pup pairs were all

---

96 captured during April and May in the five-year study whilst in the one-year-studies a small number  
 97 were also captured in June and July. Pregnant females were captured between November and  
 98 April/May. Lactating females were found between April and July.  
 99

100 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured  
 101 in months from November to June, lactating females were captured in months from April to July.  
 102 Females with pre-weaning juveniles attached were found from April to May.

103 *Patterns of Immunity and Co-immunity*

104 We found bats were seropositive for antibodies against the henipavirus (HenipVsero+), a  
 105 filovirus (EbVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the  
 106 rubulavirus were common; 1,314 of 1752 adult bats were MenVsero+. Antibodies against Nipah virus  
 107 or filovirus were less common – 1,031 were NiVsero+ and 921 were EbVsero+. Among the 921  
 108 juveniles, 192 were MenVsero+, 311 were NiVsero+ and 348 were EbVsero+. Of the 122 pre-weaned  
 109 juveniles, 43 were MenVsero+, 52 were NiVsero+, and 32 were EbVsero+.

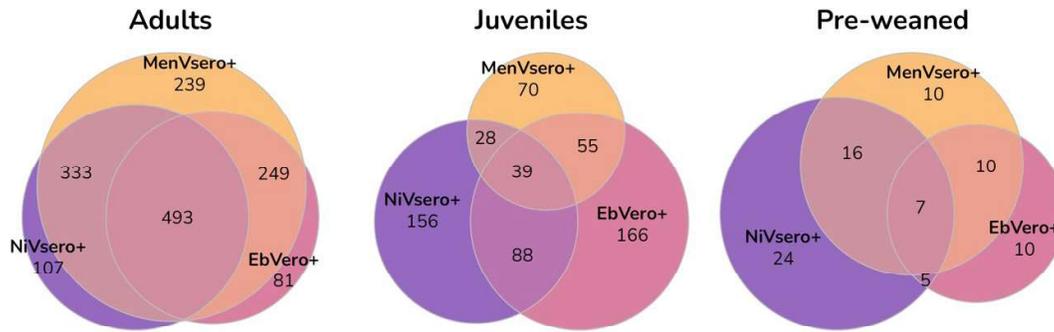

110 Co-exposure to multiple viruses was common (Figure 2). Over half (1,173) of the 1752 adults had  
 111 antibodies against more than one of the three viruses, and 493 had antibodies against all three.  
 112 Among the 921 juveniles, 210 had antibodies against more than one, and 39 had antibodies all three.  
 113 38 of 122 pre-weaned juveniles had more than one of the three antibodies, with seven having all three.

114 We found correlations between serostatus between all three pairs of viruses in a model  
 115 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other  
 116 more than would be expected than if they were distributed independently among bats. Nipah virus  
 117 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).  
 118 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of  
 119 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had a covariance of 0.23 (0.17-0.29).

I think it is better to treat the three group of viruses equally as you have done for the title. It makes no difference whether we use NiV or Henipavirus in the context of the current study. Luminex-based assays targeting binding antibodies will in theory detect cross-RX antibodies in all three cases. See also comments in Methods

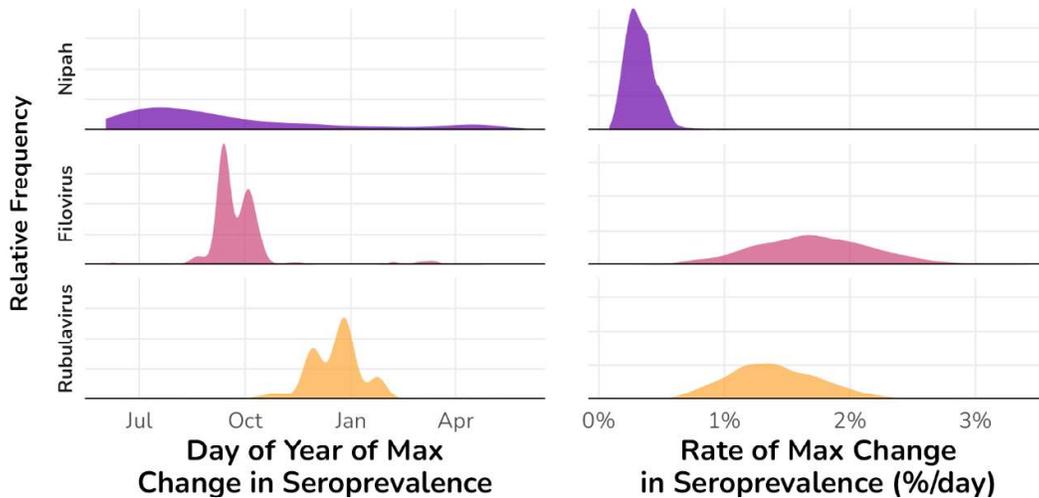

120 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn  
 121 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,  
 122 filovirus, and Rubulavirus. Numbers under labels are counts of bats with only those viruses, numbers  
 123 in overlapping areas represent number of bats detected with multiple viruses.

124 *Serodynamics*

125 Dynamics of population seroprevalence were different across the viral types. In adults,  
 126 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)  
 127 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-  
 128 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very  
 129 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in [Epstein, et al. 34](#)).  
 130

131  
 132 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population  
 133 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey  
 134 points and bars represent measured population seroprevalence from individual sampling events on  
 135 and 95% exact binomial confidence intervals. Thick lines and shaded areas represent the inter-annual  
 136 (non-seasonal) spline component of a generalized additive mixed model (GAMM) of serodynamics  
 137 and 95% confidence intervals for the mean pattern over time. Bottom: Circulation periods, when  
 138 modeled slopes of the [GAMM splines](#) are positive for >95% of 1000 draws from the model posterior.

148

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

**Figure 5. Serodynamics in juvenile bats in five-year study.** Measured and modeled population seroprevalence in juvenile bats caught over their first year of life. Sampling events from multiple years are transposed onto a single year starting June (the earliest month free-flying young-of-the-year juveniles were captured). X-axis ticks mark the first day of each month. Grey points and bars represent measured population seroprevalence from individual sampling events on and 95% exact binomial confidence intervals. Thick lines and shaded areas represent GAMM-modeled average serodynamics across all years and 95% confidence intervals for the mean effect. Thin lines represent individual-year deviations from the average year pattern.

158

159 **Figure 6. Timing and strength of seasonality of viral circulation in juveniles over the five-year**  
 160 **study.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left),  
 161 and the rate of increase (right), for juvenile bats. Densities are of these quantities derived from 1000  
 162 samples of model posteriors.

163 Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against  
 164 filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus  
 165 seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had  
 166 periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah  
 167 virus) (Fig. 3). filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

168 Among juveniles within the average year, filovirus seroprevalence started very low in June at  
 169 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age  
 170 before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it  
 171 consistently occurred in December or January. The average date with the greatest rate of  
 172 seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day  
 173 (4.5%/day-9.9%/day).

174 Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus  
 175 seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74%  
 176 (62%-84%), though there were some temporary periods of decline. There were distinct periods of  
 177 increasing circulation in early 2010 and early 2012. Only for the rubulavirus did adult seroprevalence  
 178 exhibit patterns of seasonality. Periods of increasing seroprevalence in adults exhibited strong  
 179 seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean peak date  
 180 occurring on Dec 15 (Oct 15-Feb 1)

181 In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in  
 182 the youngest bats in June, though in individual years this could range from 7%-43%. In all years  
 183 juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec  
 184 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%) The  
 185 peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and occurred  
 186 Jan 9 (Dec 21-Mar 16).

187 *Spatial Comparisons*

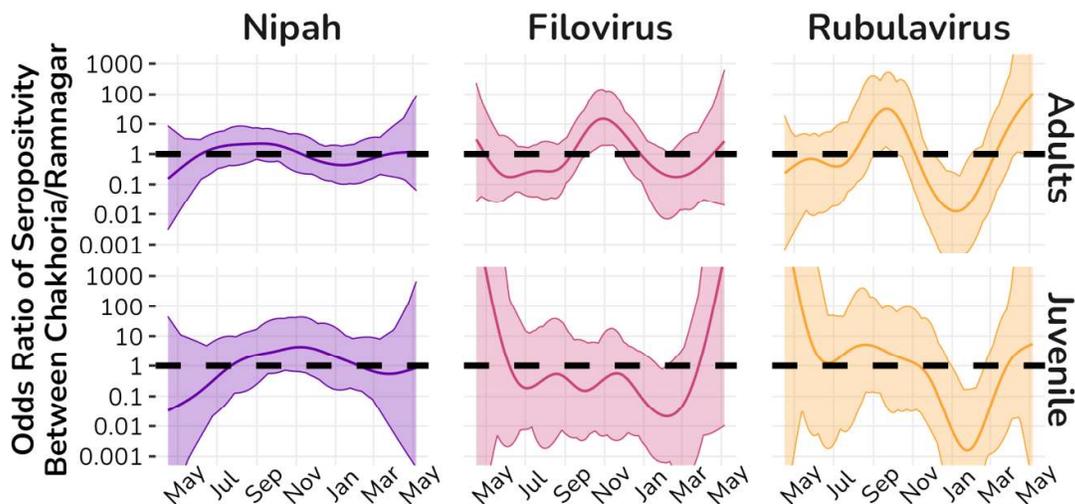

188 Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria  
 189 and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2).  
 190 In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of  
 191 April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

192 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-61%) in April 2010, rising to  
193 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over  
194 the same period. The trend in juveniles was as described for the five-year study.

195 For the filovirus, the seroprevalence in the one-year studies was higher than the reported  
196 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-  
197 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of  
198 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the  
199 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the  
200 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,  
201 there were two periods of increasing seroprevalence in adults over the course of the year. The first of  
202 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August  
203 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the  
204 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)  
205 between early March 2011 to late April 2011.

206 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from  
207 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in  
208 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December  
209 2010/January 2011 in Chakhoria. These decreases were followed by rapid increases back to high  
210 seroprevalence, coincident with increasing levels in juveniles. The pattern in juveniles was as  
211 described in the five-year study, with seroprevalence estimates in yearlings in April 2011 of 80%  
212 (28%-99%) in both locations.

213 Comparison of the seroprevalence trends within each age group and virus between the two one-  
214 year study locations did not support spatial differences in the timing of changes in seroprevalence  
215 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between  
216 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at  
217 the end of 2010.

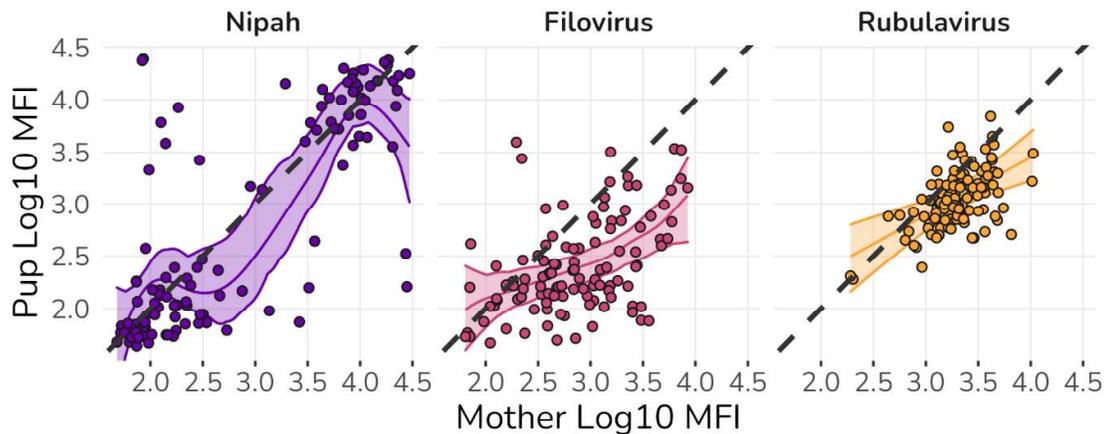

218  
219 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**  
220 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference  
221 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.  
222 Where the confidence interval excludes zero, there is evidence for a significant difference in the  
223 serodynamics between the Ramnagar and Chakhoria populations over that period.

#### 224 *Maternal Inheritance of antibodies*

225 We examined the relationship between mother and pup antibody titers, as measured by our  
226 Luminex assays (see Methods). This relationship varied between viruses (Figure 7). For Nipah virus,

227 the relationship was nonlinear due to clustering at high and low values, but largely followed a 1:1  
228 relationship between mother and pup antibody titers. For the rubulavirus the relationship was near-  
229 linear and near 1:1. For the filovirus, though, the relationship between MFI values measured in  
230 mothers and their pups fell well below the 1:1 line, indicating pups having low inheritance of  
231 antibodies against the filovirus relative to the other two viruses.

232

233 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for  
234 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the  
235 predicted mean relationship between the two and their associated 95% confidence intervals.

### 236 3. Discussion

237 We found serological evidence for regular circulation of multiple viruses in *P. medius*  
238 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to  
239 humans in the region, as well as a filovirus and a rubulavirus. It was common for bats to have  
240 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity  
241 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance  
242 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types  
243 being positively correlated within bats.

244 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The  
245 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations  
246 inherit maternal antibodies against the rubulavirus, which wane over the first six months of their life,  
247 after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in  
248 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the  
249 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence  
250 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating  
251 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of  
252 the rubulavirus to be strongest in the late winter and early spring months in these populations.  
253 Mortlock et al.<sup>39</sup> found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via  
254 PCR detection in pooled urine samples), including a peak during a period of presumed antibody  
255 waning, though only within a one-year study.

256 An outstanding question is how the rubulavirus is maintained in the population despite high  
257 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent  
258 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*<sup>40</sup>, Hendra virus in  
259 *P. alecto* and *P. poliocephalus*<sup>41</sup>, and Lagos bat lyssavirus and African henipavirus in *Eidolon helvum*<sup>42</sup>.  
260 Another possibility is re-importation. In concurrent work with this study, we found that bat home

261 ranges overlapped with nearby colonies so as to form a meta-population<sup>34</sup>, allowing occasional  
262 infection from outside bats, as has been shown to maintain Hendra virus in *Pteropus* populations<sup>43,44</sup>.

263 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle  
264 virus, which has been found in multiple *Pteropus* species in Australia<sup>45,46</sup>. At least 11 distinct  
265 Paramyxoviruses have been found in *P. medius* in Bangladesh alone: Nipah virus and ten  
266 uncharacterized species, including six Rubulaviruses closely related to Menangle virus and the  
267 Tioman virus<sup>9,47</sup>. It is possible that the serological patterns observed represent antibodies against a  
268 complex of multiple Rubulaviruses, though the regular interannual patterns in seroprevalence would  
269 indicate that they are operating similarly.

270 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with  
271 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some  
272 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup  
273 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults  
274 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,  
275 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah  
276 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by  
277 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years<sup>28</sup>.  
278 Human Nipah virus outbreaks in Bangladesh, on the other hand, exhibit seasonality associated with  
279 the palm-sap consumption, the most likely spillover mechanism<sup>48</sup>.

280 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-Zaire  
281 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have  
282 been found in *R. leschenaultii* in the country<sup>49</sup>. This could be one of several known filoviruses or an  
283 unknown species. There have been several recent findings of new Ebola-like filoviruses in bats  
284 extending across Africa and Asia. These include Bombali virus in Sierra Leone<sup>50</sup>, and Mënglà virus  
285 in *Rousettus* bats in China<sup>51</sup>. Ebola-Reston virus was found in multiple bat species (*M. australis*, *C.*  
286 *brachyotis* and *Ch. plicata*) in the Philippines<sup>52</sup>. Marburg virus and Ebola-Zaire virus may have been  
287 detected in Sierra Leone and Liberia (unpublished,<sup>53,54</sup>). Serological evidence of filoviruses in bats has  
288 been found in multiple bat species in Central<sup>12,55</sup> and Western<sup>56</sup> African countries, Singapore<sup>57</sup>,  
289 China<sup>58</sup>, as well as Trinidad<sup>59</sup>. Our finding here adds to the evidence of broad host and geographic  
290 host ranges for filoviruses.

291 Several components of the serological patterns of filovirus antibodies are of interest. Young  
292 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months  
293 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite  
294 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult  
295 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period  
296 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase  
297 among juveniles. One possible hypothesis explaining this pattern is that the filovirus may exhibit low  
298 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.  
299 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain  
300 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was  
301 found to be rapid, but bats retained protective immunity even with very low antibody titers<sup>60,61</sup>. If a  
302 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite  
303 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles  
304 following the peak is consistent with this explanation.

305 However, if adults remain immune to the filovirus despite low antibody titers, this immunity  
306 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and  
307 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the  
308 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly  
309 differential maternally derived immunity. If pups derive weaker immunity from dams than for other  
310 viruses, this may provide another mechanism for maintenance of the virus. It possible that patterns  
311 in filovirus antibody detection are an artifact of our test, specific to Ebola-Zaire virus, and that  
312 temporal trends are in part reflective of differential cross-reaction with viruses in this bat population.

---

Number: 1 Author: Hume Field Date: 8/24/2022 9:59:00 AM

And recently in Australia.

Barr et al. J Gen Virol. 2022 Aug;103(8).

doi: 10.1099/jgv.0.001785.

313 However, while this may modify estimates of overall seroprevalence, the differential pup/dam MFI  
314 relationship, and consistent rise in seroprevalence among young juveniles, would require the test to  
315 exhibit differential sensitivity by age.

316 Serodynamics in our two one-year studies were broadly similar to those found in the five-year  
317 study. We found weak evidence for differences in serodynamics between sites for the filovirus in  
318 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the  
319 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study<sup>34</sup>,  
320 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their  
321 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are approximately 225  
322 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible  
323 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or  
324 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple  
325 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

326 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-  
327 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from  
328 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or  
329 transmission, via competition for host nutritional or cellular resources, or via immune-mediation  
330 involving cross-immunity or antibody-dependent enhancement, and these interactions structure  
331 viral communities<sup>26</sup>. These interactions can have complex, even opposite effects when scaled to the  
332 population<sup>27</sup>. Here, we found positive correlations between serostatus against different viruses.  
333 External factors may also affect these relationships. For instance, all three viruses appear to have  
334 circulated in adults in mid-2010. It is possible that common factors like population density and/or  
335 nutrition availability<sup>62</sup> affected transmission of multiple viruses.

336 While rich observational serological data reveal these patterns, greater study is required to  
337 characterize these viruses and their effects on the host population and potential for spillover, as well  
338 as the degree and mechanisms of interactions. Our inferred periods of viral circulation point to  
339 optimal sub-populations and times to sample this population to detect viral shedding and isolate  
340 these viruses, and potentially capture co-infected hosts.

341 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term  
342 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and  
343 shedding, but establishing patterns or variation in seasonality requires extended, multi-year  
344 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was  
345 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The  
346 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.  
347 Similarly, we were able to understand these patterns far better by separating juvenile and adult  
348 patterns, which we would be unable to distinguish in pooled samples.

349 While such extended individual-capture longitudinal studies are resource-intensive,  
350 understanding the joint circulation of multiple viruses can be accomplished via multiplex  
351 immunoassays such as those used here. The continuous measures from these assays also have the  
352 potential to identify key patterns such as the differential inheritance of filovirus antibodies we  
353 identified here. Interpretation of these values is challenging and the relationship between immune  
354 status, antibody titer, and measured fluorescence is complex<sup>32</sup>, but they have much potential to shed  
355 light on mechanistic drivers of disease circulation.

## 356 **Methods**

### 357 *Field collection*

358 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-  
359 year studies in different locations, sampling monthly. All capture and sampling methods were  
360 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol  
361 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as  
362 previously described in Epstein, et al. <sup>34</sup> The area of the roost complex consists of patchy forest

363 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July  
364 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst  
365 roosts within the 80km<sup>2</sup> roost complex over the period of the study. Sampling occurred at the largest  
366 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex  
367 across consecutive sampling nights if required to capture a sufficient number of individuals.

368 Approximately 100 bats were captured at each sampling event, which lasted 7-10 days. We  
369 captured bats with a 10x15m mist net between 11pm and 5am each night as bats returned from  
370 foraging until the count of 100 was reached.

371 In the one-year longitudinal studies, sampling was undertaken in two roost complexes in  
372 Ramnagar and Chakhoria, Bangladesh between April 2010 and May 2011. Monthly sampling of  
373 approximately 40 bats in each location was performed to obtain data at a finer temporal scale. Details  
374 of collection are otherwise as described for the five-year study.

375 For each study, we recorded each bat's age class, reproductive status, weight, size, and body  
376 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with  
377 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box  
378 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and  
379 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton  
380 Cryogenics, NJ, USA).

381 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal  
382 swabs and pooled urine samples from under colonies. Further details can be found in [Epstein, et al.](#)  
383 [34](#)

#### 384 *Serological Assays*

385 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and  
386 gamma irradiated upon receipt. We used a bead-based microsphere assay that specifically detects  
387 antibodies to the soluble attachment glycoproteins<sup>57,63,64</sup> for a panel of viruses. Beads coated with each  
388 protein were mixed with sera at a dilution of 1:100. Biotinylated Protein A/G and Streptavidin-PE  
389 were then used to detect bound antibody. Beads were interrogated by lasers in a BioRad BioPlex  
390 machine and the results recorded as the Median Fluorescent Intensity (MFI) of 100 beads. We report  
391 here results for Nipah, Ebola-Zaire, and Menangle, the only three for which we established regular  
392 positive results.

393 While the Nipah virus has been detected in this population<sup>65</sup> and the specificity of the Nipah test  
394 is well-established<sup>66</sup>, the Ebola-Zaire and Menangle virus tests are cross-reactive with other Ebola  
395 and rubulavirus species<sup>67,68</sup>. Thus we refer to these as tests for filovirus and Rubulavirus.

#### 396 *Data Analysis*

397 We determined individual bat serostatus using Bayesian mixture models<sup>69</sup> fit on pooled data  
398 across all three longitudinal studies, calculating a cutoff of log-MFI as the point of equal probability  
399 between the smallest and second-smallest cluster of equal distributions for each assay.

400 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian  
401 multivariate probit model<sup>70,71</sup> which allows estimation of the joint outcomes (serostatus against each  
402 virus) and the correlation between the outcomes. We included age and sex variables to account for  
403 these effects on serostatus.

404 To examine time-varying changes in population seroprevalence, we fit binomial generalized  
405 additive mixed models (GAMMs)<sup>72,73</sup> to the time-series of serostatus measurements. For the five-year  
406 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit  
407 a model for seroprevalence dynamics over the course of the whole study. This treats the adult  
408 population as a single unit, though individuals within the population may turn over via migration,  
409 death and recruitment. We included both long-term and annual cyclic components for the multi-year  
410 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate  
411 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile  
412 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles

---

Number: 1 Author: Wang Linfa Date: 8/21/2022 10:50:00 AM

I am not 100% sure about this. All serological tests (the NiV test included) will detect cross-RX antibodies from related viruses. For NiV, you can argue that longitudinal surveillance has NOT detected any related viruses in the study populations, but we can't say that the Ab test is specific to NiV.

413 over their first year. To estimate periods of peak viral circulation within the population, we calculated  
414 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior  
415 distributions and classified periods with >95% of samples with positive derivatives - that is,  
416 increasing population seroprevalence - as periods of viral circulation. We also calculated strength  
417 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date  
418 at which this maximum occurred, again sampling these values from the model posterior, and  
419 calculating mean and high-density posterior interval (HDPI) values.

420 For the one-year studies, we fit models primarily to detect differences in time-varying changes  
421 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus  
422 measurements with separate models for each immunoassay. We included a separate, fixed-term  
423 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in  
424 serodynamics for each virus in each age group were compared between locations to test for spatial  
425 differences<sup>74</sup>. Juveniles identified as being from the previous year's cohort were excluded from the  
426 analysis.

427 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI  
428 between adult lactating females and their attached pups for each viral assay. We limited these to data  
429 from the five-year longitudinal study.

430 **Data Availability:** Raw data from this study and reproducible code used to perform analyses is available at the  
431 Zenodo Scientific Archive [Zenodo DOI to be generated] and also on GitHub at  
432 <https://github.com/ecohealthalliance/bangladesh-bat-serodynamics>

433 **Author Contributions:** Conceptualization, N.R. and J.H.E.; methodology, N.R., L-FW and J.H.E.; software, N.R.  
434 and S.H.; formal analysis, N.R. and S.H.; investigation, J.H.E., A.I. and L-FW....; resources, X.X.; data curation,  
435 N.R. and J.H.E.; writing—original draft preparation, N.R. J.H.E., and S.H.; writing—review and editing, HEF,  
436 X.X.; visualization, N.R. supervision, N.R. and J.H.E.; project administration, J.H.E.; funding acquisition, P.D., L-  
437 FW and J.H.E

438 **Funding:** This study was funded by an NIH NIAID awards to JHE (AI153420) and CCB (AI054715), an NIH  
439 Fogarty International Center Ecology and Evolution of Infectious Diseases (EEID) award to PD (TW005869) a  
440 NSF-NIH EEID award to AMK (EF-0914866), the US Agency for International Development Emerging Pandemic  
441 Threats: PREDICT program (NR, PD, JHE , AI), and grants from CSIRO (OCE Science Leader Award) the  
442 Singapore National Research Foundation (NRF2012NRF-CRP001-056) to L-FW.

443 **Acknowledgments:** We thank Pitu Biswas, Md. Sheikh Gofur, Abdul Hai, Ausraful Islam, and Craig Smith for  
444 assistance in the field, Eric J. Pedersen, Gavin L. Simpson and David Miller for technical input, Jennifer Barr and  
445 Mohammad Ziadur for laboratory diagnostic and technical support, and the Government of Bangladesh for  
446 permits and logistical support that made this work possible.

447 **Conflicts of Interest:** The authors declare no conflict of interest. The funders had no role in the design of the  
448 study; in the collection, analyses, or interpretation of data; in the writing of the manuscript, or in the decision to  
449 publish the results.

---

hi Jon,

Happy Labor day weekend.

What is the story on the screening here? The paper reads only NiV EBOV and MenV attachment proteins used so I am assuming all our proteins. NiV-sG / EBO sGp / MeV-sHN ? What the entire panel of proteins used? Linfa's comment about saying heniv sero+ and not just NiV only matters if the other sG beads were used and what the data looks like.

technically, sGp EBO trimer, is attachment+fusion Glycoprotein, but the sHN if used this was a new project of both Eric and I working with Linda to construct and we shipped to Ina Smith, Jenn and Gary in early 18'

I think we need to see all the raw data

Chris

Hi Jon,

Thanks for sharing this interesting work. Kudos to Noam and the team for pulling all of this together.

Attached are my comments.

To reduce the amount of my time and improve the thoroughness of my review, I use error codes when I identify common errors within a scientific document. A full description of the error and strategies for addressing it can be found in a scientific writing guide written by Dorothy Southern and I (Pathway to Publishing-A Guide to Quantitative Writing in the Health

Sciences) published as an Open Access ebook through Springer. It can be downloaded from here: <https://link.springer.com/book/10.1007/978-3-030-98175-4>

Colleagues,

I hope you're all doing well. I'm excited to share a draft manuscript, led by Noam, that details the serodynamics of henipaviruses, filoviruses and rubulaviruses in a population of *Pteropus medius*. We plan to submit this to *Nature Communications* in September. Please send Noam and I your comments by **September 10th**.

Cheers,

Jon

**Abstract:** Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles and little circulation but lower seroprevalence amongst adults. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

**Keywords:** bats; Nipah virus; filovirus; Rubulavirus; *Pteropus medius*; Bangladesh; serology; disease dynamics; generalized additive models

## Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics<sup>1-3</sup>. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses<sup>4,5</sup> including close relatives of SARS-CoV-2<sup>6</sup>, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses<sup>1,2,7</sup>.

Bat species can carry diverse viruses which circulate simultaneously within single populations<sup>8-11</sup>. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire virus have also been detected in this bat in Central Africa, suggesting that it may play a role in the circulation of multiple filoviruses<sup>12,13</sup>. In addition to these filoviruses, a novel zoonotic and pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations<sup>14</sup>.

46 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to  
47 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity<sup>15</sup>. Various  
48 surveillance efforts have found diverse viruses from with the same viral family in various bat  
49 species<sup>5,16,17</sup>, and other studies have used metagenomic approaches to look broadly at viral diversity  
50 within individual bat species<sup>9,11,18-21</sup>.

51 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of  
52 viruses and their relationships to specific hosts<sup>5,22</sup> and inform public health strategies<sup>23</sup>. However,  
53 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated  
54 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or  
55 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other  
56 species, including domestic animals and humans<sup>24</sup>. For these, more detailed demographic and  
57 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect  
58 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics<sup>25-27</sup>.  
59 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral  
60 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been  
61 observed to have annual shedding patterns<sup>28</sup>, whereas Hendra virus, which is closely related to  
62 Nipah virus and is carried by multiple pteropodid bat species in Australia, has asynchronous and non-  
63 periodic cycles which appear to be influenced by localized factors such as specific bat species  
64 abundance and climatic factors<sup>29</sup>. Bi-annual pulses of Marburg virus shedding were observed in  
65 Uganda, coinciding with synchronous birth pulses in *R. aegyptiacus*<sup>30</sup>. Serological data is often  
66 valuable in understanding disease dynamics and transmission<sup>31-33</sup>, especially in cases where direct  
67 detection and incidence rates of viruses are low<sup>34</sup>.

68 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, lethal neurotropic  
69 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus<sup>35-37</sup>. In Bangladesh and India,  
70 *P. medius* is a reservoir of Nipah virus, which has spilled over to human populations repeatedly<sup>38</sup>.  
71 Viruses from eight other viral families have been detected in *P. medius* in Bangladesh<sup>9</sup>. The  
72 epidemiology of these other viruses is far less characterized, and little is known about their  
73 interactions or zoonotic potential.

74 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,  
75 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in  
76 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-  
77 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of  
78 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral  
79 circulation. We find that Nipah virus circulates primarily among adults without distinct seasonality,  
80 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by  
81 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also  
82 circulated in juveniles but exhibited distinct patterns antibody waning and limited maternal  
83 inheritance.

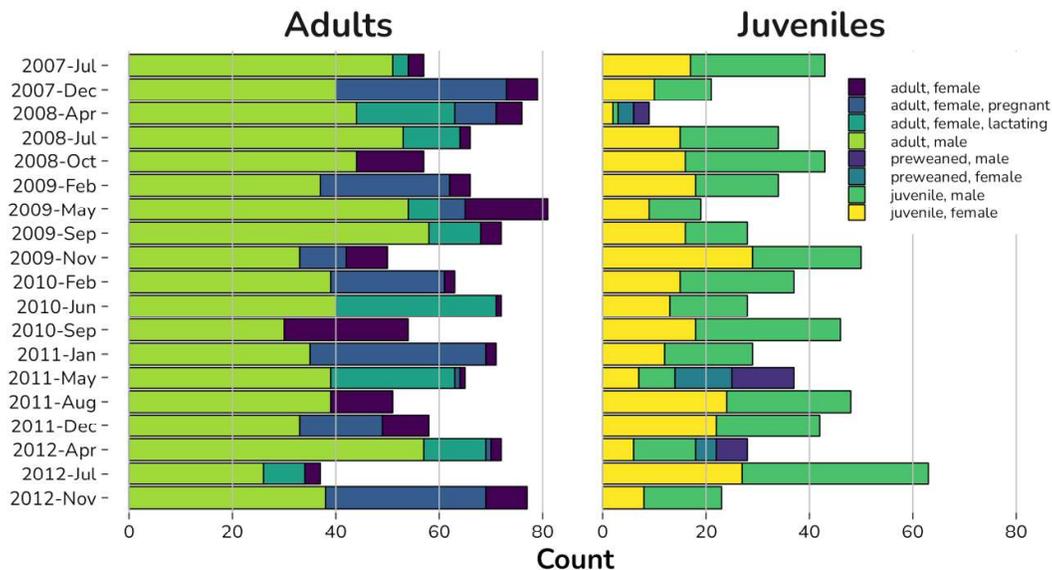

## 84 2. Results

### 85 *Bat Dynamics and Demographics*<sup>1</sup>

86 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly from a roost  
87 complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies sampling bats  
88 monthly from roosts in Chakhoria and Ramnagar, Bangladesh. In the five-year study, we sampled  
89 and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39 weaning juveniles  
90 (captured attached to adult females) over 19 sampling events (Figure 1). During the one-year studies,  
91 919 bats were sampled: 435 in Chakhoria (251 adults, 144 free-flying juveniles and 40 weaning  
92 juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning juveniles (Figure  
93 S1). Nearly all juveniles (as determined by examination of maturation of sex organs) were 14 months  
94 old or less and could be assigned to a birth cohort based on size. Pregnant and juvenile bats were  
95 captured more frequently during the late spring and summer months. Mother-pup pairs were all

96 captured during April and May in the five-year study whilst in the one-year-studies a small number  
 97 were also captured in June and July. Pregnant females were captured between November and  
 98 April/May. Lactating females were found between April and July.  
 99

100 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured  
 101 in months from November to June, lactating females were captured in months from April to July.  
 102 Females with pre-weaning juveniles attached were found from April to May.

103 *Patterns of Immunity and Co-immunity*

104 We found bats were seropositive for antibodies against the henipavirus (HenipVsero+), a  
 105 filovirus (EbVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the  
 106 rubulavirus were common; 1,314 of 1752 adult bats were MenVsero+. Antibodies against Nipah virus  
 107 or filovirus were less common – 1,031 were NiVsero+ and 921 were EbVsero+. Among the 921  
 108 juveniles, 192 were MenVsero+, 311 were NiVsero+ and 348 were EbVsero+. Of the 122 pre-weaned  
 109 juveniles, 43 were MenVsero+, 52 were NiVsero+, and 32 were EbVsero+.

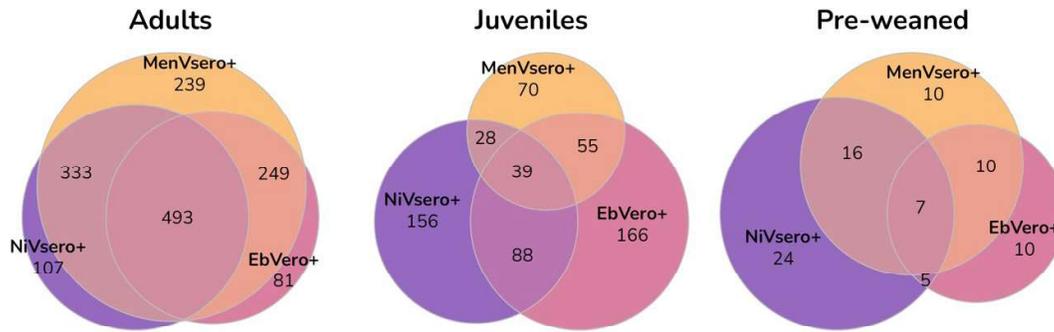

110 Co-exposure to multiple viruses was common (Figure 2). Over half (1,173) of the 1752 adults had  
 111 antibodies against more than one of the three viruses, and 493 had antibodies against all three.  
 112 Among the 921 juveniles, 210 had antibodies against more than one, and 39 had antibodies all three.  
 113 38 of 122 pre-weaned juveniles had more than one of the three antibodies, with seven having all three.

114 We found correlations **between** serostatus between all three pairs of viruses in a model  
 115 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other  
 116 more than would be expected than if they were distributed independently among bats. Nipah virus  
 117 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).  
 118 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of  
 119 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had a covariance of 0.23 (0.17-0.29).

---

Number: 1 Author: Wang Linfa Date: 8/21/2022 10:48:00 AM

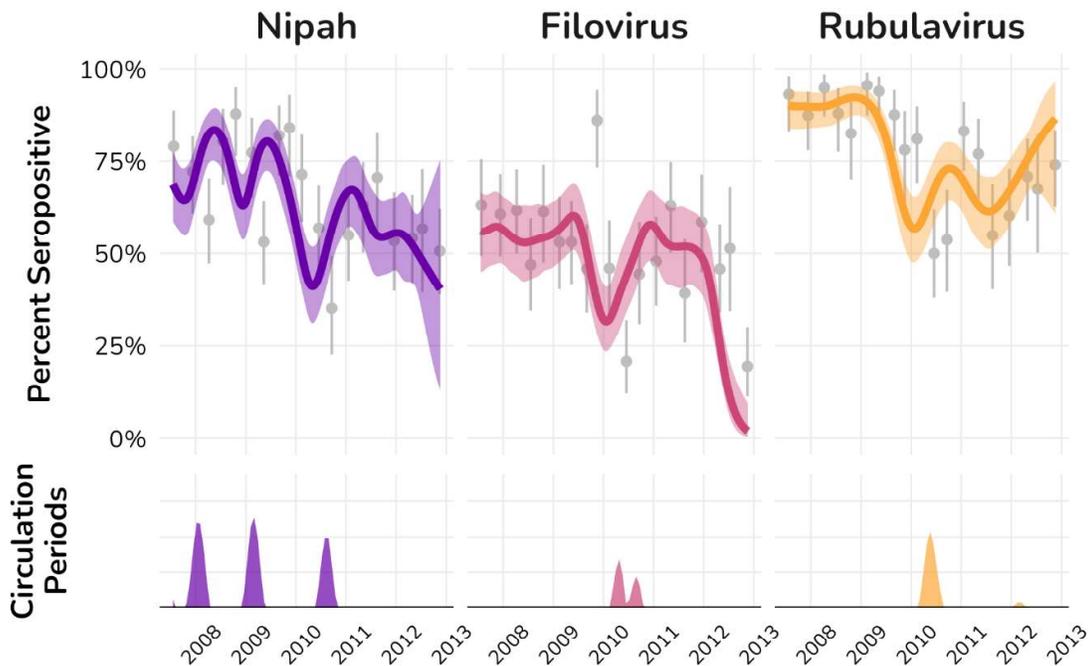

I think it is better to treat the three group of viruses equally as you have done for the title. It makes no difference whether we use NiV or Henipavirus in the context of the current study. Luminex-based assays targeting binding antibodies will in theory detect cross-RX antibodies in all three cases. See also comments in Methods

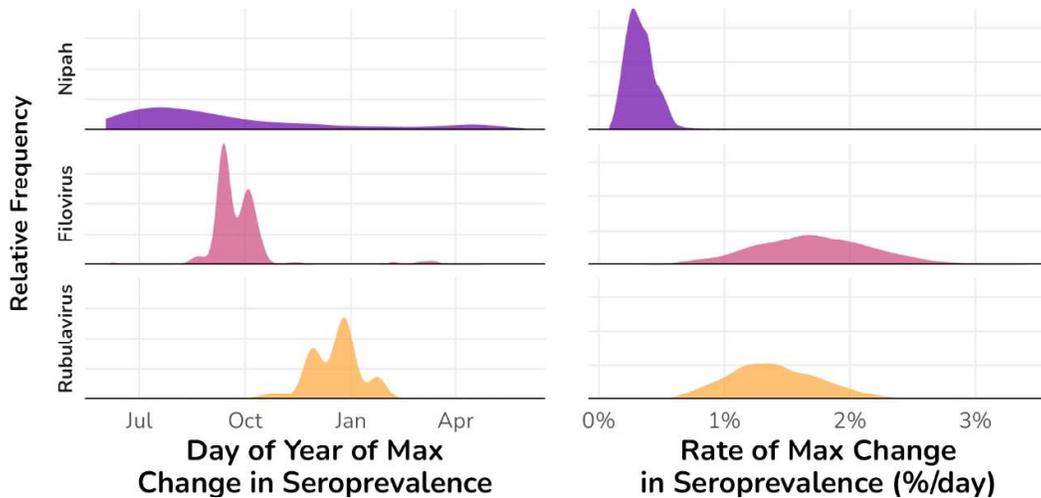

120 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn  
 121 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,  
 122 filovirus, and Rubulavirus. Numbers under labels are counts of bats with only those viruses, numbers  
 123 in overlapping areas represent number of bats detected with multiple viruses.

124 *Serodynamics*

125 Dynamics of population seroprevalence were different across the viral types. In adults,  
 126 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)  
 127 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-  
 128 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very  
 129 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in in [Epstein, et al. 34](#)).  
 130

131  
 132 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population  
 133 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey  
 134 points and bars represent measured population seroprevalence from individual sampling events on  
 135 and 95% exact binomial confidence intervals. Thick lines and shaded areas represent the inter-annual  
 136 (non-seasonal) spline component of a generalized additive mixed model (GAMM) of serodynamics  
 137 and 95% confidence intervals for the mean pattern over time. Bottom: Circulation periods,  
 138 when modeled slopes of the [GAMM splines](#) are positive for >95% of 1000 draws from the model posterior.

139

140

141

142

143

**Figure 4. Timing and strength of seasonality of viral circulation in adults.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left), and the rate of increase (right), for adult bats, drawn from GAMM models of seasonality. Densities are of these quantities derived from 1000 samples of model posteriors.

144

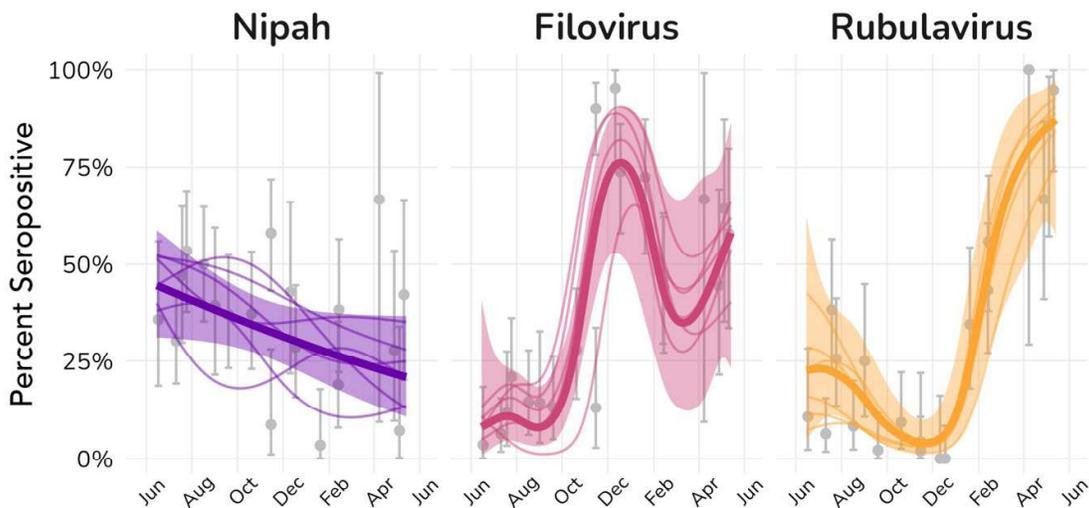

145

146

147

148

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

149

150

151

152

153

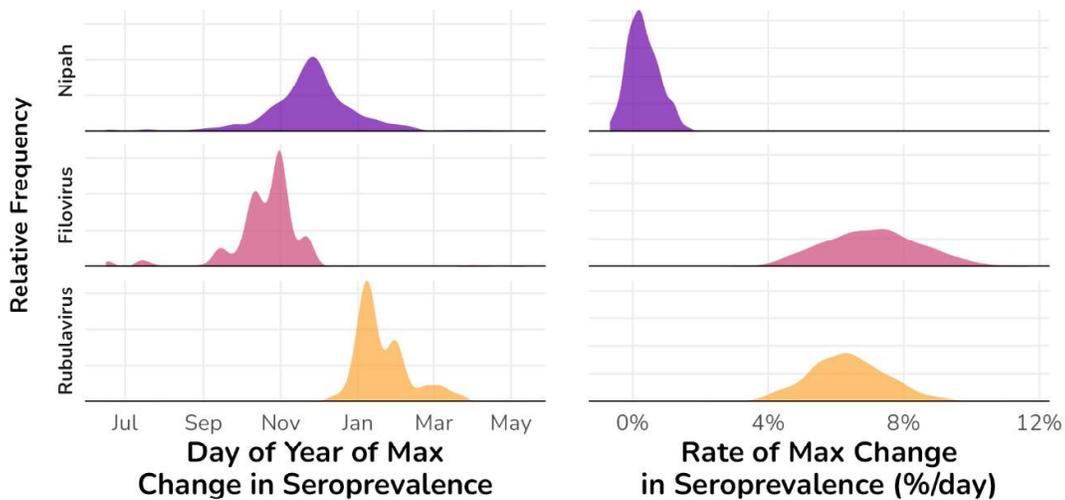

154

155

156

157

**Figure 5. Serodynamics in juvenile bats in five-year study.** Measured and modeled population seroprevalence in juvenile bats caught over their first year of life. Sampling events from multiple years are transposed onto a single year starting June (the earliest month free-flying young-of-the-year juveniles were captured). X-axis ticks mark the first day of each month. Grey points and bars represent measured population seroprevalence from individual sampling events on and 95% exact binomial confidence intervals. Thick lines and shaded areas represent GAMM-modeled average serodynamics across all years and 95% confidence intervals for the mean effect. Thin lines represent individual-year deviations from the average year pattern.

158

159 **Figure 6. Timing and strength of seasonality of viral circulation in juveniles over the five-year**  
 160 **study.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left),  
 161 and the rate of increase (right), for juvenile bats. Densities are of these quantities derived from 1000  
 162 samples of model posteriors.

163 Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against  
 164 filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus  
 165 seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had  
 166 periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah  
 167 virus) (Fig. 3). filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

168 Among juveniles within the average year, filovirus seroprevalence started very low in June at  
 169 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age  
 170 before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it  
 171 consistently occurred in December or January. The average date with the greatest rate of  
 172 seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day  
 173 (4.5%/day-9.9%/day).

174 Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus  
 175 seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74%  
 176 (62%-84%), though there were some temporary periods of decline. There were distinct periods of  
 177 increasing circulation in early 2010 and early 2012. Only for the rubulavirus did adult seroprevalence  
 178 exhibit patterns of seasonality. Periods of increasing seroprevalence in adults exhibited strong  
 179 seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean peak date  
 180 occurring on Dec 15 (Oct 15-Feb 1)

181 In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in  
 182 the youngest bats in June, though in individual years this could range from 7%-43%. In all years  
 183 juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec  
 184 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%) The  
 185 peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and occurred  
 186 Jan 9 (Dec 21-Mar 16).

187 *Spatial Comparisons*

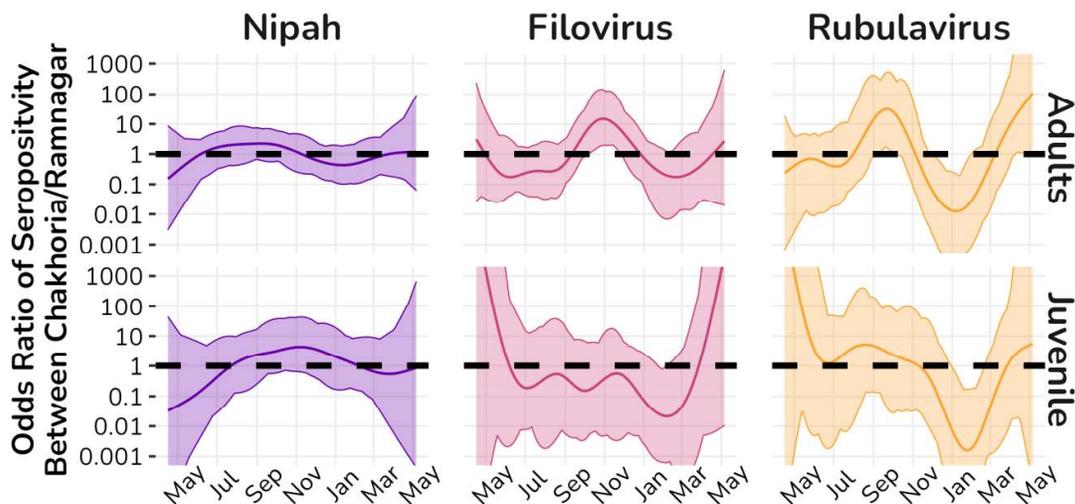

188 Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria  
 189 and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2).  
 190 In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of  
 191 April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

192 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-61%) in April 2010, rising to  
193 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over  
194 the same period. The trend in juveniles was as described for the five-year study.

195 For the filovirus, the seroprevalence in the one-year studies was higher than the reported  
196 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-  
197 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of  
198 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the  
199 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the  
200 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,  
201 there were two periods of increasing seroprevalence in adults over the course of the year. The first of  
202 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August  
203 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the  
204 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)  
205 between early March 2011 to late April 2011.

206 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from  
207 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in  
208 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December  
209 2010/January 2011 in Chakhoria. These decreases were followed by rapid increases back to high  
210 seroprevalence, coincident with increasing levels in juveniles. The pattern in juveniles was as  
211 described in the five-year study, with seroprevalence estimates in yearlings in April 2011 of 80%  
212 (28%-99%) in both locations.

213 Comparison of the seroprevalence trends within each age group and virus between the two one-  
214 year study locations did not support spatial differences in the timing of changes in seroprevalence  
215 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between  
216 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at  
217 the end of 2010.

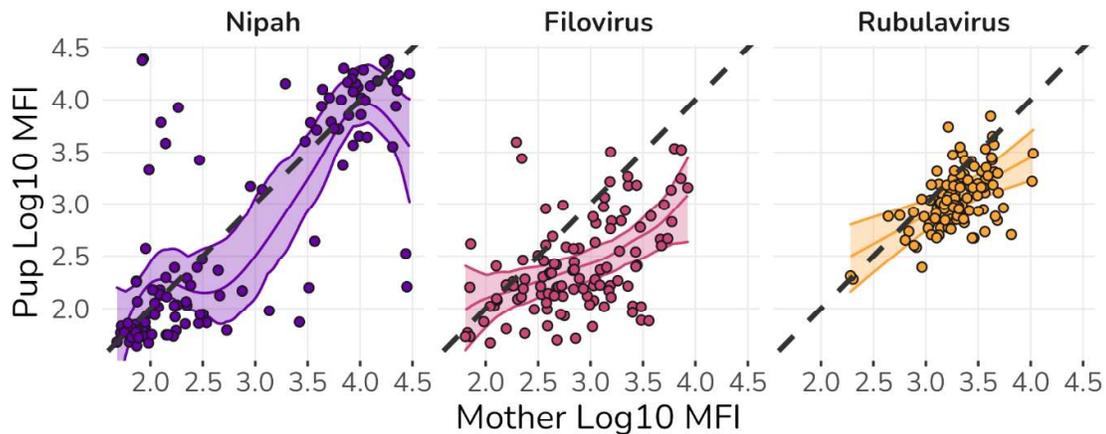

218  
219 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**  
220 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference  
221 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.  
222 Where the confidence interval excludes zero, there is evidence for a significant difference in the  
223 serodynamics between the Ramnagar and Chakhoria populations over that period.

#### 224 *Maternal Inheritance of antibodies*

225 We examined the relationship between mother and pup antibody titers, as measured by our  
226 Luminex assays (see Methods). This relationship varied between viruses (Figure 7). For Nipah virus,

227 the relationship was nonlinear due to clustering at high and low values, but largely followed a 1:1  
228 relationship between mother and pup antibody titers. For the rubulavirus the relationship was near-  
229 linear and near 1:1. For the filovirus, though, the relationship between MFI values measured in  
230 mothers and their pups fell well below the 1:1 line, indicating pups having low inheritance of  
231 antibodies against the filovirus relative to the other two viruses.

232

233 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for  
234 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the  
235 predicted mean relationship between the two and their associated 95% confidence intervals.

### 236 3. Discussion

237 We found serological evidence for regular circulation of multiple viruses in *P. medius*  
238 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to  
239 humans in the region, as well as a filovirus and a Rubulavirus. It was common for bats to have  
240 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity  
241 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance  
242 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types  
243 being positively correlated within bats.

244 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The  
245 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations  
246 inherit maternal antibodies against the Rubulavirus, which wane over the first six months of their  
247 life, after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in  
248 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the  
249 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence  
250 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating  
251 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of  
252 the rubulavirus to be strongest in the late winter and early spring months in these populations.  
253 Mortlock et al.<sup>39</sup> found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via  
254 PCR detection in pooled urine samples), including a peak during a period of presumed antibody  
255 waning, though only within a one-year study.

256 An outstanding question is how the rubulavirus is maintained in the population despite high  
257 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent  
258 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*<sup>40</sup>, Hendra virus in  
259 *P. Medius*<sup>41</sup>, and Lagos bat lyssavirus and African henipavirus in *Eidolon helvum*<sup>42</sup>. Another possibility  
260 is re-importation. In concurrent work with this study, we found that bat home ranges overlapped

261 with nearby colonies so as to form a meta-population<sup>34</sup>, allowing occasional infection from outside  
262 bats, as has been shown to maintain Hendra virus in *Pteropus* populations<sup>43,44</sup>.

263 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle  
264 virus, which has been found in *P. medius* in Australia<sup>45,46</sup>. At least 11 distinct Paramyxoviruses have  
265 been found in *P. medius* in Bangladesh alone: Nipah virus and ten uncharacterized species, including  
266 six Rubulaviruses closely related to Menangle virus and the Tioman virus<sup>9,47</sup>. It is possible that the  
267 serological patterns observed represent antibodies against a complex of multiple Rubulaviruses,  
268 though the regular interannual patterns in seroprevalence would indicate that they are operating  
269 similarly.

270 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with  
271 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some  
272 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup  
273 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults  
274 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,  
275 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah  
276 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by  
277 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years<sup>28</sup>.  
278 Human Nipah virus outbreaks in Bangladesh, on the other hand, exhibit seasonality associated with  
279 the palm-sap consumption, the most likely spillover mechanism<sup>48</sup>.

280 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-Zaire  
281 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have  
282 been found in *R. leschenaultii* in the country<sup>49</sup>. This could be one of several known filoviruses or an  
283 unknown species. There have been several recent findings of new Ebola-like filoviruses in bats  
284 extending across Africa and Asia. These include Bombali virus in Sierra Leone<sup>50</sup>, and Mënglà virus  
285 in *Rousettus* bats in China<sup>51</sup>. Ebola-Reston virus was found in multiple bat species (*M. australis*, *C.*  
286 *brachyotis* and *Ch. plicata*) in the Philippines<sup>52</sup>. Marburg virus and Ebola-Zaire virus may have been  
287 detected in Sierra Leone and Liberia (unpublished,<sup>53,54</sup>). Serological evidence of filoviruses in bats has  
288 been found in multiple bat species in Central<sup>12,55</sup> and Western<sup>56</sup> African countries, Singapore<sup>57</sup>,  
289 China<sup>58</sup>, as well as Trinidad<sup>59</sup>. Our finding here adds to the evidence of broad host and geographic  
290 host ranges for filoviruses.

291 Several components of the serological patterns of filovirus antibodies are of interest. Young  
292 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months  
293 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite  
294 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult  
295 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period  
296 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase  
297 among juveniles. One possible hypothesis explaining this pattern is that the filovirus may exhibit low  
298 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.  
299 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain  
300 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was  
301 found to be rapid, but bats retained protective immunity even with very low antibody titers<sup>60,61</sup>. If a  
302 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite  
303 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles  
304 following the peak is consistent with this explanation.

305 However, if adults remain immune to the filovirus despite low antibody titers, this immunity  
306 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and  
307 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the  
308 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly  
309 differential maternally derived immunity. If pups derive weaker immunity from dams than for other  
310 viruses, this may provide another mechanism for maintenance of the virus. It possible that patterns  
311 in filovirus antibody detection are an artifact of our test, specific to Ebola-Zaire virus, and that  
312 temporal trends are in part reflective of differential cross-reaction with viruses in this bat population.

313 However, while this may modify estimates of overall seroprevalence, the differential pup/dam MFI  
314 relationship, and consistent rise in seroprevalence among young juveniles, would require the test to  
315 exhibit differential sensitivity by age.

316 Serodynamics in our two one-year studies were broadly similar to those found in the five-year  
317 study. We found weak evidence for differences in serodynamics between sites for the filovirus in  
318 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the  
319 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study<sup>34</sup>,  
320 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their  
321 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are approximately 225  
322 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible  
323 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or  
324 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple  
325 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

326 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-  
327 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from  
328 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or  
329 transmission, via competition for host nutritional or cellular resources, or via immune-mediation  
330 involving cross-immunity or antibody-dependent enhancement, and these interactions structure  
331 viral communities<sup>26</sup>. These interactions can have complex, even opposite effects when scaled to the  
332 population<sup>27</sup>. Here, we found positive correlations between serostatus against different viruses.  
333 External factors may also affect these relationships. For instance, all three viruses appear to have  
334 circulated in adults in mid-2010. It is possible that common factors like population density and/or  
335 nutrition availability<sup>62</sup> affected transmission of multiple viruses.

336 While rich observational serological data reveal these patterns, greater study is required to  
337 characterize these viruses and their effects on the host population and potential for spillover, as well  
338 as the degree and mechanisms of interactions. Our inferred periods of viral circulation point to  
339 optimal sub-populations and times to sample this population to detect viral shedding and isolate  
340 these viruses, and potentially capture co-infected hosts.

341 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term  
342 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and  
343 shedding, but establishing patterns or variation in seasonality requires extended, multi-year  
344 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was  
345 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The  
346 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.  
347 Similarly, we were able to understand these patterns far better by separating juvenile and adult  
348 patterns, which we would be unable to distinguish in pooled samples.

349 While such extended individual-capture longitudinal studies are resource-intensive,  
350 understanding the joint circulation of multiple viruses can be accomplished via multiplex  
351 immunoassays such as those used here. The continuous measures from these assays also have the  
352 potential to identify key patterns such as the differential inheritance of filovirus antibodies we  
353 identified here. Interpretation of these values is challenging and the relationship between immune  
354 status, antibody titer, and measured fluorescence is complex<sup>32</sup>, but they have much potential to shed  
355 light on mechanistic drivers of disease circulation.

## 356 **Methods**

### 357 *Field collection*

358 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-  
359 year studies in different locations, sampling monthly. All capture and sampling methods were  
360 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol  
361 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as  
362 previously described in [Epstein, et al.](#) <sup>34</sup> The area of the roost complex consists of patchy forest

363 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July  
364 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst  
365 roosts within the 80km<sup>2</sup> roost complex over the period of the study. Sampling occurred at the largest  
366 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex  
367 across consecutive sampling nights if required to capture a sufficient number of individuals.

368 Approximately 100 bats were captured at each sampling event, which lasted 7-10 days. We  
369 captured bats with a 10x15m mist net between 11pm and 5am each night as bats returned from  
370 foraging until the count of 100 was reached.

371 In the one-year longitudinal studies, sampling was undertaken in two roost complexes in  
372 Ramnagar and Chakhoria, Bangladesh between April 2010 and May 2011. Monthly sampling of  
373 approximately 40 bats in each location was performed to obtain data at a finer temporal scale. Details  
374 of collection are otherwise as described for the five-year study.

375 For each study, we recorded each bat's age class, reproductive status, weight, size, and body  
376 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with  
377 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box  
378 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and  
379 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton  
380 Cryogenics, NJ, USA).

381 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal  
382 swabs and pooled urine samples from under colonies. Further details can be found in [Epstein, et al.](#)  
383 [34](#)

#### 384 *Serological Assays*

385 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and  
386 gamma irradiated upon receipt. We used a bead-based microsphere assay that specifically detects  
387 antibodies to the soluble attachment glycoproteins<sup>57,63,64</sup> for a panel of viruses. Beads coated with each  
388 protein were mixed with sera at a dilution of 1:100. Biotinylated Protein A/G and Streptavidin-PE  
389 were then used to detect bound antibody. Beads were interrogated by lasers in a BioRad BioPlex  
390 machine and the results recorded as the Median Fluorescent Intensity (MFI) of 100 beads. We report  
391 here results for Nipah, Ebola-Zaire, and Menangle, the only three for which we established regular  
392 positive results.

393 While the Nipah virus has been detected in this population<sup>65</sup> and the specificity of the Nipah test  
394 is well-established<sup>66</sup>, the Ebola-Zaire and Menangle virus tests are cross-reactive with other Ebola  
395 and rubulavirus species<sup>67,68</sup>. Thus we refer to these as tests for filovirus and Rubulavirus.

#### 396 *Data Analysis*

397 We determined individual bat serostatus using Bayesian mixture models<sup>69</sup> fit on pooled data  
398 across all three longitudinal studies, calculating a cutoff of log-MFI as the point of equal probability  
399 between the smallest and second-smallest cluster of equal distributions for each assay.

400 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian  
401 multivariate probit model<sup>70,71</sup> which allows estimation of the joint outcomes (serostatus against each  
402 virus) and the correlation between the outcomes. We included age and sex variables to account for  
403 these effects on serostatus.

404 To examine time-varying changes in population seroprevalence, we fit binomial generalized  
405 additive mixed models (GAMMs)<sup>72,73</sup> to the time-series of serostatus measurements. For the five-year  
406 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit  
407 a model for seroprevalence dynamics over the course of the whole study. This treats the adult  
408 population as a single unit, though individuals within the population may turn over via migration,  
409 death and recruitment. We included both long-term and annual cyclic components for the multi-year  
410 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate  
411 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile  
412 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles

---

I am not 100% sure about this. All serological tests (the NiV test included) will detect cross-RX antibodies from related viruses. For NiV, you can argue that longitudinal surveillance has NOT detected any related viruses in the study populations, but we can't say that the Ab test is specific to NiV.

413 over their first year. To estimate periods of peak viral circulation within the population, we calculated  
414 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior  
415 distributions and classified periods with >95% of samples with positive derivatives - that is,  
416 increasing population seroprevalence - as periods of viral circulation. We also calculated strength  
417 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date  
418 at which this maximum occurred, again sampling these values from the model posterior, and  
419 calculating mean and high-density posterior interval (HDPI) values.

420 For the one-year studies, we fit models primarily to detect differences in time-varying changes  
421 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus  
422 measurements with separate models for each immunoassay. We included a separate, fixed-term  
423 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in  
424 serodynamics for each virus in each age group were compared between locations to test for spatial  
425 differences<sup>74</sup>. Juveniles identified as being from the previous year's cohort were excluded from the  
426 analysis.

427 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI  
428 between adult lactating females and their attached pups for each viral assay. We limited these to data  
429 from the five-year longitudinal study.

430 **Data Availability:** Raw data from this study and reproducible code used to perform analyses is available at the  
431 Zenodo Scientific Archive [Zenodo DOI to be generated] and also on GitHub at

---

Dear Jon and all,

It is great to see this in a ready to go form after so much effort put into this longitudinal study.

See my edits/comments in the attached. My main suggestion is to treat all three groups the same, i.e., at the genus level.

@Steve @Emily: I finally made my trip to Bangladesh (and icddr,b) working on a BMGF-funded pathogen genomics project. I “challenged” the new ED to host the Nipah@25 in 2024 there and he said he will do his best to make sure it happens. So hopefully we all meet again in Bangladesh in 2024.

Cheers,

LF

- External Email -

Colleagues,

I hope you're all doing well. I'm excited to share a draft manuscript, led by Noam, that details the serodynamics of henipaviruses, filoviruses and rubulaviruses in a population of *Pteropus medius*. We plan to submit this to *Nature Communications* in September. Please send Noam and I your comments by **September 10th**.

Cheers,

Jon

## Section 1. Executive Summary

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary center focused on analyzing zoonotic disease risk in a key EID hotspot region. Our aims are to 1) characterize diverse coronaviruses, paramyxoviruses, filoviruses, and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in Thailand, Malaysia, and Singapore. Highlights of research and significant findings during the reporting period (October 2021 – August 2022) include:

To be updated with bullet points by Peter...

## Section 2: Research Center Overview

### A. Specific Aims

The overarching goal of the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is to characterize the diversity of key viral pathogens in wildlife, assess the frequency and causes of their spillover, and identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in people. The research goals of the EID-SEARCH follow three specific aims designed to advance our understanding of spillover and outbreak risk for novel viruses in a globally important EID hotspot, strengthen in-country research capacity, and enhance international collaboration:

- Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.
- Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.
- Specific Aim 3: Identify and characterize the viral etiology of ‘cryptic’ outbreaks in clinical cohorts.

### B. Partners and Staffing

EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions (EcoHealth Alliance PI Peter Daszak; University of North Carolina Co-I Ralph Baric; Uniformed Service University Co-Is Christopher Broder and Eric Laing), and in Thailand (Chulalongkorn University Co-Is Supaporn Wacharapluesadee and Opass Putcharoen), Singapore (Duke-NUS Medical School Co-I Linfa Wang), and the three major Malaysian administrative regions (Conservation Medicine Co-I Tom Hughes). These organizations represent the ‘hub’ of the center, with an additional, more informal collaborative network spanning >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries. By enhancing and focusing research within the three hub countries, and coordinating communication among the network, we envision EID-SEARCH acting as an early warning system for outbreaks; a way to exchange information, reagents, samples, and technology; and a collaborative powerhouse for translational research. EID-SEARCH is supported by a multidisciplinary team of researchers at our partner institutions, with skills in epidemiology, clinical management, molecular biology, virology, wildlife biology, and advanced data and statistical analyses. The long collaborative history between the key personnel and partner institutions is a significant asset that can be deployed to support outbreak research response in the region.

### C. Research Sites

The three core (hub) countries for the EID-SEARCH are Thailand, Malaysia, and Singapore, *expanded to Viet Nam and Cambodia through the CREID Pilot Research Program*. These stretch through one of the

most significant foci of EID risk globally. Additionally, we have assembled a greater network of EID-SEARCH partners that includes >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries – stretching from Nepal to the Philippines. Our targeted field research includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak, Sabah, Viet Nam, and Cambodia. The central location of our hub countries in mainland Southeast Asia allows us to sample representative wildlife species that occur in other countries across the greater biogeographic region, including India, Bangladesh, Myanmar, Southwest China, Laos, Cambodia, Philippines, and Indonesia.

### Section 3: Research Center Progress and Accomplishments

#### Progress and Accomplishments

- Organized by Aim
- Focus on key accomplishments
- Address outbreak research response if applicable
- Address how the 2021 EAC recommendations have been incorporated (*see Appendix A for 2021 EAC report*)

#### A. Projects and Studies

- Have you reverted to your original (pre-pandemic) CREID research agenda in the last year? If not, how has your research agenda changed in the last year due to the ongoing impact of SARS-CoV-2?
- What additional changes to your CREID research agenda have taken place in the last year?

#### Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife

- Field surveillance among wild bats, rodents, and non-human primates.** We have collected 14,302 specimens from 2,055 animals of 31 bat species, one non-human primate (NHP) species, and five rodent species from six sites at high-risk human-wildlife interfaces in Malaysia and Thailand. (Table 1)

	Thailand	Malaysia
No. of collected specimens	3,862	14,171
No. of individuals	454 bats, 106 rodents	2,000 bats
No. of species	6 (bats), 5 (rodents)	24 (bats)
No. of sites	5	4
No. of tested individuals	407	1,332
No. PCR tests for coronaviruses (CoVs), paramyxoviruses (PMVs), filoviruses (FLVs), influenza viruses (IVs)	4,070	9,228
Identified viruses	3 new CoVs from 11 bats 3 known PMVs from 4 rodents 4 new PMVs from 11 bats	5 new CoVs from 112 bats 4 new PMVs from 10 bats 2 known PMVs from 2 bats
No. of specimen for multiplex immunoassay for FLVs, CoV and Henipavirus	100 macaques 92 rodents	720 bats

**Table 1.** EID-SEARCH viral surveillance in wildlife in Malaysia and Thailand.

- Discovery of novel SARS-like beta-coronavirus in bats in Thailand.** The whole genomes revealed a 91.72% nucleotide similarity to SARS-CoV-2. Phylogenetic analysis suggested that this virus is closer to pangolin CoV-GD-1 than to SARS-CoV-2; however, the RBD is more similar to that of bat-CoV RaTG13, suggesting that this new virus may also bind to mammalian ACE2 receptors. Whole-genome sequencing of other new CoVs from Thailand and Malaysia is ongoing.

# Summary of Comments on Email 8 - Attachment 1 - 2022 EAC Report\_EID-SEARCH\_draft v01-EDL-KR-SN\_15Aug22 (002).pdf

I'm not a mol. evol. geneticist but the way this is laid out in the table gives equal weight to a full genome, Thailand 1 new CoV, and distinct RdRp NT sequences that are used to create phylogenetic trees. I don't think I'll ever understand how the virology field uses small NT reads to discover new viruses. I suggest adding another row for "full virus genome sequenced" and a footnote about the methods used to determine how a new virus has been genetically identified.

Check ICTV guideline, I thought it was established to use, e.g., bat SARS-related coronavirus (bat SARSr-CoV). The use of beta-coronavirus widens the focus away from sarbecoviruses.

- Genome-wide CRISPR knockout screen identifies essential factor for HKU2/SADS-CoV infection.** Using a genome-wide CRISPR knockout screen, we identified placenta-associated 8 protein (PLAC8) as an essential host factor for SADS-CoV infection of human cells. Infection is prevented in PLAC8 knockouts and can be restored by transiently transfecting PLAC8 from multiple species, including human, pig, mouse, and bat. Trypsin treatment of SADS-CoV bypasses the PLAC8-dependent pathway and partially rescues SADS-CoV infection. PLAC8 is involved in both early entry and later dissemination of SADS-CoV infection and PLAC8 KO cells have: 1) delayed and reduced viral subgenomic RNA expression and 2) diminished cell-to-cell viral spreading of infected cells. *These results suggest that PLAC8 is a promising target for antiviral development for the potential pandemic SADS-CoV virus.*
- Host range, transmissibility, and antigenicity of a pangolin coronavirus.** Using a synthetically derived infectious cDNA clone, we recovered the wildtype pangolin (Pg) CoV-GD and derivatives encoding indicator genes. Like SARS-CoV-2, PgCoV-GD virus efficiently uses human and many other orthologous mammalian ACE2 receptors for entry, shares a similarly broad host range *in vitro*, and displays altered sensitivity to host proteases. PgCoV-GD replicates to slightly higher to lower titers in primary human cells derived from the proximal to distal lung, respectively, and with reduced fitness compared to SARS-CoV-2. PgCoV-GD also replicates efficiently in hamsters and could transmit via the **aerosol route**, but at a lower frequency than SARS-CoV2. Efficient PgCoV-GD replication in primary nasal airway epithelial cells and transmission in the hamster <sup>5</sup> highlights the high emergence potential of this virus. However, PgCoV-GD <sup>2</sup> is efficiently neutralized by COVID-19 patient sera and many commercially available SARS-CoV-2 therapeutic antibodies, but not by human antibodies targeting the spike N-terminal domain. Furthermore, a pan-sarbecovirus antibody, ADG-2, and a SARS-CoV-2 prefusion stabilized <sup>3</sup> spike protein (S2P) recombinant protein vaccine protected mice in a PgCoV-GD replication model. Lastly, we showed that cross-neutralizing antibodies in pre-immune SARS-CoV-2 humans and the benefit of current COVID-19 countermeasures should impede its ability to emerge and <sup>7</sup> spread globally in humans. *This research helps build FDA-approved therapeutic antibodies against a range of CoVs with emergence potential and shows that FDA-approved SARS-CoV-2 vaccines also protect animals from PgCoV-GD when <sup>8</sup> challenged in vivo.*

**Aims 2 & 3: Identify evidence and analyze risk factors for viral spillover in high-risk communities and clinical cohorts, and characterize <sup>9</sup> viral etiology of ‘cryptic’ outbreaks**

- Incorporation our bat-CoV spike proteins into the multi-family multiplex-based immunoassay (MMIA).** Specific bat-CoV spike proteins including bat SARSr-CoVs RaT13, bat SARSr-CoV ZXC21, bat MERSr-CoV PDF2180, and HKU9 were designed as pre-fusion stabilized spike glycoprotein ectodomain trimers (S-2P). These were spike protein antigens were incorporated into our 17-plex henipavirus/filovirus-focused serology assay expanding the representation of virus targets to include priority coronaviruses such as SARS-CoV-2 and bat SARSr-CoVs/bat MERSr-CoV. SOPs were revised and updated to reflect best practices that were optimized during Year 1.
- Community serology surveillance.** We initiated the human surveillance work in Thailand, with 56 participants enrolled at one at-risk community site, and 2 individuals from a clinic site, with a total of 58 participants enrolled. Serology testing of samples from 56 participants from the community site showed positive for henipaviruses (HNVs) (family *Paramyxoviridae*), filoviruses (FLVs), and CoVs (Fig. 1). Human sera were tested in the multi-family MMIA for serologic evidence of previous infection by Asiatic FLVs, HNVs, and CoV. **We observed minimal reactivity and IgG binding with the NiV receptor-binding protein (RBP)**, implying that subclinical cryptic NiV infections had not occurred in these

The fusion data Chee Wah presented indicated that it does bind to and mediate cellular entry/fusion via the human ACE-2 orthologue.
- 
- Number: 2 Author: Microsoft Office User Date: 8/2/2022 8:35:00 AM  
? not sure what this means. Were there lower viral loads in the respiratory tract? Is aerosol route correct, or should it be respiratory secretions? There is a lot of data in this section, is there a reference to a pre-print or article?
- 
- Number: 3 Author: Microsoft Office User Date: 8/2/2022 8:33:00 AM  
List these?
- 
- Number: 4 Author: Microsoft Office User Date: 8/2/2022 8:37:00 AM  
This is pretty nuanced. Do the commercially available mAbs that neutralized PgCoV-GD target the RBD or Q neutralizing epitopes in the S glycoprotein and not the NTD?
- 
- Number: 5 Author: Microsoft Office User Date: 8/2/2022 8:33:00 AM  
Is this an FDA EUA or authorized treatment?
- 
- Number: 6 Author: Microsoft Office User Date: 8/2/2022 8:32:00 AM  
This is something not FDA EUA? Will stakeholders understand what S-2P etc means? This is what NovaVax is making.
- 
- Number: 7 Author: Microsoft Office User Date: 8/2/2022 8:39:00 AM  
Replication, not infection or disease model? What did these mAb and vaccine protect from, infection?
- 
- Number: 8 Author: Microsoft Office User Date: 8/2/2022 8:41:00 AM  
What does this mean, sera from humans with memory to seasonal beta-human coronaviruses can cross-neutralize PgCoV-GD, by binding recognition to the S2 fusion domains?
- 
- Number: 9 Author: Microsoft Office User Date: 8/2/2022 8:43:00 AM  
I didn't see any mention of FDA-approved antibody therapies or vaccine countermeasures being tested in the sentences before.

Tighten this up with explicit details.

participants (Figure 1B). One human serum sample possessed IgG that was reactive with envelope glycoproteins (GP) from Ebola virus, Bundibugyo virus, Bombali virus, Sudan virus, and Lloviu virus, consistent with a serologic pattern of cross-reactivity among phylogenetically-related ebolaviruses (Figure 1A). A diversity of genetically and antigenically uncharacterized Asiatic filoviruses is likely to exist, and this serology results is consistent with other serology-focused projects in the region. The antigenic relationships and contribution of glycoepitopes to heterotypic cross-reactions among ebolaviruses and broadly within FLVs remains poorly understood, follow-up testing will explore whether broad cross-reactions with FLVs antigens is driven by glycosylated epitopes that may be more conserved across the ebolaviruses than protein sequence similarity/identity would imply. Lastly, human sera displayed maximum preferential reactivity with SARS-CoV-2 spike protein, consistent with COVID-19 vaccination status of participants. At the low testing titer, cross-reactions with phylogenetically-related bat sarbecoviruses was expectedly observed (Figure 1C). Interestingly, two participants had sera IgG that bound to the bat MERSr-CoV PDF2180, which does not utilize the orthologous human DPP4/CD20 receptor for cellular entry, and it quite distinct from the sarbecoviruses.

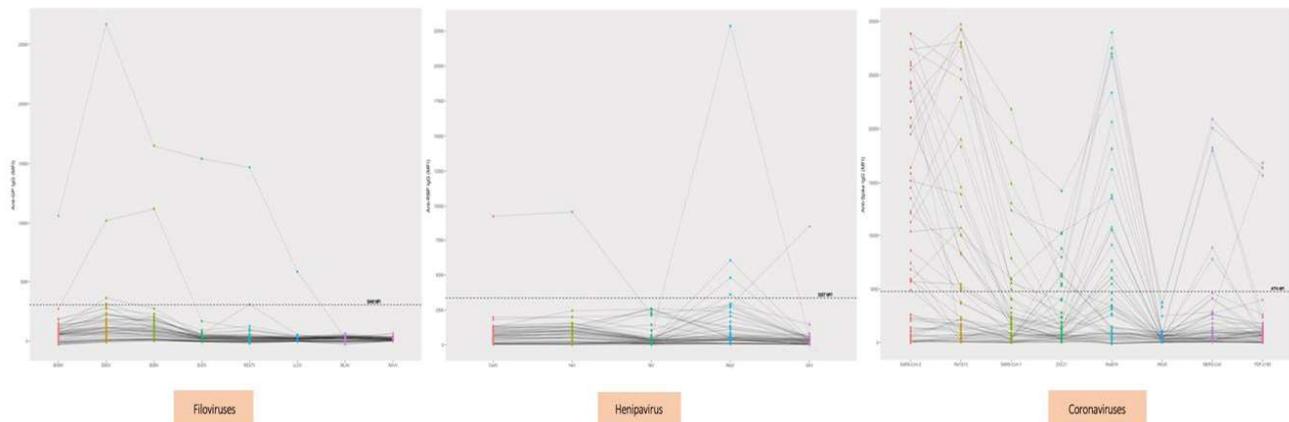

Fig. 1 Serology testing results for FLVs, HNVs, and CoVs among community participants in Thailand (n=56).

- **Design and application of pan-sarbecovirus multiplex surrogate virus neutralization test (sVNT)** that covers SARS-CoV-2 and variants of concern (Alpha, Beta, Gamma, Delta, Mu, Lambda, Omicron BA.1 and BA.2), clade-2 sarbecoviruses (BANAL-52, BANAL-263, GD-1, RaTG13, GX-P5L), clade-1 sarbecoviruses (Rs2018B, LYRa11, WIV-1, RsSHC014, Rs4231), SARS-CoV-1, and *the newly discovered bat SARSr-CoV we recently sequenced from Thailand*. This assay allows for the discrimination of past SARS-CoV-2 infection from that of other sarbecoviruses in human and animal samples, which will be critical for identifying cryptic spillover of sarbecoviruses in people. It also has the potential to aid in identifying the progenitor of SARS-CoV-2 in animals.
- **Optimization and establishment of pan-henipavirus multiplex sVNT at Chulalongkorn University.** We also optimized an sVNT for Nipah virus and provided enough material to characterize Nipah virus IgG positive serum samples for neutralizing antibodies via a virus-free/cell-culture free bead-based serology assay.

Needs a proper legend.

### Outbreak investigation and preparedness in Thailand

- The Ministry of Public Health in Thailand requested support from EID-SEARCH for a viral diarrhea outbreak investigation in Chanthaburi province. We received samples from both Prapokklao Hospital (regional hospital) and Khlong Khut Health-Promoting hospital collected from 59 healthcare workers and students who had diarrhea during Dec. 2021-Feb. 2022. PCR tests were conducted for six gastrointestinal viruses causing gastrointestinal tract infections including adenovirus, astrovirus, norovirus GI, norovirus GII, rotavirus, and sapovirus. 32 samples (**54.24%**) were positive for norovirus GII. Further genomic characterization of the detected norovirus GII will be performed, allowing for comparison with noroviruses found in other provinces in Thailand.
- In preparedness for Monkeypox outbreaks, EID-SEARCH's lab partner in Thailand coordinated with the Department of Medical Science, MOPH, National lab to establish the Monkeypox testing platform in April 2022 and detected the first Monkeypox case in Thailand in July 2022.

### B. Dissemination of Results

- Summarize dissemination plan
- Include number of peer-reviewed publications; highlight those in high-impact journals
- Number and content of presentations on CREID research, including audience

EID-SEARCH members were invited to present the project work at government and inter-government briefings (> 10), conference and university lectures (>13), panels and webinars (>18), and public interviews (>6) in Thailand, Malaysia, the US, regionally and internationally on the trends in global disease emergence, zoonotic surveillance, pandemic control and prevention, and research results from this project research activities. Nine (9) peer-reviewed paper has been published or with preprint available from EID-SEARCH work, two (2) manuscripts are currently under revision, and three (3) manuscripts are in preparation for submission, **including papers on.. please highlight the high-impact ones**. We organized a workshop with 55 scientists and government officials from Thailand, Malaysia, Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, and Australia to present EID-SEARCH work, share knowledge, strengthen research capacity, and foster scientific collaborations in Southeast Asia.

### C. Training and Capacity Building Activities

- Summarize capacity building plan
- Include number of training activities and number of participants for each training
- Address how capacity building activities were adapted due to COVID-19 and long-term changes as a result of the pandemic

During this reporting period, XX training sessions with a total of XX participants were conducted by EID-SEARCH partners in Thailand, Malaysia, and Vietnam for project members, local government partners, universities, research institutes, and NGOs. These training focused on biosafety (x training x participants by x), applying new technologies (x training x participants by x), and field and laboratory SOPs (x training x participants by x), to strengthen in-country research capacity and improve information sharing. Both in-person and online training was conducted to accommodate COVID conditions. As travel and COVID-19 restrictions have begun to be lifted, students, postdocs, and all EID-SEARCH research staff have been provided with professional development opportunities to travel to attend conferences, workshops, and other in-person training activities. **To be updated with numbers...**

---

Number: 1 Author: Sasiprapa Ninwattana Date: 8/15/2022 5:28:00 PM

As mentioned earlier, I re-tested the two serum samples that were weakly positive for NiV and it turned out that both of them showed seronegative. So I'm not sure that should this part still be included.

---

Number: 2 Author: Microsoft Office User Date: 8/2/2022 8:51:00 AM

If not including the PMID, I'd at least add the Surname, First Initial, et al. J. Infect Dis. 2022.

---

Number: 3 Author: Sasiprapa Ninwattana Date: 8/13/2022 11:02:00 AM

1. Our paper "Rapid and Simultaneous Detection of Omicron and Other Concerned SARS-CoV-2 Variants (Alpha, Beta, and Delta) in Clinical Specimens Using Multiplex PCR MassARRAY Technology" is under revision

2. "Homologous or Heterologous COVID-19 Booster Regimens Significantly Impact Sero-Neutralization of SARS-CoV-2 Virus and its Variants" has been accepted for publication in vaccines journal

#### D. Challenges and Proposed Solutions

- Bottlenecks to CREID-related research that might be like those that you could face when pivoting research activities in direct response to an EID outbreak. What solutions could be or have you put in place in advance to solve those challenges? How is being part of the CREID Network mitigating those or not?

The significant challenges we encountered during the reporting period were travel restrictions to our field partner countries and within countries, as well as a large number of hospitalized patients in local hospitals in Thailand and Malaysia due to COVID-19 that delayed human participant enrollment at targeted community and hospital sites and the subsequent laboratory analysis we anticipated in Year 2. To address these issues, we worked closely with in-country partners and stakeholders to continue assessing the situations (i.e., safety and research priorities of study sites) to ensure a rapid start of enrollment and focused on the refinement of assays to be ready for human surveillance. Meanwhile, to prevent a possible supply shortage of PPE and swabs as happened in early Year 2, we have identified supply sources to ensure we can procure the necessary consumables without significant delays. With travel restrictions in Southeast Asian countries now beginning to be lifted, international travel of US-based staff to our field sites has begun (April 2022).

#### E. Examples of Network Collaboration

- How has the work/research of your RC been affected by or involved collaboration with other members of the CREID Network?
- Examples: highlight joint publications, joint activities, sharing materials and data, benefits of Working Groups, etc.

Through the participation of different CREID Working Groups, EID-SEARCH members participated in the network's outbreak responses, capacity building, and cross-center collaboration by sharing existing local partnerships, techniques, and relevant resources.

- For outbreak responses, EID-SEARCH has been actively participating in the network's response to Monkeypox by providing local partnerships and monitoring platforms in DRC and Thailand.
- For lab assay sharing, EID-SEARCH partner Uniformed Services University is working with UWARN PIs, Dr. Robert Cross and Dr. Scott Weaver, to establish a MTA with UTMB and regional partners in Liberia and Nigeria for the multi-family FLV/HNV MMIA for anti-EBOV serology testing. Enquiries has been made with Dr. Mark Page and the National Institute for Biological Standards and Control (NIBSC) regarding additional MARV and NiV serology standards.
- We are contacted by multiple Research Centers regarding the Field Biosafety Manual presented at the CREID Scientific Meeting by EID-SEARCH senior field veterinarian, the Manual and corresponding training resources will be made available to all CREID members once it's completed with peer review. **Marc, please feel to edit...**
- EID-SEARCH are also committed to providing our expertise on CCHF, Henipavirus, RVF related research by connecting CREID members with our research partners.

#### Section 4: Future Directions

- Plan for the next reporting period.
- How is your Research Center adapting to the April 2022 NIAID Program Priorities and how does this change (or not) your planned activities in the next year? *See Appendix B for NIAID Program Priorities.*

- Moving forward, what is the greatest opportunity your RC has to advance the knowledge base for emerging infectious diseases? What are the significant knowledge gaps that the RC can advance research on?

In the next reporting period, we will follow the research plans laid out in our proposal with the specific actions to **continue expanding our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats that align with the CREID network research priorities:**

**Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.**

- Wildlife (bats, rodents, and non-human primates) sampling at selected sites, with increased efforts for rodents and non-human primates and potential longitudinal sampling at a few selected sites to analyze patterns of viral shedding and spillover risk.
- Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 3-5 of the project.
- Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses, filoviruses, and paramyxoviruses.
- Perform serology testing on the wildlife samples for coronaviruses, filoviruses, and henipavirus.
- Continue developing a more comprehensive multiplex CoV RBD-based sVNT covering newly identified sarbecoviruses and additional merbecoviruses to allow the evaluation of neutralizing activity in serum samples against a much broader and more comprehensive range of RBDs.
- Conduct whole-genome and spike glycoprotein sequencing in countries with newly identified viruses.
- Continue research to further characterize a subset of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies, including pangolin GD strain, BANAL-52, and other significant viruses identified in Y1-2.
- Develop zoonotic risk analyses for relevant viruses, including the analysis of Spike and whole-genome sequences to predict host range using a variety of in silico approaches, model the host range, geographic distribution, extent of overlap with high-density human populations, etc. using existing apps/models to assess potential zoonotic disease risk

**Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays**

- Increase the number of sites and enrolled participants for community surveillance among at-risk populations for biological and behavioral data collection in Thailand, Peninsular Malaysia, and Sabah Malaysia
- Continue to identify community sites concurrent with animal surveillance sites (Specific Aim 1).
- Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and paramyxoviruses
- Begin epidemiological analyses of biological and behavioral data.

**Specific Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts**

- Start enrolling participants at selected hospital/clinic sites for syndromic surveillance at two sites in Thailand, and identified sites in Sabah, Malaysia and Peninsular Malaysia, Malaysia
- Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.

- Start serological and molecular testing on collected human samples.
- Start viral characterization work if any novel viruses are identified.

*Through the work under Specific Aims 2&3, we are engaging multiple disciplines of social science, anthropology, health policy, and behavioral science towards EID risk mitigation strategies on key human-animal interfaces, we will share relevant research methods (e.g., behavioral questionnaires) and best practices with the CREID Network members.*

**Training and capacity-building activities among in-country team members, especially young EIDs researchers, to strengthen domestic, regional, and international capacity and readiness to efficiently undertake the research required in response to emerging or re-emerging threats. Available training materials or resources will be made available to the CREID Network.**

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures and discussion as well as hands-on guidance.
- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing.
- Conduct training in traditional viral whole-genome sequencing using primer walking for paramyxoviruses.
- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training.
- Trial the use of the portable Oxford Nanopore MinION platform as an in-house sequencing solution in Malaysia.
- Continue training on multiplex microsphere immunoassay (MMIA) data analysis and interpretation.
- Conduct refresh training on human research regarding survey design, interview skills, and data analysis.
- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer-review, publication, and broad distribution.
- Continue sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government in a timely manner.
- Organize meetings and workshops with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region (November 2022).
- Initiate exchange training for young researchers among EID-SEARCH partners for NGS and other laboratory technology transfers.
- Support in-country outbreak research and response.

---

Number: 1 Author: Sasiprapa Ninwattana Date: 8/15/2022 5:31:00 PM

Would it be possible to propose training on RBD and/or spike glycoprotein design and coupling?

## Appendix A: 2021 EAC Report

### Centers for Research in Emerging Infectious Diseases (CREID)

#### CREID External Advisory Committee (EAC) Summary

#### In follow up to the CREID Network Annual Meeting

#### November 3-5, 2021 (virtual meeting)

Prepared by Mark Feinberg, MD, PhD on behalf of the CREID EAC

### Overview of EAC Perspectives and Recommendations

The EAC members were unanimous in their assessment that the CREID Network team made very impressive and positive progress in their first year of this very important and timely new NIAID/DMID initiative. While the amount of progress realized in starting up a new global collaborative research network would be highly laudable overall in any circumstance, the EAC members were even further impressed by the fact that the initiation of the CREID Network coincided with the emergence of the COVID-19 pandemic (with all of its attendant challenges). This coincidence provided a clear initial focus of many of the CREID efforts on SARS-CoV-2-related topics, but it also provided very strong validation for the original rationale for establishment of the CREID Network by the NIAID/DMID leadership as a means of fostering global networks for research collaboration on emerging infectious disease threats.

While the EAC members identified a number of areas where additional attention and effort will be beneficial to maximize the impact of the CREID Network, and key to fostering the sustainability of its efforts, our expectations for what the Network has the potential to accomplish were raised by the strong foundation that the CREID PIs and collaborators have already put in place in their first year. We were also very impressed with the clear commitment, thoughtfulness and inclusive approach of the CC leadership, and with the expertise, passion, and experience of the broader CREID Network community of scientists. At the heart of the CREID is a commitment to new models of collaborative science that links investigators from around the world to understand, prepare for, and respond to emerging infectious disease threats. As such, the extent to which CREID utilizes current best practices for collaborative research and pioneers new ones; embraces the essential role played by investigators working in countries at risk for disease emergence (including resource-limited settings); partners in new and more effective and mutually trusting ways with governments, normative agencies and other emerging infectious disease-focused research organizations; exemplifies and communicates the value of scientific research in providing solutions to emerging infectious disease threats to governments and the public; and delivers on its commitment to genuine research capacity strengthening and sustainability will be critical measures for evaluating the future success of the CREID. The EAC recognizes that this is a very ambitious agenda filled with often challenging objectives, and that the inherent nature of time-limited NIH funding mechanisms presents additional challenges to their potential realization.

In considering these issues, the EAC felt that significant progress has been made in the first year of the CREID Network, but that additional opportunities exist for the PIs and CREID investigators to be even more intentional and strategic about their collaborative research efforts. The CREID Network has the opportunity to establish a number of positive precedents in models of effective global collaborative science where the “whole is truly greater than the sum of its parts”; by demonstrating new approaches for the “decolonization” of international research; and by delivering on a strong commitment to diversity and inclusion in all of its endeavors. In many ways, achieving these goals will require innovation in collaborative research models within a large global network, and not just in delivering innovative, high quality scientific research results. The EAC members recognize the challenge of finding the right balance between investigator- and RC-initiated science with broader strategies and shared goals of a large collaborative network, but also note that doing so will require an overarching strategy, effective

communication tools and ongoing performance monitoring and adjustment. The EAC members also recognize that the important Network goals of research capacity strengthening and sustainability are not trivial undertakings and that they are very promising, but also rather novel objectives, within the context of NIH-supported research programs. These are additional important areas where the CREID CC and RC leadership can further articulate a respectful, inclusive, realistic, achievable and measurable strategy.

In all of these areas, the EAC recommends that the CREID investigators further develop and implement (a) a clear, well-defined and shared set of Network priorities (that links the work across RCs) and key performance indicators (KPIs) to measure performance toward realizing them, (b) a shared strategic vision and plan that connects the research efforts being prioritized and conducted across the Network centers, (c) a mechanism to share best practices across the Coordinating Center (CC) and Research Centers and (d) a proactive approach to identify collaborative research opportunities, fill gaps, avoid duplication and pursue synergies both within the CREID Network and, importantly, with the large and growing number of other organization working on preparing for and responding to emerging infectious disease outbreaks. Clarity and specificity in these efforts will be beneficial, as well as adopting an appropriate sense of realism about what can be accomplished by the CREID Network itself and where the new partnerships it implements with other organizations working in the emerging infectious disease arena will be essential. In this regard, given the complexity of the emerging infectious disease landscape, the CREID Network's ability to have the most significant impact will likely depend on the connections it establishes with other stakeholders and the innovation it drives in conceptualizing and delivering on effective new collaborative endeavors it develops with other capable partners. Towards this end, the Network would benefit from developing a thorough understanding of the ecosystem of potential partners and a defined approach to engage with the most relevant and promising ones. In addition, while the CREID Network includes collaborators from many centers and countries, its true global scope is limited by gaps in its geographic coverage (eg, countries in Asia, the Middle East, Northern Africa, Australia, etc...including those where risk of pathogen emergence are significant). Understanding if the CREID Network will be limited by its current geographic reach or plans to work to build additional connections (perhaps via strategic partnerships) in other regions will be beneficial from both practical and strategic levels.

Given that the readiness of the CREID Network for future outbreak response (and to be able to perform research in the midst of an outbreak when many challenges prevail) and for pandemic preparedness is a priority for NIAID/DMID, it will be important for the Network to clearly define how they best proactively plan to be able to promptly implement critical research programs when a new pathogen emerges or a previously known one reemerges. It will also be beneficial for the CREID CC and RCs to develop a clear plan (including protocols for coordination, implementation, data sharing and communication) to enable the Network to be able to respond expeditiously to an emerging infectious disease threat. Towards this end, tabletop exercises (or similar) to "pressure test" Network approaches and identify gaps/opportunities for improvement are worth considering.

The EAC is excited about what the CREID CC and RCs, and all of the collaborating CREID investigators, have accomplished in their first year of work and look forward to seeing the innovations and insights the Network will deliver in the future. The EAC recognizes that the CREID Network cannot realistically be "all things for all people", and should not strive to be. WE therefore also look forward to seeing how your Network priorities are further articulated, implemented and measured moving forward.

### **Additional EAC Impressions**

The EAC felt that the Executive Summary of the CREID Network Annual Meeting provided an accurate overview of the meeting proceedings and of the EAC feedback provided at the end of the meeting proceedings. Some specific additional impressions/requests shared by EAC members include:

- Gaining a better understanding of how CREID investigators are interfacing with local governments and ministries, public health authorities (eg, WHO, US CDC, Africa CDC, etc), normative agencies will be helpful, and how learnings of effective approaches should be shared across the Network. In addition, optimization of engagements with other research organizations, enabling disciplines (eg, social science, health economics, health policy, ethics), as well as the medical countermeasures community, will be helpful
- Gaining a better understanding of the experience to date in data sharing efforts and how these can be optimized
- Gaining a better understanding of how bilateral sharing of research materials and specimens can be optimized (given the role of host institutions and government policies) and how these might operate during an outbreak/pandemic
- How the CREID investigators view and are approaching their educational efforts with governments, political leaders and the public, and sharing of best practices for engagement and trust-building
- How the CREID Network is engaging with industry partners that both supply enabling tools and technologies and who may also assist in the development and commercialization of CREID-advanced innovations (eg, diagnostics)
- Opportunities exist to demonstrate the CREID commitment to decolonization of global health (with increased attention to having the voices from LMIC-based investigators better balanced with those of US-based investigators)
- Opportunities exist to better model the Network's and the NIH's commitment to DEI objectives (with increased attention to full representation in all aspects of the work...including presentations, leadership groups, pilot research awards)
- Opportunities for enhancing epidemiology, bioinformatics, digital tools and modeling capacity
- Gaining a better understanding of the role of social and cultural aspects of the outbreak response and communication, and exploring innovative approaches to address them
- Understanding how engagement with governments and other local stakeholders is being pursued to advance capacity strengthening and sustainability goals
- Further articulation of rapid response collaboration frameworks
- Gaining a better understanding of how local priorities influence the prioritization decisions of the CC and RCs
- Gaining a better understanding/"needs assessment" of capacity gaps (eg, BSL-3 training and labs) and how these are being addressed via strategic connections or focused investment
- How "parachute or safari research" is avoided, and how local researchers are engaged as full partners/leaders
- Definition of opportunities to maximize speed and efficiency in research implementation efforts (eg, US permits and in-country regulations, IRB delays, key relationship gaps) needed for prompt outbreak responses
- Value of developing a clear vision and plan for sustainability that maximizes the connection with and contributions of other partners and local governments
- South-South collaboration should be applauded and fostered
- Shared EAC interest in seeing the CREID Network's progress in ongoing database and biorepository workstreams

## Appendix B: NIAID CREID Network Program Priorities (April 2022)

*(4 main priorities all carry equal weight and are intended to cover research and activities to prepare for and respond to emerging and re-emerging threats.)*

- **Conduct innovative research to expand our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats**
  - Research Priorities:
    - Pathogen discovery & characterization
    - Pathogen/host surveillance
    - Pathogen transmission
    - Pathogenesis & immunologic responses in the host
    - Natural history & contemporary clinical disease
    - Develop reagents & diagnostic/detection assays
  - Engage in coordinated, Network wide outbreak/pandemic research readiness, differentiated from standard public health responses
- **Establish a collaborative, strategic, and preemptive research Network to ensure coordination of efforts across the Network**
  - Centralize communication
  - Conduct Network wide capacity inventory
  - Establish effective data harmonization and platforms for sharing
  - Harmonize sample collection, biorepositories, and network sharing/agreements
  - Share laboratory assay best practices and protocols
  - Share reagents, diagnostic/detection assays, and other resources
- **Develop and expand flexible domestic and international capacity and readiness to efficiently undertake research required in response to emerging or re-emerging threats**
  - Prioritize and engage with key stakeholders that will enhance network capabilities and integrate into the global health landscape
  - Strengthen and enhance research collaboration and partnerships globally
  - Pivot programmatic priorities and resources when needed for a timely response to emerging or re-emerging pathogen threats
    - Develop protocols for coordination, implementation, data sharing, and communication.
    - Execute tabletop exercises to test, refine, and maintain Network readiness
  - Formulate novel strategies to detect, control, and prevent outbreaks
    - Translate findings to downstream partners to facilitate development of medical countermeasures or preventive interventions
    - Develop adaptable risk assessment tools for evaluating a pathogen threat's potential for significant emergence and impact
- **Contribute to the development of the next generation of emerging/re-emerging infectious disease scientists and leaders**
  - Develop and maintain a pilot research program
  - Foster a diverse and inclusive research environment and program

## Section 1. Executive Summary

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary center focused on analyzing zoonotic disease risk in a key EID hotspot region. Our aims are to 1) characterize diverse coronaviruses, paramyxoviruses, filoviruses, and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in Thailand, Malaysia, and Singapore. Highlights of research and significant findings during the reporting period (October 2021 – August 2022) include:

To be updated with bullet points by Peter...

## Section 2: Research Center Overview

### A. Specific Aims

The overarching goal of the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is to characterize the diversity of key viral pathogens in wildlife, assess the frequency and causes of their spillover, and identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in people. The research goals of the EID-SEARCH follow three specific aims designed to advance our understanding of spillover and outbreak risk for novel viruses in a globally important EID hotspot, strengthen in-country research capacity, and enhance international collaboration:

- Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.
- Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.
- Specific Aim 3: Identify and characterize the viral etiology of ‘cryptic’ outbreaks in clinical cohorts.

### B. Partners and Staffing

EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions (EcoHealth Alliance PI Peter Daszak; University of North Carolina Co-I Ralph Baric; Uniformed Service University Co-Is Christopher Broder and Eric Laing), and in Thailand (Chulalongkorn University Co-Is Supaporn Wacharapluesadee and Opass Puchcharoen), Singapore (Duke-NUS Medical School Co-I Linfa Wang), and the three major Malaysian administrative regions (Conservation Medicine Co-I Tom Hughes). These organizations represent the ‘hub’ of the center, with an additional, more informal collaborative network spanning >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries. By enhancing and focusing research within the three hub countries, and coordinating communication among the network, we envision EID-SEARCH acting as an early warning system for outbreaks; a way to exchange information, reagents, samples, and technology; and a collaborative powerhouse for translational research. EID-SEARCH is supported by a multidisciplinary team of researchers at our partner institutions, with skills in epidemiology, clinical management, molecular biology, virology, wildlife biology, and advanced data and statistical analyses. The long collaborative history between the key personnel and partner institutions is a significant asset that can be deployed to support outbreak research response in the region.

### C. Research Sites

The three core (hub) countries for the EID-SEARCH are Thailand, Malaysia, and Singapore, *expanded to Viet Nam and Cambodia through the CREID Pilot Research Program*. These stretch through one of the

most significant foci of EID risk globally. Additionally, we have assembled a greater network of EID-SEARCH partners that includes >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries – stretching from Nepal to the Philippines. Our targeted field research includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak, Sabah, Viet Nam, and Cambodia. The central location of our hub countries in mainland Southeast Asia allows us to sample representative wildlife species that occur in other countries across the greater biogeographic region, including India, Bangladesh, Myanmar, Southwest China, Laos, Cambodia, Philippines, and Indonesia.

### Section 3: Research Center Progress and Accomplishments

#### Progress and Accomplishments

- Organized by Aim
- Focus on key accomplishments
- Address outbreak research response if applicable
- Address how the 2021 EAC recommendations have been incorporated (*see Appendix A for 2021 EAC report*)

#### A. Projects and Studies

- Have you reverted to your original (pre-pandemic) CREID research agenda in the last year? If not, how has your research agenda changed in the last year due to the ongoing impact of SARS-CoV-2?
- What additional changes to your CREID research agenda have taken place in the last year?

#### Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife

- **Field surveillance among wild bats, rodents, and non-human primates.** We have collected 14,302 specimens from 2,055 animals of 31 bat species, one non-human primate (NHP) species, and five rodent species from six sites at high-risk human-wildlife interfaces in Malaysia and Thailand. (Table 1)

	Thailand	Malaysia
No. of collected specimens	3,862	14,171
No. of individuals	454 bats, 106 rodents	2,000 bats
No. of species	6 (bats), 5 (rodents)	24 (bats)
No. of sites	5	4
No. of tested individuals	407	1,332
No. PCR tests for coronaviruses (CoVs), paramyxoviruses (PMVs), filoviruses (FLVs), influenza viruses (IVs)	4,070	9,228
Identified viruses	3 new CoVs from 11 bats 3 known PMVs from 4 rodents 4 new PMVs from 11 bats	5 new CoVs from 112 bats 4 new PMVs from 10 bats 2 known PMVs from 2 bats
No. of specimen for multiplex immunoassay for FLVs, CoV and Henipavirus	100 macaques 92 rodents	720 bats

**Table 1.** EID-SEARCH viral surveillance in wildlife in Malaysia and Thailand.

- **Discovery of novel SARS-like beta-coronavirus in bats in Thailand.** The whole genomes revealed a 91.72% nucleotide similarity to SARS-CoV-2. Phylogenetic analysis suggested that this virus is closer to pangolin CoV-GD-1 than to SARS-CoV-2; however, the RBD is more similar to that of bat-CoV RaTG13, suggesting that this new virus may also bind to mammalian ACE2 receptors. Whole-genome sequencing of other new CoVs from Thailand and Malaysia is ongoing.

---

I'm not a mol. evol. geneticist but the way this is laid out in the table gives equal weight to a full genome, Thailand 1 new CoV, and distinct RdRp NT sequences that are used to create phylogenetic trees. I don't think I'll ever understand how the virology field uses small NT reads to discover new viruses. I suggest adding another row for "full virus genome sequenced" and a footnote about the methods used to determine how a new virus has been genetically identified.

Check ICTV guideline, I thought it was established to use, e.g., bat SARS-related coronavirus (bat SARSr-CoV). The use of beta-coronavirus widens the focus away from sarbecoviruses.

- Genome-wide CRISPR knockout screen identifies essential factor for HKU2/SADS-CoV infection.** Using a genome-wide CRISPR knockout screen, we identified placenta-associated 8 protein (PLAC8) as an essential host factor for SADS-CoV infection of human cells. Infection is prevented in PLAC8 knockouts and can be restored by transiently transfecting PLAC8 from multiple species, including human, pig, mouse, and bat. Trypsin treatment of SADS-CoV bypasses the PLAC8-dependent pathway and partially rescues SADS-CoV infection. PLAC8 is involved in both early entry and later dissemination of SADS-CoV infection and PLAC8 KO cells have: 1) delayed and reduced viral subgenomic RNA expression and 2) diminished cell-to-cell viral spreading of infected cells. *These results suggest that PLAC8 is a promising target for antiviral development for the potential pandemic SADS-CoV virus.*
- Host range, transmissibility, and antigenicity of a pangolin coronavirus.** Using a synthetically derived infectious cDNA clone, we recovered the wildtype pangolin (Pg) CoV-GD and derivatives encoding indicator genes. Like SARS-CoV-2, PgCoV-GD virus efficiently uses human and many other orthologous mammalian ACE2 receptors for entry, shares a similarly broad host range *in vitro*, and displays altered sensitivity to host proteases. PgCoV-GD replicates to slightly higher to lower titers in primary human cells derived from the proximal to distal lung, respectively, and with reduced fitness compared to SARS-CoV-2. PgCoV-GD also replicates efficiently in hamsters and could transmit via the **aerosol route**, but at a lower frequency than SARS-CoV2. Efficient PgCoV-GD replication in primary nasal airway epithelial cells and transmission in the hamster <sup>5</sup> highlights the high emergence potential of this virus. However, PgCoV-GD <sup>2</sup> is efficiently neutralized by COVID-19 patient sera and many commercially available SARS-CoV-2 therapeutic antibodies, but not by human antibodies targeting the spike N-terminal domain. Furthermore, a pan-sarbecovirus antibody, ADG-2, and a SARS-CoV-2 prefusion stabilized <sup>3</sup> spike protein (S2P) recombinant protein vaccine protected mice in a PgCoV-GD replication model. Lastly, we showed that cross-neutralizing antibodies in pre-immune SARS-CoV-2 humans and the benefit of current COVID-19 countermeasures should impede its ability to emerge and <sup>7</sup> spread globally in humans. *This research helps build FDA-approved therapeutic antibodies against a range of CoVs with emergence potential and shows that FDA-approved SARS-CoV-2 vaccines also protect animals from PgCoV-GD when <sup>8</sup> challenged in vivo.*

**Aims 2 & 3: Identify evidence and analyze risk factors for viral spillover in high-risk communities and clinical cohorts, and characterize <sup>9</sup> viral etiology of ‘cryptic’ outbreaks**

- Incorporation our bat-CoV spike proteins into the multi-family multiplex-based immunoassay (MMIA).** Specific bat-CoV spike proteins including bat SARSr-CoVs RaT13, bat SARSr-CoV ZXC21, bat MERSr-CoV PDF2180, and HKU9 were designed as pre-fusion stabilized spike glycoprotein ectodomain trimers (S-2P). These were spike protein antigens were incorporated into our 17-plex henipavirus/filovirus-focused serology assay expanding the representation of virus targets to include priority coronaviruses such as SARS-CoV-2 and bat SARSr-CoVs/bat MERSr-CoV. SOPs were revised and updated to reflect best practices that were optimized during Year 1.
- Community serology surveillance.** We initiated the human surveillance work in Thailand, with 56 participants enrolled at one at-risk community site, and 2 individuals from a clinic site, with a total of 58 participants enrolled. Serology testing of samples from 56 participants from the community site showed positive for henipaviruses (HNVs) (family *Paramyxoviridae*), filoviruses (FLVs), and CoVs (Fig. 1). Human sera were tested in the multi-family MMIA for serologic evidence of previous infection by Asiatic FLVs, HNVs, and CoV. **We observed minimal reactivity and IgG binding with the NiV receptor-binding protein (RBP)**, implying that subclinical cryptic NiV infections had not occurred in these

## Page: 5

-

The fusion data Chee Wah presented indicated that it does bind to and mediate cellular entry/fusion via the human ACE-2 orthologue.
- 
- Number: 2 Author: Microsoft Office User Date: 8/2/2022 8:35:00 AM  
? not sure what this means. Were there lower viral loads in the respiratory tract? Is aerosol route correct, or should it be respiratory secretions? There is a lot of data in this section, is there a reference to a pre-print or article?
- 
- Number: 3 Author: Microsoft Office User Date: 8/2/2022 8:33:00 AM  
List these?
- 
- Number: 4 Author: Microsoft Office User Date: 8/2/2022 8:37:00 AM  
This is pretty nuanced. Do the commercially available mAbs that neutralized PgCoV-GD target the RBD or Q neutralizing epitopes in the S glycoprotein and not the NTD?
- 
- Number: 5 Author: Microsoft Office User Date: 8/2/2022 8:33:00 AM  
Is this an FDA EUA or authorized treatment?
- 
- Number: 6 Author: Microsoft Office User Date: 8/2/2022 8:32:00 AM  
This is something not FDA EUA? Will stakeholders understand what S-2P etc means? This is what NovaVax is making.
- 
- Number: 7 Author: Microsoft Office User Date: 8/2/2022 8:39:00 AM  
Replication, not infection or disease model? What did these mAb and vaccine protect from, infection?
- 
- Number: 8 Author: Microsoft Office User Date: 8/2/2022 8:41:00 AM  
What does this mean, sera from humans with memory to seasonal beta-human coronaviruses can cross-neutralize PgCoV-GD, by binding recognition to the S2 fusion domains?
- 
- Number: 9 Author: Microsoft Office User Date: 8/2/2022 8:43:00 AM  
I didn't see any mention of FDA-approved antibody therapies or vaccine countermeasures being tested in the sentences before.

Tighten this up with explicit details.

participants (Figure 1B). One human serum sample possessed IgG that was reactive with envelope glycoproteins (GP) from Ebola virus, Bundibugyo virus, Bombali virus, Sudan virus, and Lloviu virus, consistent with a serologic pattern of cross-reactivity among phylogenetically-related ebolaviruses (Figure 1A). A diversity of genetically and antigenically uncharacterized Asiatic filoviruses is likely to exist, and this serology results is consistent with other serology-focused projects in the region. The antigenic relationships and contribution of glycoepitopes to heterotypic cross-reactions among ebolaviruses and broadly within FLVs remains poorly understood, follow-up testing will explore whether broad cross-reactions with FLVs antigens is driven by glycosylated epitopes that may be more conserved across the ebolaviruses than protein sequence similarity/identity would imply. Lastly, human sera displayed maximum preferential reactivity with SARS-CoV-2 spike protein, consistent with COVID-19 vaccination status of participants. At the low testing titer, cross-reactions with phylogenetically-related bat sarbecoviruses was expectedly observed (Figure 1C). Interestingly, two participants had sera IgG that bound to the bat MERSr-CoV PDF2180, which does not utilize the orthologous human DPP4/CD20 receptor for cellular entry, and it quite distinct from the sarbecoviruses.

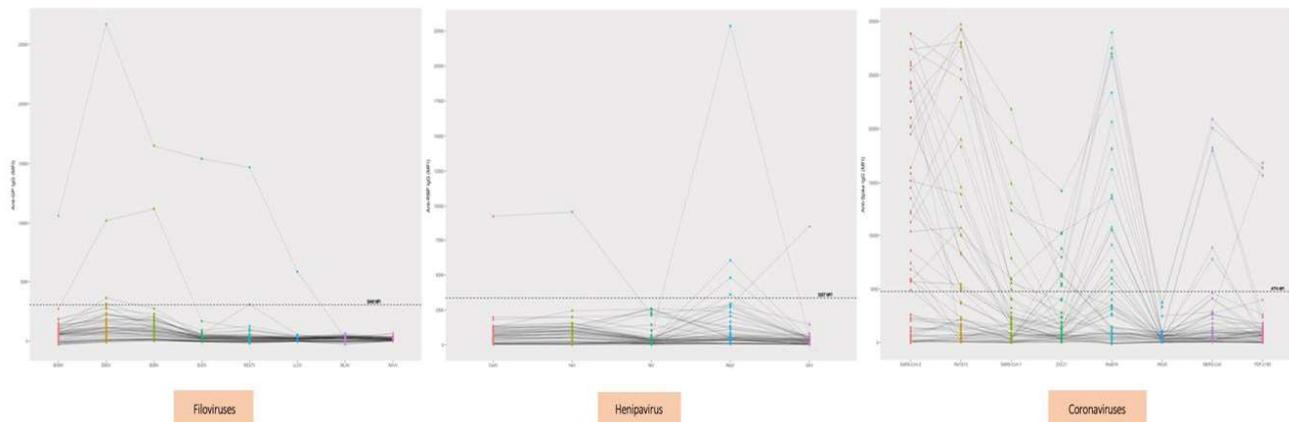

Fig. 1 Serology testing results for FLVs, HNVs, and CoVs among community participants in Thailand (n=56).

- **Design and application of pan-sarbecovirus multiplex surrogate virus neutralization test (sVNT)** that covers SARS-CoV-2 and variants of concern (Alpha, Beta, Gamma, Delta, Mu, Lambda, Omicron BA.1 and BA.2), clade-2 sarbecoviruses (BANAL-52, BANAL-263, GD-1, RaTG13, GX-P5L), clade-1 sarbecoviruses (Rs2018B, LYRa11, WIV-1, RsSHC014, Rs4231), SARS-CoV-1, and *the newly discovered bat SARSr-CoV we recently sequenced from Thailand*. This assay allows for the discrimination of past SARS-CoV-2 infection from that of other sarbecoviruses in human and animal samples, which will be critical for identifying cryptic spillover of sarbecoviruses in people. It also has the potential to aid in identifying the progenitor of SARS-CoV-2 in animals.
- **Optimization and establishment of pan-henipavirus multiplex sVNT at Chulalongkorn University.** We also optimized an sVNT for Nipah virus and provided enough material to characterize Nipah virus IgG positive serum samples for neutralizing antibodies via a virus-free/cell-culture free bead-based serology assay.

Needs a proper legend.

### Outbreak investigation and preparedness in Thailand

- The Ministry of Public Health in Thailand requested support from EID-SEARCH for a viral diarrhea outbreak investigation in Chanthaburi province. We received samples from both Prapokklao Hospital (regional hospital) and Khlong Khut Health-Promoting hospital collected from 59 healthcare workers and students who had diarrhea during Dec. 2021-Feb. 2022. PCR tests were conducted for six gastrointestinal viruses causing gastrointestinal tract infections including adenovirus, astrovirus, norovirus GI, norovirus GII, rotavirus, and sapovirus. 32 samples (**54.24%**) were positive for norovirus GII. Further genomic characterization of the detected norovirus GII will be performed, allowing for comparison with noroviruses found in other provinces in Thailand.
- In preparedness for Monkeypox outbreaks, EID-SEARCH's lab partner in Thailand coordinated with the Department of Medical Science, MOPH, National lab to establish the Monkeypox testing platform in April 2022 and detected the first Monkeypox case in Thailand in July 2022.

### B. Dissemination of Results

- Summarize dissemination plan
- Include number of peer-reviewed publications; highlight those in high-impact journals
- Number and content of presentations on CREID research, including audience

EID-SEARCH members were invited to present the project work at government and inter-government briefings (> 10), conference and university lectures (>13), panels and webinars (>18), and public interviews (>6) in Thailand, Malaysia, the US, regionally and internationally on the trends in global disease emergence, zoonotic surveillance, pandemic control and prevention, and research results from this project research activities. Nine (9) peer-reviewed paper has been published or with preprint available from EID-SEARCH work, two (2) manuscripts are currently under revision, and three (3) manuscripts are in preparation for submission, *including papers on.. please highlight the high-impact ones*. We organized a workshop with 55 scientists and government officials from Thailand, Malaysia, Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, and Australia to present EID-SEARCH work, share knowledge, strengthen research capacity, and foster scientific collaborations in Southeast Asia.

### C. Training and Capacity Building Activities

- Summarize capacity building plan
- Include number of training activities and number of participants for each training
- Address how capacity building activities were adapted due to COVID-19 and long-term changes as a result of the pandemic

During this reporting period, XX training sessions with a total of XX participants were conducted by EID-SEARCH partners in Thailand, Malaysia, and Vietnam for project members, local government partners, universities, research institutes, and NGOs. These training focused on biosafety (x training x participants by x), applying new technologies (x training x participants by x), and field and laboratory SOPs (x training x participants by x), to strengthen in-country research capacity and improve information sharing. Both in-person and online training was conducted to accommodate COVID conditions. As travel and COVID-19 restrictions have begun to be lifted, students, postdocs, and all EID-SEARCH research staff have been provided with professional development opportunities to travel to attend conferences, workshops, and other in-person training activities. *To be updated with numbers...*

---

Number: 1 Author: Sasiprapa Ninwattana Date: 8/15/2022 5:28:00 PM

As mentioned earlier, I re-tested the two serum samples that were weakly positive for NiV and it turned out that both of them showed seronegative. So I'm not sure that should this part still be included.

---

Number: 2 Author: Microsoft Office User Date: 8/2/2022 8:51:00 AM

If not including the PMID, I'd at least add the Surname, First Initial, et al. J. Infect Dis. 2022.

---

Number: 3 Author: Sasiprapa Ninwattana Date: 8/13/2022 11:02:00 AM

1. Our paper "Rapid and Simultaneous Detection of Omicron and Other Concerned SARS-CoV-2 Variants (Alpha, Beta, and Delta) in Clinical Specimens Using Multiplex PCR MassARRAY Technology" is under revision

2. "Homologous or Heterologous COVID-19 Booster Regimens Significantly Impact Sero-Neutralization of SARS-CoV-2 Virus and its Variants" has been accepted for publication in vaccines journal

#### D. Challenges and Proposed Solutions

- Bottlenecks to CREID-related research that might be like those that you could face when pivoting research activities in direct response to an EID outbreak. What solutions could be or have you put in place in advance to solve those challenges? How is being part of the CREID Network mitigating those or not?

The significant challenges we encountered during the reporting period were travel restrictions to our field partner countries and within countries, as well as a large number of hospitalized patients in local hospitals in Thailand and Malaysia due to COVID-19 that delayed human participant enrollment at targeted community and hospital sites and the subsequent laboratory analysis we anticipated in Year 2. To address these issues, we worked closely with in-country partners and stakeholders to continue assessing the situations (i.e., safety and research priorities of study sites) to ensure a rapid start of enrollment and focused on the refinement of assays to be ready for human surveillance. Meanwhile, to prevent a possible supply shortage of PPE and swabs as happened in early Year 2, we have identified supply sources to ensure we can procure the necessary consumables without significant delays. With travel restrictions in Southeast Asian countries now beginning to be lifted, international travel of US-based staff to our field sites has begun (April 2022).

#### E. Examples of Network Collaboration

- How has the work/research of your RC been affected by or involved collaboration with other members of the CREID Network?
- Examples: highlight joint publications, joint activities, sharing materials and data, benefits of Working Groups, etc.

Through the participation of different CREID Working Groups, EID-SEARCH members participated in the network's outbreak responses, capacity building, and cross-center collaboration by sharing existing local partnerships, techniques, and relevant resources.

- For outbreak responses, EID-SEARCH has been actively participating in the network's response to Monkeypox by providing local partnerships and monitoring platforms in DRC and Thailand.
- For lab assay sharing, EID-SEARCH partner Uniformed Services University is working with UWARN PIs, Dr. Robert Cross and Dr. Scott Weaver, to establish a MTA with UTMB and regional partners in Liberia and Nigeria for the multi-family FLV/HNV MMIA for anti-EBOV serology testing. Enquiries has been made with Dr. Mark Page and the National Institute for Biological Standards and Control (NIBSC) regarding additional MARV and NiV serology standards.
- We are contacted by multiple Research Centers regarding the Field Biosafety Manual presented at the CREID Scientific Meeting by EID-SEARCH senior field veterinarian, the Manual and corresponding training resources will be made available to all CREID members once it's completed with peer review. **Marc, please feel to edit...**
- EID-SEARCH are also committed to providing our expertise on CCHF, Henipavirus, RVF related research by connecting CREID members with our research partners.

#### Section 4: Future Directions

- Plan for the next reporting period.
- How is your Research Center adapting to the April 2022 NIAID Program Priorities and how does this change (or not) your planned activities in the next year? *See Appendix B for NIAID Program Priorities.*

- Moving forward, what is the greatest opportunity your RC has to advance the knowledge base for emerging infectious diseases? What are the significant knowledge gaps that the RC can advance research on?

In the next reporting period, we will follow the research plans laid out in our proposal with the specific actions to **continue expanding our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats that align with the CREID network research priorities:**

**Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.**

- Wildlife (bats, rodents, and non-human primates) sampling at selected sites, with increased efforts for rodents and non-human primates and potential longitudinal sampling at a few selected sites to analyze patterns of viral shedding and spillover risk.
- Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 3-5 of the project.
- Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses, filoviruses, and paramyxoviruses.
- Perform serology testing on the wildlife samples for coronaviruses, filoviruses, and henipavirus.
- Continue developing a more comprehensive multiplex CoV RBD-based sVNT covering newly identified sarbecoviruses and additional merbecoviruses to allow the evaluation of neutralizing activity in serum samples against a much broader and more comprehensive range of RBDs.
- Conduct whole-genome and spike glycoprotein sequencing in countries with newly identified viruses.
- Continue research to further characterize a subset of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies, including pangolin GD strain, BANAL-52, and other significant viruses identified in Y1-2.
- Develop zoonotic risk analyses for relevant viruses, including the analysis of Spike and whole-genome sequences to predict host range using a variety of in silico approaches, model the host range, geographic distribution, extent of overlap with high-density human populations, etc. using existing apps/models to assess potential zoonotic disease risk

**Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays**

- Increase the number of sites and enrolled participants for community surveillance among at-risk populations for biological and behavioral data collection in Thailand, Peninsular Malaysia, and Sabah Malaysia
- Continue to identify community sites concurrent with animal surveillance sites (Specific Aim 1).
- Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and paramyxoviruses
- Begin epidemiological analyses of biological and behavioral data.

**Specific Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts**

- Start enrolling participants at selected hospital/clinic sites for syndromic surveillance at two sites in Thailand, and identified sites in Sabah, Malaysia and Peninsular Malaysia, Malaysia
- Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.

- Start serological and molecular testing on collected human samples.
- Start viral characterization work if any novel viruses are identified.

*Through the work under Specific Aims 2&3, we are engaging multiple disciplines of social science, anthropology, health policy, and behavioral science towards EID risk mitigation strategies on key human-animal interfaces, we will share relevant research methods (e.g., behavioral questionnaires) and best practices with the CREID Network members.*

**Training and capacity-building activities among in-country team members, especially young EIDs researchers, to strengthen domestic, regional, and international capacity and readiness to efficiently undertake the research required in response to emerging or re-emerging threats. Available training materials or resources will be made available to the CREID Network.**

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures and discussion as well as hands-on guidance.
- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing.
- Conduct training in traditional viral whole-genome sequencing using primer walking for paramyxoviruses.
- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training.
- Trial the use of the portable Oxford Nanopore MinION platform as an in-house sequencing solution in Malaysia.
- Continue training on multiplex microsphere immunoassay (MMIA) data analysis and interpretation.
- Conduct refresh training on human research regarding survey design, interview skills, and data analysis.
- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer-review, publication, and broad distribution.
- Continue sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government in a timely manner.
- Organize meetings and workshops with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region (November 2022).
- Initiate exchange training for young researchers among EID-SEARCH partners for NGS and other laboratory technology transfers.
- Support in-country outbreak research and response.

Would it be possible to propose training on RBD and/or spike glycoprotein design and coupling?

## Appendix A: 2021 EAC Report

### Centers for Research in Emerging Infectious Diseases (CREID)

#### CREID External Advisory Committee (EAC) Summary

#### In follow up to the CREID Network Annual Meeting

#### November 3-5, 2021 (virtual meeting)

Prepared by Mark Feinberg, MD, PhD on behalf of the CREID EAC

### Overview of EAC Perspectives and Recommendations

The EAC members were unanimous in their assessment that the CREID Network team made very impressive and positive progress in their first year of this very important and timely new NIAID/DMID initiative. While the amount of progress realized in starting up a new global collaborative research network would be highly laudable overall in any circumstance, the EAC members were even further impressed by the fact that the initiation of the CREID Network coincided with the emergence of the COVID-19 pandemic (with all of its attendant challenges). This coincidence provided a clear initial focus of many of the CREID efforts on SARS-CoV-2-related topics, but it also provided very strong validation for the original rationale for establishment of the CREID Network by the NIAID/DMID leadership as a means of fostering global networks for research collaboration on emerging infectious disease threats.

While the EAC members identified a number of areas where additional attention and effort will be beneficial to maximize the impact of the CREID Network, and key to fostering the sustainability of its efforts, our expectations for what the Network has the potential to accomplish were raised by the strong foundation that the CREID PIs and collaborators have already put in place in their first year. We were also very impressed with the clear commitment, thoughtfulness and inclusive approach of the CC leadership, and with the expertise, passion, and experience of the broader CREID Network community of scientists. At the heart of the CREID is a commitment to new models of collaborative science that links investigators from around the world to understand, prepare for, and respond to emerging infectious disease threats. As such, the extent to which CREID utilizes current best practices for collaborative research and pioneers new ones; embraces the essential role played by investigators working in countries at risk for disease emergence (including resource-limited settings); partners in new and more effective and mutually trusting ways with governments, normative agencies and other emerging infectious disease-focused research organizations; exemplifies and communicates the value of scientific research in providing solutions to emerging infectious disease threats to governments and the public; and delivers on its commitment to genuine research capacity strengthening and sustainability will be critical measures for evaluating the future success of the CREID. The EAC recognizes that this is a very ambitious agenda filled with often challenging objectives, and that the inherent nature of time-limited NIH funding mechanisms presents additional challenges to their potential realization.

In considering these issues, the EAC felt that significant progress has been made in the first year of the CREID Network, but that additional opportunities exist for the PIs and CREID investigators to be even more intentional and strategic about their collaborative research efforts. The CREID Network has the opportunity to establish a number of positive precedents in models of effective global collaborative science where the “whole is truly greater than the sum of its parts”; by demonstrating new approaches for the “decolonization” of international research; and by delivering on a strong commitment to diversity and inclusion in all of its endeavors. In many ways, achieving these goals will require innovation in collaborative research models within a large global network, and not just in delivering innovative, high quality scientific research results. The EAC members recognize the challenge of finding the right balance between investigator- and RC-initiated science with broader strategies and shared goals of a large collaborative network, but also note that doing so will require an overarching strategy, effective

communication tools and ongoing performance monitoring and adjustment. The EAC members also recognize that the important Network goals of research capacity strengthening and sustainability are not trivial undertakings and that they are very promising, but also rather novel objectives, within the context of NIH-supported research programs. These are additional important areas where the CREID CC and RC leadership can further articulate a respectful, inclusive, realistic, achievable and measurable strategy.

In all of these areas, the EAC recommends that the CREID investigators further develop and implement (a) a clear, well-defined and shared set of Network priorities (that links the work across RCs) and key performance indicators (KPIs) to measure performance toward realizing them, (b) a shared strategic vision and plan that connects the research efforts being prioritized and conducted across the Network centers, (c) a mechanism to share best practices across the Coordinating Center (CC) and Research Centers and (d) a proactive approach to identify collaborative research opportunities, fill gaps, avoid duplication and pursue synergies both within the CREID Network and, importantly, with the large and growing number of other organization working on preparing for and responding to emerging infectious disease outbreaks. Clarity and specificity in these efforts will be beneficial, as well as adopting an appropriate sense of realism about what can be accomplished by the CREID Network itself and where the new partnerships it implements with other organizations working in the emerging infectious disease arena will be essential. In this regard, given the complexity of the emerging infectious disease landscape, the CREID Network's ability to have the most significant impact will likely depend on the connections it establishes with other stakeholders and the innovation it drives in conceptualizing and delivering on effective new collaborative endeavors it develops with other capable partners. Towards this end, the Network would benefit from developing a thorough understanding of the ecosystem of potential partners and a defined approach to engage with the most relevant and promising ones. In addition, while the CREID Network includes collaborators from many centers and countries, its true global scope is limited by gaps in its geographic coverage (eg, countries in Asia, the Middle East, Northern Africa, Australia, etc...including those where risk of pathogen emergence are significant). Understanding if the CREID Network will be limited by its current geographic reach or plans to work to build additional connections (perhaps via strategic partnerships) in other regions will be beneficial from both practical and strategic levels.

Given that the readiness of the CREID Network for future outbreak response (and to be able to perform research in the midst of an outbreak when many challenges prevail) and for pandemic preparedness is a priority for NIAID/DMID, it will be important for the Network to clearly define how they best proactively plan to be able to promptly implement critical research programs when a new pathogen emerges or a previously known one reemerges. It will also be beneficial for the CREID CC and RCs to develop a clear plan (including protocols for coordination, implementation, data sharing and communication) to enable the Network to be able to respond expeditiously to an emerging infectious disease threat. Towards this end, tabletop exercises (or similar) to “pressure test” Network approaches and identify gaps/opportunities for improvement are worth considering.

The EAC is excited about what the CREID CC and RCs, and all of the collaborating CREID investigators, have accomplished in their first year of work and look forward to seeing the innovations and insights the Network will deliver in the future. The EAC recognizes that the CREID Network cannot realistically be “all things for all people”, and should not strive to be. WE therefore also look forward to seeing how your Network priorities are further articulated, implemented and measured moving forward.

### **Additional EAC Impressions**

The EAC felt that the Executive Summary of the CREID Network Annual Meeting provided an accurate overview of the meeting proceedings and of the EAC feedback provided at the end of the meeting proceedings. Some specific additional impressions/requests shared by EAC members include:

- Gaining a better understanding of how CREID investigators are interfacing with local governments and ministries, public health authorities (eg, WHO, US CDC, Africa CDC, etc), normative agencies will be helpful, and how learnings of effective approaches should be shared across the Network. In addition, optimization of engagements with other research organizations, enabling disciplines (eg, social science, health economics, health policy, ethics), as well as the medical countermeasures community, will be helpful
- Gaining a better understanding of the experience to date in data sharing efforts and how these can be optimized
- Gaining a better understanding of how bilateral sharing of research materials and specimens can be optimized (given the role of host institutions and government policies) and how these might operate during an outbreak/pandemic
- How the CREID investigators view and are approaching their educational efforts with governments, political leaders and the public, and sharing of best practices for engagement and trust-building
- How the CREID Network is engaging with industry partners that both supply enabling tools and technologies and who may also assist in the development and commercialization of CREID-advanced innovations (eg, diagnostics)
- Opportunities exist to demonstrate the CREID commitment to decolonization of global health (with increased attention to having the voices from LMIC-based investigators better balanced with those of US-based investigators)
- Opportunities exist to better model the Network's and the NIH's commitment to DEI objectives (with increased attention to full representation in all aspects of the work...including presentations, leadership groups, pilot research awards)
- Opportunities for enhancing epidemiology, bioinformatics, digital tools and modeling capacity
- Gaining a better understanding of the role of social and cultural aspects of the outbreak response and communication, and exploring innovative approaches to address them
- Understanding how engagement with governments and other local stakeholders is being pursued to advance capacity strengthening and sustainability goals
- Further articulation of rapid response collaboration frameworks
- Gaining a better understanding of how local priorities influence the prioritization decisions of the CC and RCs
- Gaining a better understanding/"needs assessment" of capacity gaps (eg, BSL-3 training and labs) and how these are being addressed via strategic connections or focused investment
- How "parachute or safari research" is avoided, and how local researchers are engaged as full partners/leaders
- Definition of opportunities to maximize speed and efficiency in research implementation efforts (eg, US permits and in-country regulations, IRB delays, key relationship gaps) needed for prompt outbreak responses
- Value of developing a clear vision and plan for sustainability that maximizes the connection with and contributions of other partners and local governments
- South-South collaboration should be applauded and fostered
- Shared EAC interest in seeing the CREID Network's progress in ongoing database and biorepository workstreams

## Appendix B: NIAID CREID Network Program Priorities (April 2022)

*(4 main priorities all carry equal weight and are intended to cover research and activities to prepare for and respond to emerging and re-emerging threats.)*

- **Conduct innovative research to expand our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats**
  - Research Priorities:
    - Pathogen discovery & characterization
    - Pathogen/host surveillance
    - Pathogen transmission
    - Pathogenesis & immunologic responses in the host
    - Natural history & contemporary clinical disease
    - Develop reagents & diagnostic/detection assays
  - Engage in coordinated, Network wide outbreak/pandemic research readiness, differentiated from standard public health responses
- **Establish a collaborative, strategic, and preemptive research Network to ensure coordination of efforts across the Network**
  - Centralize communication
  - Conduct Network wide capacity inventory
  - Establish effective data harmonization and platforms for sharing
  - Harmonize sample collection, biorepositories, and network sharing/agreements
  - Share laboratory assay best practices and protocols
  - Share reagents, diagnostic/detection assays, and other resources
- **Develop and expand flexible domestic and international capacity and readiness to efficiently undertake research required in response to emerging or re-emerging threats**
  - Prioritize and engage with key stakeholders that will enhance network capabilities and integrate into the global health landscape
  - Strengthen and enhance research collaboration and partnerships globally
  - Pivot programmatic priorities and resources when needed for a timely response to emerging or re-emerging pathogen threats
    - Develop protocols for coordination, implementation, data sharing, and communication.
    - Execute tabletop exercises to test, refine, and maintain Network readiness
  - Formulate novel strategies to detect, control, and prevent outbreaks
    - Translate findings to downstream partners to facilitate development of medical countermeasures or preventive interventions
    - Develop adaptable risk assessment tools for evaluating a pathogen threat's potential for significant emergence and impact
- **Contribute to the development of the next generation of emerging/re-emerging infectious disease scientists and leaders**
  - Develop and maintain a pilot research program
  - Foster a diverse and inclusive research environment and program

**DRAFT AGENDA**  
Hybrid Meeting  
Washington DC region and Zoom

DAY 1   Wednesday, September 21	
Time (ET)	Session
7:30-9:00	<b>Research Center meetings</b> <i>Participants: Research Center members</i>
09:00-09:15	<b>TableTop Exercise: Introduction</b> <i>In-person Participants: External Advisory Committee (EAC), DMID, Network Leadership</i> <i>Virtual Participants: Network members</i>
09:15-12:00	<b>Business Meeting</b> <i>Participants: EAC, DMID, Network Leadership</i> <ul style="list-style-type: none"> <li>▪ Potential topics: Operationalizing vision to achieve Network priorities, key performance indicators, pivoting resources, mentorship/development</li> </ul>
12:00-13:00	<b>Lunch</b>
13:00-14:00	<b>Opening, Priorities, and Vision</b> <i>Participants: EAC, DMID, Network members, USG, and select external stakeholders</i> <ul style="list-style-type: none"> <li>▪ Welcome (Chris &amp; Nikos)</li> <li>▪ Opening, CREID Role and Network Priorities (DMID)</li> <li>▪ CREID Network Shared Vision (SC reps x 2)</li> </ul>
14:00-14:15	<b>Break</b>
14:15-16:45	<b>Collaboration and Engagement</b> <i>Participants: EAC, DMID, Network members, USG, and select external stakeholders</i> <ul style="list-style-type: none"> <li>▪ Collaboration for Outbreak Research Response</li> <li>▪ Cross-RC collaboration: Additional opportunities, benefits, and needs</li> <li>▪ NIH Networks, USG, and External Collaborations</li> <li>▪ Benefit sharing, preparing for downstream translation</li> </ul>
16:45-17:00	<b>Day 1 Wrap up</b> (1 RC and/or 1 DMID rep)

DAY 2   Thursday, September 23	
Time (ET)	Session
07:30-09:00	<b>Research Center meetings</b> <i>Participants: Research Center members</i>
08:30-10:40	<b>TableTop Exercise: Session II</b> <i>Participants: EAC, DMID, Network members</i>
10:40-11:00	<b>Break</b>
11:00-12:00	<b>CREID Year 2 Review Panels</b> 5 RCs x 10 min ea., Q&A/discussion x 10 min <i>Participants: EAC, DMID, Network members</i>
12:00-13:00	<b>Lunch</b>
13:00-14:00	<b>CREID Year 2 Review Panels (cont.)</b> 5 RCs x 10 min ea., Q&A/discussion x 10 min <i>Participants: EAC, DMID, Network members</i>
14:00-15:10	<b>Abstract-Driven Session</b> <i>Participants: EAC, DMID, Network members</i>
15:10-15:30	<b>Break</b>
15:30-16:40	<b>Abstract-Driven Session</b> <i>Participants: EAC, DMID, Network members</i>
16:40-17:00	<b>Day 2 Takeaways</b> (1 RC and/or 1 DMID rep) <i>Participants: EAC, DMID, Network members</i>

DAY 3   Friday, September 23	
Time (ET)	Session
07:30-09:00	<b>Research Center meetings</b> <i>Participants: Research Center members</i>
08:30-10:40	<b>TableTop Exercise: Session III</b> <i>Participants: EAC, DMID, Network members</i>
10:40-11:00	<b>Break</b>
11:00-12:00	<b>Pilot Awardees Presentations (in-person and virtual)</b> <i>Participants: EAC, DMID, Network members</i>
12:00-13:00	<b>Lunch</b>
13:00-15:10	<b>Abstract-Driven Session</b> <i>Participants: EAC, DMID, Network members</i>
15:10-15:30	<b>Break</b>
15:30-16:00	<b>Abstract-Driven Session</b> <i>Participants: EAC, DMID, Network members</i>
16:00-17:00	<b>DMID and EAC Wrap-Up</b> <i>Participants: EAC, DMID, Network members</i>

## Section 1. Executive Summary

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary center focused on analyzing zoonotic disease risk in a key EID hotspot region. Our aims are to 1) characterize diverse coronaviruses, paramyxoviruses, filoviruses, and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in Thailand, Malaysia, and Singapore. Highlights of research and significant findings during the reporting period (October 2021 – August 2022) include:

To be updated with bullet points by Peter...

## Section 2: Research Center Overview

### A. Specific Aims

The overarching goal of the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is to characterize the diversity of key viral pathogens in wildlife, assess the frequency and causes of their spillover, and identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in people. The research goals of the EID-SEARCH follow three specific aims designed to advance our understanding of spillover and outbreak risk for novel viruses in a globally important EID hotspot, strengthen in-country research capacity, and enhance international collaboration:

- Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.
- Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.
- Specific Aim 3: Identify and characterize the viral etiology of ‘cryptic’ outbreaks in clinical cohorts.

### B. Partners and Staffing

EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions (EcoHealth Alliance PI Peter Daszak; University of North Carolina Co-I Ralph Baric; Uniformed Service University Co-Is Christopher Broder and Eric Laing), and in Thailand (Chulalongkorn University Co-Is Supaporn Wacharapluesadee and Opass Puchcharoen), Singapore (Duke-NUS Medical School Co-I Linfa Wang), and the three major Malaysian administrative regions (Conservation Medicine Co-I Tom Hughes). These organizations represent the ‘hub’ of the center, with an additional, more informal collaborative network spanning >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries. By enhancing and focusing research within the three hub countries, and coordinating communication among the network, we envision EID-SEARCH acting as an early warning system for outbreaks; a way to exchange information, reagents, samples, and technology; and a collaborative powerhouse for translational research. EID-SEARCH is supported by a multidisciplinary team of researchers at our partner institutions, with skills in epidemiology, clinical management, molecular biology, virology, wildlife biology, and advanced data and statistical analyses. The long collaborative history between the key personnel and partner institutions is a significant asset that can be deployed to support outbreak research response in the region.

### C. Research Sites

The three core (hub) countries for the EID-SEARCH are Thailand, Malaysia, and Singapore, *expanded to Viet Nam and Cambodia through the CREID Pilot Research Program*. These stretch through one of the

most significant foci of EID risk globally. Additionally, we have assembled a greater network of EID-SEARCH partners that includes >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries – stretching from Nepal to the Philippines. Our targeted field research includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak, Sabah, Viet Nam, and Cambodia. The central location of our hub countries in mainland Southeast Asia allows us to sample representative wildlife species that occur in other countries across the greater biogeographic region, including India, Bangladesh, Myanmar, Southwest China, Laos, Cambodia, Philippines, and Indonesia.

### Section 3: Research Center Progress and Accomplishments

#### Progress and Accomplishments

- Organized by Aim
- Focus on key accomplishments
- Address outbreak research response if applicable
- Address how the 2021 EAC recommendations have been incorporated (*see Appendix A for 2021 EAC report*)

#### A. Projects and Studies

- Have you reverted to your original (pre-pandemic) CREID research agenda in the last year? If not, how has your research agenda changed in the last year due to the ongoing impact of SARS-CoV-2?
- What additional changes to your CREID research agenda have taken place in the last year?

#### Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife

- **Field surveillance among wild bats, rodents, and non-human primates.** We have collected 14,302 specimens from 2,055 animals of 31 bat species, one non-human primate (NHP) species, and five rodent species from six sites at high-risk human-wildlife interfaces in Malaysia and Thailand. (Table 1)

	Thailand	Malaysia
No. of collected specimens	3,862	14,171
No. of individuals	454 bats, 106 rodents	2,000 bats
No. of species	6 (bats), 5 (rodents)	24 (bats)
No. of sites	5	4
No. of tested individuals	407	1,332
No. PCR tests for coronaviruses (CoVs), paramyxoviruses (PMVs), filoviruses (FLVs), influenza viruses (IVs)	4,070	9,228
Identified viruses	1 new CoV from 3 bats 3 known PMVs from 4 rodents 4 new PMVs from 11 bats	5 new CoVs from 112 bats 4 new PMVs from 10 bats 2 known PMVs from 2 bats
No. of specimen for multiplex immunoassay for FLVs and Henipavirus	-	720 bats

**Table 1.** EID-SEARCH viral surveillance in wildlife in Malaysia and Thailand.

- **Discovery of novel SARS-like beta-coronavirus in bats in Thailand.** The whole genomes revealed a 91.72% nucleotide similarity to SARS-CoV-2. Phylogenetic analysis suggested that this virus is closer to pangolin CoV-GD-1 than to SARS-CoV-2; however, the RBD is more similar to that of bat-CoV RaTG13, suggesting that this new virus may also bind to mammalian ACE2 receptors. Whole-genome sequencing of other new CoVs from Thailand and Malaysia is ongoing.
- **Genome-wide CRISPR knockout screen identifies essential factor for HKU2/SADS-CoV infection.** Using a genome-wide CRISPR knockout screen, we identified placenta-associated 8 protein (PLAC8) as

BA.2), clade-2 sarbecoviruses (BANAL-52, BANAL-263, GD-1, RaTG13, GX-P5L), clade-1 sarbecoviruses (Rs2018B, LYRa11, WIV-1, RsSHC014, Rs4231), SARS-CoV-1, and *the newly discovered bat CoV we recently sequenced from Thailand*. This assay allows for the discrimination of past SARS-CoV-2 infection from that of other sarbecoviruses in human and animal samples, which will be critical for identifying cryptic spillover of sarbecoviruses in people. It also has the potential to aid in identifying the progenitor of SARS-CoV-2 in animals.

- **Designed and secured the expression of bat-CoV spike proteins for incorporation into our multiplex (multi-family) serological assay.** Specific bat-borne CoV spike proteins include bat SARSr-CoVs RaT13, ZXC21, bat MERSr-CoV PDF2180, and HKU9. These were incorporated into our 17-plex henipavirus/filovirus-focused serology assay to include SARS-CoV-2 and bat-borne CoV antigens. We also optimized an sVNT for Nipah virus and provided enough material to characterize Nipah virus IgG positive serum samples neutralizing antibodies. SOPs were revised and updated to reflect best practices that were optimized during Year 1.

### **Outbreak investigation and preparedness in Thailand**

- The Ministry of Public Health in Thailand requested support from EID-SEARCH for a viral diarrhea outbreak investigation in Chanthaburi province. We received samples from both Prapokklao Hospital (regional hospital) and Khlong Khut Health-Promoting hospital collected from 59 healthcare workers and students who had diarrhea during Dec. 2021-Feb. 2022. PCR tests were conducted for six gastrointestinal viruses causing gastrointestinal tract infections including adenovirus, astrovirus, norovirus GI, norovirus GII, rotavirus, and sapovirus. 32 samples (**54.24%**) were positive for norovirus GII. Further genomic characterization of the detected norovirus GII will be performed, allowing for comparison with noroviruses found in other provinces in Thailand.
- In preparedness for Monkeypox outbreaks, EID-SEARCH's lab partner in Thailand coordinated with the Department of Medical Science, MOPH, National lab to establish the Monkeypox testing platform in April 2022 and detected the first Monkeypox case in Thailand in July 2022.

### **B. Dissemination of Results**

- Summarize dissemination plan
- Include number of peer-reviewed publications; highlight those in high-impact journals
- Number and content of presentations on CREID research, including audience

EID-SEARCH members were invited to present the project work at government and inter-government briefings (> 10), conference and university lectures (>13), panels and webinars (>18), and public interviews (>6) in Thailand, Malaysia, the US, regionally and internationally on the trends in global disease emergence, zoonotic surveillance, pandemic control and prevention, and research results from this project research activities. Nine (9) peer-reviewed paper has been published or with preprint available from EID-SEARCH work, two (2) manuscripts are currently under revision, and three (3) manuscripts are in preparation for submission, **including papers on.. please highlight the high-impact ones**. We organized a workshop with 55 scientists and government officials from Thailand, Malaysia, Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, and Australia to present EID-SEARCH work, share knowledge, strengthen research capacity, and foster scientific collaborations in Southeast Asia.

### C. Training and Capacity Building Activities

- Summarize capacity building plan
- Include number of training activities and number of participants for each training
- Address how capacity building activities were adapted due to COVID-19 and long-term changes as a result of the pandemic

During this reporting period, XX training sessions with a total of XX participants were conducted by EID-SEARCH partners in Thailand, Malaysia, and Vietnam for project members, local government partners, universities, research institutes, and NGOs. These training focused on biosafety (x training x participants by x), applying new technologies (x training x participants by x), and field and laboratory SOPs (x training x participants by x), to strengthen in-country research capacity and improve information sharing. Both in-person and online training was conducted to accommodate COVID conditions. As travel and COVID-19 restrictions have begun to be lifted, students, postdocs, and all EID-SEARCH research staff have been provided with professional development opportunities to travel to attend conferences, workshops, and other in-person training activities. **To be updated with numbers....**

### D. Challenges and Proposed Solutions

- Bottlenecks to CREID-related research that might be like those that you could face when pivoting research activities in direct response to an EID outbreak. What solutions could be or have you put in place in advance to solve those challenges? How is being part of the CREID Network mitigating those or not?

The significant challenges we encountered during the reporting period were travel restrictions to our field partner countries and within countries, as well as a large number of hospitalized patients in local hospitals in Thailand and Malaysia due to COVID-19 that delayed human participant enrollment at targeted community and hospital sites and the subsequent laboratory analysis we anticipated in Year 2. To address these issues, we worked closely with in-country partners and stakeholders to continue assessing the situations (i.e., safety and research priorities of study sites) to ensure a rapid start of enrollment and focused on the refinement of assays to be ready for human surveillance. Meanwhile, to prevent a possible supply shortage of PPE and swabs as happened in early Year 2, we have identified supply sources to ensure we can procure the necessary consumables without significant delays. With travel restrictions in Southeast Asian countries now beginning to be lifted, international travel of US-based staff to our field sites has begun (April 2022).

### E. Examples of Network Collaboration

- How has the work/research of your RC been affected by or involved collaboration with other members of the CREID Network?
- Examples: highlight joint publications, joint activities, sharing materials and data, benefits of Working Groups, etc.

Through the participation of different CREID Working Groups, EID-SEARCH members participated in the network's outbreak responses, capacity building, and cross-center collaboration by sharing existing local partnerships, techniques, and relevant resources.

- For outbreak responses, EID-SEARCH has been actively participating in the network's response to Monkeypox by providing local partnerships and monitoring platforms in DRC and Thailand.
- For lab assay sharing, EID-SEARCH partner Uniformed Services University is working with UWAEN to share the multiplex microsphere immunoassay (MMIA) with the regional partners for EBOV serology testing, and plan to work with the National Institute for Biological Standards and Control (NIBSC) to... **Eric, please feel free to edit to add more info**

- We are contacted by multiple Research Centers regarding the Field Biosafety Manual presented at the CREID Scientific Meeting by EID-SEARCH senior field veterinarian, the Manual and corresponding training resources will be made available to all CREID members once it's completed with peer review. **Marc, please feel to edit...**
- EID-SEARCH are also committed to providing our expertise on CCHF, Henipavirus, RVF related research by connecting CREID members with our research partners.

## Section 4: Future Directions

- Plan for the next reporting period.
- How is your Research Center adapting to the April 2022 NIAID Program Priorities and how does this change (or not) your planned activities in the next year? *See Appendix B for NIAID Program Priorities.*
- Moving forward, what is the greatest opportunity your RC has to advance the knowledge base for emerging infectious diseases? What are the significant knowledge gaps that the RC can advance research on?

In the next reporting period, we will follow the research plans laid out in our proposal with the specific actions to **continue expanding our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats that align with the CREID network research priorities:**

### **Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.**

- Wildlife (bats, rodents, and non-human primates) sampling at selected sites, with increased efforts for rodents and non-human primates and potential longitudinal sampling at a few selected sites to analyze patterns of viral shedding and spillover risk.
- Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 3-5 of the project.
- Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses, filoviruses, and paramyxoviruses.
- Perform serology testing on the wildlife samples for coronaviruses, filoviruses, and henipavirus.
- Continue developing a more comprehensive multiplex CoV RBD-based sVNT covering newly identified sarbecoviruses and additional merbecoviruses to allow the evaluation of neutralizing activity in serum samples against a much broader and more comprehensive range of RBDs.
- Conduct whole-genome and spike glycoprotein sequencing in countries with newly identified viruses.
- Continue research to further characterize a subset of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies, including pangolin GD strain, BANAL-52, and other significant viruses identified in Y1-2.
- Develop zoonotic risk analyses for relevant viruses, including the analysis of Spike and whole-genome sequences to predict host range using a variety of in silico approaches, model the host range, geographic distribution, extent of overlap with high-density human populations, etc. using existing apps/models to assess potential zoonotic disease risk

### **Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays**

- Increase the number of sites and enrolled participants for community surveillance among at-risk populations for biological and behavioral data collection in Thailand, Peninsular Malaysia, and Sabah Malaysia
- Continue to identify community sites concurrent with animal surveillance sites (Specific Aim 1).
- Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and paramyxoviruses
- Begin epidemiological analyses of biological and behavioral data.

**Specific Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts**

- Start enrolling participants at selected hospital/clinic sites for syndromic surveillance at two sites in Thailand, and identified sites in Sabah, Malaysia and Peninsular Malaysia, Malaysia
- Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.
- Start serological and molecular testing on collected human samples.
- Start viral characterization work if any novel viruses are identified.

*Through the work under Specific Aims 2&3, we are engaging multiple disciplines of social science, anthropology, health policy, and behavioral science towards EID risk mitigation strategies on key human-animal interfaces, we will share relevant research methods (e.g., behavioral questionnaires) and best practices with the CREID Network members.*

**Training and capacity-building activities among in-country team members, especially young EIDs researchers, to strengthen domestic, regional, and international capacity and readiness to efficiently undertake the research required in response to emerging or re-emerging threats. Available training materials or resources will be made available to the CREID Network.**

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures and discussion as well as hands-on guidance.
- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing.
- Conduct training in traditional viral whole-genome sequencing using primer walking for paramyxoviruses.
- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training.
- Trial the use of the portable Oxford Nanopore MinION platform as an in-house sequencing solution in Malaysia.
- Continue training on multiplex microsphere immunoassay (MMIA) data analysis and interpretation.
- Conduct refresh training on human research regarding survey design, interview skills, and data analysis.
- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer-review, publication, and broad distribution.
- Continue sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government in a timely manner.
- Organize meetings and workshops with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region (November 2022).
- Initiate exchange training for young researchers among EID-SEARCH partners for NGS and other laboratory technology transfers.
- Support in-country outbreak research and response.

## Appendix A: 2021 EAC Report

### **Centers for Research in Emerging Infectious Diseases (CREID) CREID External Advisory Committee (EAC) Summary In follow up to the CREID Network Annual Meeting November 3-5, 2021 (virtual meeting)**

Prepared by Mark Feinberg, MD, PhD on behalf of the CREID EAC

#### **Overview of EAC Perspectives and Recommendations**

The EAC members were unanimous in their assessment that the CREID Network team made very impressive and positive progress in their first year of this very important and timely new NIAID/DMID initiative. While the amount of progress realized in starting up a new global collaborative research network would be highly laudable overall in any circumstance, the EAC members were even further impressed by the fact that the initiation of the CREID Network coincided with the emergence of the COVID-19 pandemic (with all of its attendant challenges). This coincidence provided a clear initial focus of many of the CREID efforts on SARS-CoV-2-related topics, but it also provided very strong validation for the original rationale for establishment of the CREID Network by the NIAID/DMID leadership as a means of fostering global networks for research collaboration on emerging infectious disease threats.

While the EAC members identified a number of areas where additional attention and effort will be beneficial to maximize the impact of the CREID Network, and key to fostering the sustainability of its efforts, our expectations for what the Network has the potential to accomplish were raised by the strong foundation that the CREID PIs and collaborators have already put in place in their first year. We were also very impressed with the clear commitment, thoughtfulness and inclusive approach of the CC leadership, and with the expertise, passion, and experience of the broader CREID Network community of scientists. At the heart of the CREID is a commitment to new models of collaborative science that links investigators from around the world to understand, prepare for, and respond to emerging infectious disease threats. As such, the extent to which CREID utilizes current best practices for collaborative research and pioneers new ones; embraces the essential role played by investigators working in countries at risk for disease emergence (including resource-limited settings); partners in new and more effective and mutually trusting ways with governments, normative agencies and other emerging infectious disease-focused research organizations; exemplifies and communicates the value of scientific research in providing solutions to emerging infectious disease threats to governments and the public; and delivers on its commitment to genuine research capacity strengthening and sustainability will be critical measures for evaluating the future success of the CREID. The EAC recognizes that this is a very ambitious agenda filled with often challenging objectives, and that the inherent nature of time-limited NIH funding mechanisms presents additional challenges to their potential realization.

In considering these issues, the EAC felt that significant progress has been made in the first year of the CREID Network, but that additional opportunities exist for the PIs and CREID investigators to be even more intentional and strategic about their collaborative research efforts. The CREID Network has the opportunity to establish a number of positive precedents in models of effective global collaborative science where the “whole is truly greater than the sum of its parts”; by demonstrating new approaches for the “decolonization” of international research; and by delivering on a strong commitment to diversity and inclusion in all of its endeavors. In many ways, achieving these goals will require innovation in collaborative research models within a large global network, and not just in delivering innovative, high quality scientific research results. The EAC members recognize the challenge of finding the right balance between investigator- and RC-initiated science with broader strategies and shared goals of a large collaborative network, but also note that doing so will require an overarching strategy, effective

communication tools and ongoing performance monitoring and adjustment. The EAC members also recognize that the important Network goals of research capacity strengthening and sustainability are not trivial undertakings and that they are very promising, but also rather novel objectives, within the context of NIH-supported research programs. These are additional important areas where the CREID CC and RC leadership can further articulate a respectful, inclusive, realistic, achievable and measurable strategy.

In all of these areas, the EAC recommends that the CREID investigators further develop and implement (a) a clear, well-defined and shared set of Network priorities (that links the work across RCs) and key performance indicators (KPIs) to measure performance toward realizing them, (b) a shared strategic vision and plan that connects the research efforts being prioritized and conducted across the Network centers, (c) a mechanism to share best practices across the Coordinating Center (CC) and Research Centers and (d) a proactive approach to identify collaborative research opportunities, fill gaps, avoid duplication and pursue synergies both within the CREID Network and, importantly, with the large and growing number of other organization working on preparing for and responding to emerging infectious disease outbreaks. Clarity and specificity in these efforts will be beneficial, as well as adopting an appropriate sense of realism about what can be accomplished by the CREID Network itself and where the new partnerships it implements with other organizations working in the emerging infectious disease arena will be essential. In this regard, given the complexity of the emerging infectious disease landscape, the CREID Network's ability to have the most significant impact will likely depend on the connections it establishes with other stakeholders and the innovation it drives in conceptualizing and delivering on effective new collaborative endeavors it develops with other capable partners. Towards this end, the Network would benefit from developing a thorough understanding of the ecosystem of potential partners and a defined approach to engage with the most relevant and promising ones. In addition, while the CREID Network includes collaborators from many centers and countries, its true global scope is limited by gaps in its geographic coverage (eg, countries in Asia, the Middle East, Northern Africa, Australia, etc...including those where risk of pathogen emergence are significant). Understanding if the CREID Network will be limited by its current geographic reach or plans to work to build additional connections (perhaps via strategic partnerships) in other regions will be beneficial from both practical and strategic levels.

Given that the readiness of the CREID Network for future outbreak response (and to be able to perform research in the midst of an outbreak when many challenges prevail) and for pandemic preparedness is a priority for NIAID/DMID, it will be important for the Network to clearly define how they best proactively plan to be able to promptly implement critical research programs when a new pathogen emerges or a previously known one reemerges. It will also be beneficial for the CREID CC and RCs to develop a clear plan (including protocols for coordination, implementation, data sharing and communication) to enable the Network to be able to respond expeditiously to an emerging infectious disease threat. Towards this end, tabletop exercises (or similar) to "pressure test" Network approaches and identify gaps/opportunities for improvement are worth considering.

The EAC is excited about what the CREID CC and RCs, and all of the collaborating CREID investigators, have accomplished in their first year of work and look forward to seeing the innovations and insights the Network will deliver in the future. The EAC recognizes that the CREID Network cannot realistically be "all things for all people", and should not strive to be. WE therefore also look forward to seeing how your Network priorities are further articulated, implemented and measured moving forward.

### **Additional EAC Impressions**

The EAC felt that the Executive Summary of the CREID Network Annual Meeting provided an accurate overview of the meeting proceedings and of the EAC feedback provided at the end of the meeting proceedings. Some specific additional impressions/requests shared by EAC members include:

- Gaining a better understanding of how CREID investigators are interfacing with local governments and ministries, public health authorities (eg, WHO, US CDC, Africa CDC, etc), normative agencies will be helpful, and how learnings of effective approaches should be shared across the Network. In addition, optimization of engagements with other research organizations, enabling disciplines (eg, social science, health economics, health policy, ethics), as well as the medical countermeasures community, will be helpful
- Gaining a better understanding of the experience to date in data sharing efforts and how these can be optimized
- Gaining a better understanding of how bilateral sharing of research materials and specimens can be optimized (given the role of host institutions and government policies) and how these might operate during an outbreak/pandemic
- How the CREID investigators view and are approaching their educational efforts with governments, political leaders and the public, and sharing of best practices for engagement and trust-building
- How the CREID Network is engaging with industry partners that both supply enabling tools and technologies and who may also assist in the development and commercialization of CREID-advanced innovations (eg, diagnostics)
- Opportunities exist to demonstrate the CREID commitment to decolonization of global health (with increased attention to having the voices from LMIC-based investigators better balanced with those of US-based investigators)
- Opportunities exist to better model the Network's and the NIH's commitment to DEI objectives (with increased attention to full representation in all aspects of the work...including presentations, leadership groups, pilot research awards)
- Opportunities for enhancing epidemiology, bioinformatics, digital tools and modeling capacity
- Gaining a better understanding of the role of social and cultural aspects of the outbreak response and communication, and exploring innovative approaches to address them
- Understanding how engagement with governments and other local stakeholders is being pursued to advance capacity strengthening and sustainability goals
- Further articulation of rapid response collaboration frameworks
- Gaining a better understanding of how local priorities influence the prioritization decisions of the CC and RCs
- Gaining a better understanding/"needs assessment" of capacity gaps (eg, BSL-3 training and labs) and how these are being addressed via strategic connections or focused investment
- How "parachute or safari research" is avoided, and how local researchers are engaged as full partners/leaders
- Definition of opportunities to maximize speed and efficiency in research implementation efforts (eg, US permits and in-country regulations, IRB delays, key relationship gaps) needed for prompt outbreak responses
- Value of developing a clear vision and plan for sustainability that maximizes the connection with and contributions of other partners and local governments
- South-South collaboration should be applauded and fostered
- Shared EAC interest in seeing the CREID Network's progress in ongoing database and biorepository workstreams

## Appendix B: NIAID CREID Network Program Priorities (April 2022)

*(4 main priorities all carry equal weight and are intended to cover research and activities to prepare for and respond to emerging and re-emerging threats.)*

- **Conduct innovative research to expand our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats**
  - Research Priorities:
    - Pathogen discovery & characterization
    - Pathogen/host surveillance
    - Pathogen transmission
    - Pathogenesis & immunologic responses in the host
    - Natural history & contemporary clinical disease
    - Develop reagents & diagnostic/detection assays
  - Engage in coordinated, Network wide outbreak/pandemic research readiness, differentiated from standard public health responses
- **Establish a collaborative, strategic, and preemptive research Network to ensure coordination of efforts across the Network**
  - Centralize communication
  - Conduct Network wide capacity inventory
  - Establish effective data harmonization and platforms for sharing
  - Harmonize sample collection, biorepositories, and network sharing/agreements
  - Share laboratory assay best practices and protocols
  - Share reagents, diagnostic/detection assays, and other resources
- **Develop and expand flexible domestic and international capacity and readiness to efficiently undertake research required in response to emerging or re-emerging threats**
  - Prioritize and engage with key stakeholders that will enhance network capabilities and integrate into the global health landscape
  - Strengthen and enhance research collaboration and partnerships globally
  - Pivot programmatic priorities and resources when needed for a timely response to emerging or re-emerging pathogen threats
    - Develop protocols for coordination, implementation, data sharing, and communication.
    - Execute tabletop exercises to test, refine, and maintain Network readiness
  - Formulate novel strategies to detect, control, and prevent outbreaks
    - Translate findings to downstream partners to facilitate development of medical countermeasures or preventive interventions
    - Develop adaptable risk assessment tools for evaluating a pathogen threat's potential for significant emergence and impact
- **Contribute to the development of the next generation of emerging/re-emerging infectious disease scientists and leaders**
  - Develop and maintain a pilot research program
  - Foster a diverse and inclusive research environment and program

---

Dear Hongying,

Apologies for the delayed response.

Attached please find the edited report from our side. Here are some changes that we have made, further detail can be found in the report.

- Number of identified viruses
- Number of specimens for MMIA
- Serology testing graphs (I repeated some of the samples that were positive to confirm the results, most of the samples are still positive **except** the two samples that were weakly positive for NiV)
- Number of manuscripts

Please let me know if you require any further information/clarification.

Best regards,  
Bow

Dear All,

As mentioned at the EID-SEARCH meeting in July, we'll submit an External Advisory Committee (EAC) report for our Research Center in August, so the EAC can evaluate our work as an individual Research Center and the overall CREID Network to give feedback at the CREID annual meeting with DMID, USG, and other stakeholders in September.

Attached please find the very first draft report for your edit and review. We'll greatly appreciate everyone's input on incorporating the EAC recommendations and aligning with NIAID CREID Network Program Priorities as described in the Appendix.

For unpublished data, I tried to keep the information general, will also make sure the CREID keeps all information for internal use only (to the EAC), but please let me know if you have any concerns.

We hope to submit the report on August 19, and your feedback **by August 15 Monday** will be appreciated! Thank you all very much in advance!

All the best,  
Hongying

Thank you, Eric and Spencer, for the information!

Wonderful to hear all these results, we should encourage Bow to submit an abstract and present. I'll take note of this and remind you all to discuss it at the lab meeting next Wednesday.

Chu's guano farmer set has baseline (pre-vaccination, not sure if it's pre-pandemic) and two yearly follow up points. I think it's about 54 farmers, all have been vaccinated. I want to say they are mostly Sinovac but some are Astra, and I don't know if there were any cross-vaccinations.

I recall Chu talking about a separate healthcare worker cohort at one point but I don't know if that is still on the table.

Hi Hongying,

I can focus on the bat-cov multiplex development, but we only have SARS-CoV-2 validated sera and research studies outside the scope of EID-SEARCH. We'd need some data from Bow (who should be the lead), and it can be data related to guano farmers, pre-COVID-19, or vaccine recipients.

There are 3 virus families being screened in the multiplex - there should be at least 2 stories (filo/henipa and sars-2/covid) coming from Bow/Chu's team a Chula. I've been meaning to email Chu about their covid-19 cohort, I have this memory that they have some vaccine recipients (Spencer, am I remembering this correctly?). My research team has been involved in Pfizer vaccine response research, and head-head comparison with Moderna. Thailand is mostly vaccinated with AZ and Sinovax, a product comparison would be pretty easy to write-up since the assay is a bridge.

Thank you, Eric.

Assay development related to EID-SEARCH may fit into the topic of "New techniques, or novel approaches, to sampling, detection, and characterization of pathogen risk" if you would like to present the methodology, but understand it's better to present with sample testing results from the project.

As you suggested, we have shared this with the teams at CM and Chulalongkorn, hope to hear from them soon and work together with you on the abstracts if they're interested to present some preliminary findings from the serological testing. We may check in with Tom about this next Wednesday at the lab meeting (if you and Cadhla agree).

Thanks,  
Hongying

Hi Hongying,

Serology testing is underway in Chulalongkorn, but I think that Chu's lead, Bow, would be the appropriate SEARCH researcher to draft an abstract. Spencer mentioned that at the previous month's 'lab meeting', Tom had concluded testing some serologies.

Spencer and I are happy to help with results analysis and drafting abstracts from either Chulalongkorn or CM, LLC/EHA, but we don't have access to any data from our side.

Good Morning, Chris, Eric, and Spencer,

The CREID Network is holding the annual meeting on September 21-23 in Washington DC, there will be sessions to present scientific findings supported by the CREID, and we need to submit abstracts for the presentations.

Please see the Call for Abstraction information below, it would be great if anyone from your team can submit an abstract for presentation, if you are busy, it will be a terrific opportunity for graduate students or postdocs, too. Please consider this and feel free to contact me if any questions.

The meeting will be hybrid, and we'll let you know once we received the final agenda, so we can discuss travel and meeting in person if you will be available during that time.

Best,

Hongying

Dear CREID Network Leadership,

Thanks to your feedback, we will not be placing any limits on the number of allowed abstract submissions. Any submissions not selected for a rapid, virtual poster presentations or longer oral presentations will have the opportunity to create e-posters/slides to be shared with the CREID Network.

Below, please find the updated call for abstracts for the CREID Network's 2022 Annual Meeting. The meeting will include multiple abstract-driven scientific sessions. Each CREID Research Center is requested to submit at least one abstract by May 17, per the guidelines below.

Thank you,

CREID Network 2022 Annual Meeting Organizing Committee

---

## 2022 Annual Meeting: Call for Abstracts

The CREID Network 2022 Annual Meeting (September 21-23, in person and online) will include multiple abstract-driven scientific sessions. Each CREID Research Center is requested to submit at least one abstract, per the guidelines below. Abstracts will be assigned for rapid/lightning talks, longer oral presentations, or e-posters/slides that will be shared with the CREID Network. A committee will convene to review the content of the abstracts and determine the assigned format. More information on the review committee process is forthcoming. Submission template is attached.

Due	May 17, 2022
Length	Abstract body (excluding title and authors): 250 words max
Focus	<p>Abstracts should focus on work supported by CREID, including but not limited to:</p> <ul style="list-style-type: none"><li>▪ Innovative research on pathogen discovery and characterization, pathogen/host surveillance, transmission, pathogenesis, host immunological response, natural history, or related assays or reagents;</li><li>▪ New techniques, or novel approaches, to sampling, detection, and characterization of pathogen risk;</li><li>▪ Preparation for, or results of, research conducted in response to an outbreak;</li><li>▪ Novel strategies to translate related findings downstream</li></ul> <p>Selected abstracts will be grouped into sessions based on content/focus.</p>
Format	As the 2022 Meeting will be hybrid, both in-person and virtual presentations are welcome. Abstracts may be selected for a rapid, virtual poster presentation, a full (>10 min) oral presentation, or for e-posters/slides to be shared with the CREID Network. Assigned format and presentation times will be determined based on the content and number of submissions.
Authors/ Presenters	Authors may include investigators and staff from CREID Research Centers, sites, and partners. Women and those from low- and middle-income countries (LMICs) are strongly encouraged to author and present.

	Submissions with authors from multiple Research Centers are welcome.
Submissions	Each Research Center is asked to submit 1-4 abstracts. Each abstracts should include a title, presenters/authors (names, institutional affiliations, emails, and CREID Research Center), and body (250 words max). See basic template, attached.  Send to <a href="mailto:info@creid-network.org">info@creid-network.org</a> by May 17, 2022.

## B. ACCOMPLISHMENTS

### B.1 WHAT ARE THE MAJOR GOALS OF THE PROJECT?

Southeast Asia is one of the world's highest-risk EID hotspots, and the origin of the SARS pandemic, repeated outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as the Nipah virus. It is a wildlife 'megadiversity' region, where a rapidly expanding human population is increasing contact with wildlife, and increasing the risk of zoonotic disease outbreaks. The overarching goal of this proposal is to launch the Emerging Infectious Diseases - South East Asia Research Collaboration Hub (EID-SEARCH) to analyze the diversity of key viral pathogens in wildlife, the frequency and causes of their spillover, and to identify viral etiologies of undiagnosed 'cryptic' outbreaks in people. EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions, and in Thailand, Singapore, and the 3 major Malaysian administrative regions, whose collaborative networks span >50 clinics, laboratories, and research institutes across almost all SE Asian countries. This hub, and the network, will act as an early warning system for outbreaks - a way to exchange information, reagents, samples, and technology, and a collaborative power-house for translational research. The long-term collaboration among the key personnel and multidisciplinary skillsets from epidemiology, clinical management, lab analysis, through wildlife biology and data analysis will act as significant assets when deployed to help counter outbreaks in the region. The research goals of this EIDRC follow three specific aims:

Specific Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife. We will: 1) analyze some of the tens of thousands of archived wildlife samples at our disposal, conduct geographically- and taxonomically-targeted field surveillance in wild mammals (bats, rodents, primates), and use serological & PCR assays to identify known high-profile zoonotic pathogens, or close relatives with potential to infect people; 2) biologically characterize novel viruses that our analyses suggest have high spillover and pandemic potential; and 3) conduct in vitro receptor binding assays and cell culture experiments, and in vivo animal model infections using humanized mice and the collaborative cross mouse to assess their potential to infect people and cause disease.

Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays. Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities and approaches that can deal with the low statistical probability of identifying rare events. To achieve this, we will 1) conduct targeted cross-sectional serological surveys of human communities with extremely high geographic and cultural, occupational, and behavioral exposure to wildlife-origin viruses; 2) design and deploy novel serological assays to identify baseline spillover of known or novel CoVs, PMVs, and FVs in these populations; and 3) analyze and test hypotheses on the occupational, cultural and other risk factors for spillover (e.g. hunting wildlife).

Specific Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts. Our prior work provides substantial evidence of spillover leading to undiagnosed illness in people in the region. To test if these represent 'cryptic' outbreaks of novel viruses, we will conduct syndromic surveillance at regional clinics for the communities sampled in SA2. We will: 1) enroll and collect biological samples, and detailed survey data on risk factors, from patients presenting with influenza-like illness, severe respiratory illness, encephalitis, and other specific symptoms; 2) conduct molecular and follow-up serological diagnostic assays to test causal links between their syndromes and known and novel viral agents identified in SA1. Where viruses are identified, we will attempt to isolate and characterize them, then use the survey data, ecological and phylogenetic analyses to identify likely reservoir hosts/spillover pathways and inform intervention programs.

This research will advance our understanding of the risk of novel viral emergence in a uniquely important region. It will strengthen in-country research capacity by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. These include testing of tens of thousands of samples from wildlife, humans, and livestock in the region; discovery of hundreds of novel viruses from zoonotic viral families in wildlife; outbreak investigations in rural communities across SE Asia; discovery of the bat-origin of SARS-CoVs; discovery of a novel bat-origin SADS-CoV killing >25,000 pigs in S. China; and development of novel serological and molecular assays for high-impact viruses, and state-of-the-art in vitro and in vivo assays to characterize viral pathogenic potential. This body of collaborative research provides proof-of-concept that EID-SEARCH has the background, collaborative network, experience, and skillset to act as a unique early warning system for novel EIDs of any etiology threatening to emerge in this hottest of the EID

hotspots.

**B.1.a Have the major goals changed since the initial competing award or previous report?**

No

**B.2 WHAT WAS ACCOMPLISHED UNDER THESE GOALS?**

File Uploaded : B.2 Accomplishments\_Final.pdf

**B.3 COMPETITIVE REVISIONS/ADMINISTRATIVE SUPPLEMENTS**

**For this reporting period, is there one or more Revision/Supplement associated with this award for which reporting is required?**

No

**B.4 WHAT OPPORTUNITIES FOR TRAINING AND PROFESSIONAL DEVELOPMENT HAS THE PROJECT PROVIDED?**

File Uploaded : B.4 Training and Professional Development\_Final.pdf

**B.5 HOW HAVE THE RESULTS BEEN DISSEMINATED TO COMMUNITIES OF INTEREST?**

PI Daszak, and Co-investigators Wacharapluesadee, Hughes, Olival, Wang, Baric, Broder, Laing, and other key personnel from the EID-SEARCH were invited to give lectures, keynote speeches, government and inter-government briefings, and public interviews in Thailand, Malaysia, US, Southeast Asia, and internationally on the trends in global disease emergence, zoonotic surveillance, pandemic control and prevention, and research results from this project research activities.

Government and inter-government agency briefings

- Advising US GAO on risks and benefits of viral characterization
- Advising US GAO on drivers of emerging infectious diseases
- Meeting with the Bureau of Epidemiology, Department of Disease Control of Thailand on COVID detection and outbreak investigation.
- Meeting with the Sabah Wildlife Department (SWD) in Malaysia for project briefing and ongoing collaboration.
- Meeting with the Deputy Director General at Ministry of Health (MOH) in Malaysia for project briefing and human research planning
- Meeting with the new US Ambassador in Malaysia to discuss project and relevant research in Malaysia.
- Report to the World Health Organization (WHO) on how to utilize this moment to improve genomic sequencing for CoVs worldwide.
- Report to Newham City Council in the UK on the emergence of new zoonotic diseases to advise on new policies set forth in the wake of COVID-19.
- Meeting with the Wildlife Health Genetic and Forensic Laboratory and Economic Officer of U.S. Embassy in Malaysia for project briefing and planning.
- Meeting with the Wildlife Health Genetic and Forensic Laboratory and Director of Sabah State Health Department and Director of Kota Kinabalu Public Health Lab for ongoing collaboration and syndromic surveillance in Malaysia.

Panels, workshop, webinars discussion

- Organized a regional workshop with scientists from Thailand, Malaysia, Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, Australia on the challenges and opportunities for emerging infectious diseases research in Southeast Asia.

- Wildlife Crime Panel at the Wilson Center, "Emerging zoonoses and the wildlife trade"
- The Association of Medical Technologist of Thailand, "COVID-19 variants"
- Australasian Society for Infectious Diseases Zoonoses, "Lessons for the next zoonotic pandemic"
- PREZODE International scientific workshop, "Introduction of the CREID Network and EID-SEARCH"
- The Science and Practice of Networks at the National Academy of Sciences
- Global Research and Innovation Forum, WHO, "Increasing risks at the human-animal interface: Research needs for risk reduction and prevention"
- World Zoonoses Day webinar by UPM, MyoHUN and USAID, Malaysia

#### Conference and university lectures

- Thailand One Health University Network International - Short Course on Ecosystem Health, "One Health Social Innovations for EIDs research"
- Global Bat Network of Networks (GBatNet), "Scientific priority setting for bat disease surveillance and research"
- Chulalongkorn University, "All about COVID-19 detection, multidisciplinary team"
- American Society of Tropical Medicine and Hygiene's annual meeting, "Surveillance for zoonotic coronavirus discovery"
- University of Rochester to the Goergen Institute, "How can we analyze pandemics to predict and prevent the next one"
- Duke-NUS Emerging Infectious Diseases (EID) Programme Seminar, "SARS-related CoVs provide a unique test-case of a global strategy to predict & prevent pandemics"
- Mahidol University, "One Health for emerging infectious diseases"
- CU-TU-BUU-BSRU, Burapha University (Thailand), "Roles of medical technologist in Disease X"
- Global Health Program, University of Geneva, "Understand zoonotic risk at human-wildlife interaction"
- Ecology and Evolution of Infectious Diseases Conference, "A strategy to assess spillover risk of bat SARS-related coronaviruses in Southeast Asia"
- American Public Health Association annual meeting, "Behavioral-biological surveillance of emerging infectious diseases among a dynamic cohort in Thailand"
- Columbia University, "Understanding zoonotic spillover and risk"

#### Public outreach and interviews

- Interview with Dr. Sanjay Gupta for an upcoming documentary on COVID-19 origins on the risk of viruses emerging from wildlife and how we can prepare for the next pandemic through modeling and surveillance to address hotspots for disease
- Podcast with Viertausendhertz on the strategy to assess spillover risk of bat SARS-related coronaviruses in Southeast Asia <https://viertausendhertz.de/pan31/>
- Closest known relatives of virus behind COVID-19 found in Laos <https://www.nature.com/articles/d41586-021-02596-2>
- Bats carrying coronaviruses closely related to the one that causes Covid-19 found outside China <https://www.straitstimes.com/singapore/health/bats-carrying-coronaviruses-closely-related-to-virus-which-causes-covid-19-found>
- Study finds coronavirus-related bat viruses in Thailand <https://www.modernhealthcare.com/safety-quality/study-finds-coronavirus-related-bat-viruses-thailand>
- Bat coronaviruses may infect up to 400,000 people in China and Southeast Asia every year <https://www.telegraph.co.uk/global-health/science-and-disease/bat-coronaviruses-may-infect-400000-people-china-southeast-asia/>

### **B.6 WHAT DO YOU PLAN TO DO DURING THE NEXT REPORTING PERIOD TO ACCOMPLISH THE GOALS?**

In the next reporting period, we will follow the research plans laid out in our proposal with the specific actions as follows (no modifications of the scope of work):

Specific Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife

1.1 Wildlife (bats, rodents, non-human primates) sampling at selected sites.

1.1.1 First 6 months, testing and analysis of all samples; refine sampling strategies to target under-sampled species; 2nd 6 months, targeted sampling.

1.1.2 Increase sampling efforts for rodents and non-human primates.

- 1.1.3 Conduct longitudinal sampling at few selected sites to analyze patterns of viral shedding and spillover risk.
- 1.2 Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 3-5 of the project.
- 1.3 Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses, filoviruses, and paramyxoviruses.
- 1.4 Perform serology testing on the wildlife samples collected in Y1-3.
  - 1.4.1 Perform serological characterization of Sarbecovirus-positive samples using surrogate virus neutralization test (sVNT) RBD-based assay.
  - 1.4.2 Perform additional serological characterization of Henipavirus-positive samples using sVNT glycoprotein-based assay.
  - 1.4.3 Continue developing a more comprehensive multiplex CoV RBD-based sVNT covering newly identified sarboviruses and additional merbecoviruses to allow the evaluation of neutralizing activity in serum samples against a much broader and more comprehensive range of RBDs.
  - 1.4.4 Validate, and initiate in-country use of Filovirus sVNT glycoprotein RBD assay.
- 1.5 Conduct whole-genome and spike glycoprotein sequencing in countries with newly identified viruses.
- 1.6 Continue research to further characterize a subset of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies.
  - 1.6.1 Rescue additional pangolin viruses that are genetically more distant from SARS-CoV-2 and the pangolin GD strain, as well as synthetically reconstruct and characterize the BANAL-52 isolate using in vitro and in vivo approaches.
  - 1.6.2 Review novel bat sarbecovirus full genomes that have been identified in Y1-2 for synthetic recovery.
- 1.7 Develop zoonotic risk analyses for relevant viruses
  - 1.7.1 Analyze Spike and whole-genome sequences to predict host range using a variety of in silico approaches
  - 1.7.2 Model the host range, geographic distribution, extent of overlap with high-density human populations, etc. using existing apps/models to assess potential zoonotic disease risk
  - 1.7.3 Improve data workflow to integrate viral characterization results into zoonotic virus prediction models.

Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays

- 2.1 Increase the number of sites and enrolled participants for community surveillance among at-risk populations collect biological and behavioral data collection.
  - 2.1.1 Enroll human participants from a site in Thailand where Henipavirus serology positives were identified among bats
  - 2.1.2 Continue enrolling human participants from bat guano collection site(s) in Thailand.
  - 2.1.3 Enroll human participants from high wildlife exposure communities, Peninsular Malaysia.
  - 2.1.4 Enroll human participants from high wildlife exposure communities, Kinabatangan, Sabah, Malaysia
- 2.2 Continue to identify community sites concurrent with animal surveillance sites (Specific Aim 1).
- 2.3 Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and paramyxoviruses (1.3.1 - 1.3.4).
  - 2.3.1 Perform additional serological characterization using virus family-specific sVNTs for positive samples
- 2.4 Begin epidemiological analyses of biological and behavioral data.

Specific Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts

- 3.1 Start enrolling participants at selected hospital/clinic sites for syndromic surveillance.
  - 3.1.1 Continue enrolling human participants at King Chulalongkorn Memorial Hospital, Thailand
  - 3.1.2 Enroll human participants in Sabah, Malaysia
  - 3.1.3 Enroll human participants in Peninsular Malaysia, Malaysia
- 3.2 Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.
- 3.3 Start serological and molecular testing on collected human samples.
- 3.4 Start viral characterization work if any novel viruses are identified.

Training and capacity building activities to achieve project goals

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures and

discussion as well as hands-on guidance. In situ training for in-country teams is planned in 2022 to accommodate the ease of COVID-19 travel restrictions. (1.1)

- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing (1.5)
- Conduct training in traditional viral whole-genome sequencing using primer walking for paramyxoviruses (1.5)
- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training (1.5)
- Trial the use of the portable Oxford Nanopore MinION platform as an in-house sequencing solution in Malaysia (1.5)
- Continue training on multiplex microsphere immunoassay (MMIA) data analysis and interpretation (1.3)
- Conduct refresh training on human research regarding survey design, interview skills, and data analysis (2.1, 2.3, 3.1)

#### Additional activities

- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer-review, publication, and broad distribution.
- Continue sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government in a timely manner.
- Organize meetings and workshops with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region.
- Continue supporting in-country outbreak research and response as requested.

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary research center with aims to: 1) characterize diverse coronaviruses, paramyxoviruses, filoviruses, and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed ‘cryptic’ outbreaks. Despite COVID-19 lockdowns and restrictions, we have fulfilled our project goals for the period of 06/01/2021 – 05/31/2022, with the following highlighted accomplishments:

**Targeted Surveillance**

	Thailand	Malaysia
<b>Animal</b>		
No. of collected specimens	3,862	14,171
No. of individuals	454 bats, 106 rodents	2,000 bats
No. of species	6 (bats), 5 (rodents)	24 (bats)
No. of sites	5	4
No. of tested individuals	407	1,332
No. PCR tests for coronaviruses (CoVs), paramyxoviruses (PMVs), filoviruses (FLVs), influenza viruses (IVs)	4,070	9,228
Identified viruses	1 new CoV from 3 bats; 3 known PMVs from 4 rodents; 4 new PMVs from 11 bats	5 new CoVs from 112 bats; 4 new PMVs from 10 bats; 2 known PMVs from 2 bats
No. of specimen for multiplex immunoassay for FLVs and henipavirus	-	720 (bats)
<b>Human</b>		
No. of enrolled human participants	56 community; 2 clinic; 59 outbreak	-
No. of site	1(community), 1(clinic)	-

- Human surveillance began during this reporting period in Thailand, but overall was delayed due to COVID-19 travel restrictions and safety concerns at community sites, and limited human resources at hospital sites. Testing of previously collected human specimens is ongoing.

**Viral Characterization**

- Analysis of one complete and two near-complete whole genome sequences of a novel SARS-like betacoronavirus identified in three bat specimens collected in Thailand revealed a 91.72% nucleotide similarity to SARS-CoV-2.

Phylogenetic analysis suggested that this virus is closer to pangolin CoV-GD-1 than to SARS-CoV-2; however, the RBD is more similar to that of bat-CoV RaTG13, suggesting that this new virus may also bind to mammalian ACE2 receptors. Whole-genome sequencing of other new CoVs is ongoing. (Fig. 1)

**Figure 1.** Close similarity of a newly discovered bat SARSr-CoV from Thailand to SARS-CoV-2 and relatives, including RaTG13.

- Genome-wide CRISPR knockout screen identifies essential factor for HKU2/SADS-CoV infection.** Using a genome-wide CRISPR knockout screen, we identified placenta-associated 8 protein (PLAC8) as an essential host factor for SADS-CoV infection of human cells. Infection is prevented in PLAC8 knockouts and can be restored by transiently transfecting PLAC8 from multiple species, including human, pig, mouse, and bat. Trypsin treatment of SADS-CoV bypasses the PLAC8 dependent pathway and partially rescues SADS-CoV infection. PLAC8 is involved in both early entry and later dissemination of SADS-CoV infection and PLAC8 KO cells have: 1) delayed and reduced viral subgenomic RNA expression and 2) diminished cell-to-cell viral spreading of infected cells. These results suggest that PLAC8 is a promising target for antiviral development for the potential pandemic SADS-CoV virus.
- Host Range, Transmissibility and Antigenicity of a Pangolin Coronavirus.** Using a synthetically derived infectious cDNA clone, we recovered the wildtype pangolin (Pg) CoV-GD and derivatives encoding

indicator genes. Like SARS-CoV-2, PgCoV-GD virus efficiently uses human and many other mammalian ACE2 receptors for entry, shares a similarly broad host range *in vitro*, and displays altered sensitivity to host proteases. PgCoV replicates to slightly higher to lower titers in primary human cells derived from the proximal to distal lung, respectively, and with reduced fitness compared to SARS-CoV-2. PgCoV also replicates efficiently in hamsters and could transmit via the aerosol route, but at a lower frequency than SARS-CoV2. PgCoV is efficiently neutralized by COVID-19 patient sera and many commercially available SARS-CoV-2 therapeutic antibodies, but not by human antibodies targeting the spike N-terminal domain. A pan-Sarbecovirus antibody ADG-2 and SARS-CoV-2 S2P recombinant protein vaccine protected mice in a PgCoV replication model; however, efficient PgCoV replication in primary nasal airway epithelial cells and transmission in the hamster highlights the high emergence potential of this virus. We showed that cross-neutralizing antibodies in pre-immune SARS-CoV-2 humans and the benefit of current COVID-19 countermeasures should impede its ability to emerge and spread globally in humans. **This research helps build FDA-approved therapeutic antibodies against a range of CoVs with emergence potential, and shows that FDA-approved SARS-CoV-2 vaccines also protect animals from PgCoV when challenged *in vivo*.**

### Assay Development

- We established a **multiplex surrogate virus neutralization test (sVNT) platform** that covers SARS-CoV-2 and variants of concern (Alpha, Beta, Gamma, Delta, Mu, Lambda, Omicron BA.1 and BA.2), clade-2 sarbecoviruses (BANAL-52, BANAL-263, GD-1, RaTG13, GX-P5L), clade-1 sarbecoviruses (Rs2018B, LYRa11, WIV-1, RsSHC014, Rs4231), SARS-CoV-1, and *the newly discovered bat CoV we recently sequenced from Thailand*. This assay allows for the discrimination of past SARS-CoV-2 infection from that of other sarbecoviruses in human and animal samples, which will be critical for identifying cryptic spillover of sarbecoviruses in people. It also has potential to aid in identifying the progenitor of SARS-CoV-2 in animals.
- We designed and secured the expression of **bat-CoV spike proteins for incorporation into our multiplex (multi-family) serological assay**. Specific bat-borne CoV spike proteins include bat SARSr-CoVs RaT13, ZXC21, bat MERSr-CoV PDF2180, and HKU9. These were incorporated into our 17-plex henipavirus/filovirus-focused serology assay to include SARS-CoV-2 and bat-borne CoV antigens. We also optimized an sVNT for Nipah virus and provided enough material to characterize Nipah virus IgG positive serum samples neutralizing antibodies. SOPs were revised and updated to reflect best practices that were optimized during Year 1.

### Outbreak Investigation in Thailand

- The Ministry of Public Health in Thailand requested our support for a viral diarrhea outbreak investigation in Chanthaburi province. We received samples from both Prapokkklao Hospital (regional hospital) and Khlong Khut Health-Promoting hospital collected from 59 healthcare workers and students who had diarrhea during Dec. 2021-Feb. 2022. PCR test were conducted for six gastrointestinal viruses causing gastrointestinal tract infections including adenovirus, astrovirus, norovirus GI, norovirus GII, rotavirus and sapovirus. 32 samples (**54.24%**) were positive for norovirus GII. Further genomic characterization of the detected norovirus GII will be performed, allowing for comparison with noroviruses found in other provinces in Thailand.

### Research Network and Capacity Building

- To fulfill the goal of building a regional EID research and response network and capacity, we have worked with scientists and government officials from Thailand, Malaysia, Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, and Australia via meetings, workshops, training, pilot research project development, data analysis, and knowledge exchange, to strengthen research capacity and foster scientific collaborations in Southeast Asia. (*Section B.4 and B.5*)
- The collaborations under this project have generated 14 scientific articles for peer-review journals (six published, five under review/revision, three in preparation) during the reporting period, field and lab research protocols, training materials, and technologies that are shared and transferred beyond this project in the region. (*Section C.1 and C.3*)

During this reporting period, we conducted a series of trainings with EID-SEARCH project partners and in-country stakeholders in Thailand, Malaysia, and Vietnam from local government, universities, research institutes, and NGOs. These focused on biosafety, applying new technologies, and field and laboratory SOPs to strengthen in-country research capacity and improve information sharing. As travel and COVID-19 restrictions have begun to be lifted, students, postdocs, and all EID-SEARCH research staff have been provided with professional development opportunities to travel to attend conferences, workshops, and other in-person training activities. Highlighted trainings are as follows:

**June - July 2021** Biosafety training at the Molecular Zoonosis Lab in the National Wildlife Forensic Lab (NWFL) and Wildlife Health, Genetic and Forensic Laboratory (WHGFL) focusing on biosafety guidelines and all biosafety documents (lab and field SOPs, risk assessments, and safety manual) for EID-SEARCH project biosafety lab evaluation. Risk assessment training was conducted based on the WHO lab biosafety manual 4th edition was conducted for 11 Conservation Medicine and three other local NGO staff. The training was provided by Prof Stuart Blacksell of MORU, Thailand.

The Wildlife Health, Genetic and Forensic Laboratory (WHGFL) in Sabah was certified for the eighth year in a row as a BSL- 2 laboratory (July 2021), the molecular Zoonosis Laboratory at the Department of Wildlife and National Parks of Peninsular Malaysia (PERHILITAN)'s new National Wildlife Forensic Laboratory (NWFL) was certified for the fifth year in a row as a BSL-2 laboratory (September 2021), in accordance with the Biosafety in Microbiological and Biomedical Laboratories (BMBL) 6th Edition (June 2020) which is the US standard for laboratory specifications.

**June 2021** Online training among Conservation Medicine staff regarding advancement in wireless temperature monitoring in Malaysia for clinical syndromic surveillance.

**September 2021** Online biosafety training session among field team members from Conservation Medicine (Malaysia), Chulalongkorn University (Thailand) focusing on:

- Identification of health risks (disease, routes of exposure, field equipment, medical supplies, climate, trauma, etc.)
- Understanding how to mitigate risks (personal health, immunizations, site risk analysis, personal protective equipment [selection, donning, doffing], disinfection, & disposal)
- Responding to health threats (pathogen exposure, trauma, envenomation, physical exhaustion)

**September 2021** Training of EID-SEARCH Thailand team on using Airtable to facilitate real-time project data sharing.

**September 2021** User training with standard operating procedures and safe use of biosafety cabinets among 18 members from Conservation Medicine, Universiti Malaysia Sabah, PERHILITAN, and a local NGO in Malaysia.

**October 2021** Serology data analysis training was provided to Conservation Medicine staff, Wildlife Health, Genetics and Forensic Laboratory (WHGFL), Chulalongkorn University laboratory team members on using R Studio to analyze laboratory data from multiplex microsphere immunoassay (MMIA) testing.

**November 2021** On-site lectures and hands-on training on biosafety, human safety, safe animal handling and sampling, safe sample transportation training for 3 PERHILITAN Science Officers at National Wildlife Forensic Laboratory. The objective of this training was to build capacity for those involved with the bio-surveillance of wildlife species and for them to better understand the distribution of these pathogens and train researchers on how to collect samples safely and securely in the field with a focus on biosafety and biosecurity.

**November 2021** Virtual training among Conservation Medicine staff on nanopore sequencing. This training explores the functions of nanopore sequencing, a technology that enables direct, real-time analysis of long DNA or RNA fragments.

**January 2022** Room differential pressure training for three Conservation Medicine staff in Malaysia. The objective of this training was how to use manometers in a laboratory to help us monitor room pressures at PERHILITAN and Sabah Wildlife Department (SWD) laboratories.

**March 2022** Training among two PERHILITAN Science Officers on Bio-Plex/Luminex that consists of theories on lab safety, introduction to Bio-Plex and multiplex immunoassay, Bio-Plex best practices and maintenance and raw data handling, and practical training on operating the Bio-Plex machine and running the filovirus and Henipavirus multiplex immunoassay on samples collected in Malaysia.

**April 2022** On-site lectures and hands-on training to members from Oxford University Clinical Research Unit (OUCRU) and Institute of Ecology and Biological Resources (IEBR) (Vietnam) on:

- Field biosafety
- Site assessment
- Bat handling and sampling

**Regular meetings and training** on serologic testing were provided to Thailand and Malaysia partners on using surrogate virus neutralization test (sVNT) and multiplex microsphere immunoassay (MMIA) developed by EID-SEARCH partners.

## C. PRODUCTS

## C.1 PUBLICATIONS

Are there publications or manuscripts accepted for publication in a journal or other publication (e.g., book, one-time publication, monograph) during the reporting period resulting directly from this award?

Yes

Dear All,

Attached please find a copy of the submitted Year 2 Progress Report (technical part), thank you very much for your wonderful work, and for sending updates to complete the report!

As we are approaching the end of Year 2 on May 31, we will follow up closely on the Year 2 funding expenses and invoices in the next couple of weeks.

Sincerely,  
Hongying

Dear Partners,

The NIH Research Performance Progress Report (reporting period 06/01/2021-05/31/2022) for EID-SEARCH (No. 5U01AI151797) is due on April 1, 2022. I'm sending this email as an initial notification in case your institution needs some time to proceed and prepare a report, but the information required for this report is majorly focused on the research findings and plans, very minimal on administration unless you have any major changes on key/senior personnel.

Attached please find a template with the different sections we would like to get updates from you as part of the report to submit. Any relevant work for each section is welcomed (don't worry about the languages or word limits), but I labeled some sections as \*required where are the most important to concentrate.

We would greatly appreciate it if you can send us updates by **March 21, 2022, Monday** so that we can have a few days to edit and combine all things together to submit.

Please feel free to let me know if you have any questions. You will also receive reminders

from me on March 01 and March 14 if it's still too early and you're waiting for more results to include in the report. Thank you very much!!

Sincerely,  
Hongying

Nipah virus is an emerging zoonotic paramyxovirus that has repeatedly caused outbreaks of encephalitis associated with high case fatality rates in South Asia. Surveillance for Nipah and related henipaviruses across their geographic distribution is generally lacking, and this group of viruses has the potential to cause significant outbreaks in people and domestic animals. In Bangladesh, Nipah virus outbreaks have been reported nearly every year since 2001. *Pteropus medius*, a common and abundant frugivorous bat, is the natural reservoir for Nipah virus in Bangladesh and spillover occurs primarily through the consumption of date palm sap contaminated with bat excreta. Human-to-human transmission has been a typical feature of Nipah virus outbreaks, although observed transmissibility has, so far, been relatively low. Yet little is known about the genetic diversity of henipaviruses in bats, the relationship between viral genotype and clinical or epidemiological characteristics, or the frequency of spillover. To address these knowledge gaps and ultimately develop more effective interventions to prevent Nipah virus outbreaks, the government of Bangladesh and its partners have implemented a multidisciplinary, One Health approach to Nipah virus surveillance, outbreak response and research, combining longitudinal studies of Nipah virus in bats, contemporaneous human and animal testing during outbreak investigations, behavioral risk assessments, virological studies and serological surveys. Here we describe a current model for integrated surveillance and research designed to better understand, respond to, and ultimately prevent spillover of a high consequence, emerging zoonotic virus.

Dear colleagues,

I've just become aware of an upcoming Keystone Symposium on pandemic prevention being co-organized by CEPI.

[www.keystonesymposia.org/conferences/conference-listing/meeting?eventid=6862](http://www.keystonesymposia.org/conferences/conference-listing/meeting?eventid=6862)

I think it would be a good opportunity to submit an abstract for a short talk to showcase our Nipah virus work. The deadline for submission is Monday night (Eastern Time)

With apologies for the short notice, I would be grateful if you would review the attached abstract and send me your consent to be a co-author, along with any comments, by Monday 3pm.

Cheers,  
Jon

## PROJECT DESCRIPTION

### Introduction and Background

The spillover and spread of novel, zoonotic (animal origin) pathogens can have tragic societal and economic impacts, as is evidenced by the ongoing COVID-19 pandemic. The emergence of SARS-CoV-2 (the virus that causes COVID-19) is the latest in a series of viral emergence events that have accelerated in recent decades. In just the last year, as the world continues to respond and adapt to COVID-19, we have seen other deadly zoonotic viruses re-emerge in the human population, including Ebola and Marburg in Guinea<sup>1,2</sup>, Nipah virus in India<sup>3</sup>, Rift Valley Fever virus in Kenya<sup>4</sup>, and novel strains of influenza in China<sup>5</sup>. Most emerging infectious diseases (EIDs) originate in wildlife hosts and are transmitted across species boundaries, or (“spill over”), when livestock or human populations increase contact with wildlife through factors including land use change, agricultural intensification, and the wildlife trade<sup>6-8</sup>. Zoonotic spillover is a dynamic process determined by many steps including ‘pre-emergence’ viral evolution, diversification, and transmission among wildlife hosts; ‘human exposure’ via direct or indirect contact between humans, livestock, and wildlife; ‘post-exposure’ limits to cell entry, host range, human-to-human transmission; and population level virus amplification and spread. Once efficiently transmitted, EIDs spread rapidly through globalized travel and trade networks, threatening countries with high population growth, urbanization and international trade (Fig 1).

**Fig 1.** Four stages of zoonotic disease emergence and spread, with gaps in knowledge at each stage. Our proposed project will develop and pilot novel, multidisciplinary and technological advances to address critical gaps in the first three stages of emergence, when pandemic prevention is possible.

Novel human EIDs are typically only discovered when they cause severe or unusual symptoms, when astute clinicians are linked with laboratories capable of pathogen discovery research, and after they have been transmitted from person to person (after which control becomes more difficult)<sup>8,9</sup>. Emerging human viruses characterized to date are a small sample of hundreds of thousands of predicted zoonotic viruses in nature but undiscovered due to limited surveillance capacity globally<sup>10</sup>. New research has upended the paradigm that zoonotic disease spillover is a rare event. A combination of more advanced molecular and serological assays, improved laboratory capacity around the world, and targeted surveillance of “high risk” human populations found evidence of frequent zoonotic virus transmission and infection, even in the absence of notable disease outbreaks. Often these spillover events lead to “dead end” infections in people or limited “stuttering” chains of transmission, a phenomenon referred to as “viral chatter”<sup>11</sup>. Community-based serological surveys from our group and others have illuminated relatively frequent and previously-unknown instances of zoonotic virus spillover including Henipaviruses in bat hunters from Cameroon<sup>12</sup>, SARS-related CoVs in rural communities living near caves in China (pre-2019), and Ebola virus exposure in DRC<sup>13</sup> and even Southeast Asia<sup>14</sup>.

Innovative and multidisciplinary approaches are needed to disrupt the emergence of diseases at the “viral chatter” stage and further upstream at the human-animal interface to prevent epidemics and pandemics before they are out of control. While we have made significant scientific advances over the last ~15 years in understanding where and through what mechanisms novel zoonotic viruses spill over into the human population<sup>6,15-18</sup>, **there are still fundamental knowledge and implementation gaps that stymie our ability to preempt and prevent future disease emergence events.**

### **Our Grand Challenge Problem**

Prior to 2019, EcoHealth Alliance (EHA) and our partners demonstrated that SARS-related coronaviruses (SARSr-CoVs) in China pose a clear and present danger for a future human outbreak. We conducted extensive viral discovery in wildlife from China and Southeast Asia, phylogenetic analysis, and host-range experiments to show that certain bat species harbor a diverse assemblage of SARSr-CoVs<sup>19,20</sup>, as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics<sup>21-24</sup>. We conducted behavioral risk factor surveys and serological sampling from human populations living close to caves and found serological evidence of SARSr-CoV spillover in people exposed to wildlife<sup>25</sup>. Building on this body of knowledge, we estimate bat-origin SARSr-CoVs infect 50,000 people in Southeast Asia each year<sup>26</sup>. While confidence intervals around this median estimate are large, our sensitivity analyses identify key area for future research to improve these spillover risk models: quantification and better contextual understanding of human-bat contact, the role of wildlife farming and livestock hosts, scaling up human serological surveys, and better data on sero-dynamics following exposure<sup>26</sup>.

Despite this strong body of evidence for SARSr-CoV spillover risk prior to the emergence of SARS-CoV-2, surveillance was not conducted across a wide enough geography, nor at a temporal or spatial scale to inform actionable disease mitigation. Despite large-scale efforts to strengthen zoonotic virus early warning systems, like the 10-year, 30 country USAID PREDICT program<sup>27</sup>, led by a global consortium including EHA, current methods and systems cannot capture and disseminate enough data quickly enough to enable prevention measures at national or global scales. This is especially so for multiple and novel viral threats, and in large countries with heterogeneous human populations, diverse wildlife fauna, and known ecological and societal risk factors for emergence. Approaches to massively scale up zoonotic spillover surveillance are needed.

**Our grand challenge: "How can we capture actionable data about the risk of zoonotic spillover and spread at the scale and speed required to prevent outbreaks?"** How can we leverage tools developed by computer scientists, data engineers, and technology companies to collect data from large, diverse populations and geographies to advance zoonotic spillover intelligence? How do we incorporate new insights from medical anthropology, sociology, wildlife biology, disease ecology, molecular virology, biomedical assay design, and data science to pioneer accelerate data collection and interpretation for zoonotic disease prediction and prevention? We propose to build a collaborative research and training network to confront this challenge, that will scale up to a future *Center for Spillover Intelligence (CSI)*. Our network will deeply integrate computer scientists, engineers, and data scientists using machine learning and other novel technological approaches together with experts in emerging disease and social-behavioral research. New insights from social, behavioral, and anthropological research make it clear that the emergence and future trajectory of human epidemics require that we recognize potential biological risks alongside risks posed by cultural and societal factors<sup>28-30</sup>. Our cross-disciplinary, multi-institution project will combine innovative research activities with training and education programs to facilitate to scale-up the collection and interpretation of data to inform where, how, and what zoonotic viruses are poised to emerge – a field we collectively refer to as

*spillover intelligence*. Our inclusion of social-behavioral researchers, data ethicists, and inter-governmental EID policymakers will ensure that our aims and approaches are culturally and locally relevant, and align with our ultimate goal of improving global health.

**Our Vision:** We envision a world where diffuse data streams can be combined and interpreted in near real-time to disrupt the spillover and spread of future zoonotic viruses. We envision diverse leaders and scientific disciplines coming together to advance spillover intelligence and transform the ways we think about, monitor, and respond to global viral threats.

## **Our Team**

We have assembled a multidisciplinary team of experts to lead our development project and to create and grow the Center for Spillover Intelligence (CSI). Our **Leadership Team (PI, coPIs, Senior Personnel)** includes established scientists and early career leaders working across the fields of emerging infectious diseases, computer and data science, engineering, mathematical modeling, virology, technology and biotechnology, data ethics, social science, and medical anthropology. Our project will be led by EHA (PI Olival) building off the foundational pandemic prediction work our institution has developed over the last decade, and include new partnerships and collaborations. These include with computer scientists and engineers from University of Rochester (UR) and behavioral anthropologists from Georgetown University (GU). We will develop and pilot new technologies for field biosurveillance and data interpretation with Uniformed Services University (USU). Our leadership team is ethnically, culturally, and geographically diverse, including US-based researchers who originate from and/or currently conduct their primary research in global EID hotspot regions<sup>6,15</sup>, e.g. South Asia (Hoque); Latin America (Mateos); Africa (Mendenhall); and Southeast Asia and the Pacific (Olival). Our geographic and disciplinary diversity, including long-standing international collaborators from each region, make our team well-equipped to address spillover at a global scale, while incorporating the nuance of local context.

**PI Olival** (EHA) is a disease ecologist and evolutionary biologist with a primary interest in developing novel analyses to target zoonoses surveillance and viral discovery. He currently leads two regional biosurveillance projects in Southeast and Western Asia, and recently served as Modeling & Analytics Coordinator for the USAID PREDICT project<sup>27</sup> overseeing a multi-institution team developing pandemic prediction strategies using public and project-specific data from 30 countries<sup>6,16,31-36</sup>. **coPI Mendenhall** (GU) is a medical anthropologist and Professor at the Edmund A. Walsh School of Foreign Service. Mendenhall works at the intersection of social, psychological, and biological lives, attempting to understand what makes people sick, why, and where. Mendenhall is currently a PI of NIH Fogarty International Center grant “Soweto Syndemics”, the first ever study to evaluate a syndemic from the ground up. **coPI Hoque** (UR) is an Associate Professor of Computer Science working at the intersection of Human-centric Computing (HCC) and Artificial Intelligence with a focus on multimodal machine learning with applications in health and wellness. Hoque is currently a PI of NSF NRT grant, and received NSF CAREER and CRII grant. Hoque has been identified as an ‘emerging leader of health and medicine’ at the National Academy of Medicine (NAM). **coPI Mateos** (UR) is Assoc. Professor of Electrical and Computer Engineering and a Data Science Fellow, his research focuses on algorithmic foundations, analysis, application of (graph) signal processing tools to the study of large-scale and dynamic networks. He has pioneered foundational work in network topology inference, online learning from graph streams, and interpretable representation learning for unstructured data. **coPI Ross** (EHA) is Principal Scientist for Computational Research. His research includes model development to interpret complex spatio-temporal disease surveillance data in heterogeneous populations, real-time community and hospital testing, and simulating and forecasting epidemic dynamics over populations, space, and networks. He is PI on awards from DHS Science & Technology Directorate and the Defense Threat Reduction Agency

(DTRA) for designing disease forecasting systems. **SP Mendelsohn** (EHA) is a data scientist specializing in the development and application of machine-learning models to draw insights into the occurrence and spread of emerging infectious diseases. With a focus on reproducible research methods and data management, she has been the lead analyst on data driven disease forecasting and behavioral survey-based projects characterizing animal-human contact patterns. **SP Daszak** (EHA) is an EID expert who has studied the process of disease emergence for decades and pioneered groundbreaking work in “hotspot” risk mapping to target surveillance. **SP Broder and Laing** (USU) are experts in the design of multiplex serological assays, molecular virology, and implementation of field-based human and wildlife biosurveillance strategies. **OP Busa** is a biotechnology consultant with a specialty in developing lateral flow assays and optical readers. **OP Pompe** is the Research Manager for Facebook Data for Good, who specializes in applying human mobility datasets from social media feeds and data privacy and ethical issues.

### Intellectual Merit

The primary intellectual merit of our proposed project is in **developing and piloting innovative approaches to rapid and large-scale spillover intelligence across previously siloed scientific domains** including biology, computer science, electrical engineering, and social-behavioral research. We apply new theoretical advances and convergent research to address our grand challenge of capturing actionable data about the risk of zoonotic spillover and early spread at a scale and speed required to prevent outbreaks. We will identify gaps and solutions for step-level changes in zoonotic spillover prediction via three multidisciplinary working groups that will engage in pilot projects, organize workshops, and engage students in immersive training. Our pilot research projects will serve as a test bed for applying new theoretical frameworks to advance spillover intelligence test scalability in future work. For example, in Aim 1 we will transform decades-old anthropological approaches and pilot cost-effective methods to collect large samples of quantitative and qualitative behavioral data via unique public-private partnership with Facebook; and use image recognition and artificial intelligence to quantify and map human-wildlife contact globally. In Aim 2 we will develop rapid bioinformatics pipelines to process and interpret rich data from multiplex serological surveillance; and develop the first field-forward lateral-flow assay for Nipah virus antibody detection. In Aim 3 will use advances in network science, anomaly detection, and machine learning to detect changes in human mobility patterns that may portend spillover (e.g. increase congregation around wildlife markets) and that signal early epidemic spread after the point of spillover.

### Broader impacts

This proposal could potentially transform our understanding of zoonotic spillover risks using survey, multimedia, and mobility data on a global scale, including aggregated and anonymized data from ~3B active Facebook users. Insights and intellectual outputs from our working group activities will have direct benefits to public health by informing disease mitigation strategies for pandemic prevention. All outputs from our three Working Group activities, including workshop materials and code and analyses from pilot projects, will be made publicly available (**see Data Management Plan**), and published as both peer-reviewed manuscripts and popular press articles for wider dissemination. EHA’s *Alliance*, includes a network of over 70 partner institutions in 30+ countries, presents a unique opportunity to work with local stakeholders in emerging virus ‘hotspots’ and validate models using data sets obtained through our long-standing collaboration with government partners including human health, agriculture, and environmental sectors. Our education mission consists of multiple workshops, hackathons, monthly seminar series, and access to state-of-the-art visualization facilities.

We will train a new generation of graduate and undergraduate students in understanding medical anthropology, disease surveillance, and data and network science so as to become

future leaders in spillover intelligence. We will do so via a unique partnership between the academic (UR, GU, USU), non-profit (EHA), and private (FB) sectors, allowing students to apply lessons learned from classroom settings to the real-world. Students will participate in project workshops, hackathons, monthly seminar series, and have access to state-of-the-art visualization and computing facilities. Our recruitment will focus on including >50% women and underrepresented minorities in science and engineering. This planning grant will be a path towards developing an interdisciplinary curriculum, including cross-training courses across institutions, and hands-on experience via internships and research exchanges. Through the planning grant, a new MS data science track on zoonotic surveillance will be established at UR, the first step in our plans to expand our Education and Training plan should we move towards a Center-level award in the future.

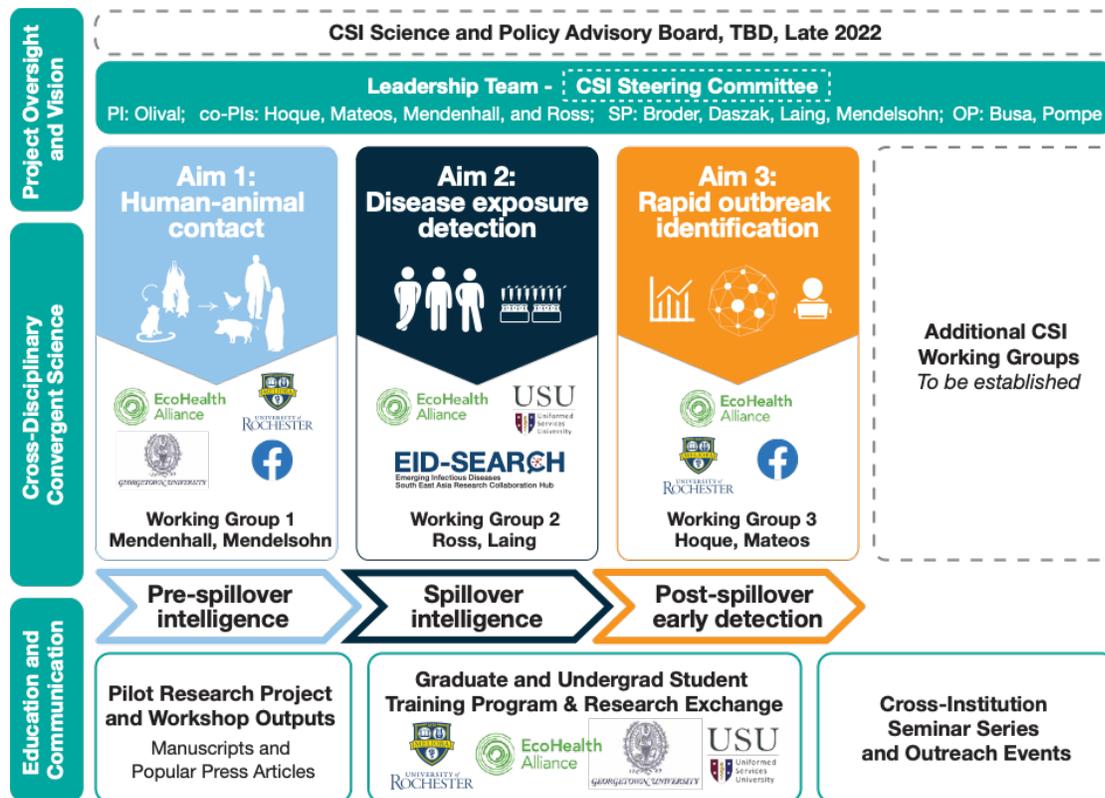

### Education and Training Plan

Our Leadership Team will serve as mentors for our **CSI Student Training Program** that will offer a fellowship stipend to cross-train 20 Master's level graduate students via semester-long projects associated with proposed pilot research activities (3-4 students per project) and 3-week research exchanges between our institutions (UR, GU, EHA, USU, 4-8 students from each). The research exchange builds off EHA's successful NSF-funded EcoHealthNet training program (2011-21) and will take place in either the Summer of 2022 or 2023. We will link with currently-funded international programs at our respective institutions (e.g. Gui<sup>2</sup>de in Nairobi, Kenya run by GU; and the NIH funded CREID research pilot program with EHA's EID-SEARCH project in Southeast Asia) to support students who desire to gain international, hands-on research experience as part of their research exchange. The focus of each research exchange will be on cross-disciplinary training, hands-on experience working with experts outside student's area of study, and big-picture strategic thinking in pandemic prevention. Students will be drawn from respective departments across our institutions: students with a computational background and with interests in interdisciplinary work will be recruited from UR's cross-department Goergen Institute for Data Science, Anthropology and International Affairs students from GU, and Emerging Disease and Virology students from USU. EHA will recruit Ecology, Evolutionary Biology, and Environmental sciences students from universities where we have active partnerships, including Columbia University's E3B department where PI Olival and SP Daszak serve as adjunct faculty. We will explore specific mentorship opportunities with data scientists from Facebook. If awarded, we will additionally apply for funds through NSF's Research Experiences for Undergraduates (REU) program, with the goal of supporting summer stipend for 1 undergraduate per institution or the maximum allowable. We will host a joint monthly virtual seminar series (2 semesters long) open to graduate and undergraduate students from our respective institutions, with dedicated student "lab meetings" before each seminar. Two CSI students from diverse disciplines will lead each lab meeting discussion based on a deep read of relevant publications that each speaker will distribute in advance. The first semester of the seminar series will be led by our Leadership Team and Working Group experts, and the second semester will be for CSI Graduate students to present results or current challenges related to their pilot research projects. We hope to encourage these students to pursue Ph.D. studies. If we are successful at establishing a center through our planning grant, we should have access to a trained cohort of students with appropriate multidisciplinary skillset.

### Project Overview

Our 18-month research agenda aims to understand how new methods and technologies can improve the efficiency, intensity, speed, and scope of zoonotic disease surveillance. **We have structured our development grant around three primary research aims** that will guide our interdisciplinary research and training activities. We will establish a working group composed of multi-disciplinary experts for each primary aim that will be co-led by members of our Leadership

Team. We will develop pilot research projects that capture different parts of the disease spillover process focused on specific geographies, and lead 3-day intensive workshops, monthly student seminars, and student training activities that cut across our inter-linked research aims.

**Fig 2. Project overview schematic** showing our project management; three primary aims with graphical representation of pilot research activities to scale up and advance spillover intelligence; institutional partners leading activities for each aim including designated working group leads, and student education and communication activities, including pilot research projects, graduate student research exchanges, seminars, and other outreach activities. Our development level project is built to scale to a Center level award (the Center for Spillover Intelligence, CSI) as noted with the dashed outline boxes, including the future addition of other CSI Working Groups, a Science and Policy Advisory Board, and transitioning our current Leadership Team (PI, coPIs and SP) into a more formal Steering Committee for oversight.

### **Aim 1: Measuring human-animal contact at scale**

Interactions among humans, wildlife, and livestock create interfaces for pathogen spillover and are proximate risk factors for the emergence of all directly-transmitted zoonotic diseases.<sup>15,37</sup> Human-animal contact is commonplace around the world, with many factors mediating the type and frequency of contact, including cultural practices, environmental conditions, food security, and occupational demands<sup>37</sup>. In regions of the world considered prone to spillover--forested tropical landscapes with high biodiversity and recent land-use changes--understanding human-animal contact is crucial to pandemic prevention<sup>6</sup>. To measure these interactions and characterize associated behaviors, beliefs, and knowledge, researchers often implement resource-intensive surveys in key communities<sup>38,39</sup>. While crucial to understanding human-animal contact dynamics, on-the-ground surveys cannot yield scalable data that is comparable across populations. Often, in place of surveys, researchers conducting analyses at broad scales rely on coarse estimates of contact such as the joint density of human and animal populations.

**Our working group will uniquely combine social scientists, disease ecologists, and computational scientists to increase the scale at which we can directly measure human-animal contact.** We will develop and implement two pilot research projects. The first will use novel, social-media-based survey approaches to reach larger populations at higher frequencies while maintaining the cultural sensitivity and relevance of on-the-ground surveys. Working collaboratively with cross-disciplinary researchers, we will design surveys to understand social behaviors, cultural perceptions, and occupational hazards that may pose zoonotic spillover risk to individuals and communities. We will target geographies based on our existing spatial risk modeling work that maps infectious disease spillover potential and the ecological distributions of key reservoir host species<sup>6,16,26</sup>. Second, we will conduct pilot research on the use of social-media-based image recognition algorithms to identify locations of human contact with key species known to host high pathogen diversity. This pilot will include a collaboration effort to test the efficacy of such technology for understanding taxon-specific contact patterns globally, and to bring multidisciplinary context to meaningfully interpret the outputs (including species validation with taxonomic experts). If successful, will use these data on frequency of animal contact from image data to identify locations for additional survey data collection.

**Aim 1 Pilot Research Projects:** We will develop two pilot projects to assess the potential of 1a) social-media dispensed surveys and 1b) passive surveillance using artificial intelligence for image recognition to capture information about human-animal contact. We will target populations at wildland interfaces where contact with wildlife is likely high but internet penetration may be mixed.

***1a. Social-media dispensed surveys to quantify and contextualize human-animal contact***

We will pilot social-media dispensed, large scale population surveys about perceptions of and interactions with animals. We will optimize the design of these surveys for mobile platforms to facilitate higher response rates, and will also explore the possibility of longitudinal sampling (of either individuals or populations) to understand changes in conditions and responses over time. Survey questions will be based on a combination of EHA's past experience designing on-the-ground human-animal contact surveys<sup>38,40,41</sup> and ideas generated from our proposed working group activities involving anthropologists, data scientists, and disease ecologists who have worked extensively in the geographic and societal contexts in which we focus our work. We will design surveys that account for populations and individuals holding different beliefs, carrying different histories, and living in different ecologies. We will survey demographically and geographically diverse populations to capture direct and indirect animal-contact patterns and behaviors, and to capture the role that international, state, and local policy plays in individuals' lives. Further, we will aim to identify particular hesitations among individuals to interact with technologies or other public health interventions.

We will explore multiple online platforms at the start of our project for survey administration. Given our unique public-private partnership with Facebook for many components of this project, using the Facebook platform to disseminate our pilot survey is likely to be a strong option, especially given Facebook's global reach (nearly half of the world's population, ~3 billion users), which introduces opportunities for digital interaction across class, gender, ethnicity, and cultural divides. We will leverage Facebook's extensive experience designing and administering surveys, especially for mobile devices, both directly on its platform (e.g. Yale Climate Change opinion survey) or off-platform (e.g. Carnegie Mellon University COVID-19 surveys). Facebook also has extensive privacy infrastructure and data-review policies to ensure anonymity and data security.

We will also explore creating games that users will be encouraged to play online to enable us to learn more about how they think about host species, viral threats, environment, and

health/disease. For example, users may be given a list of 30 images and will be asked to put them into categories and describe what each category means. Adapting these “pile sorting” anthropological methods<sup>42</sup> to an online interface and for spillover risk will be a novel application with potential for a massive scale-up of data around cultural and conceptual dimensions of zoonotic disease risk. Data generated from this exercise will generate an ethnographic understanding of people’s experiences and thought processes, typically locally mediated.

We understand that there are geographic and demographic gaps in internet and social media use, and will incorporate bias corrections into our study design. We will initially focus on Southeast Asia, a region with a high likelihood of future zoonotic disease emergence and where EHA has good coverage of on-the-ground surveillance programs to ground truth online data collection<sup>6</sup>, and expand to new geographies as we develop Center-level activities.

### ***1b. Image recognition of zoonotic disease host species***

We will pilot image-based surveillance of Facebook and Instagram feeds to attempt to identify human contact with key zoonotic disease host species and to explore the limits of taxonomic and behavioral recognition in images. We will work with Facebook Data for Good (see **Letter of Collaboration**) to adapt and refine their existing machine vision algorithms to target key taxa and to assess the efficacy of different approaches, working within strict guidelines and ethical standards for data de-identification. While data will be de-identified, we will use location metadata, allowing us to not only quantify the type of species and contact, but where it occurred. There are multiple image libraries that may serve as AI training datasets, including iNaturalist, the American Society of Mammologists, and Integrated Digitized Biocollections (iDigBio). We will iteratively implement and test algorithms starting with broad taxonomic groups (e.g., bats) and will explore the extent to which our approaches can identify finer taxonomic resolutions down to the genus or species level. In addition to taxa identification, we will explore image recognition of features that may suggest specific types of human-animal contact, such as cages or market settings. We will use text and image metadata and explore using hashtags associated with images to boost the ability of our algorithms to identify key taxa.

This work will involve collaboration between machine learning scientists, biologists/ecologists, and social scientists. We will follow all data anonymity and privacy guidelines from Facebook and will also discuss data handling ethics in our working group. We will assess the ability of passive surveillance with image recognition to target surveys to populations that have higher frequency of contact with wildlife, and ultimately to target biological surveillance of human and animal populations. We will consider both the accuracy of the image recognition algorithms as well as implications for survey distributions, results interpretation, and ethical data practices. We will also compare the spatial distribution of human-animal contact patterns derived from image recognition with previously generated spillover risk maps based on joint occurrences of animal and human distributions (e.g., our SARS-related CoV spillover risk<sup>26</sup>).

**Working Group 1 Activities:** Our working group will convene 12-15 experts from the social sciences, disease ecology, and computational sciences for an intensive, 3-day workshop. We will structure the workshop to focus first on data ethics in human behavioral surveying and image recognition surveillance and secondly on survey design and analysis planning, with specific attention to accounting for gaps or biases in survey distributions. We will center the workshop on data collection that addresses long term social, ecological, and economic realities to understand how people perceive, experience, and interact with the risk of and repercussions from spillover events, rather than technological “quick fixes”. We will also address experiences and challenges in engaging longtime ethnographers and local leaders to understand what’s at stake for communities engaging with online and field surveillance programs. Our working group will help mentor students part of the CSI Student Training Program, to facilitate information sharing and idea generation among undergraduate and master-level students. Working group 1

will also contribute to the CSI Seminar Series with cross-disciplinary topics such as AI image recognition (lead by a data scientist and bat biologist) and human-behavioral survey design (lead by an epidemiologist and medical anthropologist).

**Partners, Initial Working Group 1 Members, and Roles:** EHA (SP Mendelsohn): survey design and implementation, image recognition algorithm development and testing, novel data analyses. Facebook Data for Good (OP Pompe): survey implementation, image recognition algorithm development and testing, data ethics. University of Rochester (coPI Hoque): Image recognition algorithm development and testing. Georgetown University (coPI Mendenhall): Survey design with focus on ethnography and anthropology; online free listing/pile sorting game design; help lead expansion of WG to include emerging international leaders in social-behavioral science (e.g. Dr. Edna Bosire from Kenya). We will invite additional leaders from our extensive funded collaborations to be part of the Working Group for Aim 1.

## **Aim 2: Detecting zoonotic disease exposure at scale**

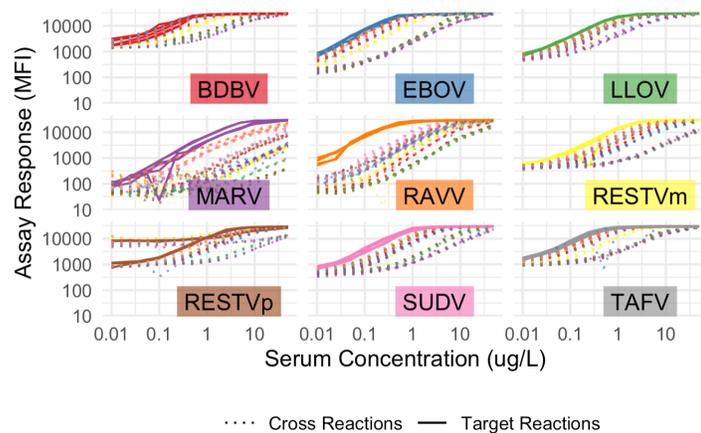

Animal-human contact is the necessary condition for spillover of potential pandemic, directly-transmitted viruses. While a small fraction of such encounters result in exposure or infection, such exposures are frequent given the total sum of encounters. Some viruses such as Lassa spill over thousands of times per year<sup>43</sup>. Most spillover infections are never reported and rarely spread widely, and a very rare subset become widespread in the human population<sup>44</sup>. In areas of frequent spillover, the eco-evolutionary dynamics of "stuttering chains" of infection are what give rise to epidemics and pandemics<sup>45</sup>. Identifying populations where frequent exposure occurs is critical for deploying preventative measures and following viruses upstream to their wildlife hosts. Yet even large-scale surveillance projects cover too small populations and produce far too few detections to determine the most exposed geographic, demographic, or occupational groups at an actionable scale. This is for two reasons: field and laboratory cost of surveilling populations interacting with wildlife interface, and low detection rates of widely-used molecular PCR or metagenomic approaches.

We aim to drastically increase the scale at which populations can be monitored for exposure to animal-origin viruses by developing and piloting novel tools and analyses needed to implement large-scale serological surveys. While metagenomic methods have been favored for their ability to capture genetic sequences of previously unknown viruses, serological methods can be used to detect exposure to known and unknown viruses using multiplex assays tailored with a mixture of sensitivities and specificities<sup>46</sup>. Serological tools can detect antibodies for months or years after viral infection, rather than the limited window of days or weeks using molecular methods, and thus can provide a much richer profile of populations where pandemics may emerge<sup>47</sup>.

**Aim 2 Pilot Research Projects:** In this planning period, we will begin pilots to test the feasibility of two complementary approaches to enabling serological screening at large scales: 2a) the creation of rapid bioinformatics pipelines to interpret high-dimensional serological data from large streams of surveillance data, and 2b) the development of rapid field serological tests for wildlife-origin diseases.

**2a. Rapid bioinformatics for high-throughput, multiplex serology** Members of our team (SP Laing, Broder) have developed multiplex serology tests that can be used to screen for exposure for many species and variants of filo-, henipa-, and coronaviruses simultaneously, and screening pipelines that can process samples at the scale of tens of thousands of samples. However, these tests pose challenges for interpretation, as high-dimensional results from multiplex bead or chip assays frequently contain signals of cross-reaction and autocorrelation (**Fig 3**). Through cross-disciplinary research between molecular virologists, serologists, mathematical modelers and data scientists on our team, we will create models to interpret this high-dimensional data and integrate them into a rapid bioinformatic pipeline that identifies

individuals and populations to known viruses as well as flagging serological signals indicative of novel viruses. We will make use of data collected under our ongoing NIH and DTRA funded biosurveillance activities (Laing, Broder, Ross, Olival, Daszak) to develop detailed reaction/cross reaction profiles of a broad panel of zoonotic viruses to serological tests. We will build mechanistic, hierarchical Bayesian models that allow us to determine whether serological “profiles” are more likely to represent antibodies of known viruses, mixtures of multiple known viruses, or previously uncharacterized viruses. We will extend techniques of antigenic mapping<sup>48</sup>, using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential. Using simulation experiments, we will test reduced-form, simple models against fully structured models so as to develop statistically robust procedures to interpret these data without high-performance computation.

**Fig 3.** Preliminary data: Reaction-cross reaction plots of multiplex Luminex assay response to antibodies for closely-related filoviruses.

**Scaling center operations:** This pilot project will produce methods and a proof-of-concept pipeline for high-throughput analyses. We will leverage EHA’s Emerging Infectious Disease – Southeast Asia Research Hub (EID-SEARCH) project, a NIH-funded Center for Research in Emerging Infectious Diseases (PI Daszak) who’s partners include USU, Duke NUS, Chulalongkorn University in Thailand, and various clinics and institutions in Malaysia – currently screening large numbers of human samples (>10K/yr) for various coronavirus, filovirus, and paramyxovirus antibodies. In the future the CSI will implement surveillance studies screening these sample streams using multiplex serology, and utilize the analytical and bioinformatic tools we develop in the next 18 months. As part of our planning activities, we will establish protocols and approvals for this work.

## **2b. Development of a field-ready semi-quantitative lateral flow assays for an emerging zoonotic virus (Nipah virus)**

Lateral flow assays (LFAs) are low-cost tests where reagents printed on cellulose strips react with a sample that flows via diffusion. LFAs are capable of providing quantitative results (in proportion to antibody titer) when produced via high-quality manufacturing and with carefully designed and calibrated optical scans<sup>49</sup>. LFAs can be used to provide diagnostics at low cost at the point of care and by consumers. Lack of commercial-scale applications has prevented LFAs from being used for serological testing for novel or emerging disease. To our knowledge, no studies have used LFAs for zoonotic virus serosurveillance in the field.

We will develop a proof-of-concept LFA for Nipah Virus (NiV). NiV has a high mortality rate and is considered to have pandemic potential that is ranked by CEPI as one of 7 high pandemic risk pathogens<sup>50</sup>. The range of NiV’s primary wildlife hosts (*Pteropus spp*, fruit bats) cover South and Southeast Asia but human cases have only been detected in Malaysia, Bangladesh, and the Philippines. Spillovers occur regularly in Bangladesh, but are rarely reported in large portions of the country<sup>51</sup> and reporting is strongly associated with health care accessibility<sup>52</sup>. Broad-scale serological monitoring has the potential to identify populations from which

pandemic strains may emerge. Through previous work, members of our working group (Laing, Broder) have developed multiplex serological assays for NiV<sup>53</sup> and the soluble proteins and reagents required for an LFA. We have also added experience in engineering, quality control and commercialization of LFAs (Busa, industry consultant) to our working group. For the pilot, we will engage with commercial manufacturers to create and test a prototype Nipah LFA and a protocol for smartphone-based optical reading of quantitative responses.

*Scaling center operations:* The pilot will create a prototype LFAs. As part of full center operations under CSI, we will aim to scale up production and test LFAs efficacy using control sera and field deployment as part of EID-SEARCH. We will additionally assess feasibility and cost of deployment, and compare performance against current laboratory-based assays.

**Working Group 2 Activities:** In addition to the two pilots above, working group members will contribute to our CSI monthly seminar series, presenting on topics including high-dimensional data models, field serology, serological assay development, laboratory product design, and public-private partnerships and commercialization. We will conduct two online workshops on serological data analysis, jointly with undergraduate, masters, and doctoral students at USU and UR, leveraging partnerships with field researchers currently working in serological surveillance. Our working group will lead a 3-day intensive workshop, where we will recruit additional participants with expertise in serological assay design and surveillance, immunology, emerging zoonoses, and focus discussion on key barriers to scaling serological surveillance for known and unknown zoonotic viruses.

**Partners, Initial Working Group 2 Members, and Roles:** EHA (coPI Ross): Model and pipeline design, software optimization. Uniformed Services University (SP Laing, SP Broder): data and model interpretation, reagent manufacture, assay design. SP Busa: device manufacturing, quality control, industry outreach and partnership development. We will recruit additional participants from our partner network engaged in serological field studies as well as industry representatives to be part of the Working Group for Aim 2.

### **Aim 3: Rapidly Identifying Anomalous Health Events**

In early stages of epidemic spread, contact and mobility-induced behavioral data as well as communication patterns may provide a signal of health-seeking behavior, indicative of an outbreak cluster. We contend that these signals may be detectable in large-scale data streams of population mobility and contact, or in disease reporting available through telecommunications and health care providers. Timely detection requires approaches that can manage data at scale, analyze high-dimensional, spatio-temporally correlated streaming data in (pseudo) real time, and distinguish between known signals (e.g., typical influenza-related activity) and novel spillover-related signatures that we wish to unveil, characterize, and explain in order to trigger the necessary public policy responses.

This desideratum calls for fundamental methodological and computational advances, along with epidemiologically-relevant data sources, to describe how humans are moving and interacting across physical space with unprecedented temporal resolution and geographical coverage. Traditional flow-based mobility datasets used to parameterize epidemiological models have been aggregated and formatted in the form of origin-destination (OD) matrices. While valuable towards understanding population flows between regions of interest, OD matrices lack information on how much time a traveler spends in any given location. For spillover detection, duration of time spent in potentially risky geographical areas is key towards deciphering actionable contact and exposure patterns<sup>54</sup>. Moreover, recent studies have shown that flow counts between pairs of geographical areas can be loosely correlated with, and not representative of, epidemiology-relevant mixing patterns<sup>55</sup>. Instead, these couplings among subpopulations are measured by effective contact rates, meaning how often people from each

region come into contact in a way that is sufficient to transmit a disease. To address these challenges, our consortium will partner with the Facebook Data for Good team and leverage two recently assembled global-scale datasets - Activity Space Maps and Colocation Maps<sup>54,55</sup>.

**Our ambitious goal in this aim is to markedly advance the surveillance infrastructure available to predict anomalous health-related events before a major outbreak occurs.**

This differs from existing approaches that have focused on measuring the causal impact of mobility-oriented interventions. While undoubtedly a multi-faceted endeavor, in this planning grant we will take initial, but significant steps with an emphasis on network-centric, computational analyses of dynamic mobility and interaction data at a global scale. By developing the appropriate statistical tools, we will support the ultimate goal of characterizing early pandemic “fingerprints” or signatures that can be extracted from these global datasets.

**Aim 3 Pilot Research Projects:** Working closely with Facebook Data for Good (see Letter of Collaboration from Alex Pompe), this working group will pilot data-driven research activities to explore the feasibility of extracting early (post spillover) signals of epidemic onset from Activity Space Maps and Colocation Maps. Our multi-disciplinary working group will bring together leading experts in systems engineering, AI for healthcare, data science, mathematical epidemiology, graph signal and information processing, privacy-preserving mobility data generation and management, human behavioral modeling, and environmental science. Our current team, will instigate the cross-pollination of ideas leading to center-level activities while making significant inroads towards our grand challenge. We propose two specific pilot projects:

***3a. Spatio-temporal monitoring of spillover-induced activity anomalies in Southeast Asia***

*Activity Space Maps (ASMs) are a novel global-scale movement and mobility data set which describes how people distribute their time through geographic space.<sup>54</sup> They are designed to complement existing digitally-collected mobility datasets by quantifying the amount of time that people spend in different locations. Accordingly, this information is valuable for estimating the duration of contact with the environment and the potential risk of exposure to disease -- something critical especially early after spillover. It also offers the unique possibility of developing and testing sequential change-point detection algorithms to monitor multiple spatial grid cells of interest (informed, for instance, by outcomes of the image-recognition effort under Aim 1). We will target areas known to include health care facilities in pursuit of abnormal trends of (increased) activity. Moreover, using ASMs we will examine flow and temporal activity anomalies around our expert-annotated wildlife and wet market locations, e.g.<sup>56</sup>. Said events are expected if there are human infections, or significant associated changes in behavior around these sites early after spillover. Our initial efforts during this planning grant will be focused on Southeast Asia, which on top of its epidemiological relevance is one of the regions where Facebook ASMs have the most coverage. We will target Indonesia, where EHA has extensive on-the-ground efforts tracing networks of wildlife trade as well as market sites.<sup>56</sup> We will also tap into the resources stemming from EHA’s Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) to identify clinics and market sites of interest in Thailand and Malaysia. Some key challenges we will address include accounting for the implicit biases in data collection associated with the construction of ASMs,<sup>54</sup> and their subsequent effects on the statistical algorithms that we will develop. Our Working Group will address additional challenges of data interpretation of anomaly detection analyses with input from emerging disease experts and epidemiologists. To calibrate our models, we will bring to bear recent activity data before and after the SARS-CoV-2 outbreak in those locations, in addition to historical influenza seasonal trends extending further back in time. With the prospect of new ASM data being officially released in the last quarter of 2021, *we are in a privileged position to be the first multi-disciplinary team to leverage this invaluable global-scale resource to advance our understanding of zoonotic spillover risk and its immediate effect on human mobility.**

### **3b. Online network change-point detection in dynamic, global-scale Colocation Maps**

Activity data are complemented by *Colocation Maps (CMs)*, which estimate how often people from different regions worldwide are colocated. In particular, for a pair of geographic regions  $i$  and  $j$  (e.g., counties in the US), CMs estimate the probability that a randomly chosen person from  $i$  and a randomly chosen person from  $j$  are simultaneously located in the same place during a randomly chosen minute in a given week<sup>55</sup>. In other words, CMs are global-scale, dynamic network datasets with colocation probabilities encoded as edge weights. Thus, they are well suited to parametrize metapopulation models of disease spread<sup>57</sup>, or to measure temporal changes in interactions between people from different regions<sup>58</sup>. To monitor said changes as part of our second pilot activity in this aim, we will build on our recent advances in online (i.e., sequential) algorithms for anomaly and change-point detection from network streams<sup>59,60</sup>; see also<sup>61-63</sup>. Our approach starkly contrasts with most existing graph change-point detection approaches, which either rely on extensive computation<sup>64</sup>, or require storing and processing the entire observed CM time series<sup>65</sup>. We will prototype and test a lightweight online change-point detection algorithm with quantifiable performance guarantees, that is also explainable since it relies on interpretable node embeddings<sup>59,66</sup>. The latter feature will be leveraged to construct dynamic anomaly maps for user-friendly visualization of post-spillover events, such as our recent network-scientific visualizations of spatio-temporal COVID-19 contagion patterns across the US<sup>67</sup>. Moreover, the extreme size of the CM graphs calls for algorithmic and modeling innovations we will investigate as part of our research agenda, such as seamlessly integrating graph subsampling or dimensionality reduction techniques to the analytics pipeline. We will partner with computer vision experts affiliated to the University of Rochester Goergen Institute for Data Science (GIDS, see attached Letter of Collaboration from institute director Mujdat Cetin), to also explore the exciting prospect of integrating geo-tagged multimodal data such as video and imagery in our studies, for instance as nodal attributes embedded to the CMs.

**Working Group 3 Activities:** *Recruitment and diversity:* We will recruit 6 students from the GIDS-run master's program in data science, which attracts students from multidisciplinary backgrounds and significant computational proficiency to contribute in the aforementioned pilot research activities. *The CSI Leadership Team and broader UR community are committed to providing research training and educational experiences for those traditionally under-represented in STEM, including women and underrepresented minority students.* Our team has a solid track-record in actively recruiting and supervising such students at the undergraduate, masters and doctoral level, with demonstrated efforts towards broadening participation in STEM. As examples of the commitment to diversifying the field, co-PI Mateos serves as founding faculty advisor to the UR's SACNAS chapter and regularly organizes diversity, equity and inclusion panels to highlight challenges and successes of UR's Hispanic and Latino STEM community. We plan to prioritize engaging >50% women and minority students in the research and working group activities proposed here. *Coursework:* UR students will be on the existing health and bio track with an opportunity to take classes in immunology, microbiology and virology programs as well as data ethics at the University of Rochester Medical Center (URMC) as well as the college of engineering. Through our development grant, we plan to establish a special MS track on 'zoonotic surveillance' in order to train and mentor the students to lead center level activities. *Seminar and workshop series:* The students will be part of the large cohort of all the participating institutions and participate in the CSI monthly seminar series. The co-PIs (Mateos and Hoque) will conduct two workshops (and invite additional faculty members from UR as guest speakers) with hands-on lessons in mobility and human behavior modeling. *Hackathon:* The students will be encouraged to submit CSI projects in the yearly hackathon, Dandyhacks (<https://dandyhacks.net/>), organized every fall by the University of Rochester

Computer Science Department and work with the dataset from Facebook. Additionally, co-PIs Mateos and Hoque will work with the organizers of Dandyhacks to release some of the public dataset from Facebook for other teams to explore, model, and mine the data.

*Data visualization meetups at the University of Rochester's VISTA Collaboratory:* To get

acquainted with the different data resources at our disposal, over the first 3 months of the project the Rochester team (along with Facebook and EHA collaborators via Zoom) will hold bi-weekly team meetings with the MSc students at the UR's VISTA Collaboratory. This is a 1,000 square-foot visualization lab equipped with an interactive (20 ft. wide x 8 ft. tall) tiled-display wall, that renders massive data sets in real time, giving team members the ability to visualize and analyze complex data instantaneously and collaboratively (**Fig. 4**). As we dissect what dataset components are central for the aforementioned pilot activities, our graduate students will develop customized data visualization tools, maps and dashboards to facilitate downstream analyses. Updates and progress reports will be shared in these meetings, giving the students a unique opportunity to develop their communication skills. The whole team will provide feedback and share ideas, making this a truly collaborative activity. Moving forward, the VISTA Collaboratory offers a unique resource that we will fruitfully leverage as we scale up to full center operation.

**Fig. 4.** UR's Vista Collaborative will serve as a spillover intelligence “situation room” for training UR and CSI exchange students on analysis of real-time epidemiologically relevant datasets.

**Partners, Initial Working Group 3 Members, and Roles:** University of Rochester (co-PIs Hoque and Mateos): coordination of working group activities, development and testing of computational tools for early detection of post-spillover signatures, dissemination of research products and educational materials, recruiting and mentoring of master students, liaisons to GIDS. Facebook Data for Good (OP Pompe and Maps for Good team members Iyer and Citron): data ethics, quantification of privacy protections, data scientific support for Activity Space and Colocation Maps, mathematical epidemiology expertise for data and model interpretation. EHA (SP Mendelsohn and Ross): identification of target spatial locations in Southeast Asia, epidemiological interpretation of anomaly detection analyses and validation of detected early pandemic fingerprints.

**Scaling center operations:** First, our working group intensive 3-day workshop is designed to lead to new partnerships and synergies for expansion of Aim 3 activities. Second, we will expand our pilot anomaly detection—mobility data project to new geographies by adding new data on georeferenced clinics, wildlife markets and other relevant locations by engaging with our in-country network of partners. Third, we will test new streams of predictive data, e.g. mobile phone datasets, via expanded partnerships with public and private stakeholders to access and ingest these data. We will expand our policy engagement via EHA's *Alliance* and existing connections with WHO, FAO, the World Bank and others to develop behavioral risk interventions in the regions and populations we identify as high risk for zoonotic diseases.

### **Associated Risks and Mitigation Plans**

We envision two primary risks associated with our proposed work 1) data access and privacy violations, and 2) biosafety concerns inherent with emerging zoonoses research. For data related risks, we have already established a strong collaborative relationship with FB's Data for Good team in developing this proposal and already have access to all the relevant datasets for our pilots. Data privacy concerns are taken seriously by our group, including deidentification of any personal identifying information following strict protocols on using human subject data from

FB and our already approved IRBs as part of EHA's NIH-funded work. We will amend or apply for additional IRBs as needed. For biosafety related risks, there will be no active sample collection under our proposed NSF project. We have already secured appropriate approvals (IRB, IACUCs, sampling permits) that outline PPE use and biosafety monitoring plans for our NIH-funded work. Our lateral flow assay development will be undertaken in laboratories designate at the appropriate Biosafety Level following US regulations (USU and other partner labs to be confirmed upon award).

### Results from Prior NSF Support

**Kevin J. Olival** has not had prior NSF support, but is co-PI on NIH-funded "EID-SEARCH" (NIAID-CREID U01AI151797, 2020-25 PI Daszak). Previously co-PI on "Understanding the risk of bat coronavirus emergence" (NIAID R01 AI110964, 2014-2019, PI Daszak). **Intellectual merit:** Identified >50 SARSr-CoVs in bats, showed evidence of ability to infect human cells, humanized mouse models, and people in China, and used evolutionary and mammalian biodiversity patterns to analyze spillover risk for use in public health control. Produced 18 peer-reviewed papers<sup>21,35,68-80</sup>, including two papers in *Nature*<sup>81,82</sup>, and a review in *Cell*<sup>83</sup>, and others submitted. **Broader impacts:** 2 PhD and 6 MS students trained; disease risk and potential management strategies shared with US agencies, WHO, OIE, FAO, and the public.

**Ehsan Hoque: Project IIS-1750380.** PI: Hoque. Period (2018-23). Amount: \$511,453 "CAREER: A collaboration coach with effective intervention strategies to optimize group performance". **Intellectual merit:** Developing and validating the efficacy of automated mediation strategies in online meetings. **Broader Impacts:** >6 research papers<sup>84-89</sup>. **Project NRT-DESE-1449828.** PI: Hoque (2015-21). Amount: \$2,965,341.00 "Graduate Training in Data-Enabled Research into Human Behavior and its Cognitive and Neural Mechanisms". **Intellectual merit:** Chartering a new traineeship program to train Ph.D. students at UR to advance discoveries at the intersection of computer science (cs), brain and cognitive sciences (bcs), and neuroscience. **Broader Impacts:** Supported over 50 PhD students in cs and bcs.

**Gonzalo Mateos: Project: CCF-1750428.** PI: Gonzalo Mateos Buckstein. Period: 4/1/18 - 3/31/23. Amount: \$407,944. Title: CAREER: Inferring Graph Structure via Spectral Representations of Network Processes. **Intellectual Merit:** Using graph signals to estimate underlying network topology through innovative convex optimization approaches operating in the graph spectral domain. **Broader Impacts:** We prepared a feature article on identifying network structure via GSP<sup>90</sup>, presented tutorials in EUSIPCO'19, CAMSAP'19 an SSP'20, organized the 2019 IEEE SPS Summer School on Network- and Data-driven Learning. Research products are available in<sup>67,90-97</sup>.

**Emily Mendenhall:** National Science Foundation Doctoral Dissertation Improvement Grant, \$10,000; Stories at the Border of Mind and Body: Mexican Immigrant Women's Narratives of Distress and Diabetes. **Intellectual merit:** Led to crucial insights studying syndemics - the interactions of social, environmental, psychological, and biological factors that are synergies of epidemics. Papers in *The Lancet*<sup>30</sup>, *Medical Anthropology Quarterly*<sup>98-100</sup>, and as a full-length book<sup>101</sup>. **Broader Impacts:** Understanding diabetes, trauma, and broader socio-political factors linked with infectious diseases in India, Kenya, South Africa, and Ethiopia.

## Project Management Plan

We have assembled a diverse team of experts in computational, biological, engineering, and social/behavioral research who share common interest in developing new approaches to advance *spillover intelligence* and prevent pandemics for a common good. Our multidisciplinary team will lead our proposed development project activities and build the foundations to grow our project in to the future *Center for Spillover Intelligence (CSI)*. Our team includes 5 primary institutions: EcoHealth Alliance (EHA), University of Rochester (UR), Georgetown University (GU), Uniformed Services University (USU), and Facebook's Data for Good (FB). All of these partnerships and collaborations are new, with the exception of previous collaborative work between EHA and USU. As such, we detail the plan below to facilitate the smooth communication, management, and implementation of our proposed project activities.

### Specific roles of the PI, co-PIs, senior personnel, and consultants

Our project will be led by EHA as the prime organization (PI, Dr. Kevin Olival) and co-managed in conjunction with coPIs Ross (EHA), Hoque and Mateos (UR), and Mendenhall (GU). PI Olival will be responsible for all contractual obligations, including establishing subawards with UR and GU to support coPI salary, student support, and travel funds – as is detailed in our budget and budget justification. A parttime Program Coordinator at EHA will help support management and communications. USU will participate as an unfunded collaborator, as they are a government-supported institution. **Our Leadership Team (PI, coPIs, Senior Personnel)** includes a mixture of established scientists and early career leaders with diverse subject matter expertise. PI Olival will work closely with coPIs and other members of the Leadership Team to coordinate research and training activities, including with Senior Personnel (SP) Broder (serological assay development), Laing (molecular virology and serological expert), and Mendelsohn (data analytics and behavioral survey analysis); and subject matter expertise from Other Personnel (OP) Busa (biotechnology and assay development consultant) and Pompe (Facebook Data for Good liaison and data ethics). As communication is paramount for the success of our project and building new scientific collaborations, we will meet every month for 1-hour virtual meetings, and every 6 months in person (an annual Leadership Team meeting and workshop events) over the course of our project. We have budgeted for these in person meetings, as well as for 3 coPIs to accompany PI Olival to an in-person project close-out meeting with NSF.

### Project management and coordination across organizations and disciplines

Our project is structured to facilitate meaningful cross-disciplinary engagement during the 18-month period of performance, via multidisciplinary pilot research projects, three working groups co-chaired by members of our Leadership Team with complementary subject matter expertise, 3-day workshops for each aim (for 12-15 people, including budget for 8 to travel from out of state), monthly project management calls and yearly dedicated Leadership Team in-person meetings, and cross-institution/cross-disciplinary student training. Our development level project was built to scale to a Center-level award (the Center for Spillover Intelligence, CSI) including the future addition of other Working Groups focused on priority research gaps yet-to-be identified, a Science and Policy Advisory Board for high level oversight and to liaise with other US and international institutions, and in transitioning our development Leadership Team (PI, coPIs and SP) into a more formal Steering Committee for Center-level oversight.

### Coordination mechanisms for cross-organization and cross-disciplinary integration

We outline a detailed 18-month plan of activities to build and strengthen connections among our **5 partner institutions**, and break down disciplinary barriers that have hindered innovation and progress towards pandemic prevention. Our Leadership Team (to later grow in to a more formal CSI Steering Committee) will together oversee the project's overall goals, and ensure that the 3 working groups are aligned and sharing information. The Leadership Team will meet virtually via video conference once each month, and every six months in person.

Each of our 3 **working groups** will be led by two members of our steering committee, who will help identify and develop the full working group member list by the first 6 months of the project: Aim 1: coPI Mendenhall (GU) and SP Mendelsohn (EHA), Aim 2: coPI Ross (EHA) and SP Liaing (USU), Aim 3: coPI Hoque and coPI Mateos (RU). Each working group will be co-facilitated by one of our graduate student trainees, to develop skills in scientific program management, networking, and coordination and establish students as an additional layer of cross-team communication and collaboration.

Each of the three working groups will organize and host a **3-day intensive workshop** that will aim to identify existing gaps and synergies in each research area of our Grand Challenge and establish priorities for future Center development. We have budgeted for ~12 people to attend each workshop in person, with the aim of having 3 experts representing each of the following scientific domains: computer science, engineering, socio-behavioral, and biological. Facilities will be provided for ~12 more experts to join in virtually for a hybrid meeting. We will limit the total size of each workshop to 25 participants to enable effective discussions, breakout sessions brainstorming, and synthesis. Each workshop will culminate with a peer-reviewed, open access publication, and all materials and outputs from the workshop posted online.

**Collaboration with existing disease surveillance and pandemic prevention initiatives:** For Aim 2, we will leverage serological data collected under EHA's Emerging Infectious Disease Southeast Asia Research Hub (EID-SEARCH) project (2020-2025, PI Daszak, coPI Olival), one of 10 NIH-funded Center for Research in Emerging Infectious Diseases (<https://creid-network.org>). EID-SEARCH's partners include USU, Duke NUS, Chulalongkorn University in Thailand, and various clinics and institutions in Malaysia, and the project is currently screening large numbers of human and wildlife samples (>10K/yr) for various coronavirus, filovirus, and paramyxovirus antibodies. EHA additionally manages several biosurveillance projects funded by the US Department of Defense, Defence Threat Reduction Agency (DTRA) including one using multiplex serological assays to screen people and livestock for Henipavirus and Filovirus serology in Malaysia, that we will also collaborate with for Aim 2 model development.

#### **Metrics of success and planning for Phase II (Center-level)**

*Center activity prioritization:* Each Working Group will aim to define key gaps in their research area, research goals to address those gaps, and prioritization of research, implementation, and educational activities for the Phase II center to pursue. We will be successful if each group is able to prepare for publication a synthesis of these topics.

*Advisory board development:* Through recruitment of experts for workshops and partnerships within pilot activities, we will identify members of a Science and Policy Advisory board that would oversee the Phase II Center, as well as potential members of the Center Steering Committee beyond the Phase I leadership team. We will be successful if we have a fully-assembled team for prepared to initiate Phase II.

*Pilot project success and scalability:* Each working group will engage in two pilot projects aimed at facilitating larger-scale studies and surveillance of zoonotic intelligence via small-scale studies or methods development. We be successful if half of pilot projects result in success enable a Phase II study as part of research activity. Submitting peer-reviewed publications is another metric of success during Phase I.

*Student and curriculum development:* Our pilot phase will include seminars and student participation in workshops. We will be successful if these activities result in the development of a curriculum for a zoonotic intelligence MS track in the UR data science program, and the recruitment of our undergraduate and MS students into graduate programs in the field. The number of students that take part in and complete our semester-long Research Fellowships and 3-week Research Exchanges will be a metric of success.

## Overview

The spillover and spread of wildlife-origin zoonotic viruses can have tragic societal and economic impacts, as is evidenced by the ongoing COVID-19 pandemic. Most emerging zoonoses are transmitted across species boundaries, or “spill over”, when livestock or human populations increase contact with wildlife via changing ecological and behavioral risk factors. Despite significant scientific advances in understanding spillover in the last ~15 years, fundamental knowledge and implementation gaps stymie our ability to preempt and prevent future disease emergence. For example, prior to 2019 EcoHealth Alliance (EHA) and colleagues demonstrated that SARS-related coronaviruses in China pose a clear and present danger for a future human outbreak, but surveillance and research on these potential pathogens, their hosts, and their interface with humans was not conducted across a wide enough geography nor at a temporal or spatial scale needed for disease mitigation. Our grand challenge: How can we capture actionable data about the risk of zoonotic spillover (and early spread) at the scale and speed required to prevent outbreaks? In this planning proposal, we bring together a diverse team of established and emerging leaders from EHA, University of Rochester, Georgetown University, Uniformed Services University, and Facebook’s Data for Good to build a collaborative research and training network to confront this grant challenge – designed to scale up to a future *Center for Spillover Intelligence (CSI)*. Our cross-disciplinary project will integrate computer scientists, engineers, and data scientists with emerging disease and social-behavioral researchers to accelerate the collection and interpretation of data to inform where, how, and what zoonotic viruses are poised to emerge.

## Intellectual Merit

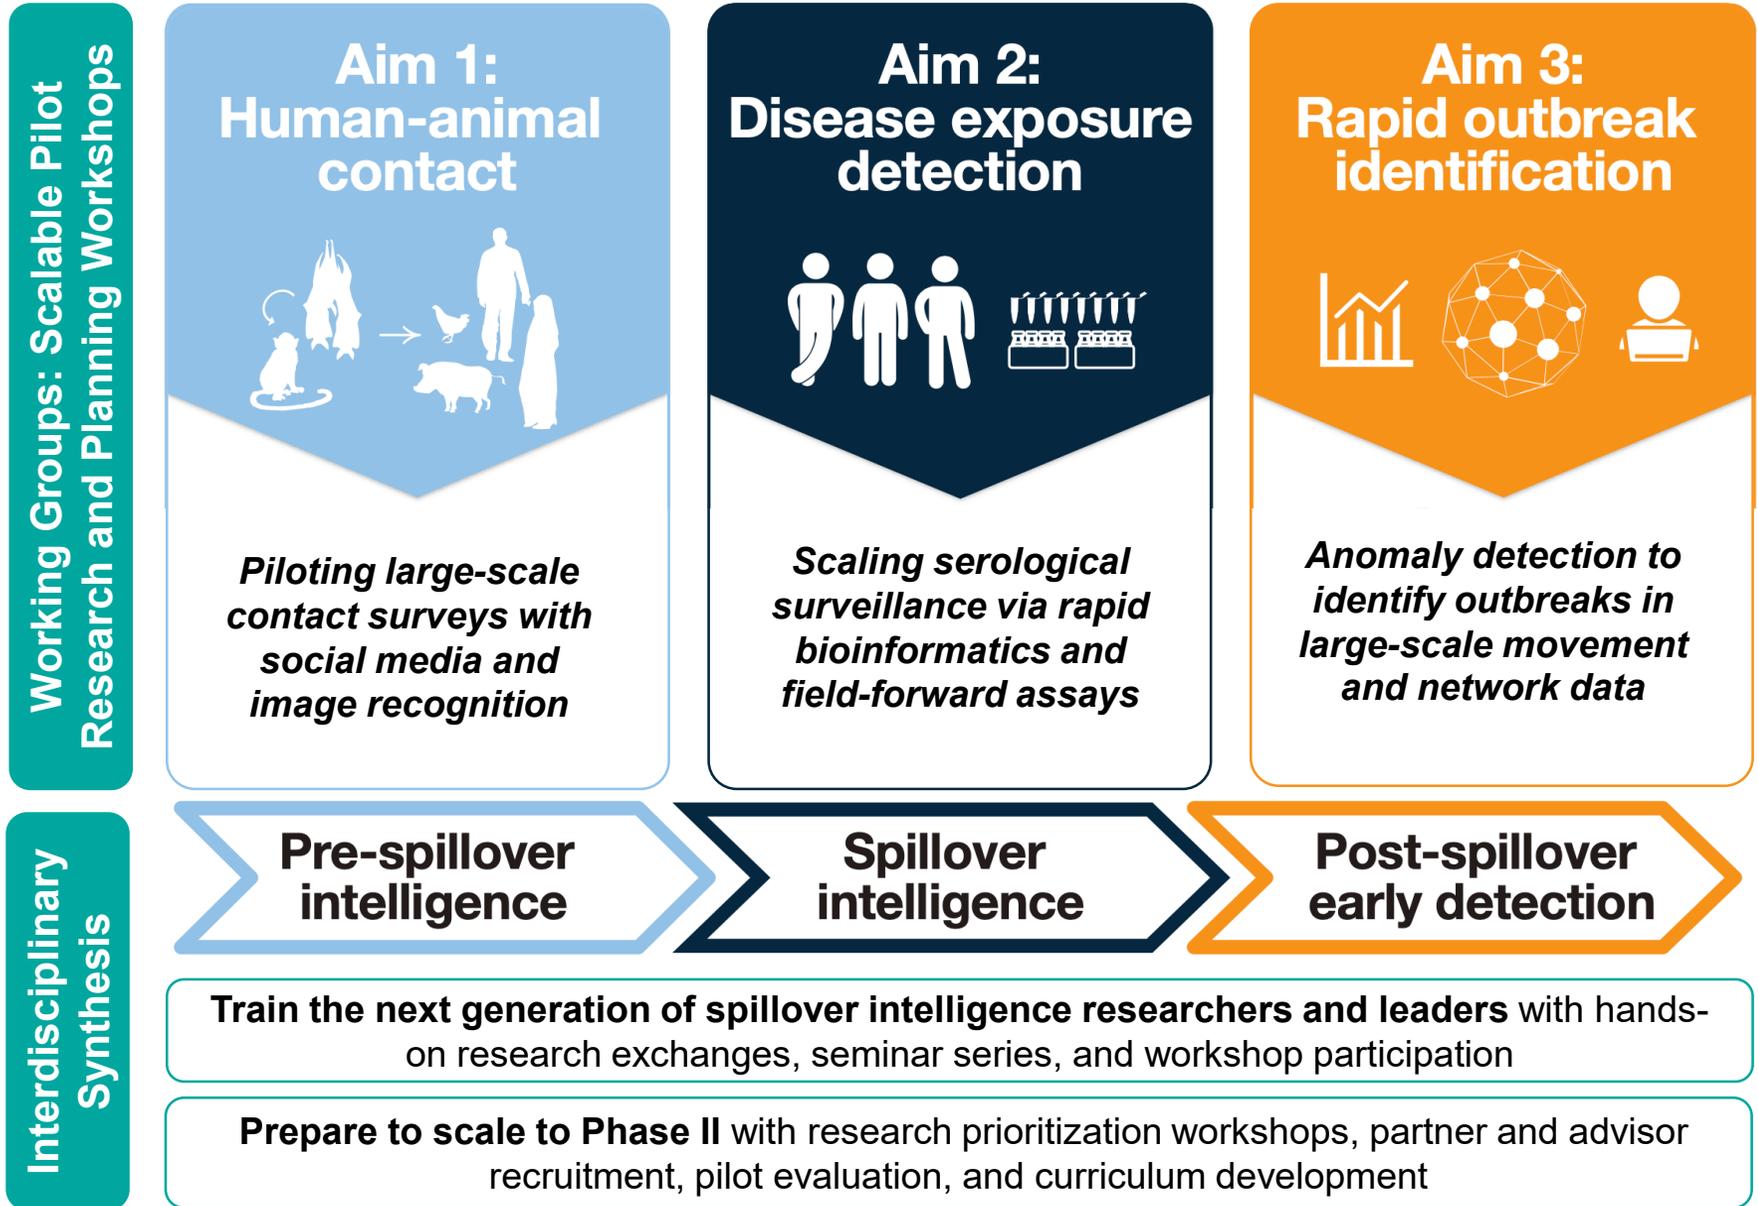

The primary intellectual merit of our project is in developing and piloting innovative approaches to large-scale spillover intelligence across previously siloed scientific domains. We will identify gaps and solutions for step-level changes in zoonotic spillover prediction via three multidisciplinary working groups that will engage in pilot projects, organize workshops, and engage students in immersive training. Pilot research projects will serve as a test bed for applying new theoretical frameworks to advance spillover intelligence. In Aim 1 we will transform decades-old anthropological approaches and pilot collecting large samples of quantitative and qualitative behavioral data via a unique public-private partnership with Facebook, and use image recognition and artificial intelligence to quantify and map human-wildlife contact. In Aim 2 we will advance rapid serological testing by developing rapid bioinformatics pipelines to process and interpret rich data from multiplex serological surveillance, and develop the first field-forward lateral-flow assay for Nipah virus antibody detection. In Aim 3 we will use cutting edge theoretical advances in network science, anomaly detection, and machine learning to detect changes in human mobility patterns that may portend spillover (e.g., increase congregation around wildlife markets) and that signal early epidemic spread after the point of spillover.

## Broader impacts

We envision that our proposed project, and a future CSI, will transform our understanding of zoonotic spillover risk for public health via global scale data collection of survey, multimedia, and mobility data. All outputs from our 3 Working Group activities, including workshop materials, will be made publicly available, and published as both peer-reviewed manuscripts and popular press articles for wider dissemination. This development grant will initiate an interdisciplinary program to train a new generation of graduate and undergraduate students understanding medical anthropology, disease surveillance, and data and network science so as to become future leaders in spillover intelligence. It will include support for both semester-long research stipends to work on our pilot research projects and hands-on training via 3-week cross-institution research exchanges for 20 Master’s level graduate students. Students from across all our institutions will participate in workshops, hackathons, and a monthly seminar series.

# Multidisciplinary advances to scale up zoonotic spillover intelligence

- The **Center for Spillover Intelligence** will engage leaders from diverse scientific disciplines coming together to transform the ways we think about, monitor, and respond to global viral threats.
- We will **accelerate and scale** actionable disease surveillance to **disrupt the future spillover and spread of zoonotic viruses**

---

Dear NSF PIPP Proposal Colleagues,

**Our NSF PIPP proposal was successfully submitted via [grants.gov](#) about an hour ago!**

Please see my email below to NSF, as it was requested that all applicants submit single powerpoint slide of our project's vision via email right after we submit (Luke caught this just a couple hours before it was due, and we whipped the slide together).

Also attached for your reference are the **final Project Description, Project Summary, and Project Management Plan** that we submitted.

Please note in my message below that there seems to be a problem with [grants.gov](#) relaying our proposal over to [research.gov](#) (formerly Fastlane to get to NSF). Seems there is a backlog in the system (probably too many submissions), so we're hoping for positive news from [research.gov](#) that it clears (as of now still pending).

**Thank you all for your hard work and collaboration on this**, finger's crossed the submission full clears and we win this! Huge thanks to the EHA team: Noam, Emma, Luke, Aleksei, Hongying, and Robin for a huge team effort to get this done on our end.

Best regards,  
Kevin

## PROJECT DESCRIPTION

### Introduction and Background

The spillover and spread of novel, zoonotic (animal origin) pathogens can have tragic societal and economic impacts, as is evidenced by the ongoing COVID-19 pandemic. The emergence of SARS-CoV-2 (the virus that causes COVID-19) is the latest in a series of viral emergence events that have accelerated in recent decades. In the last year, as the world continues to respond and adapt to COVID-19, we have seen several deadly zoonotic viruses re-emerge in the human population, including Ebola and Marburg in Guinea<sup>1,2</sup>, Nipah virus in India<sup>3</sup>, Rift Valley Fever virus in Kenya<sup>4</sup>, and novel strains of influenza in China [REF]. Most emerging infectious diseases (EIDs) originate in wildlife reservoir hosts and are transmitted across species boundaries, or (“spill over”), when livestock or human populations increase contact with wildlife through factors including land use change, agricultural intensification, and the wildlife trade<sup>5-7</sup>. Zoonotic spillover is a dynamic process determined by many steps including ‘pre-emergence’ viral evolution, diversification, and transmission among wildlife hosts; ‘human exposure’ via direct or indirect contact between humans, livestock, and wildlife; ‘post-exposure’ limits to cell entry, host range, human-to-human transmission; and population-level virus amplification and spread. Once efficiently transmitted, EIDs spread rapidly through globalized travel and trade networks, threatening countries with high population growth, urbanization and international trade (Fig 1).

**Fig 1.** Four stages of zoonotic disease emergence and spread, with gaps in knowledge at each stage. Our proposed project will develop and pilot novel, multidisciplinary and technological advances to address critical gaps in the first three stages of emergence, when pandemic prevention is possible.

Novel human EIDs are typically only discovered when they cause severe or unusual symptoms, when astute clinicians are linked with laboratories capable of pathogen discovery research, and after they have been transmitted from person to person (after which control becomes more difficult).<sup>7,8</sup> Emerging human viruses characterized to date are a small sample of hundreds of thousands of predicted zoonotic viruses in nature but undiscovered due to limited surveillance capacity globally<sup>9</sup>. New research has upended the paradigm that zoonotic disease spillover is a rare event. A combination of more advanced molecular and serological assays, improved laboratory capacity around the world, and targeted surveillance of “high risk” human populations found evidence of frequent zoonotic virus transmission and infection, even in the absence of notable disease outbreaks. Often these spillover events lead to “dead end” infections in people or limited “stuttering chains” of transmission, a phenomenon referred to as “viral chatter”<sup>10</sup>. Community-based serological surveys from our group and others have illuminated relatively frequent and previously-unknown instances of zoonotic virus spillover including Henipaviruses

in bat hunters from Cameroon<sup>11</sup>, SARS-related CoVs in rural communities living near caves in China (pre-2019), and Ebola virus exposure in DRC<sup>12</sup> and even Southeast Asia<sup>13</sup>.

Innovative and multidisciplinary approaches are needed to disrupt the emergence of diseases at the “viral chatter” stage and further upstream at the human-animal interface to prevent epidemics and pandemics before they are out of control. While we have made significant scientific advances over the last ~15 years in understanding where and through what mechanisms novel zoonotic viruses spill over into the human population<sup>5,14-17</sup>, there **are still fundamental knowledge and implementation gaps that stymie our ability to preempt and prevent future disease emergence events.**

### **Our Grand Challenge Problem**

Prior to 2019, EcoHealth Alliance (EHA) and our partners demonstrated that SARS-related coronaviruses (SARSr-CoVs) in China pose a clear and present danger for a future human outbreak. We conducted extensive viral discovery in wildlife from China and Southeast Asia, phylogenetic analysis, and host-range experiments to show that certain bat species harbor a diverse assemblage of SARSr-CoVs<sup>18,19</sup>, as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics<sup>20-23</sup>. We conducted behavioral risk factor surveys and serological sampling from human populations living close to caves and found serological evidence of SARSr-CoV spillover in people exposed to wildlife<sup>24</sup>. Building on this body of knowledge, we estimate bat-origin SARSr-CoVs infect 50,000 people in Southeast Asia each year<sup>25</sup>. While confidence intervals around this median estimate are large, our sensitivity analyses identify key area for future research to improve these spillover risk models: quantification and better contextual understanding of human-bat contact, the role of wildlife farming and livestock hosts, scaling up human serological surveys, and better data on sero-dynamics following novel SARSr-CoV exposure.<sup>25</sup>

Despite this strong body of evidence for SARSr-CoV spillover risk prior to the emergence of SARS-CoV-2, surveillance was not conducted across a wide enough geography, nor at a temporal or spatial scale to inform actionable disease mitigation. Despite large-scale efforts to strengthen zoonotic virus early warning systems, like the 10-year, 30 country USAID PREDICT program<sup>26</sup>, led by a global consortium including EHA, current methods and systems cannot capture and disseminate enough data quickly enough to enable prevention measures at national or global scales. This is especially so for multiple and novel viral threats, and in large countries with heterogeneous human populations, diverse wildlife fauna, and known ecological and societal risk factors for emergence. Approaches to massively scale up zoonotic spillover surveillance are needed.

### **Our grand challenge problem: "How can we capture actionable data about the risk of zoonotic spillover and spread at the scale and speed required to prevent outbreaks?"**

How can we leverage tools developed by computer scientists, data engineers, and technology companies to collect data from large, diverse populations and geographies to advance zoonotic spillover intelligence? How do we incorporate new insights from medical anthropology, sociology, wildlife biology, disease ecology, molecular virology, biomedical assay design, and data science to pioneer accelerate data collection and interpretation for zoonotic disease prediction and prevention? We propose to build a collaborative research and training network to confront this challenge, that will scale up to a future *Center for Spillover Intelligence (CSI)*. Our network will deeply integrate computer scientists, engineers, and data scientists with experts in emerging disease and social-behavioral research. New insights from social, behavioral, and anthropological research make it clear that the emergence and future trajectory of human epidemics require that we recognize potential biological risks alongside risks posed by cultural and societal factors<sup>27-29</sup>. Our cross-disciplinary, multi-institution project will combine innovative

research activities with training and education programs to facilitate to scale-up the collection and interpretation of data to inform where, how, and what zoonotic viruses are poised to emerge – a field we collectively refer to as *spillover intelligence*. Our inclusion of social-behavioral researchers, data ethicists, and inter-governmental EID policymakers will ensure that our aims and approaches are culturally and locally relevant, and align with our ultimate goal of improving global health.

**Our Vision:** We envision a world where diffuse data streams can be combined and interpreted in near real-time to disrupt the spillover and spread of future zoonotic viruses. We envision diverse leaders and scientific disciplines coming together to advance spillover intelligence and transform the ways we think about, monitor, and respond to global viral threats.

### **Our Team**

We have assembled a multidisciplinary team of experts to lead our development project and to create and grow the Center for Spillover Intelligence (CSI). Our **Leadership Team (PI, coPIs, Senior Personnel)** includes established scientists and early career leaders working across the fields of emerging infectious diseases, computer and data science, engineering, mathematical modeling, virology, technology and biotechnology, data ethics, social science, and medical anthropology. Our project will be led by EHA (PI Olival) building off the foundational pandemic prediction work our institution has developed over the last decade, and include to new partnerships and collaborations. These include with computer scientists and engineers from University of Rochester (UR) and behavioral anthropologists from Georgetown University (GU). We will develop and pilot new technologies for field biosurveillance and data interpretation with Uniformed Services University (USU). Our leadership team is ethnically, culturally, and geographically diverse, including US-based researchers who originate from and/or currently conduct their primary research in global EID hotspot regions<sup>5,14</sup>, e.g. South Asia (Hoque); Latin America (Mateos); Africa (Mendenhall); and Southeast Asia and the Pacific (Olival). Our geographic and disciplinary diversity, including long-standing international collaborators from each region, make our team well-equipped to address spillover at a global scale, while incorporating the nuance of local context.

**PI Olival** (EHA) is a disease ecologist and evolutionary biologist with a primary interest in developing novel analyses to target zoonoses surveillance and viral discovery. He currently leads two regional biosurveillance projects in Southeast and Western Asia, and recently served as Modeling & Analytics Coordinator for the USAID PREDICT project<sup>26</sup> overseeing a multi-institution team developing pandemic prediction strategies using public and project-specific data from 30 countries<sup>5,15,30-35</sup>. **coPI Mendenhall** (GU) is a medical anthropologist and Professor at the Edmund A. Walsh School of Foreign Service. Mendenhall works at the intersection of social, psychological, and biological lives, attempting to understand what makes people sick, why, and where. Mendenhall is currently a PI of NIH Fogarty International Center grant “Soweto Syndemics”, the first ever study to evaluate a syndemic from the ground up. **coPI Hoque** (UR) is an Associate Professor of Computer Science working at the intersection of Human-centric Computing (HCC) and Artificial Intelligence with a focus on multimodal machine learning with applications in health and wellness. Hoque is currently a PI of NSF NRT grant, and received NSF CAREER and CRII grant. Hoque has been identified as an ‘emerging leader of health and medicine’ at the National Academy of Medicine (NAM). **coPI Mateos** (UR) is Assoc. Professor of Electrical and Computer Engineering and a Data Science Fellow, his research focuses on algorithmic foundations, analysis, application of (graph) signal processing tools to the study of large-scale and dynamic networks. He has pioneered foundational work in network topology inference, online learning from graph streams, and interpretable representation learning for unstructured data. **coPI Ross** (EHA) is Principal Scientist for Computational Research. His research includes model development to interpret complex spatio-temporal disease surveillance

data in heterogeneous populations, real-time community and hospital testing, and simulating and forecasting epidemic dynamics over populations, space, and networks. He is PI on awards from DHS Science & Technology Directorate and the Defense Threats Research Agency (DTRA) for designing disease forecasting systems. **SP Mendelsohn** (EHA) is a data scientist specializing in the development and application of machine-learning models to draw insights into the occurrence and spread of emerging infectious diseases. With a focus on reproducible research methods and data management, she has been the lead analyst on data driven disease forecasting and behavioral survey-based projects characterizing animal-human contact patterns. **SP Daszak** (EHA) is an EID expert who has studied the process of disease emergence for decades and pioneered groundbreaking work in “hotspot” risk mapping to target surveillance. **SP Broder and Laing** (USU) are experts in the design of multiplex serological assays, molecular virology, and implementation of field-based human and wildlife biosurveillance strategies. **OP Busa** is a biotechnology consultant with a specialty in developing lateral flow assays and optical readers. **OP Pompe** is the Research Manager for Facebook Data for Good, who specializes in applying human mobility datasets from social media feeds and data privacy and ethical issues.

### Intellectual Merit

The primary intellectual merit of our proposed project is in **developing and piloting innovative approaches to rapid and large-scale spillover intelligence across previously siloed scientific domains** including biology, computer science, electrical engineering, and social-behavioral research. We apply new theoretical advances and convergent research to address our grand challenge of capturing actionable data about the risk of zoonotic spillover and early spread at a scale and speed required to prevent outbreaks. We will identify gaps and solutions for step-level changes in zoonotic spillover prediction via three multidisciplinary working groups that will engage in pilot projects, organize workshops, and engage students in immersive training. Our pilot research projects will serve as a test bed for applying new theoretical frameworks to advance spillover intelligence test scalability in future work. For example, in Aim 1 we will transform decades-old anthropological approaches and pilot cost-effective methods to collect large samples of quantitative and qualitative behavioral data via unique public-private partnership with Facebook; and use image recognition and artificial intelligence to quantify and map human-wildlife contact globally. In Aim 2 we will develop rapid bioinformatics pipelines to process and interpret rich data from multiplex serological surveillance; and develop the first field-forward lateral-flow assay for Nipah virus antibody detection. In Aim 3 will use advances in network science, anomaly detection, and machine learning to detect changes in human mobility patterns that may portend spillover (e.g. increase congregation around wildlife markets) and that signal early epidemic spread after the point of spillover.

### Broader impacts

This proposal could potentially transform our understanding of zoonotic spillover risks using survey, multimedia, and mobility data on a global scale, including aggregated and anonymized data from ~3B active Facebook users. Insights and intellectual outputs from our working group activities will have direct benefits to public health by informing disease mitigation strategies for pandemic prevention. We will synthesize our three working group outputs and prepare a special joint publication for the National Academies of Science’s Forum on Microbial Threats for wide distribution, and write popular press articles to accompany our peer-reviewed manuscripts. EHA’s *Alliance* includes a network of over 70 partner institutions in 30+ countries, presents a unique opportunity to work with local stakeholders in emerging virus ‘hotspots’ and validate models using data sets obtained through our long-standing collaboration with government partners including human health, agriculture, and environmental sectors.

We will train a new generation of graduate and undergraduate students in understanding medical anthropology, disease surveillance, and data and network science so as to become future leaders in spillover intelligence. Will do so via a unique partnership between the academic (UR, GU, USU), non-profit (EHA), and private (FB) sectors, allowing students to apply lessons learned from classroom settings to the real-world. Students will participate in project workshops, hackathons, monthly seminar series, and have access to state-of-the-art visualization and computing facilities. Our recruitment will focus on including >50% women and underrepresented minorities in science and engineering. This planning grant will be a path towards developing an interdisciplinary curriculum, including cross-training courses across institutions, and hands-on experience via internships and research exchanges inf. Through the planning grant, a new MS data science track on zoonotic surveillance will be established at UR, the first step in our plans to expand our Education and Training plan should we move towards a Center-level award in the future.

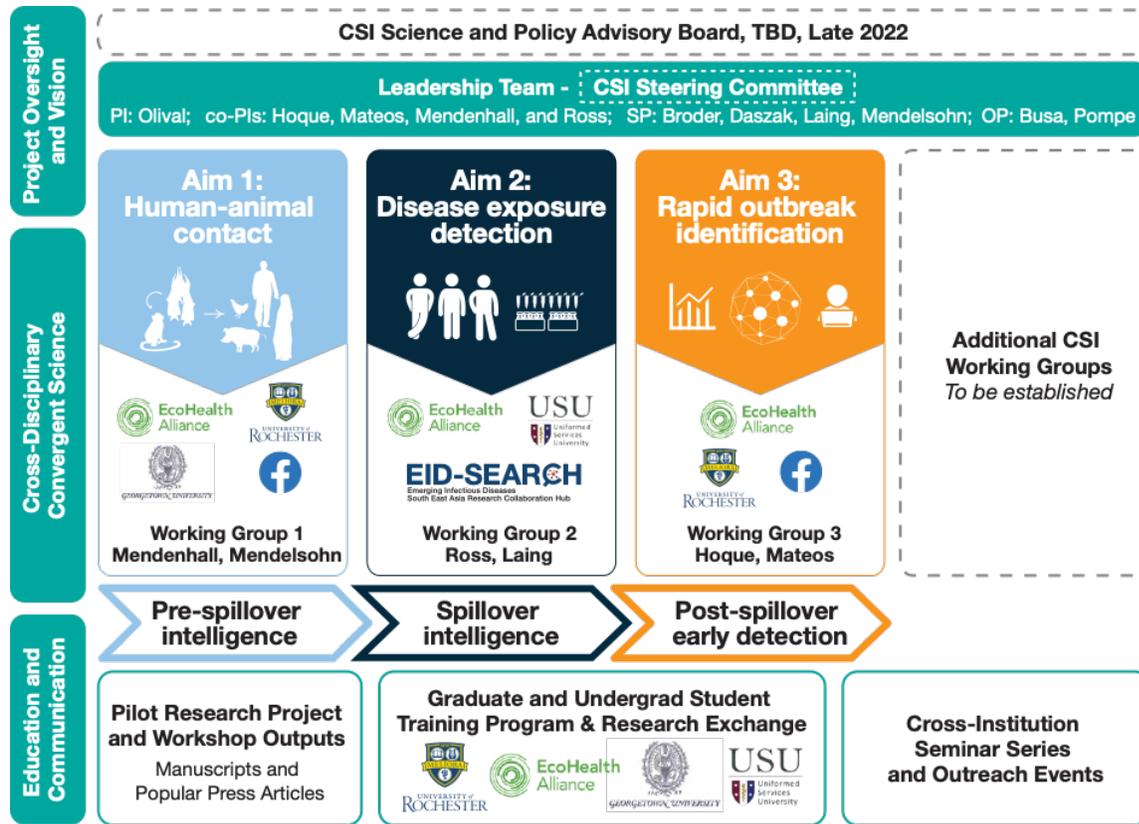

### **Education and Training Plan**

Our Leadership Team will serve as mentors for our **CSI Student Training Program** that will offer a fellowship stipend to cross-train 20 Master's level graduate students via semester-long projects associated with proposed pilot research activities (3-4 students per project) and 3-week research exchanges between our institutions (UR, GU, EHA, USU, 4-8 students from each). The research exchange builds off EHA's successful NSF-funded EcoHealthNet training program (2011-21) and will take place in either the Summer of 2022 or 2023. We will link with currently-funded international programs at our respective institutions (e.g. Gui<sup>2</sup>de in Nairobi, Kenya run by GU; and the NIH funded CREID research pilot program with EHA's EID-SEARCH project in Southeast Asia) to support students who desire to gain international, hands-on research experience as part of their research exchange. The focus of each research exchange will be on cross-disciplinary training, hands-on experience working with experts outside students area of study, and big-picture strategic thinking in pandemic prevention. Students will be drawn from respective departments across our institutions; Students with a computational background and with interests in interdisciplinary work will be recruited from UR's cross-department Goergen Institute for Data Science, Anthropology and International Affairs students from GU, and Emerging Disease and Virology students from USU. As EHA will recruit Ecology, Evolutionary Biology, and Environmental sciences students from universities where we have active partnerships, including Columbia University's E3B department where PI Olival and SP Daszak serve as adjunct faculty. We will explore specific mentorship opportunities with data scientists from Facebook. If awarded, we will additionally apply for funds through NSF's Research Experiences for Undergraduates (REU) program, with the goal of supporting summer stipend for 1 undergraduate per institution or the maximum allowable. We will host a joint monthly virtual seminar series (2 semesters long) open to graduate and undergraduate students from our respective institutions, with dedicated student "lab meetings" before each seminar. Two CSI students from diverse disciplines will lead each lab meeting discussion based on a deep read of relevant publications that each speaker will distribute in advance. The first semester of the seminar series will be led by our Leadership Team and Working Group experts, and the second semester will be for CSI Graduate students to present results or current challenges related to their pilot research projects. We hope to encourage these students to pursue Ph.D. studies. If we are successful at establishing a center through our planning grant, we should have access to a trained cohort of students with appropriate multidisciplinary skillset.

### **Project Overview**

Our 18-month research agenda aims to understand how new methods and technologies can improve the efficiency, intensity, speed, and scope of zoonotic disease surveillance. **We have structured our development grant around three primary research aims** that will guide our interdisciplinary research and training activities. We will establish a working group composed of

multi-disciplinary experts for each primary aim that will be co-led by members of our Leadership Team. We will develop pilot research projects that capture different parts of the disease spillover process focused on specific geographies, and lead 3-day intensive workshops, monthly student seminars, and student training activities that cut across our inter-linked research aims.

**Fig 2. Project overview schematic** showing our project management; three primary aims with graphical representation of pilot research activities to scale up and advance spillover intelligence; institutional partners leading activities for each aim including designated working group leads, and student education and communication activities, including pilot research projects, graduate student research exchanges, seminars, and other outreach activities. Our development-level project is built to scale to a Center level award (the Center for Spillover Intelligence, CSI) as noted with the dashed outline boxes, including the future addition of other CSI Working Groups, a Science and Policy Advisory Board, and transitioning our current Leadership Team (PI, coPIs and SP) into a more formal Steering Committee for oversight.

### Aim 1: Measuring human-animal contact at scale

Interactions among humans, wildlife, and livestock create interfaces for pathogen spillover and are proximate risk factors for the emergence of all directly-transmitted zoonotic diseases.<sup>14,36</sup> Human-animal contact is commonplace around the world, with many factors mediating the type and frequency of contact, including cultural practices, environmental conditions, food security, and occupational demands.<sup>36</sup> In regions of the world considered prone to spillover--forested tropical landscapes with high biodiversity and recent land-use changes--understanding human-animal contact is crucial to pandemic prevention.<sup>5</sup> To measure these interactions and characterize associated behaviors, beliefs, and knowledge, researchers often implement resource-intensive surveys in key communities.<sup>37,38</sup> While crucial to understanding human-animal contact dynamics, on-the-ground surveys cannot yield scalable data that is comparable

across populations. Often, in place of surveys, researchers conducting analyses at broad scales rely on coarse estimates of contact such as the joint density of human and animal populations. **Our working group will uniquely combine social scientists, disease ecologists, and computational scientists to increase the scale at which we can directly measure human-animal contact.** We will develop and implement two pilot research projects. The first will use novel, social-media-based survey approaches to reach larger populations at higher frequencies while maintaining the cultural sensitivity and relevance of on-the-ground surveys. Working collaboratively with cross-disciplinary researchers, we will design surveys to understand social behaviors, cultural perceptions, and occupational hazards that may pose zoonotic spillover risk to individuals and communities. We will target geographies based on our existing spatial risk modeling work that maps infectious disease spillover potential and the ecological distributions of key reservoir host species.<sup>5,15,25</sup> Second, we will conduct pilot research on the use of social-media-based image recognition algorithms to identify locations of human contact with key species known to host high pathogen diversity. This pilot will include a collaboration effort to test the efficacy of such technology for understanding taxon-specific contact patterns globally, and to bring multidisciplinary context to meaningfully interpret the outputs (including species validation with taxonomic experts). If successful, will use these data on frequency of animal contact from image data to identify locations for additional survey data collection.

**Aim 1 Pilot Research Projects:** We will develop two pilot projects to assess the potential of 1a) social-media dispensed surveys and 1b) passive surveillance using artificial intelligence for image recognition to capture information about human-animal contact. We will target populations at wildland interfaces where contact with wildlife is likely high but internet penetration may be mixed.

***1a) Social-media dispensed surveys to quantify and contextualize human-animal contact***

We will pilot social-media dispensed, large scale population surveys about perceptions of and interactions with animals. We will optimize the design of these surveys for mobile platforms to facilitate higher response rates, and will also explore the possibility of longitudinal sampling (of either individuals or populations) to understand changes in conditions and responses over time. Survey questions will be based on a combination of EHA's past experience designing on-the-ground human-animal contact surveys<sup>37,39,40</sup> and ideas generated from our proposed working group activities involving anthropologists, data scientists, and disease ecologists who have worked extensively in the geographic and societal contexts in which we focus our work. We will design surveys that account for populations and individuals holding different beliefs, carrying different histories, and living in different ecologies. We will survey demographically and geographically diverse populations to capture direct and indirect animal-contact patterns and behaviors, and to capture the role that international, state, and local policy plays in individuals' lives. Further, we will aim to identify particular hesitations among individuals to interact with technologies or other public health interventions.

We will explore multiple online platforms at the start of our project for survey administration. Given our unique public-private partnership with Facebook for many components of this project, using the Facebook platform to disseminate our pilot survey is likely to be a strong option, especially given Facebook's global reach (nearly half of the world's population, ~3 billion users), which introduces opportunities for digital interaction across class, gender, ethnicity, and cultural divides. We will leverage Facebook's extensive experience designing and administering surveys, especially for mobile devices, both directly on its platform (e.g. Yale Climate Change opinion survey) or off-platform (e.g. Carnegie Mellon University COVID-19 surveys). Facebook also has extensive privacy infrastructure and data-review policies to ensure anonymity and data security.

We will also explore creating games that users will be encouraged to play online to enable us to learn more about how they think about host species, viral threats, environment, and health/disease. For example, users may be given a list of 30 images and will be asked to put them into categories and describe what each category means. Adapting these “pile sorting” anthropological methods<sup>41</sup> to an online interface and for spillover risk will be a novel application with potential for a massive scale-up of data around cultural and conceptual dimensions of zoonotic disease risk. Data generated from this exercise will generate a more ethnographic understanding of people’s experiences and thought processes, which tend to be locally mediated. We understand that there are geographic and demographic gaps in internet and social media use, and will incorporate bias corrections into our study design. We will initially focus on Southeast Asia, a region with a high likelihood of future zoonotic disease emergence and where EHA has good coverage of on-the-ground surveillance programs to ground truth online data collection.<sup>5</sup>

### **1b. Image recognition of zoonotic disease host species**

We will pilot image-based surveillance of Facebook and Instagram feeds to attempt to identify human contact with key zoonotic disease host species and to explore the limits of taxonomic and behavioral recognition in images. We will work with Facebook Data for Good (see **Letter of Collaboration**) to adapt and refine their existing machine vision algorithms to target key taxa and to assess the efficacy of different approaches, working within strict guidelines and ethical standards for data de-identification. While data will be de-identified, we will photo meta-data in to not only quantify the location of animal contact in addition to species nature of contact. There are multiple image libraries that may serve as AI training datasets, including iNaturalist, the American Society of Mammologists, and Integrated Digitized Biocollections (iDigBio). We will iteratively implement and test algorithms starting with broad taxonomic groups (e.g., bats) and will explore the extent to which our approaches can identify finer taxonomic resolutions down to the genus or species level. In addition to taxa identification, we will explore image recognition of features that suggest specific types of human-animal contact, such as cages or market settings. We will use text and image metadata and explore using hashtags associated with images to boost the ability of our algorithms to identify key taxa.

This work will involve collaboration between machine learning scientists, biologists/ecologists, and social scientists. We will follow all data anonymity and privacy guidelines from Facebook and will also discuss data handling ethics in our working group. We will assess the ability of passive surveillance with image recognition to target surveys to populations that have higher frequency of contact with wildlife, and ultimately to target biological surveillance of human and animal populations. We will consider both the accuracy of the image recognition algorithms as well as implications for survey distributions, results interpretation, and ethical data practices. We will also compare the spatial distribution of human-animal contact patterns derived from image recognition with previously generated spillover risk maps based on joint occurrences of animal and human distributions (e.g., SARS-related CoV spillover risk from Sanchez et al. 2021 preprint).<sup>25</sup>

**Working Group 1 Activities:** Our working group will convene 12-15 experts from the social sciences, disease ecology, and computational sciences for an intensive, 3 day workshop. We will structure the workshop to focus first on data ethics in human behavioral surveying and image recognition surveillance and secondly on survey design and analysis planning, with specific attention to accounting for gaps or biases in survey distributions. We will center the workshop on data collection that addresses long term social, ecological, and economic realities to understand how people perceive, experience, and interact with the risk of and repercussions from spillover events, rather than technological “quick fixes.” We will also address experiences and challenges in engaging longtime ethnographers and local leaders to understand what’s at stake for communities engaging with online and field surveillance programs. Our working group will help mentor students part of the CSI Student Training Program, to facilitate information sharing and idea generation among undergraduate and master-level students. Working group 1 will also contribute to the CSI Seminar Series with cross-disciplinary topics such as AI image recognition (lead by a data scientist and bat biologist) and human-behavioral survey design (lead by an epidemiologist and medical anthropologist).

**Partners, Initial Working Group 1 Members, and Roles:** EHA (SP Mendelsohn): survey design and implementation, image recognition algorithm development and testing, novel data analyses. Facebook Data for Good (OP Pompe): survey implementation, image recognition algorithm development and testing, data ethics. University of Rochester (coPI Hoque): Image recognition algorithm development and testing. Georgetown University (coPI Mendenhall): Survey design with focus on ethnography and anthropology; online free listing/pile sorting game design; help lead expansion of WG to include emerging international leaders in social-behavioral science (e.g. Dr. Edna Bosire from Kenya). We will invite additional leaders from our extensive funded collaborations to be part of the Working Group for Aim 1.

## **Aim 2: Detecting zoonotic disease exposure at scale**

Animal-human contact is the necessary condition for spillover of potential pandemic, directly-transmitted viruses. While a small fraction of such encounters result in exposure or infection, such exposures are frequent given the total sum of encounters. Some viruses such as Lassa spill over thousands of times per year<sup>43</sup>. Most spillover infections are never reported and rarely spread widely, and a very rare subset become widespread in the human population<sup>42</sup>. In areas of frequent spillover, the eco-evolutionary dynamics of “stuttering chains” of infection are what give rise to epidemics and pandemics<sup>44</sup>. Identifying populations where frequent exposure occurs is critical for deploying preventative measures and following viruses upstream to their wildlife hosts. Yet even large-scale surveillance projects cover too small populations and produce far too few detections to determine the most exposed geographic, demographic, or occupational groups at an actionable scale. This is for two reasons: field and laboratory cost of surveilling populations interacting with wildlife interface, and low detection rates of widely-used molecular PCR or metagenomic approaches.

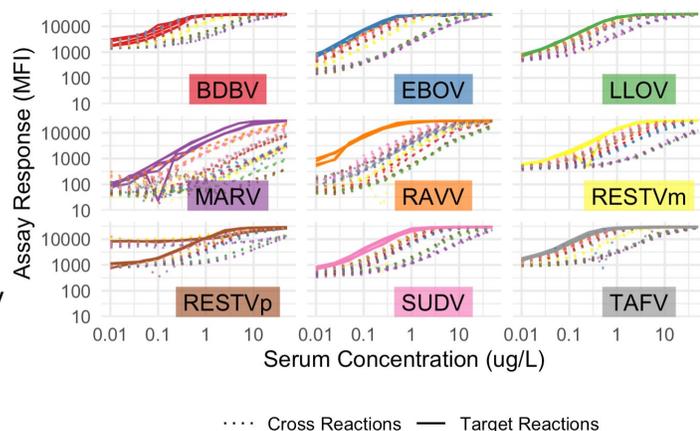

We aim to drastically increase the scale at which populations can be monitored for exposure to animal-origin viruses by developing and piloting novel tools and analyses needed to implement large-scale serological surveys. While metagenomic methods have been favored for their ability to capture genetic sequences of previously unknown viruses, serological methods can be used to detect exposure to known and unknown viruses using multiplex assays tailored with a mixture of sensitivities and specificities<sup>45</sup>. Serological tools can detect antibodies for months or years after viral infection, rather than the limited window of days or weeks using molecular methods, and thus can provide a much richer profile of populations where pandemics may emerge<sup>46</sup>. In this planning period, we will begin pilots to test the feasibility of two complementary approaches

to enabling serological screening at large scales: 2a) the creation of rapid bioinformatics pipelines to interpret high-dimensional serological data from large streams of surveillance data, and 2b) the development of rapid field serological tests for wildlife-origin diseases.

## Aim 2 Pilot Research Projects

### 2a. Rapid bioinformatics for high-throughput, multiplex serology

Members of our team (SP Laing, Broder) have developed multiplex serology tests that can be used to screen for exposure for many species and variants of filo-, henipa-, and coronaviruses simultaneously, and screening pipelines that can process samples at the scale of tens of thousands of samples. However, these tests pose challenges for interpretation, as high-dimensional results from multiplex bead or chip assays frequently contain signals of cross-reaction and autocorrelation (**Fig 3**). Through cross-disciplinary research between molecular virologists, serologists, mathematical modelers and data scientists on our team, we will create models to interpret this high-dimensional data and integrate them into a rapid bioinformatic pipeline that identifies individuals and populations to known viruses as well as flagging serological signals indicative of novel viruses. We will make use of data collected under our ongoing NIH and DTRA funded biosurveillance activities (Laing, Broder, Ross, Olival, Daszak) to develop detailed reaction/cross reaction profiles of a broad panel of zoonotic viruses to serological tests. We will build mechanistic, hierarchical Bayesian models that allow us to determine whether serological “profiles” are more likely to represent antibodies of known viruses, mixtures of multiple known viruses, or previously uncharacterized viruses. We will extend techniques of antigenic mapping,<sup>47</sup> using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential. Using simulation experiments, we will test reduced-form, simple models against fully structured models so as to develop statistically robust procedures to interpret these data without high-performance computation.

**Fig 3.** Preliminary data: Reaction-cross reaction plots of multiplex Luminex assay response to antibodies for closely-related filoviruses.

**Scaling center operations:** This pilot project will produce methods and a proof-of-concept pipeline for high-throughput analyses. We will leverage EHA’s Emerging Infectious Disease – Southeast Asia Research Hub (EID-SEARCH) project, a NIH-funded Center for Research in Emerging Infectious Diseases (PI Daszak) who’s partners include USU, Duke NUS, Chulalongkorn University in Thailand, and various clinics and institutions in Malaysia – currently screening large numbers of human samples (>10K/yr) for various coronavirus, filovirus, and paramyxovirus antibodies. In the future the CSI will implement surveillance studies screening these sample streams using multiplex serology, and utilize the analytical and bioinformatic tools we develop in the next 18 months. As part of our planning activities, we will establish protocols and approvals for this work.

## **2b. Development of a field-ready semi-quantitative lateral flow assays for an emerging zoonotic virus (Nipah virus)**

Lateral flow assays (LFAs) are low-cost tests where reagents printed on cellulose strips react with a sample that flows via diffusion. LFAs are capable of providing quantitative results (in proportion to antibody titer) when produced via high-quality manufacturing and with carefully designed and calibrated optical scans<sup>48</sup>. LFAs can be used to provide diagnostics at low cost at the point of care and by consumers. Lack of commercial-scale applications has prevented LFAs from being used for serological testing for novel or emerging disease. To our knowledge, no studies have used LFAs for zoonotic virus serosurveillance in the field.

We will develop a proof-of-concept LFA for Nipah Virus (NiV). NiV has a high mortality rate and is considered to have pandemic potential that is ranked by CEPI as one of 7 high pandemic risk pathogens<sup>49</sup>. The range of NiV's primary wildlife hosts (*Pteropus spp*, fruit bats) covers South and Southeast Asia but human cases have only been detected in Malaysia, Bangladesh, and the Philippines. Spillovers occur regularly in Bangladesh, but are rarely reported in large portions of the country<sup>50</sup> and reporting is strongly associated with health care accessibility<sup>51</sup>. Broad-scale serological monitoring has the potential to identify populations from which pandemic strains may emerge. Through previous work, members of our working group (Laing, Broder) have developed multiplex serological assays for NiV<sup>52</sup> and the soluble proteins and reagents required for an LFA. We have also added experience in engineering, quality control and commercialization of LFAs (Busa, industry consultant) to our working group. For the pilot, we will engage with commercial manufacturers to create and test a prototype Nipah LFA and a protocol for smartphone-based optical reading of quantitative responses.

**Scaling center operations:** The pilot will create a prototype LFAs. As part of full center operations under CSI, we will aim to scale up production and test LFAs efficacy using control sera and field deployment as part of EID-SEARCH. We will additionally assess feasibility and cost of deployment, and compare performance against current laboratory-based assays.

**Working Group 2 Activities:** In addition to the two pilots above, working group members will contribute to the our CSI monthly seminar series, presenting on topics including high-dimensional data models, field serology, serological assay development, laboratory product design, and public-private partnerships and commercialization. We will conduct two online workshops on serological data analysis, jointly with undergraduate, masters, and doctoral students at USU and UR, leveraging partnerships with field researchers currently working in serological surveillance. Our working group will lead a 3-day intensive workshop, where we will recruit additional participants with expertise in serological assay design and surveillance, immunology, emerging zoonoses, and focus discussion on key barriers to scaling serological surveillance for known and unknown zoonotic viruses.

**Partners, Initial Working Group 2 Members, and Roles:** EHA (coPI Ross): Model and pipeline design, software optimization. Uniformed Services University (SP Liaing, SP Broder): data and model interpretation, reagent manufacture, assay design. SP Busa: device manufacturing, quality control, industry outreach and partnership development. We will recruit additional participants from our partner network engaged in serological field studies as well as industry representatives to be part of the Working Group for Aim 2.

### **Aim 3: Rapidly Identifying Anomalous Health Events**

In early stages of epidemic spread, novel contact and mobility-induced behavioral data as well as communication patterns may provide signals of health-seeking activity indicative of an outbreak cluster. We contend that these signals may be detectable in large-scale data streams of population mobility and contact, or in disease reporting available through telecommunications and health care providers. Timely detection requires approaches that can manage data at scale,

analyze high-dimensional, spatio-temporally correlated streaming data in (pseudo) real time, and distinguish between known signals (e.g., typical influenza-related activity) and novel spillover-related signatures that we wish to unveil, characterize, and explain in order to trigger the necessary public policy responses.

This desideratum calls for fundamental methodological and computational advances, to go along with epidemiologically-relevant data sources that describe how humans are moving and interacting across physical space, with unprecedented temporal resolution and geographical coverage. Traditional flow-based mobility datasets used to parameterize epidemiological models have been aggregated and formatted in the form of origin-destination (OD) matrices. While valuable towards understanding population flows between regions of interest, OD matrices lack information on how much time a traveler spends in any given location. Naturally, when it comes to epidemiological studies the duration of time spent in potentially risky geographical areas is key towards deciphering actionable contact and exposure patterns<sup>53</sup>. Moreover, recent studies have shown that flow counts between pairs of geographical areas can be loosely correlated with, and not representative of, epidemiology-relevant mixing patterns<sup>54</sup>. Instead, these couplings among subpopulations are measured by effective contact rates, meaning how often people from each region come into contact in a way that is sufficient to transmit a disease. To address these challenges, our consortium will partner with the Facebook Data for Good team and leverage two recently assembled global-scale datasets - Activity Space Maps and Colocation Maps<sup>53,54</sup>.

**Our ambitious goal in this aim is to markedly advance the surveillance infrastructure available to predict anomalous health-related events before a major outbreak occurs.**

This differs from existing approaches that have focused on measuring the causal impact of mobility-oriented interventions. While undoubtedly a multi-faceted endeavor, in this planning grant we will take initial, but significant steps with an emphasis on network-centric, computational analyses of dynamic mobility and interaction data at a global scale. By developing the appropriate statistical tools, we will support the ultimate goal of characterizing early pandemic “fingerprints” or signatures that can be extracted from these global datasets

**Aim 3 Pilot Research Projects:** Working closely with Facebook Data for Good (see Letter of Collaboration from Alex Pompe), this working group will pilot data-driven research activities to explore the feasibility of extracting early (post spillover) signals of epidemic onset from Activity Space Maps and Colocation Maps. Our multi-disciplinary working group brings together leading experts in systems engineering, AI for healthcare, data science, mathematical epidemiology, graph signal and information processing, privacy-preserving mobility data generation and management, human behavioral modeling, and environmental science. We believe the current team, consisting of a wide array expertise and partnership, will instigate the cross-pollination of ideas leading to center-level activities while making significant inroads towards addressing our grand challenge. We propose two specific pilot projects:

### ***3a. Spatio-temporal monitoring of spillover-induced activity anomalies in Southeast Asia***

*Activity Space Maps (ASMs)* are a novel global-scale movement and mobility data set which describes how people distribute their time through geographic space.<sup>53</sup> They are designed to complement existing digitally-collected mobility datasets by quantifying the amount of time that people spend in different locations. Accordingly, this information is valuable for estimating the duration of contact with the environment and the potential risk of exposure to disease -- something critical especially early after spillover. More germane to the theme of this aim, it also offers the unique possibility of developing and testing sequential change-point detection algorithms to monitor multiple spatial grid cells of interest (informed, for instance, by outcomes of the image-recognition effort under Aim 1). We will target areas known to include health care

facilities in pursuit of abnormal trends of (increased) activity. Moreover, using ASMs we will examine flow and temporal activity anomalies around expert-annotated wildlife and wet market locations. Said events are expected if there are human infections, or significant associated changes in behavior around these sites early after spillover. Our initial efforts during this planning grant will be focused on Southeast Asia, which on top of its epidemiological relevance is one of the regions where Facebook ASMs have the most coverage. We will target Indonesia, where EHA has extensive on-the-ground efforts tracing networks of wildlife trade as well as market sites.<sup>55</sup> We will also tap into the resources stemming from EHA's Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) to identify clinics and market sites of interest in Thailand and Malaysia. Some key challenges we will address include accounting for the implicit biases in data collection associated with the construction of ASMs,<sup>53</sup> and their subsequent effects on the statistical algorithms that we will develop. Our Working Group will address additional challenges of data interpretation of anomaly detection analyses with input from emerging disease experts and epidemiologists. To calibrate our models, we will bring to bear recent activity data before and after the SARS-CoV-2 outbreak in those locations, in addition to historical influenza seasonal trends extending further back in time. With the prospect of new ASM data being officially released in the last quarter of 2021, *we are in a privileged position to be the first multi-disciplinary team that leverages this invaluable global-scale resource to advance our understanding of zoonotic spillover risk and its immediate effect on human mobility.*

### **3b. Online network change-point detection in dynamic, global-scale Colocation Maps**

Activity data are complemented by *Colocation Maps (CMs)*, which estimate how often people from different regions worldwide are colocated. In particular, for a pair of geographic regions  $i$  and  $j$  (e.g., counties in the US), CMs estimate the probability that a randomly chosen person from  $i$  and a randomly chosen person from  $j$  are simultaneously located in the same place during a randomly chosen minute in a given week.<sup>54</sup> In other words, CMs are global-scale, dynamic network datasets with colocation probabilities encoded as edge weights. Thus, they are well suited to parametrize metapopulation models of disease spread,<sup>56</sup> or to measure temporal changes in interactions between people from different regions.<sup>57</sup> To monitor said changes as part of our second pilot activity in this aim, we will build on our recent advances in online (i.e., sequential) algorithms for anomaly and change-point detection from network streams<sup>58,59</sup>; see also.<sup>60-62</sup> Our approach starkly contrasts with most existing graph change-point detection approaches, which either rely on extensive computation,<sup>63</sup> or require storing and processing the entire observed CM time series.<sup>64</sup> We will prototype and test a lightweight online change-point detection algorithm with quantifiable performance guarantees, that is also explainable since it relies on interpretable node embeddings.<sup>58,65</sup> The latter feature will be leveraged to construct dynamic anomaly maps for user-friendly visualization of post-spillover events, such as our recent network-scientific visualizations of spatio-temporal COVID-19 contagion patterns across the US.<sup>66</sup> Moreover, the extreme size of the CM graphs calls for algorithmic and modeling innovations we will investigate as part of our research agenda, such as seamlessly integrating graph subsampling or dimensionality reduction techniques to the analytics pipeline. We will partner with computer vision experts affiliated to the University of Rochester Goergen Institute for Data Science (GIDS, see attached Letter of Collaboration from institute director Mujdat Cetin), to also explore the exciting prospect of integrating geo-tagged multimodal data such as video and imagery in our studies, for instance as nodal attributes embedded to the CMs.

**Working Group 3 Activities: *Recruitment and diversity:*** We will recruit 6 students from the GIDS-run master’s program in data science, which attracts students from multidisciplinary backgrounds and significant computational proficiency to contribute in the aforementioned pilot research activities. *The CSI leadership and broader community are committed to providing research training and educational experiences for those traditionally under-represented in STEM, including women and underrepresented minority students.* The PI team has a solid track-record in actively recruiting and supervising such students at the undergraduate, masters and doctoral level, with demonstrated efforts towards broadening participation in STEM. As examples of the commitment to diversifying the field, co-PI Mateos serves as founding faculty advisor to the UR’s SACNAS chapter and regularly organizes diversity, equity and inclusion panels to highlight challenges and successes of UR’s Hispanic and Latino STEM community. We plan to prioritize engaging women and minority students in the research and working group activities proposed here. ***Coursework:*** These students will be on the existing health and bio track with an opportunity to take classes in immunology, microbiology and virology programs as well as data ethics at the University of Rochester Medical Center (URMC) as well as the college of engineering. Through the planning grant, we plan to establish a special MS track on ‘zoonotic surveillance’ in order to train and mentor the students to lead center level activities. ***Seminar and workshop series:*** The students will be part of the large cohort of all the participating institutions and participate in the CSI monthly seminar series. The co-PIs (Mateos and Hoque) will conduct two workshops (and invite additional faculty members from UR as guest speakers) with hands-on lessons in mobility and human behavior modeling. ***Hackathon:*** The students will be encouraged to participate in the yearly hackathon, Dandyhacks (<https://dandyhacks.net/>), organized every fall by the University of Rochester Computer Science Department and work with the dataset from Facebook. Additionally, co-PIs Mateos and Hoque will work with the organizers of dandyhacks to release some of the public dataset from Facebook for other teams to explore, model and mine the data.

***Data visualization meetups at the University of Rochester’s VISTA Collaboratory:*** To get acquainted with the different data resources at our disposal, over the first 3 months of the project the Rochester team (along with Facebook and EHA collaborators via Zoom) will hold bi-weekly team meetings with the MSc students at the UR’s VISTA Collaboratory. This is a 1,000 square-foot visualization lab equipped with an interactive (20 ft. wide x 8 ft. tall) tiled-display wall, that renders massive data sets in real time, giving team members the ability to visualize and analyze complex data instantaneously and collaboratively; see Fig. 4. As we dissect what dataset components are central for the aforementioned pilot activities, our graduate students will develop customized data visualization tools, maps and dashboards to facilitate downstream analyses. Updates and progress reports will be shared in these meetings, giving the students a unique opportunity to develop their communication skills. The whole team will provide feedback and share ideas, making this a truly collaborative activity. Moving forward, the VISTA Collaboratory offers a unique resource that we will fruitfully leverage as we scale up to full center operation.

**Fig. 4.** UR’s Vista Collaborative will serve as a spillover intelligence “situation room” for training UR and CSI exchange students on analysis of real-time epidemiologically relevant datasets.

**Partners, Initial Working Group 3 Members, and Roles:** University of Rochester (co-PIs Hoque and Mateos): coordination of working group activities, development and testing of computational tools for early detection of post-spillover signatures, dissemination of research products and educational materials, recruiting and mentoring of master students, liaisons to

GIDS. Facebook Data for Good (OP Pompe and Maps for Good team members Iyer and Citron): data ethics, quantification of privacy protections, data scientific support for Activity Space and Colocation Maps, mathematical epidemiology expertise for data and model interpretation. EHA (SP Mendelsohn and Ross): identification of target spatial locations in Southeast Asia, epidemiological interpretation of anomaly detection analyses and validation of detected early pandemic fingerprints.

**Scaling operations:** Our programs and pilot research are designed to scale. First, we aim to expand on successful pilots by expanding the geographies of our work, engaging with more in-country partners. Second, we test the development of each of these new streams of predictive data, we plan to develop partnerships with local, national, and global agencies to ingest these data, expand into programs to develop behavioral interventions and testing in response to identifying regions and populations at high risk of contracting zoonotic diseases.

Working groups are really about bringing our project to scale, our intensive 3-day workshop will also lead to new partnerships and synergies for expansion.

### Results from Prior NSF Support

**Kevin J. Olival** has not had prior NSF support, but is co-PI on NIH-funded “EID-SEARCH” (NIAID-CREID U01AI151797, 2020-25 PI Daszak). Previously co-PI on “Understanding the risk of bat coronavirus emergence” (NIAID R01 AI110964, 2014-2019, PI Daszak). **Intellectual merit:** Identified >50 SARSr-CoVs in bats, showed evidence of ability to infect human cells, humanized mouse models, and people in China, and used evolutionary and mammalian biodiversity patterns to analyze spillover risk for use in public health control. Produced 18 peer-reviewed papers<sup>20,34,67-79</sup>, including two papers in *Nature*<sup>80,81</sup>, and a review in *Cell*<sup>82</sup>, and others submitted. **Broader impacts:** 2 PhD and 6 MS students trained; disease risk and potential management strategies shared with US agencies, WHO, OIE, FAO, and the public.

**Ehsan Hoque: Project IIS-1750380.** PI: Hoque. Period (2018-23). Amount: \$511,453 “CAREER: A collaboration coach with effective intervention strategies to optimize group performance”. **Intellectual merit:** Developing and validating the efficacy of automated mediation strategies in online meetings. **Broader Impacts:** >6 research papers<sup>83-88</sup>. **Project NRT-DESE-1449828.** PI: Hoque (2015-21). Amount: \$2,965,341.00 “Graduate Training in Data-Enabled Research into Human Behavior and its Cognitive and Neural Mechanisms”. **Intellectual merit:** Chartering a new traineeship program to train Ph.D. students at the University of Rochester to advance discoveries at the intersection of computer science (cs), brain and cognitive sciences (bcs), and neuroscience. **Broader Impacts:** Supported over 50 PhD students in cs and bcs, several won interdisciplinary research positions at R1 institutes.

**Gonzalo Mateos** (a) Project: CCF-1750428. PI: Gonzalo Mateos Buckstein. Period: 4/1/18 - 3/31/23. Amount: \$407,944. (b) Title: CAREER: Inferring Graph Structure via Spectral Representations of Network Processes. (c) **Intellectual Merit:** We investigate how to use information available from graph signals to estimate the underlying network topology through innovative convex optimization approaches operating in the graph spectral domain. **Broader Impacts:** We prepared a feature article on identifying network structure via GSP,<sup>89</sup> presented tutorials in EUSIPCO'19, CAMSAP'19 an SSP'20, organized the 2019 IEEE SPS Summer School on Network- and Data-driven Learning. (d) Research products are available in.<sup>66,89-96</sup>

**Emily Mendenhall** (a) National Science Foundation Doctoral Dissertation Improvement Grant, \$10,000; Stories at the Border of Mind and Body: Mexican Immigrant Women’s Narratives of Distress and Diabetes. **Intellectual merit:** Led to crucial insights studying syndemics - the interactions of social, environmental, psychological, and biological factors that are synergies of epidemics. Papers in *The Lancet*<sup>29</sup>, *Medical Anthropology Quarterly*<sup>97-99</sup>, and as a full-length

book<sup>100</sup>. **Broader Impacts:** Understanding diabetes, trauma, and broader socio-political factors with infectious diseases in India, Kenya, South Africa, and Ethiopia.

## PROJECT DESCRIPTION

### Introduction and Background

The spillover and spread of novel, zoonotic pathogens can have tragic societal and economic impacts, as is evidenced by the ongoing COVID-19 pandemic. Unfortunately, the emergence of SARS-CoV-2 (the virus that causes COVID-19) is just the latest in a series of viral emergence events that have been accelerating over the last several decades. In just the last year, as the world continues to respond and adapt to COVID-19, we have seen several deadly zoonotic (animal origin) viruses re-emerge in the human population, including Ebola and Marburg in Guinea<sup>1,2</sup>, Nipah virus in India<sup>3</sup>, Rift Valley Fever virus in Kenya<sup>4</sup>, and novel strains of influenza in China [REF]. Most emerging infectious diseases (EIDs) originate in wildlife reservoir hosts and are transmitted across species boundaries, or (“spill over”), when livestock or human populations increase contact with wildlife through factors including land use change, agricultural intensification, and the wildlife trade<sup>5-7</sup>. Zoonotic spillover is a dynamic process determined by many steps including ‘pre-emergence’ viral evolution, diversification, and transmission among wildlife hosts; ‘human exposure’ via direct or indirect contact between humans, livestock, and wildlife; ‘post-exposure’ limits to cell entry, host range, human-to-human transmission; and population level virus amplification and spread. Once efficiently transmitted, EIDs can spread rapidly through globalized travel and trade networks, threatening countries with high population growth, urbanization and international trade (Fig 1).

**Fig 1.** Four stages of zoonotic disease emergence and spread, with gaps in knowledge at each stage. Our proposed project will develop and pilot novel, multidisciplinary and technological advances to address critical gaps in the first three stages of emergence, when pandemic prevention is possible.

Novel human EIDs are typically only discovered when they cause severe or unusual symptoms, when astute clinicians are linked with laboratories capable of pathogen discovery research, and after they have been transmitted from person to person (in which case control options become more difficult).<sup>7,8</sup> The emerging human viruses characterized to date likely represent just the tip of the iceberg given the hundreds of thousands of predicted zoonotic viruses that exist in nature and limited surveillance capacity globally<sup>9</sup>. New research has disrupted the paradigm that zoonotic disease spillover is a rare event. A combination of more advanced molecular and serological assays, improved laboratory capacity around the world, and targeted surveillance of “high risk” human populations have led to evidence of zoonotic virus transmission and infection, even in the absence of notable disease outbreaks. Often these spillover events lead to “dead end” infections in people or limited ‘stuttering’ chains of transmission, a phenomenon referred to as “viral chatter”<sup>10</sup>. Community-based serological surveys from our group and others have illuminated relatively frequent and previously-unknown instances of zoonotic virus spillover

including Henipaviruses in bat hunters from Cameroon<sup>11</sup>, SARS-related CoVs in rural communities living near caves in China (pre-2019), and Ebola virus exposure in DRC<sup>12</sup> and even Southeast Asia<sup>13</sup>

It is during these early stages of emergence, i.e. “viral chatter” with limited human transmission and even further upstream to include pre-emergence risk analyses at the human-animal interface, where innovative convergent research approaches are most needed for pandemic prevention. While we have made significant scientific advances over the last ~15 years in understanding where and through what mechanisms novel zoonotic viruses spill over into the human population<sup>5,14-17</sup>, there **are still fundamental knowledge (and implementation) gaps that stymie our ability to preempt and prevent future disease emergence events.**

### **Our Grand Challenge Problem**

Prior to 2019, EcoHealth Alliance (EHA) and colleagues demonstrated that SARS-related coronaviruses (SARSr-CoVs) in China pose a clear and present danger for a future human outbreak. We conducted extensive viral discovery in wildlife from China and Southeast Asia, phylogenetic analysis, and host-range experiments to show that certain bat species harbor a diverse assemblage of SARSr-CoVs<sup>18,19</sup>, as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics<sup>20-23</sup>. We conducted behavioral risk factor surveys and serological sampling from human populations living close to caves and found serological evidence of SARSr-CoV spillover in people exposed to wildlife<sup>24</sup>. Building on this body of knowledge, our recent models suggest that bat-origin SARSr-CoVs may be infecting 400,000 (median 50,000) people in Southeast Asia each year<sup>25</sup>. While confidence intervals around these estimates are large, our sensitivity analyses importantly identified key area for future research to improve these spillover risk models - notably, quantification and better contextual understanding of human-bat contact, the role of wildlife farming and livestock hosts, scaling up human serological surveys, and better data on sero-dynamics following novel SARSr-CoV exposure.<sup>25</sup>

**Despite this strong body of evidence for SARSr-CoV spillover risk (prior to the emergence of SARS-CoV-2), surveillance and research on these potential pathogens, their hosts, and their interface with humans was not conducted across a wide enough geography, nor at a temporal or spatial scale to inform actionable disease mitigation.** Even for large-scale efforts to strengthen zoonotic virus early warning systems, like the 10-year, 30 country USAID PREDICT program<sup>26</sup>, led by a global consortium including EHA, it's nearly impossible to capture enough data and disseminate that quickly enough to lead to widespread prevention measures at a national scale using existing methods – especially when considering multiple potential viral threats at once. This is especially true for large countries with heterogeneous human populations, diverse wildlife fauna, and known ecological and societal risk factors for emergence. Approaches to massively scale up zoonotic spillover surveillance are needed.

**Our grand challenge problem: "How can we capture actionable data about the risk of zoonotic spillover (and early spread) at the scale and speed required to prevent outbreaks?"** Can we leverage tools developed by computer scientists, data engineers, and technology companies to collect data from diverse populations and geographies to advance zoonotic spillover intelligence to a global scale? Can we incorporate new insights from medical anthropology, sociology, wildlife biology, disease ecology, molecular virology, biomedical assay design, and data science and use these to pioneer new methods in data collection and interpretation for zoonotic disease prediction and prevention? In this development proposal, we propose to build a collaborative research and training network to confront this challenge, designed at the start to scale up to a future Center for Spillover Intelligence (CSI). Our network will deeply integrate computer scientists, engineers, and data scientists using machine learning and other novel technological approaches together with experts in emerging disease and social-

behavioral research. New insights from social, behavioral, and anthropological research make it clear that the emergence and future trajectory of human epidemics require that we recognize potential biological risks alongside risks posed by cultural and societal factors<sup>27-29</sup>. Our cross-disciplinary, multi-institution project will combine synergistic research activities with training and education programs to facilitate new innovations to scale-up the collection and interpretation of data to inform where, how, and what zoonotic viruses are poised to emerge – a field we collectively refer to as *Spillover Intelligence*. Our inclusion of social-behavioral researchers, data ethicists, and inter-governmental EID policymakers will ensure that our aims and approaches are culturally and locally relevant, and align with our ultimate goal of improving global health.

**Our Vision:** We envision a world where diffuse data streams can be combined and interpreted in near real-time to disrupt the spillover and spread of future zoonotic viruses. We envision diverse leaders and scientific disciplines coming together to advance spillover intelligence and transform the ways we think about, monitor, and respond to global viral threats.

### **Our Team**

We have assembled a multidisciplinary team of experts to lead our development project and to create and grow the Center for Spillover Intelligence (CSI). Our **Leadership Team (PI, coPIs, Senior Personnel)** includes a mixture of established scientists and early career leaders working across the fields of: emerging infectious diseases, computer and data science, engineering, mathematical modeling, virology, technology and biotechnology, data ethics, social science, and medical anthropology. Our project will be led by EHA (PI Olival) building off the foundational pandemic prediction work our institution has developed over the last decade, but expanding to new partnerships and collaborations we have not previously been able to explore – including with computer scientists and engineers from University of Rochester (UR) and behavioral anthropologists from Georgetown University (GU). We will develop and pilot new technologies for field biosurveillance and data interpretation with Uniformed Services University (USU). Our Leadership Team is ethnically, culturally, and geographically diverse, including US-based researchers who originate from and/or currently conduct their primary research in global EID hotspot regions<sup>5,14</sup>, e.g. South Asia (Hoque); Latin America (Mateos); Africa (Mendenhall); and Southeast Asia and the Pacific (Olival). Our geographic and disciplinary diversity, including long-standing international collaborators from each region make our team well equipped to address spillover at a global scale, while understanding the importance of local context.

**PI Olival** (EHA) is a disease ecologist and evolutionary biologist with a primary interest in developing novel analyses to target zoonoses surveillance and viral discovery. He currently leads two regional biosurveillance projects in Southeast and Western Asia, and recently served as Modeling & Analytics Coordinator for the USAID PREDICT project<sup>26</sup> overseeing a multi-institution team developing pandemic prediction strategies using public and project-specific data from 30 countries<sup>5,15,30-35</sup>. **coPI Mendenhall** (GU) is a medical anthropologist and Professor at the Edmund A. Walsh School of Foreign Service. Mendenhall works at the intersection of social, psychological, and biological lives, attempting to understand what makes people sick, why, and where. Mendenhall is currently a PI of NIH Fogarty International Center grant “Soweto Syndemics”, the first ever study to evaluate a syndemic from the ground up. **coPI Hoque** (UR) is an Associate Professor of Computer Science working at the intersection of Human-centric Computing (HCC) and Artificial Intelligence with a focus on multimodal machine learning with applications in health and wellness. Hoque is currently a PI of NSF NRT grant, and received NSF CAREER and CRII grant. Hoque has been identified as an ‘emerging leader of health and medicine’ at the National Academy of Medicine (NAM). **coPI Mateos** (UR) is Assoc. Professor of Electrical and Computer Engineering and a Data Science Fellow, his research focuses on algorithmic foundations, analysis, application of (graph) signal processing tools to the study of large-scale and dynamic networks. He has pioneered foundational work in network topology

inference, online learning from graph streams, and interpretable representation learning for unstructured data. **coPI Ross** (EHA) is Principal Scientist for Computational Research. His research includes model development to interpret complex spatio-temporal disease surveillance data in heterogeneous populations, including from serological surveys, real-time community and hospital testing, and simulating and forecasting epidemic dynamics over populations, space, and networks. He is PI on awards from DHS Science & Technology Directorate and the Defense Threats Research Agency (DTRA) for designing disease forecasting systems. **SP Mendelsohn** (EHA) is a research data scientist specializing in the development and application of machine-learning models to draw insights into the occurrence and spread of emerging infectious diseases. With a focus on reproducible research methods and data management, she has been the lead analyst on data driven disease forecasting and behavioral survey-based projects characterizing animal-human contact patterns. **SP Daszak** (EHA) is an EID expert who has studied the process of disease emergence for decades and pioneered groundbreaking work in “hotspot” risk mapping to target surveillance. **SP Broder and Laing** (USU) are experts in the design of multiplex serological assays, molecular virology, and implementation of field-based human and wildlife biosurveillance strategies. **OP Busa** is a biotechnology consultant with a specialty in developing lateral flow assays and optical readers. **OP Pompe** is the Research Manager for Facebook Data for Good, who specializes in applying human mobility datasets from social media feeds and data privacy and ethical issues.

### Intellectual Merit

The primary intellectual merit of our proposed project is in **developing and piloting innovative approaches to pandemic prediction across previously siloed scientific domains** including biology, computer science, electrical engineering, and social-behavioral research. We apply new theoretical advances and convergent research to address our grand challenge of capturing actionable data about the risk of zoonotic spillover and early spread at a scale and speed required to prevent outbreaks. We will identify existing gaps and next-generation solutions for step-level changes in zoonotic spillover prediction via multi-day intensive workshops with thought-leaders organized by each of our three multidisciplinary Working Groups. Our pilot research projects will serve as a test bed for new theoretical frameworks to advance spillover intelligence. For example, in Aim 1 we will transform decades-old anthropological approaches and pilot a cost-effective, scale-up of quantitative and qualitative behavioral data collection through a unique public-private partnership Facebook; and use image recognition and artificial intelligence to quantify and map human-wildlife contact globally. In Aim 2 we will develop hierarchical Bayesian models to interpret rich, multiplex serology datasets and test these on real surveillance data as part of EHA’s NIH-funded work; and develop the first field-forward lateral-flow assay for Nipah virus antibody detection. In Aim 3 will use cutting edge theoretical advances in network science, anomaly detection, and machine learning to detect changes in human mobility patterns that may portend spillover (e.g. increase congregation around wildlife markets) or signal early epidemic spread after the point of spillover.

### Broader impacts

This proposal could potentially transform our understanding of zoonotic spillover risks using survey, multimedia, and mobility data on a global scale, including aggregated and anonymized data from ~3B active Facebook users. Insights and intellectual outputs from our working group activities will have direct benefits to public health by informing disease mitigation strategies for pandemic prevention. We will synthesize our three working group outputs and prepare a special joint publication for the National Academies of Science’s Forum on Microbial Threats for wide distribution, and write popular press articles to accompany our peer-reviewed manuscripts. EHA’s *Alliance*, includes a network of over 70 partner institutions in 30+ countries, presents a unique opportunity to work with local stakeholders in emerging virus ‘hotspots’ and validate

Peter, Ehsan, sound good?

models using data sets obtained through our long-standing collaboration with government partners including human health, agriculture, and environmental sectors.

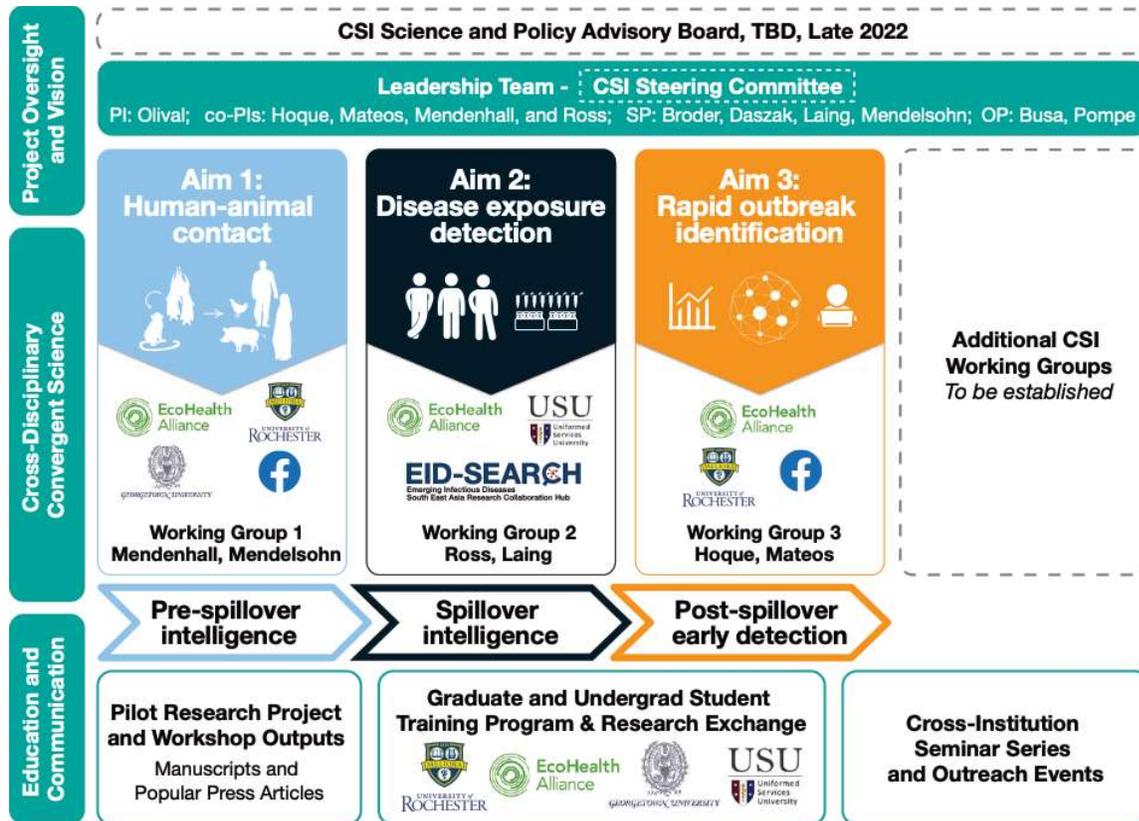

Our education mission consists of multiple workshops, hackathons, monthly seminar series, and access to state-of-the-art visualization facilities. We will begin to train a new generation of graduate and undergraduate students who will be prepared to harness the burgeoning power of data science to make novel inroads into understanding human-animal contact, serological surveillance, and aggregated mobility data and their interaction. Our proposal builds on a unique partnership between the academic (UR, GU, USU), non-profit (EHA), and private sector (FB), allowing students to apply lessons learned from classroom settings to the real-world, and our recruitment will focus on including >50% women and underrepresented minorities in science and engineering. This planning grant will be a path towards structuring interdisciplinary education, cross-training courses across institutions, followed by hands-on experience via internships and research exchanges – with options for international work via existing programs at our institutions. Through the planning grant, a new MS data science track on ‘zoonotic surveillance’ will be established at UR, the first step in our plans to expand our Education and Training plan should we move towards a Center-level award in the future.

### **Education and Training Plan**

Our Leadership Team will serve as mentors for our **CSI Student Training Program** that will offer a fellowship stipend to cross-train 20 Master’s level graduate students via semester-long projects associated with proposed pilot research activities (3-4 students per project) and 3-week research exchanges between our institutions (UR, GU, EHA, USU, 4-8 students from each). The research exchange builds off EHA’s successful NSF-funded EcoHealthNet training program (2011-21) and will take place in either the Summer of 2022 or 2023. We will link with currently-funded international programs at our respective institutions (e.g. Gui<sup>2</sup>de in Nairobi, Kenya run by GU; and the NIH funded CREID research pilot program with EHA’s EID-SEARCH project in Southeast Asia) to support students who desire to gain international, hands-on research experience as part of their research exchange. The focus of each research exchange will be on cross-disciplinary training to think ‘big’ about the future of pandemic prediction and ensure the next generation of spillover intelligence researchers gains valuable hands-on experience working with experts outside their area of study. Students will be drawn from respective departments across our institutions, i.e. students with a computational background and with interests in interdisciplinary work will be recruited from UR’s cross-department Goergen Institute for Data Science, Anthropology and International Affairs students from GU, and Emerging Disease and Virology students from USU. As EHA is a non-profit and does not have an active student body, we will recruit Ecology, Evolutionary Biology, and Environmental sciences students from universities in the NYC area, including Columbia University’s E3B department where PI Olival, coPI Ross and SP Daszak serve as adjunct faculty. We will explore specific mentorship opportunities with data scientists from Facebook. If awarded, we will additionally apply for funds through NSF’s Research Experiences for Undergraduates (REU) program, with the goal of supporting summer stipend for 1 undergraduate per institution or the maximum allowable. We will host a joint monthly virtual seminar series (2 semesters long) open to graduate and undergraduate students from our respective institutions, with a dedicated student “lab meeting” before each seminar. Two CSI students from diverse disciplines will lead each lab meeting discussion based on a deep read of relevant publications that each speaker will distribute in advance. We envision the first semester of the seminar series will be led by our Leadership Team and Working Group experts, and the second semester will be for CSI Graduate students to present results or current challenges related to their pilot research projects. We hope to encourage these students to pursue Ph.D. studies. If we are successful at establishing a center through our planning grant, we should have access to a trained cohort of students with appropriate multidisciplinary skillset.

## Project Overview

Our 18-month research agenda aims to understand how new methods and technologies can improve the efficiency, intensity, speed, and scope of zoonotic disease surveillance. **We have structured our development grant around three primary research aims** that will guide our interdisciplinary research and training activities. We will establish a working group composed of multi-disciplinary experts for each primary aim that will be co-led by members of our Leadership Team. We will develop pilot research projects that capture different parts of the disease spillover process focused on specific geographies, lead 3-day intensive workshops, monthly student seminars, and student training activities that cut across our inter-linked research aims.

**Fig 2. Project overview schematic** showing our project management; three primary aims with graphical representation of pilot research activities to scale up and advance spillover intelligence; institutional partners leading activities for each aim including designated working group leads, and student education and communication activities, including pilot research projects, graduate student research exchanges, seminars, and other outreach activities. Our development level project was built to scale to a Center level award (the Center for Spillover Intelligence, CSI) as noted with the dashed outline boxes, including the future addition of other CSI Working Groups, a Science and Policy Advisory Board, and transitioning our current Leadership Team (PI, coPIs and SP) into a more formal Steering Committee for oversight.

### Aim 1: Measuring human-animal contact at scale

Interactions among humans, wildlife, and livestock create interfaces for pathogen spillover and are proximate risk factors for the emergence of all directly-transmitted zoonotic diseases.<sup>14,36</sup> Human-animal contact is commonplace around the world, with many factors mediating the type and frequency of contact, including cultural practices, environmental conditions, food security, and occupational demands.<sup>36</sup> In regions of the world considered prone to spillover--forested tropical landscapes with high biodiversity and recent land-use changes--understanding human-

animal contact is crucial to pandemic prevention.<sup>5</sup> To measure these interactions and characterize associated behaviors, beliefs, and knowledge, researchers often implement resource-intensive surveys in key communities.<sup>37,38</sup> While crucial to understanding human-animal contact dynamics, on-the-ground surveys cannot yield scalable data that is comparable across populations. Often, in place of surveys, researchers conducting analyses at broad scales rely on coarse estimates of contact such as the joint density of human and animal populations. **Our working group will uniquely combine social scientists, disease ecologists, and computational scientists to increase the scale at which we can directly measure human-animal contact.** We will develop and implement two pilot research projects. The first will use novel, social-media-based survey approaches to reach larger populations at higher frequencies while maintaining the cultural sensitivity and relevance of on-the-ground surveys. Working collaboratively with cross-disciplinary researchers, we will design surveys to understand social behaviors, cultural perceptions, and occupational hazards that may pose zoonotic spillover risk to individuals and communities. We will target geographies based on our existing spatial risk modeling work that maps infectious disease spillover potential and the ecological distributions of key reservoir host species.<sup>5,15,25</sup> Second, we will conduct pilot research on the use of social-media-based image recognition algorithms to identify locations of human contact with key species known to host high pathogen diversity. This pilot will include a collaboration effort to test the efficacy of such technology for understanding taxon-specific contact patterns globally, and to bring multidisciplinary context to meaningfully interpret the outputs (including species validation with taxonomic experts). If successful, will use these data on frequency of animal contact from image data to identify locations for additional survey data collection.

**Aim 1 Pilot Research Projects:** We will develop two pilot projects to assess the potential of 1a) social-media dispensed surveys and 1b) passive surveillance using artificial intelligence for image recognition to capture information about human-animal contact. We will target populations at wildland interfaces where contact with wildlife is likely high but internet penetration may be mixed.

***1a. Social-media dispensed surveys to quantify and contextualize human-animal contact***

We will pilot social-media dispensed, large scale population surveys about perceptions of and interactions with animals. We will optimize the design of these surveys for mobile platforms to facilitate higher response rates, and will also explore the possibility of longitudinal sampling respondents (either individuals or populations) to understand changes in conditions and responses over time. Survey questions will be based on a combination of EHA's past experience designing on-the-ground human-animal contact surveys<sup>37,39,40</sup> and ideas generated from our proposed working group activities involving anthropologists, data scientists, and disease ecologists who have worked extensively in the geographic and societal contexts in which we focus our work. We will aim to design surveys that account for populations and individuals holding different beliefs, carrying different histories, and living in different ecologies. We will attempt to survey demographically and geographically diverse populations to capture direct and indirect animal-contact patterns and behaviors, and will attempt to capture the role that international, state, and local policy plays in individuals' lives. Further, we will aim to recognize particular hesitations among individuals to interact with certain technologies or other public health interventions.

We will explore various online platforms at the start of our project for survey administration. Given our unique public-private partnership with Facebook for many components of this project, using the Facebook platform to disseminate our pilot survey is likely to be a strong option, especially given Facebook's global reach (nearly half of the world's population, ~3 billion users), which introduces opportunities for digital interaction across class, gender, ethnicity, and cultural

divides. Facebook has extensive experience administering surveys, either directly on its platform (e.g. Yale Climate Change opinion survey) or off-platform (e.g. Carnegie Mellon University COVID-19 surveys) that we will leverage. Facebook also has extensive privacy infrastructure and data-review policies to ensure anonymity and data security.

We will also explore creating games that users will be encouraged to play online to enable us to learn more about how they think about host species, viral threats, environment, and health/disease. For example, users may be given a list of 30 images and will be asked to put them into categories and describe what each category means. Adapting these “pile sorting” anthropological methods<sup>41</sup> to an online interface and for spillover risk, will be a novel application with potential for a massive scale-up of data around cultural and conceptual dimensions of zoonotic disease risk. Data generated from this exercise will generate a more ethnographic understanding of people's experiences and thought processes, which tend to be locally mediated. We understand that there are geographic and demographic gaps in internet and social media use, and will incorporate bias corrections into our study design. We will initially focus on Southeast Asia, a region with a high likelihood of future zoonotic disease emergence and where EHA has good coverage of on-the-ground surveillance programs to ground truth online data collection.<sup>5</sup>

### ***1b. Image recognition of zoonotic disease host species***

We will pilot image-based surveillance of Facebook and Instagram feeds to attempt to identify human contact with key zoonotic disease host species and to explore the limits of taxonomic and behavioral recognition in images. We will work with Facebook Data for Good (see **Letter of Collaboration**) to adapt and refine their existing machine vision algorithms to target key taxa and to assess the efficacy of different approaches, working within strict guidelines and ethical standards for data de-identification. While data will be de-identified, we will only use photos with full location meta-data, allowing us to not only quantify the type of species and contact, but where it occurred. There are multiple image libraries that may serve as AI training datasets, including iNaturalist, the American Society of Mammologists, and Integrated Digitized Biocollections (iDigBio). We will iteratively implement and test algorithms starting with broad taxonomic groups (e.g., bats) and will explore the extent to which our approaches can identify finer taxonomic resolutions down to the genus or species level. In addition to taxa identification, we will explore image recognition of features that may suggest specific types of human-animal contact, such as cages or market settings. Further, we will use text and image metadata and explore using hashtags associated with images to boost the ability of our algorithms to identify key taxa.

This work will involve collaboration between machine learning scientists, biologists/ecologists, and social scientists. We will follow all data anonymity and privacy guidelines from Facebook and will also discuss data handling ethics in our working group. We will assess the ability of passive surveillance with image recognition to be used to target surveys to populations that may have higher frequency of contact with wildlife, and ultimately to target biological surveillance of human and animal populations. We will consider both the accuracy of the image recognition algorithms as well as implications for survey distributions, results interpretation, and ethical data practices. We will also compare the spatial distribution of human-animal contact patterns derived from image recognition with previously generated spillover risk maps based on joint occurrences of animal and human distributions (e.g., SARS-related CoV spillover risk from Sanchez et al. 2021 preprint).<sup>25</sup>

**Working Group 1 Activities:** Our working group will convene 12-15 experts from the social sciences, disease ecology, and computational sciences for an intensive, 3 day workshop. We will structure the workshop to focus first on data ethics in human behavioral surveying and image recognition surveillance and secondly on survey design and analysis planning, with specific attention to accounting for gaps or biases in survey distributions. We will center the workshop around the understanding that technological quick fixes are never enough and that data collection must address long term social, ecological, and economic realities to understand how people perceive, experience, and interact with the risk of and repercussions from spillover events. We will also address experiences and challenges in engaging longtime ethnographers and local leaders to understand what's at stake for communities engaging with online and field surveillance programs. Our working group will help mentor students part of the CSI Student Training Program, to facilitate information sharing and idea generation among undergraduate and master-level students. Working group 1 will also contribute to the CSI Seminar Series with cross-disciplinary topics such as AI image recognition (lead by a data scientist and bat biologist) and human-behavioral survey design (lead by an epidemiologist and medical anthropologist).

**Partners, Initial Working Group 1 Members, and Roles:** EHA (SP Mendelsohn): survey design and implementation, image recognition algorithm development and testing, novel data analyses. Facebook Data for Good (OP Pompe): survey implementation, image recognition algorithm development and testing, data ethics. University of Rochester (coPI Hoque): Image recognition algorithm development and testing. Georgetown University (coPI Mendenhall): Survey design with focus on ethnography and anthropology; online free listing/pile sorting game design; help lead expansion of WG to include emerging international leaders in social-behavioral science (e.g. Dr. Edna Bosire from Kenya). We will invite additional leaders from our extensive funded collaborations to be part of the Working Group for Aim 1.

## **Aim 2: Detecting zoonotic disease exposure at scale**

Animal-human contact is the necessary condition for spillover of potential pandemic, directly-transmitted viruses. While a small fraction of such encounters result in actual exposure or infection, such exposures are frequent given the total sum of encounters. Most such infections are never reported and rarely spread widely, and only a very rare subset become widespread in the human population<sup>42</sup>. Other viruses such as Lassa spill over thousands of times per year<sup>43</sup>. In areas of frequent spillover, the eco-evolutionary dynamics of "stuttering chains" of infection are what give rise to epidemics and pandemics<sup>44</sup>. Identifying populations where frequent exposure occurs is critical for deploying preventative measures and following viruses upstream to their wildlife hosts. Yet even large-scale surveillance projects cover too small populations and produce far too few detections to determine the most exposed geographic, demographic, or occupational groups at an actionable scale [REF<sup>2</sup>, showing PREDICT sampling efficiency]. This is for two reasons: the field and laboratory cost of surveilling populations interacting with wildlife interface and, and the low detection rates of the widely-used, molecular PCR or metagenomic approaches.

We aim to drastically increase the scale at which populations can be monitored for exposure to animal-origin viruses by developing and piloting novel tools and analyses needed to implement large-scale serological surveys. While metagenomic methods have been favored for their ability to capture genetic sequences of previously unknown viruses, serological methods can be used to detect exposure to known and unknown viruses using multiplex assays tailored with a mixture of sensitivities and specificities<sup>45</sup>. Serological tools can detect antibodies for months or years after viral infection, rather than the limited window of days or weeks using molecular methods, and thus can provide a much richer profile of populations where pandemics may emerge<sup>46</sup>. In this planning period, we will begin pilots to test the feasibility of two complementary approaches

Number: 1 Author: Kevin Olival Date: 9/21/2021 1:30:00 PM

Our work under PREDICT is relevant here, working with local community leaders to distribute results and the 'Living Safetly with bats book'. But how do we scale this? One idea is through a network of local leaders across the landscape, like a "Community One Health Volunteer" network.

Noam, can you find a good one?

to enabling serological screening at large scales: 2a) the creation of rapid bioinformatics pipelines to interpret high-dimensional serological data from large streams of surveillance data, and 2b) the development of rapid field serological tests for wildlife-origin diseases.

## Aim 2 Pilot Research Projects

### 2a. Rapid bioinformatics for high-throughput, multiplex serology

Members of our team (SP Laing, Broder) have developed multiplex serology tests that can be used to screen for exposure for many species and variants of filo-, henipa-, and coronaviruses simultaneously, and screening pipelines that can process samples at the scale of tens of thousands of samples. However, these tests pose challenges for interpretation, as high-dimensional results from multiplex bead or chip assays frequently contain signals of cross-reaction and autocorrelation (**Fig 3**). Through cross-disciplinary research between molecular virologists, serologists, mathematical modelers and data scientists on our team, we will create models to interpret this high-dimensional data and integrate them into a rapid bioinformatic pipeline that identifies individuals and populations to known viruses as well as flagging serological signals indicative of novel viruses. We will make use of data collected under our ongoing NIH and DTRA funded biosurveillance activities (Laing, Broder, Ross, Olival, Daszak) to develop detailed reaction/cross reaction profiles of a broad panel of zoonotic viruses to serological tests. We will build mechanistic, hierarchical Bayesian models that allow us to determine whether serological “profiles” are more likely to represent antibodies of known viruses, mixtures of multiple known viruses, or previously uncharacterized viruses. We will extend techniques of antigenic mapping,<sup>47</sup> using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential. Using simulation experiments, we will test reduced-form, simple models against fully structured models so as to develop statistically robust procedures to interpret these data without high-performance computation.

**Fig 3.** Preliminary data: Reaction-cross reaction plots of multiplex Luminex assay response to antibodies for closely-related filoviruses.

**Scaling center operations:** This pilot project will produce methods and a proof-of-concept pipeline for high-throughput analyses. We will leverage EHA’s Emerging Infectious Disease – Southeast Asia Research Hub (EID-SEARCH) project, a NIH-funded Center for Research in Emerging Infectious Diseases (PI Daszak) who’s partners include USU, Duke NUS, Chulalongkorn University in Thailand, and various clinics and institutions in Malaysia – currently screening large numbers of human samples (>10K/yr) for various coronavirus, filovirus, and paramyxovirus antibodies. In the future the CSI will implement surveillance studies screening these sample streams using multiplex serology, and utilize the analytical and bioinformatic tools we develop in the next 18 months. As part of our planning activities, we will establish protocols and approvals for this work.

## **2b. Development of a field-ready semi-quantitative lateral flow assays for an emerging zoonotic viruses (Nipah virus)**

Lateral flow assays (LFAs), are low-cost tests where reagents printed on cellulose strips react with a sample that flows via diffusion. LFAs are capable of providing quantitative results (in proportion to antibody titer) using a combination of high-quality manufacturing and carefully designed, calibrated optical scans<sup>48</sup>. LFAs can be used to provide diagnostics at low cost at the point of care and by consumers. Lack of commercial-scale applications has prevented LFAs from being used for serological testing for novel or emerging disease. To our knowledge, no studies have used LFAs for zoonotic virus serosurveillance in the field.

We will develop a proof-of-concept LFA for Nipah Virus (NiV). NiV has a high mortality rate and is considered to have pandemic potential that is ranked by CEPI as one of 7 high pandemic risk pathogens<sup>49</sup>. The range of NiV's primary wildlife hosts (*Pteropus spp*, fruit bats) cover South and Southeast Asia but human cases have only been detected in Malaysia, Bangladesh, and the Philippines. Spillovers occur regularly in Bangladesh, but are rarely reported in large portions of the country<sup>50</sup> and reporting is strongly associated with health care accessibility<sup>51</sup>. Broad-scale serological monitoring has the potential to identify populations from which pandemic strains may emerge. Through previous work, members of our working group (Laing, Broder) have developed multiplex serological assays for NiV<sup>52</sup> and the soluble proteins and reagents required for an LFA. We have also added experience in engineering, quality control and commercialization of LFAs (Busa, industry consultant) to our working group. For the pilot, we will engage with commercial manufacturers to create and test a prototype Nipah LFA and a protocol for smartphone-based optical reading of quantitative responses.

**Scaling center operations:** The pilot will create a prototype LFAs. As part of full center operations under CSI, we will aim to scale up production and test LFAs efficacy using control sera and field deployment as part of EID-SEARCH. We will additionally assess feasibility and cost of deployment, and compare performance against current laboratory-based assays.

**Working Group 2 Activities:** In addition to the two pilots above, working group members will contribute to the our CSI monthly seminar series, presenting on topics including high-dimensional data models, field serology, serological assay development, laboratory product design, and public-private partnerships and commercialization. We will conduct two online workshops on serological data analysis, jointly with undergraduate, masters, and doctoral students at USU and UR, leveraging partnerships with field researchers currently working in serological surveillance. Our working group will lead a 3-day intensive workshop, where we will recruit additional participants with expertise in serological assay design and surveillance, immunology, emerging zoonoses, and focus discussion on key barriers to scaling serological surveillance for known and unknown zoonotic viruses.

**Partners, Initial Working Group 2 Members, and Roles:** EHA (coPI Ross): Model and pipeline design, software optimization. Uniformed Services University (SP Liaing, SP Broder): data and model interpretation, reagent manufacture, assay design. SP Busa: device manufacturing, quality control, industry outreach and partnership development. We will recruit additional participants from our partner network engaged in serological field studies as well as industry representatives to be part of the Working Group for Aim 2.

### **Aim 3: Rapidly Identifying Anomalous Health Events**

In early stages of epidemic spread, novel contact and mobility-induced behavioral data as well as communication patterns may provide a signal of e.g., health-seeking activity indicative of an outbreak cluster. We contend that these signals may be detectable in large-scale data streams of population mobility and contact, or disease reporting available through telecommunications and health care providers. Timely detection requires approaches that can manage data at scale,

analyze high-dimensional, spatio-temporally correlated streaming data in (pseudo) real time, and distinguish between known signals (e.g., typical influenza-related activity) and novel spillover-related signatures that we wish to unveil, characterize, and explain in order to trigger the necessary public policy responses.

This desideratum calls for fundamental methodological and computational advances, to go along with epidemiologically-relevant data sources that describe how humans are moving and interacting across physical space, with unprecedented temporal resolution and geographical coverage. Traditional flow-based mobility datasets used to parameterize epidemiological models have been aggregated and formatted in the form of origin-destination (OD) matrices. While valuable towards understanding population flows between regions of interest, OD matrices lack information on how much time a traveler spends in any given location. Naturally, when it comes to epidemiological studies the duration of time spent in potentially risky geographical areas is key towards deciphering actionable contact and exposure patterns<sup>53</sup>. Moreover, recent studies have shown that flow counts between pairs of geographical areas can be loosely correlated with, and not representative of, epidemiology-relevant mixing patterns<sup>54</sup>. Instead, these couplings among subpopulations are measured by effective contact rates, meaning how often people from each region come into contact in a way that is sufficient to transmit a disease. To address these challenges, our consortium will partner with the Facebook Data for Good team and leverage two recently assembled global-scale datasets - Activity Space Maps and Colocation Maps<sup>53,54</sup>.

Different from existing approaches that have focused on measuring the causal impact of mobility-oriented interventions, **our ambitious goal in this aim is to markedly advance the surveillance infrastructure available to predict anomalous health-related events before a major outbreak occurs.** While undoubtedly a multi-faceted endeavor, in this planning grant we will take initial, but significant steps with an emphasis on network-centric, computational analyses of dynamic mobility and interaction data at a global scale. By developing the appropriate statistical tools, we will support the ultimate goal of characterizing early pandemic “fingerprints” or signatures that can be extracted from these global datasets.

**Aim 3 Pilot Research Projects:** Working closely with Facebook Data for Good (see Letter of Collaboration from Alex Pompe), this working group will pilot data-driven research activities to explore the feasibility of extracting early (post spillover) signals of epidemic onset from Activity Space Maps and Colocation Maps. Our multi-disciplinary working group brings together leading experts in systems engineering, AI for healthcare, data science, mathematical epidemiology, graph signal and information processing, privacy-preserving mobility data generation and management, human behavioral modeling, and environmental science. We believe the current team, consisting of a wide array expertise and partnership, will instigate the cross-pollination of ideas leading to center-level activities while making significant inroads towards addressing our grand challenge. We propose two specific pilot projects:

### ***3a. Spatio-temporal monitoring of spillover-induced activity anomalies in Southeast Asia***

*Activity Space Maps (ASMs)* are a novel global-scale movement and mobility data set which describes how people distribute their time through geographic space.<sup>53</sup> They are designed to complement existing digitally-collected mobility datasets by quantifying the amount of time that people spend in different locations. Accordingly, this information is valuable for estimating the duration of contact with the environment and the potential risk of exposure to disease -- something critical especially early after spillover. More germane to the theme of this aim, it also offers the unique possibility of developing and testing sequential change-point detection algorithms to monitor multiple spatial grid cells of interest (informed, for instance, by outcomes

of the image-recognition effort under Aim 1). We will target areas known to include health care facilities in pursuit of abnormal trends of (increased) activity. Moreover, using ASMs we will examine flow and temporal activity anomalies around expert-annotated wildlife and wet market locations. Said events are expected if there are human infections, or significant associated changes in behavior around these sites early after spillover. Our initial efforts during this planning grant will be focused on Southeast Asia, which on top of its epidemiological relevance is one of the regions where Facebook ASMs have the most coverage. We will target Indonesia, where EHA has extensive on-the-ground efforts tracing networks of wildlife trade as well as market sites.<sup>55</sup> We will also tap into the resources stemming from EHA's Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) to identify clinics and market sites of interest in Thailand and Malaysia. Some key challenges we will address include accounting for the implicit biases in data collection associated with the construction of ASMs,<sup>53</sup> and their subsequent effects on the statistical algorithms that we will develop. Our Working Group will address additional challenges of data interpretation of anomaly detection analyses with input from emerging disease experts and epidemiologists. To calibrate our models, we will bring to bear recent activity data before and after the SARS-CoV-2 outbreak in those locations, in addition to historical influenza seasonal trends that go further back in time. With the exciting prospect of ASM data being officially released in the last quarter of 2021, *we are in a privileged position to be the first multi-disciplinary team that leverages this invaluable global-scale resource to advance our understanding of zoonotic spillover risk and its immediate effect on human mobility.*

### **3b. Online network change-point detection in dynamic, global-scale Colocation Maps**

Activity data are complemented by *Colocation Maps (CMs)*, which estimate how often people from different regions worldwide are colocated. In particular, for a pair of geographic regions  $i$  and  $j$  (e.g., counties in the US), CMs estimate the probability that a randomly chosen person from  $i$  and a randomly chosen person from  $j$  are simultaneously located in the same place during a randomly chosen minute in a given week.<sup>54</sup> In other words, CMs are global-scale, dynamic network datasets with colocation probabilities encoded as edge weights. Thus, they are well suited to parametrize metapopulation models of disease spread,<sup>56</sup> or to measure temporal changes in interactions between people from different regions.<sup>57</sup> To monitor said changes as part of our second pilot activity in this aim, we will build on our recent advances in online (i.e., sequential) algorithms for anomaly and change-point detection from network streams<sup>58,59</sup>, see also.<sup>60-62</sup> The envisioned statistical methods are in stark contrast with most existing graph change-point detection approaches, which either rely on extensive computation,<sup>63</sup> or they would require storing and processing the entire observed CM time series.<sup>64</sup> We will prototype and test a lightweight online change-point detection algorithm with quantifiable performance guarantees, that is also explainable since it relies on interpretable node embeddings.<sup>58,65</sup> The latter desirable feature will be leveraged to construct dynamic anomaly maps for user-friendly visualization of post-spillover events; see also our recent network-scientific visualizations of spatio-temporal COVID-19 contagion patterns across the US.<sup>66</sup> Moreover, the sheer-size of the CM graphs calls for algorithmic and modeling innovations we will investigate as part of our research agenda, e.g., seamlessly integrating graph subsampling or dimensionality reduction techniques to the analytics pipeline. We will team up with computer vision experts affiliated to the University of Rochester Goergen Institute for Data Science (GIDS, see attached Letter of Collaboration from institute director Mujdat Cetin), to also explore the exciting prospect of integrating geo-tagged multimodal data such as video and imagery in our studies, for instance as nodal attributes embedded to the CMs.

**Working Group 3 Activities: *Recruitment and diversity:*** We will recruit 6 students from the GIDS-run master’s program in data science, which attracts students from multidisciplinary backgrounds and significant computational proficiency to contribute in the aforementioned pilot research activities. *The CSI leadership and broader community are committed to providing research training and educational experiences for those traditionally under-represented in STEM, including women and underrepresented minority students.* The PI team has a solid track-record in actively recruiting and supervising such students at the undergraduate, masters and doctoral level, with demonstrated efforts towards broadening participation in STEM. As examples of the commitment to diversifying the field, co-PI Mateos serves as founding faculty advisor to the UR’s SACNAS chapter and regularly organizes diversity, equity and inclusion panels to highlight challenges and successes of UR’s Hispanic and Latino STEM community. We plan to prioritize engaging women and minority students in the research and working group activities proposed here. ***Coursework:*** These students will be on the existing health and bio track with an opportunity to take classes in immunology, microbiology and virology programs as well as data ethics at the University of Rochester Medical Center (URMC) as well as the college of engineering. Through the planning grant, we plan to establish a special MS track on ‘zoonotic surveillance’ in order to train and mentor the students to lead center level activities. ***Seminar and workshop series:*** The students will be part of the large cohort of all the participating institutions and participate in the CSI monthly seminar series. The co-PIs (Mateos and Hoque) will conduct two workshops (and invite additional faculty members from UR as guest speakers) with hands-on lessons in mobility and human behavior modeling. ***Hackathon:*** The students will be encouraged to participate in the yearly hackathon, Dandyhacks (<https://dandyhacks.net/>), organized every fall by the University of Rochester Computer Science Department and work with the dataset from Facebook. Additionally, co-PIs Mateos and Hoque will work with the organizers of Dandyhacks to release some of the public dataset from Facebook for other teams to explore, model and mine the data.

***Data visualization meetups at the University of Rochester’s VISTA Collaboratory:*** To get acquainted with the different data resources at our disposal, over the first 3 months of the project the Rochester team (along with Facebook and EHA collaborators via Zoom) will hold bi-weekly team meetings with the MSc students at the UR’s VISTA Collaboratory. This is a 1,000 square-foot visualization lab equipped with an interactive (20 ft. wide x 8 ft. tall) tiled-display wall, that renders massive data sets in real time, giving team members the ability to visualize and analyze complex data instantaneously and collaboratively; see Fig. 4. As we dissect what dataset components are central for the aforementioned pilot activities, our graduate students will develop customized data visualization tools, maps and dashboards to facilitate downstream analyses. Updates and progress reports will be shared in these meetings, giving the students a unique opportunity to develop their communication skills. The whole team will provide feedback and share ideas, making this a truly collaborative activity. Moving forward, the VISTA Collaboratory offers a unique resource that we will fruitfully leverage as we scale up to full center operation.

**Fig. 4.** UR’s Vista Collaborative will serve as a spillover intelligence “situation room” for training UR and CSI exchange students on analysis of real-time epidemiologically relevant datasets.

**Partners, Initial Working Group 3 Members, and Roles:** University of Rochester (co-PIs Hoque and Mateos): coordination of working group activities, development and testing of computational tools for early detection of post-spillover signatures, dissemination of research products and educational materials, recruiting and mentoring of master students, liaisons to

GIDS. Facebook Data for Good (OP Pompe and Maps for Good team members Iyer and Citron): data ethics, quantification of privacy protections, data scientific support for Activity Space and Colocation Maps, mathematical epidemiology expertise for data and model interpretation. EHA (SP Mendelsohn and Ross): identification of target spatial locations in Southeast Asia, epidemiological interpretation of anomaly detection analyses and validation of detected early pandemic fingerprints.

**Scaling operations:** Our programs and pilot research are designed to scale. First, we aim to expand on successful pilots by expanding the geographies of our work, engaging with more in-country partners. Second, we test the development of each of these new streams of predictive data, we plan to develop partnerships with local, national, and global agencies to ingest these data, expand into programs to develop behavioral interventions and testing in response to identifying regions and populations at high risk of contracting zoonotic diseases.

Working groups are really about bringing our project to scale, our intensive 3-day workshop will also lead to new partnerships and synergies for expansion.

### Results from Prior NSF Support

**Kevin J. Olival** has not had prior NSF support, but is co-PI on NIH-funded “EID-SEARCH” (NIAID-CREID U01AI151797, 2020-25 PI Daszak). Previously co-PI on “Understanding the risk of bat coronavirus emergence” (NIAID R01 AI110964, 2014-2019, PI Daszak). **Intellectual merit:** Identified >50 SARSr-CoVs in bats, showed evidence of ability to infect human cells, humanized mouse models, and people in China, and used evolutionary and mammalian biodiversity patterns to analyze spillover risk for use in public health control. Produced 18 peer-reviewed papers<sup>20,34,67-79</sup>, including two papers in *Nature*<sup>80,81</sup>, and a review in *Cell*<sup>82</sup>, and others submitted. **Broader impacts:** 2 PhD and 6 MS students trained; disease risk and potential management strategies shared with US agencies, WHO, OIE, FAO, and the public.

**Ehsan Hoque: Project IIS-1750380.** PI: Hoque. Period (2018-23). Amount: \$511,453 “CAREER: A collaboration coach with effective intervention strategies to optimize group performance”. **Intellectual merit:** Developing and validating the efficacy of automated mediation strategies in online meetings. **Broader Impacts:** >6 research papers<sup>83-88</sup>. **Project NRT-DESE-1449828.** PI: Hoque (2015-21). Amount: \$2,965,341.00 “Graduate Training in Data-Enabled Research into Human Behavior and its Cognitive and Neural Mechanisms”. **Intellectual merit:** Chartering a new traineeship program to train Ph.D. students at the University of Rochester to advance discoveries at the intersection of computer science (cs), brain and cognitive sciences (bcs), and neuroscience. **Broader Impacts:** Supported over 50 PhD students in cs and bcs, several won interdisciplinary research positions at R1 institutes.

**Gonzalo Mateos** (a) Project: CCF-1750428. PI: Gonzalo Mateos Buckstein. Period: 4/1/18 - 3/31/23. Amount: \$407,944. (b) Title: CAREER: Inferring Graph Structure via Spectral Representations of Network Processes. (c) **Intellectual Merit:** We investigate how to use information available from graph signals to estimate the underlying network topology through innovative convex optimization approaches operating in the graph spectral domain. **Broader Impacts:** We prepared a feature article on identifying network structure via GSP,<sup>89</sup> presented tutorials in EUSIPCO'19, CAMSAP'19 an SSP'20, organized the 2019 IEEE SPS Summer School on Network- and Data-driven Learning. (d) Research products are available in.<sup>66,89-96</sup>

**Emily Mendenhall** (a) National Science Foundation Doctoral Dissertation Improvement Grant, \$10,000; Stories at the Border of Mind and Body: Mexican Immigrant Women’s Narratives of Distress and Diabetes. **Intellectual merit:** Led to crucial insights studying syndemics - the interactions of social, environmental, psychological, and biological factors that are synergies of epidemics. Papers in *The Lancet*<sup>29</sup>, *Medical Anthropology Quarterly*<sup>97-99</sup>, and as a full-length

book<sup>100</sup>. **Broader Impacts:** Understanding diabetes, trauma, and broader socio-political factors with infectious diseases in India, Kenya, South Africa, and Ethiopia.

## PROJECT DESCRIPTION

### Introduction and Background

The spillover and spread of novel, zoonotic pathogens can have tragic societal and economic impacts, as is evidenced by the ongoing COVID-19 pandemic. Unfortunately, the emergence of SARS-CoV-2 (the virus that causes COVID-19) is just the latest in a series of viral emergence events that have been accelerating over the last several decades. In just the last year, as the world continues to respond and adapt to COVID-19, we have seen several deadly zoonotic (animal origin) viruses re-emerge in the human population, including Ebola and Marburg in Guinea<sup>1,2</sup>, Nipah virus in India<sup>3</sup>, Rift Valley Fever virus in Kenya<sup>4</sup>, and novel strains of influenza in China [REF]. Most emerging infectious diseases (EIDs) originate in wildlife reservoir hosts and are transmitted across species boundaries, or (“spill over”), when livestock or human populations increase contact with wildlife through factors including land use change, agricultural intensification, and the wildlife trade<sup>5-7</sup>. Zoonotic spillover is a dynamic process determined by many steps including ‘pre-emergence’ viral evolution, diversification, and transmission among wildlife hosts; ‘human exposure’ via direct or indirect contact between humans, livestock, and wildlife; ‘post-exposure’ limits to cell entry, host range, human-to-human transmission; and population level virus amplification and spread. Once efficiently transmitted, EIDs can spread rapidly through globalized travel and trade networks, threatening countries with high population growth, urbanization and international trade (Fig 1).

**Fig 1.** Four stages of zoonotic disease emergence and spread, with gaps in knowledge at each stage. Our proposed project will develop and pilot novel, multidisciplinary and technological advances to address critical gaps in the first three stages of emergence, when pandemic prevention is possible.

Novel human EIDs are typically only discovered when they cause severe or unusual symptoms, when astute clinicians are linked with laboratories capable of pathogen discovery research, and after they have been transmitted from person to person (in which case control options become more difficult).<sup>7,8</sup> The emerging human viruses characterized to date likely represent just the tip of the iceberg given the hundreds of thousands of predicted zoonotic viruses that exist in nature and limited surveillance capacity globally<sup>9</sup>. New research has disrupted the paradigm that zoonotic disease spillover is a rare event. A combination of more advanced molecular and serological assays, improved laboratory capacity around the world, and targeted surveillance of “high risk” human populations have led to evidence of zoonotic virus transmission and infection, even in the absence of notable disease outbreaks. Often these spillover events lead to “dead end” infections in people or limited ‘stuttering’ chains of transmission, a phenomenon referred to as “viral chatter”<sup>10</sup>. Community-based serological surveys from our group and others have illuminated relatively frequent and previously-unknown instances of zoonotic virus spillover

including Henipaviruses in bat hunters from Cameroon<sup>11</sup>, SARS-related CoVs in rural communities living near caves in China (pre-2019), and Ebola virus exposure in DRC<sup>12</sup> and even Southeast Asia<sup>13</sup>

It is during these early stages of emergence, i.e. “viral chatter” with limited human transmission and even further upstream to include pre-emergence risk analyses at the human-animal interface, where innovative convergent research approaches are most needed for pandemic prevention. While we have made significant scientific advances over the last ~15 years in understanding where and through what mechanisms novel zoonotic viruses spill over into the human population<sup>5,14-17</sup>, there **are still fundamental knowledge (and implementation) gaps that stymie our ability to preempt and prevent future disease emergence events.**

### **Our Grand Challenge Problem**

Prior to 2019, EcoHealth Alliance (EHA) and colleagues demonstrated that SARS-related coronaviruses (SARSr-CoVs) in China pose a clear and present danger for a future human outbreak. We conducted extensive viral discovery in wildlife from China and Southeast Asia, phylogenetic analysis, and host-range experiments to show that certain bat species harbor a diverse assemblage of SARSr-CoVs<sup>18,19</sup>, as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics<sup>20-23</sup>. We conducted behavioral risk factor surveys and serological sampling from human populations living close to caves and found serological evidence of SARSr-CoV spillover in people exposed to wildlife<sup>24</sup>. Building on this body of knowledge, our recent models suggest that bat-origin SARSr-CoVs may be infecting 400,000 (median 50,000) people in Southeast Asia each year<sup>25</sup>. While confidence intervals around these estimates are large, our sensitivity analyses importantly identified key area for future research to improve these spillover risk models - notably, quantification and better contextual understanding of human-bat contact, the role of wildlife farming and livestock hosts, scaling up human serological surveys, and better data on sero-dynamics following novel SARSr-CoV exposure.<sup>25</sup>

**Despite this strong body of evidence for SARSr-CoV spillover risk (prior to the emergence of SARS-CoV-2), surveillance and research on these potential pathogens, their hosts, and their interface with humans was not conducted across a wide enough geography, nor at a temporal or spatial scale to inform actionable disease mitigation.** Even for large-scale efforts to strengthen zoonotic virus early warning systems, like the 10-year, 30 country USAID PREDICT program<sup>26</sup>, led by a global consortium including EHA, it's nearly impossible to capture enough data and disseminate that quickly enough to lead to widespread prevention measures at a national scale using existing methods – especially when considering multiple potential viral threats at once. This is especially true for large countries with heterogeneous human populations, diverse wildlife fauna, and known ecological and societal risk factors for emergence. Approaches to massively scale up zoonotic spillover surveillance are needed.

**Our grand challenge problem: "How can we capture actionable data about the risk of zoonotic spillover (and early spread) at the scale and speed required to prevent outbreaks?"** Can we leverage tools developed by computer scientists, data engineers, and technology companies to collect data from diverse populations and geographies to advance zoonotic spillover intelligence to a global scale? Can we incorporate new insights from medical anthropology, sociology, wildlife biology, disease ecology, molecular virology, biomedical assay design, and data science and use these to pioneer new methods in data collection and interpretation for zoonotic disease prediction and prevention? In this development proposal, we propose to build a collaborative research and training network to confront this challenge, designed at the start to scale up to a future Center for Spillover Intelligence (CSI). Our network will deeply integrate computer scientists, engineers, and data scientists using machine learning and other novel technological approaches together with experts in emerging disease and social-

behavioral research. New insights from social, behavioral, and anthropological research make it clear that the emergence and future trajectory of human epidemics require that we recognize potential biological risks alongside risks posed by cultural and societal factors<sup>27-29</sup>. Our cross-disciplinary, multi-institution project will combine synergistic research activities with training and education programs to facilitate new innovations to scale-up the collection and interpretation of data to inform where, how, and what zoonotic viruses are poised to emerge – a field we collectively refer to as *Spillover Intelligence*. Our inclusion of social-behavioral researchers, data ethicists, and inter-governmental EID policymakers will ensure that our aims and approaches are culturally and locally relevant, and align with our ultimate goal of improving global health.

**Our Vision:** We envision a world where diffuse data streams can be combined and interpreted in near real-time to disrupt the spillover and spread of future zoonotic viruses. We envision diverse leaders and scientific disciplines coming together to advance spillover intelligence and transform the ways we think about, monitor, and respond to global viral threats.

### **Our Team**

We have assembled a multidisciplinary team of experts to lead our development project and to create and grow the Center for Spillover Intelligence (CSI). Our **Leadership Team (PI, coPIs, Senior Personnel)** includes a mixture of established scientists and early career leaders working across the fields of: emerging infectious diseases, computer and data science, engineering, mathematical modeling, virology, technology and biotechnology, data ethics, social science, and medical anthropology. Our project will be led by EHA (PI Olival) building off the foundational pandemic prediction work our institution has developed over the last decade, but expanding to new partnerships and collaborations we have not previously been able to explore – including with computer scientists and engineers from University of Rochester (UR) and behavioral anthropologists from Georgetown University (GU). We will develop and pilot new technologies for field biosurveillance and data interpretation with Uniformed Services University (USU). Our Leadership Team is ethnically, culturally, and geographically diverse, including US-based researchers who originate from and/or currently conduct their primary research in global EID hotspot regions<sup>5,14</sup>, e.g. South Asia (Hoque); Latin America (Mateos); Africa (Mendenhall); and Southeast Asia and the Pacific (Olival). Our geographic and disciplinary diversity, including long-standing international collaborators from each region make our team well equipped to address spillover at a global scale, while understanding the importance of local context.

**PI Olival** (EHA) is a disease ecologist and evolutionary biologist with a primary interest in developing novel analyses to target zoonoses surveillance and viral discovery. He currently leads two regional biosurveillance projects in Southeast and Western Asia, and recently served as Modeling & Analytics Coordinator for the USAID PREDICT project<sup>26</sup> overseeing a multi-institution team developing pandemic prediction strategies using public and project-specific data from 30 countries<sup>5,15,30-35</sup>. **coPI Mendenhall** (GU) is a medical anthropologist and Professor at the Edmund A. Walsh School of Foreign Service. Mendenhall works at the intersection of social, psychological, and biological lives, attempting to understand what makes people sick, why, and where. Mendenhall is currently a PI of NIH Fogarty International Center grant “Soweto Syndemics”, the first ever study to evaluate a syndemic from the ground up. **coPI Hoque** (UR) is an Associate Professor of Computer Science working at the intersection of Human-centric Computing (HCC) and Artificial Intelligence with a focus on multimodal machine learning with applications in health and wellness. Hoque is currently a PI of NSF NRT grant, and received NSF CAREER and CRII grant. Hoque has been identified as an ‘emerging leader of health and medicine’ at the National Academy of Medicine (NAM). **coPI Mateos** (UR) is Assoc. Professor of Electrical and Computer Engineering and a Data Science Fellow, his research focuses on algorithmic foundations, analysis, application of (graph) signal processing tools to the study of large-scale and dynamic networks. He has pioneered foundational work in network topology

inference, online learning from graph streams, and interpretable representation learning for unstructured data. **coPI Ross** (EHA) is Principal Scientist for Computational Research. His research includes model development to interpret complex spatio-temporal disease surveillance data in heterogeneous populations, including from serological surveys, real-time community and hospital testing, and simulating and forecasting epidemic dynamics over populations, space, and networks. He is PI on awards from DHS Science & Technology Directorate and the Defense Threats Research Agency (DTRA) for designing disease forecasting systems. **SP Mendelsohn** (EHA) is a research data scientist specializing in the development and application of machine-learning models to draw insights into the occurrence and spread of emerging infectious diseases. With a focus on reproducible research methods and data management, she has been the lead analyst on data driven disease forecasting and behavioral survey-based projects characterizing animal-human contact patterns. **SP Daszak** (EHA) is an EID expert who has studied the process of disease emergence for decades and pioneered groundbreaking work in “hotspot” risk mapping to target surveillance. **SP Broder and Laing** (USU) are experts in the design of multiplex serological assays, molecular virology, and implementation of field-based human and wildlife biosurveillance strategies. **OP Busa** is a biotechnology consultant with a specialty in developing lateral flow assays and optical readers. **OP Pompe** is the Research Manager for Facebook Data for Good, who specializes in applying human mobility datasets from social media feeds and data privacy and ethical issues.

### Intellectual Merit

The primary intellectual merit of our proposed project is in **developing and piloting innovative approaches to pandemic prediction across previously siloed scientific domains** including biology, computer science, electrical engineering, and social-behavioral research. We apply new theoretical advances and convergent research to address our grand challenge of capturing actionable data about the risk of zoonotic spillover and early spread at a scale and speed required to prevent outbreaks. We will identify existing gaps and next-generation solutions for step-level changes in zoonotic spillover prediction via multi-day intensive workshops with thought-leaders organized by each of our three multidisciplinary Working Groups. Our pilot research projects will serve as a test bed for new theoretical frameworks to advance spillover intelligence. For example, in Aim 1 we will transform decades-old anthropological approaches and pilot a cost-effective, scale-up of quantitative and qualitative behavioral data collection through a unique public-private partnership Facebook; and use image recognition and artificial intelligence to quantify and map human-wildlife contact globally. In Aim 2 we will develop hierarchical Bayesian models to interpret rich, multiplex serology datasets and test these on real surveillance data as part of EHA’s NIH-funded work; and develop the first field-forward lateral-flow assay for Nipah virus antibody detection. In Aim 3 will use cutting edge theoretical advances in network science, anomaly detection, and machine learning to detect changes in human mobility patterns that may portend spillover (e.g. increase congregation around wildlife markets) or signal early epidemic spread after the point of spillover.

### Broader impacts

This proposal could potentially transform our understanding of zoonotic spillover risks using survey, multimedia, and mobility data on a global scale, including aggregated and anonymized data from ~3B active Facebook users. Insights and intellectual outputs from our working group activities will have direct benefits to public health by informing disease mitigation strategies for pandemic prevention. We will synthesize our three working group outputs and prepare a special joint publication for the National Academies of Science’s Forum on Microbial Threats for wide distribution, and write popular press articles to accompany our peer-reviewed manuscripts. EHA’s *Alliance*, includes a network of over 70 partner institutions in 30+ countries, presents a unique opportunity to work with local stakeholders in emerging virus ‘hotspots’ and validate

Peter, Ehsan, sound good?

models using data sets obtained through our long-standing collaboration with government partners including human health, agriculture, and environmental sectors.

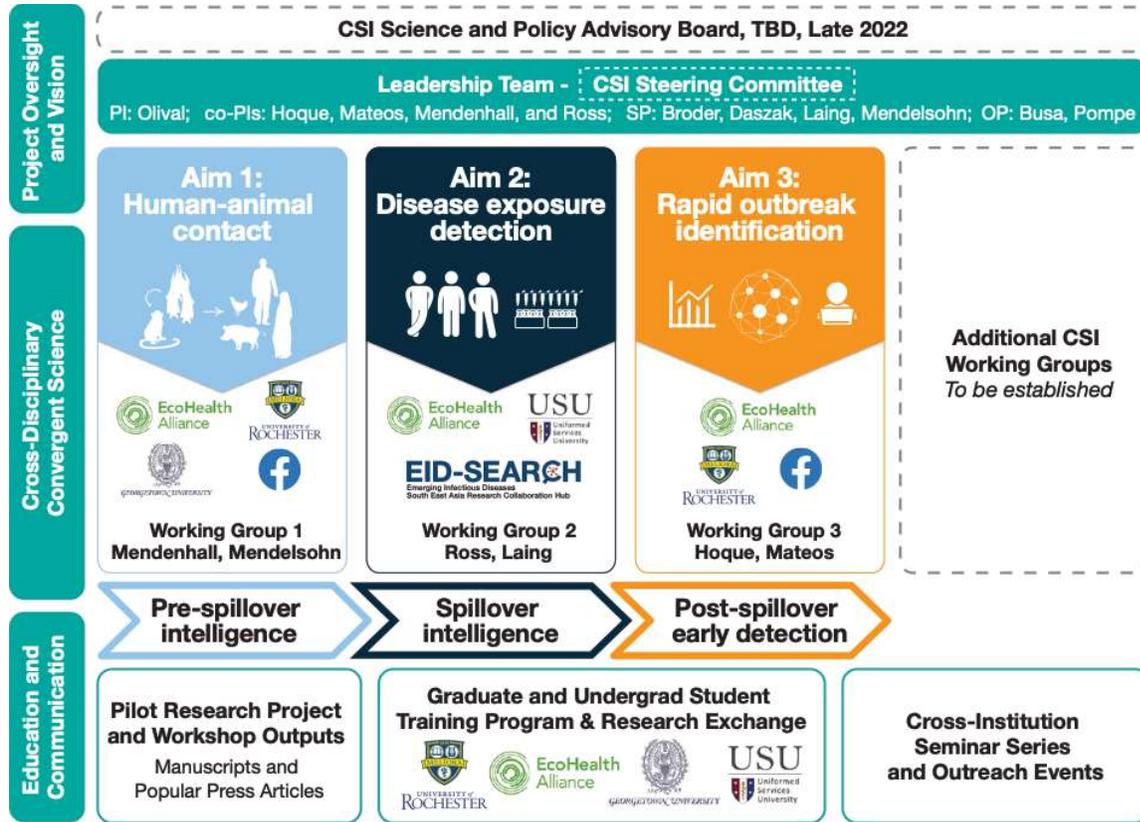

Our education mission consists of multiple workshops, hackathons, monthly seminar series, and access to state-of-the-art visualization facilities. We will begin to train a new generation of graduate and undergraduate students who will be prepared to harness the burgeoning power of data science to make novel inroads into understanding human-animal contact, serological surveillance, and aggregated mobility data and their interaction. Our proposal builds on a unique partnership between the academic (UR, GU, USU), non-profit (EHA), and private sector (FB), allowing students to apply lessons learned from classroom settings to the real-world, and our recruitment will focus on including >50% women and underrepresented minorities in science and engineering. This planning grant will be a path towards structuring interdisciplinary education, cross-training courses across institutions, followed by hands-on experience via internships and research exchanges – with options for international work via existing programs at our institutions. Through the planning grant, a new MS data science track on ‘zoonotic surveillance’ will be established at UR, the first step in our plans to expand our Education and Training plan should we move towards a Center-level award in the future.

### **Education and Training Plan**

Our Leadership Team will serve as mentors for our **CSI Student Training Program** that will offer a fellowship stipend to cross-train 20 Master’s level graduate students via semester-long projects associated with proposed pilot research activities (3-4 students per project) and 3-week research exchanges between our institutions (UR, GU, EHA, USU, 4-8 students from each). The research exchange builds off EHA’s successful NSF-funded EcoHealthNet training program (2011-21) and will take place in either the Summer of 2022 or 2023. We will link with currently-funded international programs at our respective institutions (e.g. Gui<sup>2</sup>de in Nairobi, Kenya run by GU; and the NIH funded CREID research pilot program with EHA’s EID-SEARCH project in Southeast Asia) to support students who desire to gain international, hands-on research experience as part of their research exchange. The focus of each research exchange will be on cross-disciplinary training to think ‘big’ about the future of pandemic prediction and ensure the next generation of spillover intelligence researchers gains valuable hands-on experience working with experts outside their area of study. Students will be drawn from respective departments across our institutions, i.e. students with a computational background and with interests in interdisciplinary work will be recruited from UR’s cross-department Goergen Institute for Data Science, Anthropology and International Affairs students from GU, and Emerging Disease and Virology students from USU. As EHA is a non-profit and does not have an active student body, we will recruit Ecology, Evolutionary Biology, and Environmental sciences students from universities in the NYC area, including Columbia University’s E3B department where PI Olival, coPI Ross and SP Daszak serve as adjunct faculty. We will explore specific mentorship opportunities with data scientists from Facebook. If awarded, we will additionally apply for funds through NSF’s Research Experiences for Undergraduates (REU) program, with the goal of supporting summer stipend for 1 undergraduate per institution or the maximum allowable. We will host a joint monthly virtual seminar series (2 semesters long) open to graduate and undergraduate students from our respective institutions, with a dedicated student “lab meeting” before each seminar. Two CSI students from diverse disciplines will lead each lab meeting discussion based on a deep read of relevant publications that each speaker will distribute in advance. We envision the first semester of the seminar series will be led by our Leadership Team and Working Group experts, and the second semester will be for CSI Graduate students to present results or current challenges related to their pilot research projects. We hope to encourage these students to pursue Ph.D. studies. If we are successful at establishing a center through our planning grant, we should have access to a trained cohort of students with appropriate multidisciplinary skillset.

## Project Overview

Our 18-month research agenda aims to understand how new methods and technologies can improve the efficiency, intensity, speed, and scope of zoonotic disease surveillance. **We have structured our development grant around three primary research aims** that will guide our interdisciplinary research and training activities. We will establish a working group composed of multi-disciplinary experts for each primary aim that will be co-led by members of our Leadership Team. We will develop pilot research projects that capture different parts of the disease spillover process focused on specific geographies, lead 3-day intensive workshops, monthly student seminars, and student training activities that cut across our inter-linked research aims.

**Fig 2. Project overview schematic** showing our project management; three primary aims with graphical representation of pilot research activities to scale up and advance spillover intelligence; institutional partners leading activities for each aim including designated working group leads, and student education and communication activities, including pilot research projects, graduate student research exchanges, seminars, and other outreach activities. Our development level project was built to scale to a Center level award (the Center for Spillover Intelligence, CSI) as noted with the dashed outline boxes, including the future addition of other CSI Working Groups, a Science and Policy Advisory Board, and transitioning our current Leadership Team (PI, coPIs and SP) into a more formal Steering Committee for oversight.

### Aim 1: Measuring human-animal contact at scale

Interactions among humans, wildlife, and livestock create interfaces for pathogen spillover and are proximate risk factors for the emergence of all directly-transmitted zoonotic diseases.<sup>14,36</sup> Human-animal contact is commonplace around the world, with many factors mediating the type and frequency of contact, including cultural practices, environmental conditions, food security, and occupational demands.<sup>36</sup> In regions of the world considered prone to spillover--forested tropical landscapes with high biodiversity and recent land-use changes--understanding human-

animal contact is crucial to pandemic prevention.<sup>5</sup> To measure these interactions and characterize associated behaviors, beliefs, and knowledge, researchers often implement resource-intensive surveys in key communities.<sup>37,38</sup> While crucial to understanding human-animal contact dynamics, on-the-ground surveys cannot yield scalable data that is comparable across populations. Often, in place of surveys, researchers conducting analyses at broad scales rely on coarse estimates of contact such as the joint density of human and animal populations. **Our working group will uniquely combine social scientists, disease ecologists, and computational scientists to increase the scale at which we can directly measure human-animal contact.** We will develop and implement two pilot research projects. The first will use novel, social-media-based survey approaches to reach larger populations at higher frequencies while maintaining the cultural sensitivity and relevance of on-the-ground surveys. Working collaboratively with cross-disciplinary researchers, we will design surveys to understand social behaviors, cultural perceptions, and occupational hazards that may pose zoonotic spillover risk to individuals and communities. We will target geographies based on our existing spatial risk modeling work that maps infectious disease spillover potential and the ecological distributions of key reservoir host species.<sup>5,15,25</sup> Second, we will conduct pilot research on the use of social-media-based image recognition algorithms to identify locations of human contact with key species known to host high pathogen diversity. This pilot will include a collaboration effort to test the efficacy of such technology for understanding taxon-specific contact patterns globally, and to bring multidisciplinary context to meaningfully interpret the outputs (including species validation with taxonomic experts). If successful, will use these data on frequency of animal contact from image data to identify locations for additional survey data collection.

**Aim 1 Pilot Research Projects:** We will develop two pilot projects to assess the potential of 1a) social-media dispensed surveys and 1b) passive surveillance using artificial intelligence for image recognition to capture information about human-animal contact. We will target populations at wildland interfaces where contact with wildlife is likely high but internet penetration may be mixed.

***1a) Social-media dispensed surveys to quantify and contextualize human-animal contact***

We will pilot social-media dispensed, large scale population surveys about perceptions of and interactions with animals. We will optimize the design of these surveys for mobile platforms to facilitate higher response rates, and will also explore the possibility of longitudinal sampling respondents (either individuals or populations) to understand changes in conditions and responses over time. Survey questions will be based on a combination of EHA's past experience designing on-the-ground human-animal contact surveys<sup>37,39,40</sup> and ideas generated from our proposed working group activities involving anthropologists, data scientists, and disease ecologists who have worked extensively in the geographic and societal contexts in which we focus our work. We will aim to design surveys that account for populations and individuals holding different beliefs, carrying different histories, and living in different ecologies. We will attempt to survey demographically and geographically diverse populations to capture direct and indirect animal-contact patterns and behaviors, and will attempt to capture the role that international, state, and local policy plays in individuals' lives. Further, we will aim to recognize particular hesitations among individuals to interact with certain technologies or other public health interventions.

We will explore various online platforms at the start of our project for survey administration. Given our unique public-private partnership with Facebook for many components of this project, using the Facebook platform to disseminate our pilot survey is likely to be a strong option, especially given Facebook's global reach (nearly half of the world's population, ~3 billion users), which introduces opportunities for digital interaction across class, gender, ethnicity, and cultural

divides. Facebook has extensive experience administering surveys, either directly on its platform (e.g. Yale Climate Change opinion survey) or off-platform (e.g. Carnegie Mellon University COVID-19 surveys) that we will leverage. Facebook also has extensive privacy infrastructure and data-review policies to ensure anonymity and data security.

We will also explore creating games that users will be encouraged to play online to enable us to learn more about how they think about host species, viral threats, environment, and health/disease. For example, users may be given a list of 30 images and will be asked to put them into categories and describe what each category means. Adapting these “pile sorting” anthropological methods<sup>41</sup> to an online interface and for spillover risk, will be a novel application with potential for a massive scale-up of data around cultural and conceptual dimensions of zoonotic disease risk. Data generated from this exercise will generate a more ethnographic understanding of people's experiences and thought processes, which tend to be locally mediated. We understand that there are geographic and demographic gaps in internet and social media use, and will incorporate bias corrections into our study design. We will initially focus on Southeast Asia, a region with a high likelihood of future zoonotic disease emergence and where EHA has good coverage of on-the-ground surveillance programs to ground truth online data collection.<sup>5</sup>

### ***1b. Image recognition of zoonotic disease host species***

We will pilot image-based surveillance of Facebook and Instagram feeds to attempt to identify human contact with key zoonotic disease host species and to explore the limits of taxonomic and behavioral recognition in images. We will work with Facebook Data for Good (see **Letter of Collaboration**) to adapt and refine their existing machine vision algorithms to target key taxa and to assess the efficacy of different approaches, working within strict guidelines and ethical standards for data de-identification. While data will be de-identified, we will only use photos with full location meta-data, allowing us to not only quantify the type of species and contact, but where it occurred. There are multiple image libraries that may serve as AI training datasets, including iNaturalist, the American Society of Mammologists, and Integrated Digitized Biocollections (iDigBio). We will iteratively implement and test algorithms starting with broad taxonomic groups (e.g., bats) and will explore the extent to which our approaches can identify finer taxonomic resolutions down to the genus or species level. In addition to taxa identification, we will explore image recognition of features that may suggest specific types of human-animal contact, such as cages or market settings. Further, we will use text and image metadata and explore using hashtags associated with images to boost the ability of our algorithms to identify key taxa.

This work will involve collaboration between machine learning scientists, biologists/ecologists, and social scientists. We will follow all data anonymity and privacy guidelines from Facebook and will also discuss data handling ethics in our working group. We will assess the ability of passive surveillance with image recognition to be used to target surveys to populations that may have higher frequency of contact with wildlife, and ultimately to target biological surveillance of human and animal populations. We will consider both the accuracy of the image recognition algorithms as well as implications for survey distributions, results interpretation, and ethical data practices. We will also compare the spatial distribution of human-animal contact patterns derived from image recognition with previously generated spillover risk maps based on joint occurrences of animal and human distributions (e.g., SARS-related CoV spillover risk from Sanchez et al. 2021 preprint).<sup>25</sup>

**Working Group 1 Activities:** Our working group will convene 12-15 experts from the social sciences, disease ecology, and computational sciences for an intensive, 3 day workshop. We will structure the workshop to focus first on data ethics in human behavioral surveying and image recognition surveillance and secondly on survey design and analysis planning, with specific attention to accounting for gaps or biases in survey distributions. We will center the workshop around the understanding that technological quick fixes are never enough and that data collection must address long term social, ecological, and economic realities to understand how people perceive, experience, and interact with the risk of and repercussions from spillover events. We will also address experiences and challenges in engaging longtime ethnographers and local leaders to understand what's at stake for communities engaging with online and field surveillance programs. Our working group will help mentor students part of the CSI Student Training Program, to facilitate information sharing and idea generation among undergraduate and master-level students. Working group 1 will also contribute to the CSI Seminar Series with cross-disciplinary topics such as AI image recognition (lead by a data scientist and bat biologist) and human-behavioral survey design (lead by an epidemiologist and medical anthropologist).

**Partners, Initial Working Group 1 Members, and Roles:** EHA (SP Mendelsohn): survey design and implementation, image recognition algorithm development and testing, novel data analyses. Facebook Data for Good (OP Pompe): survey implementation, image recognition algorithm development and testing, data ethics. University of Rochester (coPI Hoque): Image recognition algorithm development and testing. Georgetown University (coPI Mendenhall): Survey design with focus on ethnography and anthropology; online free listing/pile sorting game design; help lead expansion of WG to include emerging international leaders in social-behavioral science (e.g. Dr. Edna Bosire from Kenya). We will invite additional leaders from our extensive funded collaborations to be part of the Working Group for Aim 1.

## **Aim 2: Detecting zoonotic disease exposure at scale**

Animal-human contact is the necessary condition for spillover of potential pandemic, directly-transmitted viruses. While a small fraction of such encounters result in actual exposure or infection, such exposures are frequent given the total sum of encounters. Most such infections are never reported and rarely spread widely, and only a very rare subset become widespread in the human population<sup>42</sup>. Other viruses such as Lassa spill over thousands of times per year<sup>43</sup>. In areas of frequent spillover, the eco-evolutionary dynamics of "stuttering chains" of infection are what give rise to epidemics and pandemics<sup>44</sup>. Identifying populations where frequent exposure occurs is critical for deploying preventative measures and following viruses upstream to their wildlife hosts. Yet even large-scale surveillance projects cover too small populations and produce far too few detections to determine the most exposed geographic, demographic, or occupational groups at an actionable scale [REF<sup>2</sup>, showing PREDICT sampling efficiency]. This is for two reasons: the field and laboratory cost of surveilling populations interacting with wildlife interface and, and the low detection rates of the widely-used, molecular PCR or metagenomic approaches.

We aim to drastically increase the scale at which populations can be monitored for exposure to animal-origin viruses by developing and piloting novel tools and analyses needed to implement large-scale serological surveys. While metagenomic methods have been favored for their ability to capture genetic sequences of previously unknown viruses, serological methods can be used to detect exposure to known and unknown viruses using multiplex assays tailored with a mixture of sensitivities and specificities<sup>45</sup>. Serological tools can detect antibodies for months or years after viral infection, rather than the limited window of days or weeks using molecular methods, and thus can provide a much richer profile of populations where pandemics may emerge<sup>46</sup>. In this planning period, we will begin pilots to test the feasibility of two complementary approaches

---

Number: 1 Author: Kevin Olival Date: 9/21/2021 1:30:00 PM

Our work under PREDICT is relevant here, working with local community leaders to distribute results and the 'Living Safetly with bats book'. But how do we scale this? One idea is through a network of local leaders across the landscape, like a "Community One Health Volunteer" network.

---

Number: 2 Author: Kevin Olival Date: 10/1/2021 3:27:00 AM

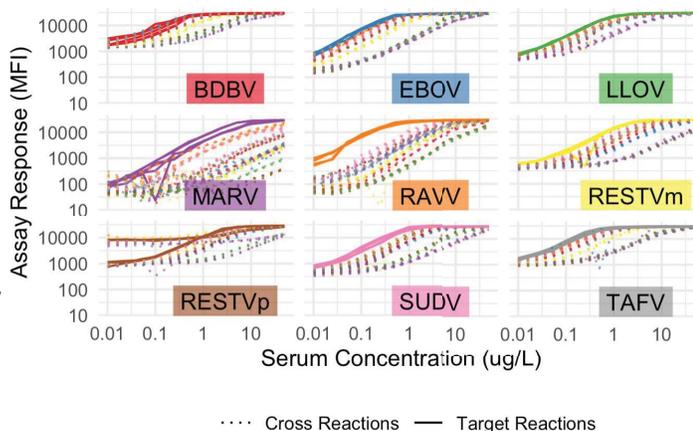

Noam, can you find a good one?

to enabling serological screening at large scales: 2a) the creation of rapid bioinformatics pipelines to interpret high-dimensional serological data from large streams of surveillance data, and 2b) the development of rapid field serological tests for wildlife-origin diseases.

## Aim 2 Pilot Research Projects

### 2a. Rapid bioinformatics for high-throughput, multiplex serology

Members of our team (SP Laing, Broder) have developed multiplex serology tests that can be used to screen for exposure for many species and variants of filo-, henipa-, and coronaviruses simultaneously, and screening pipelines that can process samples at the scale of tens of thousands of samples. However, these tests pose challenges for interpretation, as high-dimensional results from multiplex bead or chip assays frequently contain signals of cross-reaction and autocorrelation (**Fig 3**). Through cross-disciplinary research between molecular virologists, serologists, mathematical modelers and data scientists on our team, we will create models to interpret this high-dimensional data and integrate them into a rapid bioinformatic pipeline that identifies individuals and populations to known viruses as well as flagging serological signals indicative of novel viruses. We will make use of data collected under our ongoing NIH and DTRA funded biosurveillance activities (Laing, Broder, Ross, Olival, Daszak) to develop detailed reaction/cross reaction profiles of a broad panel of zoonotic viruses to serological tests. We will build mechanistic, hierarchical Bayesian models that allow us to determine whether serological “profiles” are more likely to represent antibodies of known viruses, mixtures of multiple known viruses, or previously uncharacterized viruses. We will extend techniques of antigenic mapping,<sup>47</sup> using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential. Using simulation experiments, we will test reduced-form, simple models against fully structured models so as to develop statistically robust procedures to interpret these data without high-performance computation.

**Fig 3.** Preliminary data: Reaction-cross reaction plots of multiplex Luminex assay response to antibodies for closely-related filoviruses.

**Scaling center operations:** This pilot project will produce methods and a proof-of-concept pipeline for high-throughput analyses. We will leverage EHA’s Emerging Infectious Disease – Southeast Asia Research Hub (EID-SEARCH) project, a NIH-funded Center for Research in Emerging Infectious Diseases (PI Daszak) who’s partners include USU, Duke NUS, Chulalongkorn University in Thailand, and various clinics and institutions in Malaysia – currently screening large numbers of human samples (>10K/yr) for various coronavirus, filovirus, and paramyxovirus antibodies. In the future the CSI will implement surveillance studies screening these sample streams using multiplex serology, and utilize the analytical and bioinformatic tools we develop in the next 18 months. As part of our planning activities, we will establish protocols and approvals for this work.

## **2b. Development of a field-ready semi-quantitative lateral flow assays for an emerging zoonotic viruses (Nipah virus)**

Lateral flow assays (LFAs), are low-cost tests where reagents printed on cellulose strips react with a sample that flows via diffusion. LFAs are capable of providing quantitative results (in proportion to antibody titer) using a combination of high-quality manufacturing and carefully designed, calibrated optical scans<sup>48</sup>. LFAs can be used to provide diagnostics at low cost at the point of care and by consumers. Lack of commercial-scale applications has prevented LFAs from being used for serological testing for novel or emerging disease. To our knowledge, no studies have used LFAs for zoonotic virus serosurveillance in the field.

We will develop a proof-of-concept LFA for Nipah Virus (NiV). NiV has a high mortality rate and is considered to have pandemic potential that is ranked by CEPI as one of 7 high pandemic risk pathogens<sup>49</sup>. The range of NiV's primary wildlife hosts (*Pteropus spp*, fruit bats) cover South and Southeast Asia but human cases have only been detected in Malaysia, Bangladesh, and the Philippines. Spillovers occur regularly in Bangladesh, but are rarely reported in large portions of the country<sup>50</sup> and reporting is strongly associated with health care accessibility<sup>51</sup>. Broad-scale serological monitoring has the potential to identify populations from which pandemic strains may emerge. Through previous work, members of our working group (Laing, Broder) have developed multiplex serological assays for NiV<sup>52</sup> and the soluble proteins and reagents required for an LFA. We have also added experience in engineering, quality control and commercialization of LFAs (Busa, industry consultant) to our working group. For the pilot, we will engage with commercial manufacturers to create and test a prototype Nipah LFA and a protocol for smartphone-based optical reading of quantitative responses.

**Scaling center operations:** The pilot will create a prototype LFAs. As part of full center operations under CSI, we will aim to scale up production and test LFAs efficacy using control sera and field deployment as part of EID-SEARCH. We will additionally assess feasibility and cost of deployment, and compare performance against current laboratory-based assays.

**Working Group 2 Activities:** In addition to the two pilots above, working group members will contribute to the our CSI monthly seminar series, presenting on topics including high-dimensional data models, field serology, serological assay development, laboratory product design, and public-private partnerships and commercialization. We will conduct two online workshops on serological data analysis, jointly with undergraduate, masters, and doctoral students at USU and UR, leveraging partnerships with field researchers currently working in serological surveillance. Our working group will lead a 3-day intensive workshop, where we will recruit additional participants with expertise in serological assay design and surveillance, immunology, emerging zoonoses, and focus discussion on key barriers to scaling serological surveillance for known and unknown zoonotic viruses.

**Partners, Initial Working Group 2 Members, and Roles:** EHA (coPI Ross): Model and pipeline design, software optimization. Uniformed Services University (SP Liaing, SP Broder): data and model interpretation, reagent manufacture, assay design. SP Busa: device manufacturing, quality control, industry outreach and partnership development. We will recruit additional participants from our partner network engaged in serological field studies as well as industry representatives to be part of the Working Group for Aim 2.

### **Aim 3: Rapidly Identifying Anomalous Health Events**

In early stages of epidemic spread, novel contact and mobility-induced behavioral data as well as communication patterns may provide a signal of e.g., health-seeking activity indicative of an outbreak cluster. We contend that these signals may be detectable in large-scale data streams of population mobility and contact, or disease reporting available through telecommunications and health care providers. Timely detection requires approaches that can manage data at scale,

analyze high-dimensional, spatio-temporally correlated streaming data in (pseudo) real time, and distinguish between known signals (e.g., typical influenza-related activity) and novel spillover-related signatures that we wish to unveil, characterize, and explain in order to trigger the necessary public policy responses.

This desideratum calls for fundamental methodological and computational advances, to go along with epidemiologically-relevant data sources that describe how humans are moving and interacting across physical space, with unprecedented temporal resolution and geographical coverage. Traditional flow-based mobility datasets used to parameterize epidemiological models have been aggregated and formatted in the form of origin-destination (OD) matrices. While valuable towards understanding population flows between regions of interest, OD matrices lack information on how much time a traveler spends in any given location. Naturally, when it comes to epidemiological studies the duration of time spent in potentially risky geographical areas is key towards deciphering actionable contact and exposure patterns<sup>53</sup>. Moreover, recent studies have shown that flow counts between pairs of geographical areas can be loosely correlated with, and not representative of, epidemiology-relevant mixing patterns<sup>54</sup>. Instead, these couplings among subpopulations are measured by effective contact rates, meaning how often people from each region come into contact in a way that is sufficient to transmit a disease. To address these challenges, our consortium will partner with the Facebook Data for Good team and leverage two recently assembled global-scale datasets - Activity Space Maps and Colocation Maps<sup>53,54</sup>.

Different from existing approaches that have focused on measuring the causal impact of mobility-oriented interventions, **our ambitious goal in this aim is to markedly advance the surveillance infrastructure available to predict anomalous health-related events before a major outbreak occurs.** While undoubtedly a multi-faceted endeavor, in this planning grant we will take initial, but significant steps with an emphasis on network-centric, computational analyses of dynamic mobility and interaction data at a global scale. By developing the appropriate statistical tools, we will support the ultimate goal of characterizing early pandemic “fingerprints” or signatures that can be extracted from these global datasets.

**Aim 3 Pilot Research Projects:** Working closely with Facebook Data for Good (see Letter of Collaboration from Alex Pompe), this working group will pilot data-driven research activities to explore the feasibility of extracting early (post spillover) signals of epidemic onset from Activity Space Maps and Colocation Maps. Our multi-disciplinary working group brings together leading experts in systems engineering, AI for healthcare, data science, mathematical epidemiology, graph signal and information processing, privacy-preserving mobility data generation and management, human behavioral modeling, and environmental science. We believe the current team, consisting of a wide array expertise and partnership, will instigate the cross-pollination of ideas leading to center-level activities while making significant inroads towards addressing our grand challenge. We propose two specific pilot projects:

### ***3a. Spatio-temporal monitoring of spillover-induced activity anomalies in Southeast Asia***

*Activity Space Maps (ASMs)* are a novel global-scale movement and mobility data set which describes how people distribute their time through geographic space.<sup>53</sup> They are designed to complement existing digitally-collected mobility datasets by quantifying the amount of time that people spend in different locations. Accordingly, this information is valuable for estimating the duration of contact with the environment and the potential risk of exposure to disease -- something critical especially early after spillover. More germane to the theme of this aim, it also offers the unique possibility of developing and testing sequential change-point detection algorithms to monitor multiple spatial grid cells of interest (informed, for instance, by outcomes

of the image-recognition effort under Aim 1). We will target areas known to include health care facilities in pursuit of abnormal trends of (increased) activity. Moreover, using ASMs we will examine flow and temporal activity anomalies around expert-annotated wildlife and wet market locations. Said events are expected if there are human infections, or significant associated changes in behavior around these sites early after spillover. Our initial efforts during this planning grant will be focused on Southeast Asia, which on top of its epidemiological relevance is one of the regions where Facebook ASMs have the most coverage. We will target Indonesia, where EHA has extensive on-the-ground efforts tracing networks of wildlife trade as well as market sites.<sup>55</sup> We will also tap into the resources stemming from EHA's Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) to identify clinics and market sites of interest in Thailand and Malaysia. Some key challenges we will address include accounting for the implicit biases in data collection associated with the construction of ASMs,<sup>53</sup> and their subsequent effects on the statistical algorithms that we will develop. Our Working Group will address additional challenges of data interpretation of anomaly detection analyses with input from emerging disease experts and epidemiologists. To calibrate our models, we will bring to bear recent activity data before and after the SARS-CoV-2 outbreak in those locations, in addition to historical influenza seasonal trends that go further back in time. With the exciting prospect of ASM data being officially released in the last quarter of 2021, *we are in a privileged position to be the first multi-disciplinary team that leverages this invaluable global-scale resource to advance our understanding of zoonotic spillover risk and its immediate effect on human mobility.*

### **3b. Online network change-point detection in dynamic, global-scale Colocation Maps**

Activity data are complemented by *Colocation Maps (CMs)*, which estimate how often people from different regions worldwide are colocated. In particular, for a pair of geographic regions  $i$  and  $j$  (e.g., counties in the US), CMs estimate the probability that a randomly chosen person from  $i$  and a randomly chosen person from  $j$  are simultaneously located in the same place during a randomly chosen minute in a given week.<sup>54</sup> In other words, CMs are global-scale, dynamic network datasets with colocation probabilities encoded as edge weights. Thus, they are well suited to parametrize metapopulation models of disease spread,<sup>56</sup> or to measure temporal changes in interactions between people from different regions.<sup>57</sup> To monitor said changes as part of our second pilot activity in this aim, we will build on our recent advances in online (i.e., sequential) algorithms for anomaly and change-point detection from network streams<sup>58,59</sup>; see also.<sup>60-62</sup> The envisioned statistical methods are in stark contrast with most existing graph change-point detection approaches, which either rely on extensive computation,<sup>63</sup> or they would require storing and processing the entire observed CM time series.<sup>64</sup> We will prototype and test a lightweight online change-point detection algorithm with quantifiable performance guarantees, that is also explainable since it relies on interpretable node embeddings; see e.g., *Hamilton\_Book*.<sup>58,65</sup> The latter desirable feature will be leveraged to construct dynamic anomaly maps for user-friendly visualization of post-spillover events; see also our recent network-scientific visualizations of spatio-temporal COVID-19 contagion patterns across the US.<sup>66</sup> Moreover, the sheer-size of the CM graphs calls for algorithmic and modeling innovations we will investigate as part of our research agenda, e.g., seamlessly integrating graph subsampling or dimensionality reduction techniques to the analytics pipeline. We will team up with computer vision experts affiliated to the University of Rochester Goergen Institute for Data Science (GIDS, see attached Letter of Collaboration from institute director Mujdat Cetin), to also explore the exciting prospect of integrating geo-tagged multimodal data such as video and imagery in our studies, for instance as nodal attributes embedded to the CMs.

**Working Group 3 Activities: *Recruitment and diversity:*** We will recruit 6 students from the GIDS-run master's program in data science, which attracts students from multidisciplinary backgrounds and significant computational proficiency to contribute in the aforementioned pilot research activities. *The CSI leadership and broader community are committed to providing research training and educational experiences for those traditionally under-represented in STEM, including women and underrepresented minority students.* The PI team has a solid track-record in actively recruiting and supervising such students at the undergraduate, masters and doctoral level, with demonstrated efforts towards broadening participation in STEM. As examples of the commitment to diversifying the field, co-PI Mateos serves as founding faculty advisor to the UR's SACNAS chapter and regularly organizes diversity, equity and inclusion panels to highlight challenges and successes of UR's Hispanic and Latino STEM community. We plan to prioritize engaging women and minority students in the research and working group activities proposed here. ***Coursework:*** These students will be on the existing health and bio track with an opportunity to take classes in immunology, microbiology and virology programs as well as data ethics at the University of Rochester Medical Center (URMC) as well as the college of engineering. Through the planning grant, we plan to establish a special MS track on 'zoonotic surveillance' in order to train and mentor the students to lead center level activities.

***Seminar and workshop series:*** The students will be part of the large cohort of all the participating institutions and participate in the CSI monthly seminar series. The co-PIs (Mateos and Hoque) will conduct two workshops (and invite additional faculty members from UR as guest speakers) with hands-on lessons in mobility and human behavior modeling.

***Hackathon:*** The students will be encouraged to participate in the yearly hackathon, Dandyhacks (<https://dandyhacks.net/>), organized every fall by the University of Rochester Computer Science Department and work with the dataset from Facebook. Additionally, co-PIs Mateos and Hoque will work with the organizers of dandyhacks to release some of the public dataset from Facebook for other teams to explore, model and mine the data.

***Data visualization meetups at the University of Rochester's VISTA Collaboratory:*** To get

acquainted with the different data resources at our disposal, over the first 3 months of the project the Rochester team (along with Facebook and EHA collaborators via Zoom) will hold bi-weekly team meetings with the MSc students at the UR's VISTA Collaboratory. This is a 1,000 square-foot visualization lab equipped with an interactive (20 ft. wide x 8 ft. tall) tiled-display wall, that renders massive data sets in real time, giving team members the ability to visualize and analyze complex data instantaneously and collaboratively; see Fig. 4. As we dissect what dataset components are central for the aforementioned pilot activities, our graduate students will develop customized data visualization tools, maps and dashboards to facilitate downstream analyses. Updates and progress reports will be shared in these meetings, giving the students a unique opportunity to develop their communication skills. The whole team will provide feedback and share ideas, making this a truly collaborative activity. Moving forward, the VISTA Collaboratory offers a unique resource that we will fruitfully leverage as we scale up to full center operation.

**Fig. 4.** UR's Vista Collaborative will serve as a spillover intelligence "situation room" for training UR and CSI exchange students on analysis of real-time epidemiologically relevant datasets.

**Partners, Initial Working Group 3 Members, and Roles:** University of Rochester (co-PIs Hoque and Mateos): coordination of working group activities, development and testing of computational tools for early detection of post-spillover signatures, dissemination of research products and educational materials, recruiting and mentoring of master students, liaisons to

GIDS. Facebook Data for Good (OP Pompe and Maps for Good team members Iyer and Citron): data ethics, quantification of privacy protections, data scientific support for Activity Space and Colocation Maps, mathematical epidemiology expertise for data and model interpretation. EHA (SP Mendelsohn and Ross): identification of target spatial locations in Southeast Asia, epidemiological interpretation of anomaly detection analyses and validation of detected early pandemic fingerprints.

**Scaling operations:** Our programs and pilot research are designed to scale. First, we aim to expand on successful pilots by expanding the geographies of our work, engaging with more in-country partners. Second, we test the development of each of these new streams of predictive data, we plan to develop partnerships with local, national, and global agencies to ingest these data, expand into programs to develop behavioral interventions and testing in response to identifying regions and populations at high risk of contracting zoonotic diseases.

Working groups are really about bringing our project to scale, our intensive 3-day workshop will also lead to new partnerships and synergies for expansion.

### Results from Prior NSF Support

**Kevin J. Olival** has not had prior NSF support, but is co-PI on NIH-funded “EID-SEARCH” (NIAID-CREID U01AI151797, 2020-25 PI Daszak). Previously co-PI on “Understanding the risk of bat coronavirus emergence” (NIAID R01 AI110964, 2014-2019, PI Daszak). **Intellectual merit:** Identified >50 SARSr-CoVs in bats, showed evidence of ability to infect human cells, humanized mouse models, and people in China, and used evolutionary and mammalian biodiversity patterns to analyze spillover risk for use in public health control. Produced 18 peer-reviewed papers<sup>20,34,67-79</sup>, including two papers in *Nature*<sup>80,81</sup>, and a review in *Cell*<sup>82</sup>, and others submitted. **Broader impacts:** 2 PhD and 6 MS students trained; disease risk and potential management strategies shared with US agencies, WHO, OIE, FAO, and the public.

**Ehsan Hoque: Project IIS-1750380.** PI: Hoque. Period (2018-23). Amount: \$511,453 “CAREER: A collaboration coach with effective intervention strategies to optimize group performance”. **Intellectual merit:** Developing and validating the efficacy of automated mediation strategies in online meetings. **Broader Impacts:** >6 research papers<sup>83-88</sup>. **Project NRT-DESE-1449828.** PI: Hoque (2015-21). Amount: \$2,965,341.00 “Graduate Training in Data-Enabled Research into Human Behavior and its Cognitive and Neural Mechanisms”. **Intellectual merit:** Chartering a new traineeship program to train Ph.D. students at the University of Rochester to advance discoveries at the intersection of computer science (cs), brain and cognitive sciences (bcs), and neuroscience. **Broader Impacts:** Supported over 50 PhD students in cs and bcs, several won interdisciplinary research positions at R1 institutes.

**Gonzalo Mateos** (a) Project: CCF-1750428. PI: Gonzalo Mateos Buckstein. Period: 4/1/18 - 3/31/23. Amount: \$407,944. (b) Title: CAREER: Inferring Graph Structure via Spectral Representations of Network Processes. (c) **Intellectual Merit:** We investigate how to use information available from graph signals to estimate the underlying network topology through innovative convex optimization approaches operating in the graph spectral domain. **Broader Impacts:** We prepared a feature article on identifying network structure via GSP,<sup>89</sup> presented tutorials in EUSIPCO'19, CAMSAP'19 an SSP'20, organized the 2019 IEEE SPS Summer School on Network- and Data-driven Learning. (d) Research products are available in.<sup>66,89-96</sup>

**Emily Mendenhall** (a) National Science Foundation Doctoral Dissertation Improvement Grant, \$10,000; Stories at the Border of Mind and Body: Mexican Immigrant Women’s Narratives of Distress and Diabetes. **Intellectual merit:** Led to crucial insights studying syndemics - the interactions of social, environmental, psychological, and biological factors that are synergies of epidemics. Papers in *The Lancet*<sup>29</sup>, *Medical Anthropology Quarterly*<sup>97-99</sup>, and as a full-length

book<sup>100</sup>. **Broader Impacts:** Understanding diabetes, trauma, and broader socio-political factors with infectious diseases in India, Kenya, South Africa, and Ethiopia.

Hi Kevin,

Amazing work, this reads really well. Attached are just some suggestions to fix a couple minor typos.

Something else I just caught on the solicitation (just before Section III - Award Information)

Several bullet points are listed under "Investigations that are outside the scope of this PIPP announcement include:" and one of them is:

- Projects that do not discuss associated risks and mitigation plans.

I do not think we have touched upon this explicitly in the proposal. Probably too late now, but if somebody finds a way to incorporate a paragraph that should be super.

Best,  
Gonzalo

## PROJECT DESCRIPTION

### Introduction and Background

The spillover and spread of novel, zoonotic pathogens can have tragic societal and economic impacts, as is evidenced by the ongoing COVID-19 pandemic. Unfortunately, the emergence of SARS-CoV-2 (the virus that causes COVID-19) is just the latest in a series of viral emergence events that have been accelerating over the last several decades. In just the last year, as the world continues to respond and adapt to COVID-19, we have seen several deadly zoonotic (animal origin) viruses re-emerge in the human population, including Ebola and Marburg in Guinea<sup>1,2</sup>, Nipah virus in India<sup>3</sup>, Rift Valley Fever virus in Kenya<sup>4</sup>, and novel strains of influenza in China [REF]. Most emerging infectious diseases (EIDs) originate in wildlife reservoir hosts and are transmitted across species boundaries, or (“spill over”), when livestock or human populations increase contact with wildlife through factors including land use change, agricultural intensification, and the wildlife trade<sup>5-7</sup>. Zoonotic spillover is a dynamic process determined by many steps including ‘pre-emergence’ viral evolution, diversification, and transmission among wildlife hosts; ‘human exposure’ via direct or indirect contact between humans, livestock, and wildlife; ‘post-exposure’ limits to cell entry, host range, human-to-human transmission; and population level virus amplification and spread. Once efficiently transmitted, EIDs can spread rapidly through globalized travel and trade networks, threatening countries with high population growth, urbanization and international trade (Fig 1).

**Fig 1.** Four stages of zoonotic disease emergence and spread, with gaps in knowledge at each stage. Our proposed project will develop and pilot novel, multidisciplinary and technological advances to address critical gaps in the first three stages of emergence, when pandemic prevention is possible.

Novel human EIDs are typically only discovered when they cause severe or unusual symptoms, when astute clinicians are linked with laboratories capable of pathogen discovery research, and after they have been transmitted from person to person (in which case control options become more difficult).<sup>7,8</sup> The emerging human viruses characterized to date likely represent just the tip of the iceberg given the hundreds of thousands of predicted zoonotic viruses that exist in nature and limited surveillance capacity globally<sup>9</sup>. New research has disrupted the paradigm that zoonotic disease spillover is a rare event. A combination of more advanced molecular and serological assays, improved laboratory capacity around the world, and targeted surveillance of “high risk” human populations have led to evidence of zoonotic virus transmission and infection, even in the absence of notable disease outbreaks. Often these spillover events lead to “dead end” infections in people or limited ‘stuttering’ chains of transmission, a phenomenon referred to as “viral chatter”<sup>10</sup>. Community-based serological surveys from our group and others have illuminated relatively frequent and previously-unknown instances of zoonotic virus spillover

including Henipaviruses in bat hunters from Cameroon<sup>11</sup>, SARS-related CoVs in rural communities living near caves in China (pre-2019), and Ebola virus exposure in DRC<sup>12</sup> and even Southeast Asia<sup>13</sup>

It is during these early stages of emergence, i.e. “viral chatter” with limited human transmission and even further upstream to include pre-emergence risk analyses at the human-animal interface, where innovative convergent research approaches are most needed for pandemic prevention. While we have made significant scientific advances over the last ~15 years in understanding where and through what mechanisms novel zoonotic viruses spill over into the human population<sup>5,14-17</sup>, there **are still fundamental knowledge (and implementation) gaps that stymie our ability to preempt and prevent future disease emergence events.**

### **Our Grand Challenge Problem**

Prior to 2019, EcoHealth Alliance (EHA) and colleagues demonstrated that SARS-related coronaviruses (SARSr-CoVs) in China pose a clear and present danger for a future human outbreak. We conducted extensive viral discovery in wildlife from China and Southeast Asia, phylogenetic analysis, and host-range experiments to show that certain bat species harbor a diverse assemblage of SARSr-CoVs<sup>18,19</sup>, as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics<sup>20-23</sup>. We conducted behavioral risk factor surveys and serological sampling from human populations living close to caves and found serological evidence of SARSr-CoV spillover in people exposed to wildlife<sup>24</sup>. Building on this body of knowledge, our recent models suggest that bat-origin SARSr-CoVs may be infecting 400,000 (median 50,000) people in Southeast Asia each year<sup>25</sup>. While confidence intervals around these estimates are large, our sensitivity analyses importantly identified key area for future research to improve these spillover risk models - notably, quantification and better contextual understanding of human-bat contact, the role of wildlife farming and livestock hosts, scaling up human serological surveys, and better data on sero-dynamics following novel SARSr-CoV exposure.<sup>25</sup>

**Despite this strong body of evidence for SARSr-CoV spillover risk (prior to the emergence of SARS-CoV-2), surveillance and research on these potential pathogens, their hosts, and their interface with humans was not conducted across a wide enough geography, nor at a temporal or spatial scale to inform actionable disease mitigation.** Even for large-scale efforts to strengthen zoonotic virus early warning systems, like the 10-year, 30 country USAID PREDICT program<sup>26</sup>, led by a global consortium including EHA, it's nearly impossible to capture enough data and disseminate that quickly enough to lead to widespread prevention measures at a national scale using existing methods – especially when considering multiple potential viral threats at once. This is especially true for large countries with heterogeneous human populations, diverse wildlife fauna, and known ecological and societal risk factors for emergence. Approaches to massively scale up zoonotic spillover surveillance are needed.

**Our grand challenge problem: "How can we capture actionable data about the risk of zoonotic spillover (and early spread) at the scale and speed required to prevent outbreaks?"** Can we leverage tools developed by computer scientists, data engineers, and technology companies to collect data from diverse populations and geographies to advance zoonotic spillover intelligence to a global scale? Can we incorporate new insights from medical anthropology, sociology, wildlife biology, disease ecology, molecular virology, biomedical assay design, and data science and use these to pioneer new methods in data collection and interpretation for zoonotic disease prediction and prevention? In this development proposal, we propose to build a collaborative research and training network to confront this challenge, designed at the start to scale up to a future Center for Spillover Intelligence (CSI). Our network will deeply integrate computer scientists, engineers, and data scientists using machine learning and other novel technological approaches together with experts in emerging disease and social-

behavioral research. New insights from social, behavioral, and anthropological research make it clear that the emergence and future trajectory of human epidemics require that we recognize potential biological risks alongside risks posed by cultural and societal factors<sup>27-29</sup>. Our cross-disciplinary, multi-institution project will combine synergistic research activities with training and education programs to facilitate new innovations to scale-up the collection and interpretation of data to inform where, how, and what zoonotic viruses are poised to emerge – a field we collectively refer to as *Spillover Intelligence*. Our inclusion of social-behavioral researchers, data ethicists, and inter-governmental EID policymakers will ensure that our aims and approaches are culturally and locally relevant, and align with our ultimate goal of improving global health.

**Our Vision:** We envision a world where diffuse data streams can be combined and interpreted in near real-time to disrupt the spillover and spread of future zoonotic viruses. We envision diverse leaders and scientific disciplines coming together to advance spillover intelligence and transform the ways we think about, monitor, and respond to global viral threats.

### **Our Team**

We have assembled a multidisciplinary team of experts to lead our development project and to create and grow the Center for Spillover Intelligence (CSI). Our **Leadership Team (PI, coPIs, Senior Personnel)** includes a mixture of established scientists and early career leaders working across the fields of: emerging infectious diseases, computer and data science, engineering, mathematical modeling, virology, technology and biotechnology, data ethics, social science, and medical anthropology. Our project will be led by EHA (PI Olival) building off the foundational pandemic prediction work our institution has developed over the last decade, but expanding to new partnerships and collaborations we have not previously been able to explore – including with computer scientists and engineers from University of Rochester (UR) and behavioral anthropologists from Georgetown University (GU). We will develop and pilot new technologies for field biosurveillance and data interpretation with Uniformed Services University (USU). Our Leadership Team is ethnically, culturally, and geographically diverse, including US-based researchers who originate from and/or currently conduct their primary research in global EID hotspot regions<sup>5,14</sup>, e.g. South Asia (Hoque); Latin America (Mateos); Africa (Mendenhall); and Southeast Asia and the Pacific (Olival). Our geographic and disciplinary diversity, including long-standing international collaborators from each region make our team well equipped to address spillover at a global scale, while understanding the importance of local context.

**PI Olival** (EHA) is a disease ecologist and evolutionary biologist with a primary interest in developing novel analyses to target zoonoses surveillance and viral discovery. He currently leads two regional biosurveillance projects in Southeast and Western Asia, and recently served as Modeling & Analytics Coordinator for the USAID PREDICT project<sup>26</sup> overseeing a multi-institution team developing pandemic prediction strategies using public and project-specific data from 30 countries<sup>5,15,30-35</sup>. **coPI Mendenhall** (GU) is a medical anthropologist and Professor at the Edmund A. Walsh School of Foreign Service. Mendenhall works at the intersection of social, psychological, and biological lives, attempting to understand what makes people sick, why, and where. Mendenhall is currently a PI of NIH Fogarty International Center grant “Soweto Syndemics”, the first ever study to evaluate a syndemic from the ground up. **coPI Hoque** (UR) is an Associate Professor of Computer Science working at the intersection of Human-centric Computing (HCC) and Artificial Intelligence with a focus on multimodal machine learning with applications in health and wellness. Hoque is currently a PI of NSF NRT grant, and received NSF CAREER and CRII grant. Hoque has been identified as an ‘emerging leader of health and medicine’ at the National Academy of Medicine (NAM). **coPI Mateos** (UR) is Assoc. Professor of Electrical and Computer Engineering and a Data Science Fellow, his research focuses on algorithmic foundations, analysis, application of (graph) signal processing tools to the study of large-scale and dynamic networks. He has pioneered foundational work in network topology

inference, online learning from graph streams, and interpretable representation learning for unstructured data. **coPI Ross** (EHA) is Principal Scientist for Computational Research. His research includes model development to interpret complex spatio-temporal disease surveillance data in heterogeneous populations, including from serological surveys, real-time community and hospital testing, and simulating and forecasting epidemic dynamics over populations, space, and networks. He is PI on awards from DHS Science & Technology Directorate and the Defense Threats Research Agency (DTRA) for designing disease forecasting systems. **SP Mendelsohn** (EHA) is a research data scientist specializing in the development and application of machine-learning models to draw insights into the occurrence and spread of emerging infectious diseases. With a focus on reproducible research methods and data management, she has been the lead analyst on data driven disease forecasting and behavioral survey-based projects characterizing animal-human contact patterns. **SP Daszak** (EHA) is an EID expert who has studied the process of disease emergence for decades and pioneered groundbreaking work in “hotspot” risk mapping to target surveillance. **SP Broder and Laing** (USU) are experts in the design of multiplex serological assays, molecular virology, and implementation of field-based human and wildlife biosurveillance strategies. **OP Busa** is a biotechnology consultant with a specialty in developing lateral flow assays and optical readers. **OP Pompe** is the Research Manager for Facebook Data for Good, who specializes in applying human mobility datasets from social media feeds and data privacy and ethical issues.

### Intellectual Merit

The primary intellectual merit of our proposed project is in **developing and piloting innovative approaches to pandemic prediction across previously siloed scientific domains** including biology, computer science, electrical engineering, and social-behavioral research. We apply new theoretical advances and convergent research to address our grand challenge of capturing actionable data about the risk of zoonotic spillover and early spread at a scale and speed required to prevent outbreaks. We will identify existing gaps and next-generation solutions for step-level changes in zoonotic spillover prediction via multi-day intensive workshops with thought-leaders organized by each of our three multidisciplinary Working Groups. Our pilot research projects will serve as a test bed for new theoretical frameworks to advance spillover intelligence. For example, in Aim 1 we will transform decades-old anthropological approaches and pilot a cost-effective, scale-up of quantitative and qualitative behavioral data collection through a unique public-private partnership Facebook; and use image recognition and artificial intelligence to quantify and map human-wildlife contact globally. In Aim 2 we will develop hierarchical Bayesian models to interpret rich, multiplex serology datasets and test these on real surveillance data as part of EHA’s NIH-funded work; and develop the first field-forward lateral-flow assay for Nipah virus antibody detection. In Aim 3 will use cutting edge theoretical advances in network science, anomaly detection, and machine learning to detect changes in human mobility patterns that may portend spillover (e.g. increase congregation around wildlife markets) or signal early epidemic spread after the point of spillover.

### Broader impacts

This proposal could potentially transform our understanding of zoonotic spillover risks using survey, multimedia, and mobility data on a global scale, including aggregated and anonymized data from ~3B active Facebook users. Insights and intellectual outputs from our working group activities will have direct benefits to public health by informing disease mitigation strategies for pandemic prevention. We will synthesize our three working group outputs and prepare a special joint publication for the National Academies of Science’s Forum on Microbial Threats for wide distribution, and write popular press articles to accompany our peer-reviewed manuscripts. EHA’s *Alliance*, includes a network of over 70 partner institutions in 30+ countries, presents a unique opportunity to work with local stakeholders in emerging virus ‘hotspots’ and validate

Peter, Ehsan, sound good?

models using data sets obtained through our long-standing collaboration with government partners including human health, agriculture, and environmental sectors.

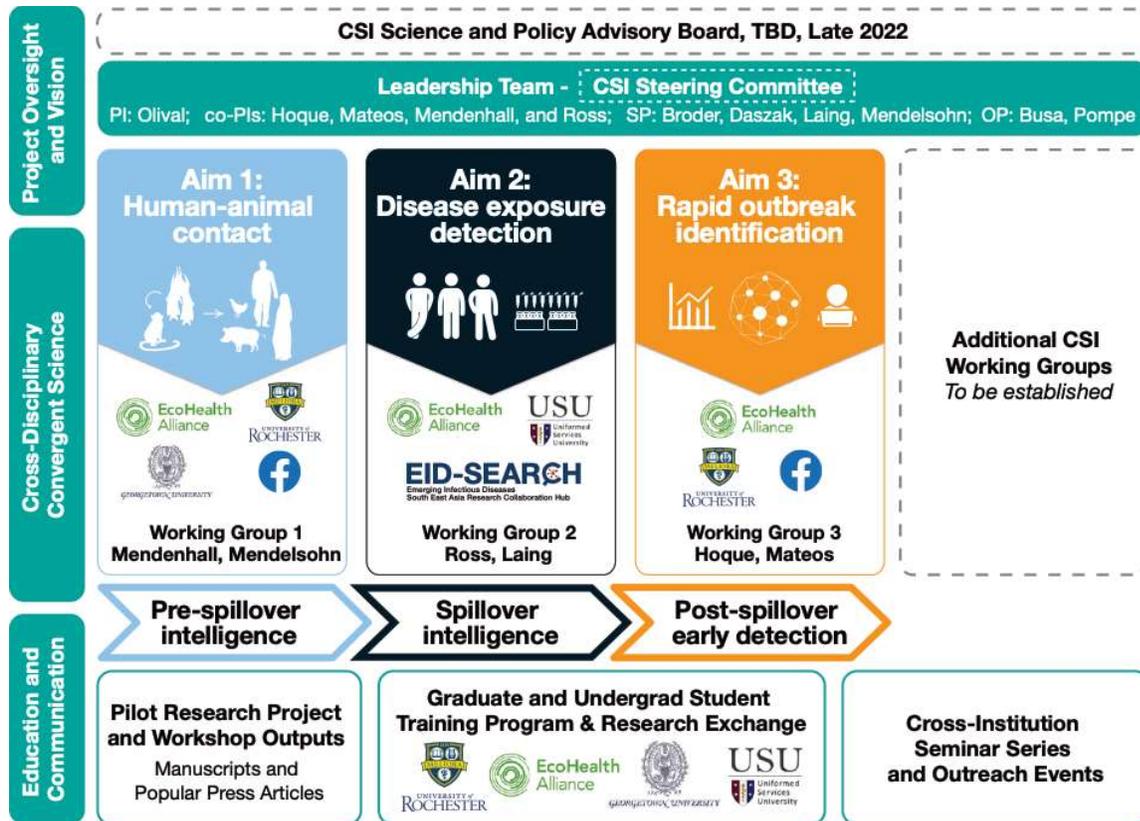

Our education mission consists of multiple workshops, hackathons, monthly seminar series, and access to state-of-the-art visualization facilities. We will begin to train a new generation of graduate and undergraduate students who will be prepared to harness the burgeoning power of data science to make novel inroads into understanding human-animal contact, serological surveillance, and aggregated mobility data and their interaction. Our proposal builds on a unique partnership between the academic (UR, GU, USU), non-profit (EHA), and private sector (FB), allowing students to apply lessons learned from classroom settings to the real-world, and our recruitment will focus on including >50% women and underrepresented minorities in science and engineering. This planning grant will be a path towards structuring interdisciplinary education, cross-training courses across institutions, followed by hands-on experience via internships and research exchanges – with options for international work via existing programs at our institutions. Through the planning grant, a new MS data science track on ‘zoonotic surveillance’ will be established at UR, the first step in our plans to expand our Education and Training plan should we move towards a Center-level award in the future.

### **Education and Training Plan**

Our Leadership Team will serve as mentors for our **CSI Student Training Program** that will offer a fellowship stipend to cross-train 20 Master’s level graduate students via semester-long projects associated with proposed pilot research activities (3-4 students per project) and 3-week research exchanges between our institutions (UR, GU, EHA, USU, 4-8 students from each). The research exchange builds off EHA’s successful NSF-funded EcoHealthNet training program (2011-21) and will take place in either the Summer of 2022 or 2023. We will link with currently-funded international programs at our respective institutions (e.g. Gui<sup>2</sup>de in Nairobi, Kenya run by GU; and the NIH funded CREID research pilot program with EHA’s EID-SEARCH project in Southeast Asia) to support students who desire to gain international, hands-on research experience as part of their research exchange. The focus of each research exchange will be on cross-disciplinary training to think ‘big’ about the future of pandemic prediction and ensure the next generation of spillover intelligence researchers gains valuable hands-on experience working with experts outside their area of study. Students will be drawn from respective departments across our institutions, i.e. students with a computational background and with interests in interdisciplinary work will be recruited from UR’s cross-department Goergen Institute for Data Science, Anthropology and International Affairs students from GU, and Emerging Disease and Virology students from USU. As EHA is a non-profit and does not have an active student body, we will recruit Ecology, Evolutionary Biology, and Environmental sciences students from universities in the NYC area, including Columbia University’s E3B department where PI Olival, coPI Ross and SP Daszak serve as adjunct faculty. We will explore specific mentorship opportunities with data scientists from Facebook. If awarded, we will additionally apply for funds through NSF’s Research Experiences for Undergraduates (REU) program, with the goal of supporting summer stipend for 1 undergraduate per institution or the maximum allowable. We will host a joint monthly virtual seminar series (2 semesters long) open to graduate and undergraduate students from our respective institutions, with a dedicated student “lab meeting” before each seminar. Two CSI students from diverse disciplines will lead each lab meeting discussion based on a deep read of relevant publications that each speaker will distribute in advance. We envision the first semester of the seminar series will be led by our Leadership Team and Working Group experts, and the second semester will be for CSI Graduate students to present results or current challenges related to their pilot research projects. We hope to encourage these students to pursue Ph.D. studies. If we are successful at establishing a center through our planning grant, we should have access to a trained cohort of students with appropriate multidisciplinary skillset.

## Project Overview

Our 18-month research agenda aims to understand how new methods and technologies can improve the efficiency, intensity, speed, and scope of zoonotic disease surveillance. **We have structured our development grant around three primary research aims** that will guide our interdisciplinary research and training activities. We will establish a working group composed of multi-disciplinary experts for each primary aim that will be co-led by members of our Leadership Team. We will develop pilot research projects that capture different parts of the disease spillover process focused on specific geographies, lead 3-day intensive workshops, monthly student seminars, and student training activities that cut across our inter-linked research aims.

**Fig 2. Project overview schematic** showing our project management; three primary aims with graphical representation of pilot research activities to scale up and advance spillover intelligence; institutional partners leading activities for each aim including designated working group leads, and student education and communication activities, including pilot research projects, graduate student research exchanges, seminars, and other outreach activities. Our development level project was built to scale to a Center level award (the Center for Spillover Intelligence, CSI) as noted with the dashed outline boxes, including the future addition of other CSI Working Groups, a Science and Policy Advisory Board, and transitioning our current Leadership Team (PI, coPIs and SP) into a more formal Steering Committee for oversight.

### Aim 1: Measuring human-animal contact at scale

Interactions among humans, wildlife, and livestock create interfaces for pathogen spillover and are proximate risk factors for the emergence of all directly-transmitted zoonotic diseases.<sup>14,36</sup> Human-animal contact is commonplace around the world, with many factors mediating the type and frequency of contact, including cultural practices, environmental conditions, food security, and occupational demands.<sup>36</sup> In regions of the world considered prone to spillover--forested tropical landscapes with high biodiversity and recent land-use changes--understanding human-

animal contact is crucial to pandemic prevention.<sup>5</sup> To measure these interactions and characterize associated behaviors, beliefs, and knowledge, researchers often implement resource-intensive surveys in key communities.<sup>37,38</sup> While crucial to understanding human-animal contact dynamics, on-the-ground surveys cannot yield scalable data that is comparable across populations. Often, in place of surveys, researchers conducting analyses at broad scales rely on coarse estimates of contact such as the joint density of human and animal populations. **Our working group will uniquely combine social scientists, disease ecologists, and computational scientists to increase the scale at which we can directly measure human-animal contact.** We will develop and implement two pilot research projects. The first will use novel, social-media-based survey approaches to reach larger populations at higher frequencies while maintaining the cultural sensitivity and relevance of on-the-ground surveys. Working collaboratively with cross-disciplinary researchers, we will design surveys to understand social behaviors, cultural perceptions, and occupational hazards that may pose zoonotic spillover risk to individuals and communities. We will target geographies based on our existing spatial risk modeling work that maps infectious disease spillover potential and the ecological distributions of key reservoir host species.<sup>5,15,25</sup> Second, we will conduct pilot research on the use of social-media-based image recognition algorithms to identify locations of human contact with key species known to host high pathogen diversity. This pilot will include a collaboration effort to test the efficacy of such technology for understanding taxon-specific contact patterns globally, and to bring multidisciplinary context to meaningfully interpret the outputs (including species validation with taxonomic experts). If successful, will use these data on frequency of animal contact from image data to identify locations for additional survey data collection.

**Aim 1 Pilot Research Projects:** We will develop two pilot projects to assess the potential of 1a) social-media dispensed surveys and 1b) passive surveillance using artificial intelligence for image recognition to capture information about human-animal contact. We will target populations at wildland interfaces where contact with wildlife is likely high but internet penetration may be mixed.

***1a. Social-media dispensed surveys to quantify and contextualize human-animal contact***

We will pilot social-media dispensed, large scale population surveys about perceptions of and interactions with animals. We will optimize the design of these surveys for mobile platforms to facilitate higher response rates, and will also explore the possibility of longitudinal sampling respondents (either individuals or populations) to understand changes in conditions and responses over time. Survey questions will be based on a combination of EHA's past experience designing on-the-ground human-animal contact surveys<sup>37,39,40</sup> and ideas generated from our proposed working group activities involving anthropologists, data scientists, and disease ecologists who have worked extensively in the geographic and societal contexts in which we focus our work. We will aim to design surveys that account for populations and individuals holding different beliefs, carrying different histories, and living in different ecologies. We will attempt to survey demographically and geographically diverse populations to capture direct and indirect animal-contact patterns and behaviors, and will attempt to capture the role that international, state, and local policy plays in individuals' lives. Further, we will aim to recognize particular hesitations among individuals to interact with certain technologies or other public health interventions.

We will explore various online platforms at the start of our project for survey administration. Given our unique public-private partnership with Facebook for many components of this project, using the Facebook platform to disseminate our pilot survey is likely to be a strong option, especially given Facebook's global reach (nearly half of the world's population, ~3 billion users), which introduces opportunities for digital interaction across class, gender, ethnicity, and cultural

divides. Facebook has extensive experience administering surveys, either directly on its platform (e.g. Yale Climate Change opinion survey) or off-platform (e.g. Carnegie Mellon University COVID-19 surveys) that we will leverage. Facebook also has extensive privacy infrastructure and data-review policies to ensure anonymity and data security.

We will also explore creating games that users will be encouraged to play online to enable us to learn more about how they think about host species, viral threats, environment, and health/disease. For example, users may be given a list of 30 images and will be asked to put them into categories and describe what each category means. Adapting these “pile sorting” anthropological methods<sup>41</sup> to an online interface and for spillover risk, will be a novel application with potential for a massive scale-up of data around cultural and conceptual dimensions of zoonotic disease risk. Data generated from this exercise will generate a more ethnographic understanding of people's experiences and thought processes, which tend to be locally mediated. We understand that there are geographic and demographic gaps in internet and social media use, and will incorporate bias corrections into our study design. We will initially focus on Southeast Asia, a region with a high likelihood of future zoonotic disease emergence and where EHA has good coverage of on-the-ground surveillance programs to ground truth online data collection<sup>5</sup>, and expand to new geographies as we develop Center-level activities.

### ***1b. Image recognition of zoonotic disease host species***

We will pilot image-based surveillance of Facebook and Instagram feeds to attempt to identify human contact with key zoonotic disease host species and to explore the limits of taxonomic and behavioral recognition in images. We will work with Facebook Data for Good (see **Letter of Collaboration**) to adapt and refine their existing machine vision algorithms to target key taxa and to assess the efficacy of different approaches, working within strict guidelines and ethical standards for data de-identification. While data will be de-identified, we will only use photos with full location meta-data, allowing us to not only quantify the type of species and contact, but where it occurred. There are multiple image libraries that may serve as AI training datasets, including iNaturalist, the American Society of Mammologists, and Integrated Digitized Biocollections (iDigBio). We will iteratively implement and test algorithms starting with broad taxonomic groups (e.g., bats) and will explore the extent to which our approaches can identify finer taxonomic resolutions down to the genus or species level. In addition to taxa identification, we will explore image recognition of features that may suggest specific types of human-animal contact, such as cages or market settings. Further, we will use text and image metadata and explore using hashtags associated with images to boost the ability of our algorithms to identify key taxa.

This work will involve collaboration between machine learning scientists, biologists/ecologists, and social scientists. We will follow all data anonymity and privacy guidelines from Facebook and will also discuss data handling ethics in our working group. We will assess the ability of passive surveillance with image recognition to be used to target surveys to populations that may have higher frequency of contact with wildlife, and ultimately to target biological surveillance of human and animal populations. We will consider both the accuracy of the image recognition algorithms as well as implications for survey distributions, results interpretation, and ethical data practices. We will also compare the spatial distribution of human-animal contact patterns derived from image recognition with previously generated spillover risk maps based on joint occurrences of animal and human distributions (e.g., SARS-related CoV spillover risk from Sanchez et al. 2021 preprint).<sup>25</sup>

**Working Group 1 Activities:** Our working group will convene 12-15 experts from the social sciences, disease ecology, and computational sciences for an intensive, 3 day workshop. We will structure the workshop to focus first on data ethics in human behavioral surveying and image recognition surveillance and secondly on survey design and analysis planning, with specific attention to accounting for gaps or biases in survey distributions. We will center the workshop around the understanding that technological quick fixes are never enough and that data collection must address long term social, ecological, and economic realities to understand how people perceive, experience, and interact with the risk of and repercussions from spillover events. We will also address experiences and challenges in engaging longtime ethnographers and local leaders to understand what's at stake for communities engaging with online and field surveillance programs. Our working group will help mentor students part of the CSI Student Training Program, to facilitate information sharing and idea generation among undergraduate and master-level students. Working group 1 will also contribute to the CSI Seminar Series with cross-disciplinary topics such as AI image recognition (lead by a data scientist and bat biologist) and human-behavioral survey design (lead by an epidemiologist and medical anthropologist).

**Partners, Initial Working Group 1 Members, and Roles:** EHA (SP Mendelsohn): survey design and implementation, image recognition algorithm development and testing, novel data analyses. Facebook Data for Good (OP Pompe): survey implementation, image recognition algorithm development and testing, data ethics. University of Rochester (coPI Hoque): Image recognition algorithm development and testing. Georgetown University (coPI Mendenhall): Survey design with focus on ethnography and anthropology; online free listing/pile sorting game design; help lead expansion of WG to include emerging international leaders in social-behavioral science (e.g. Dr. Edna Bosire from Kenya). We will invite additional leaders from our extensive funded collaborations to be part of the Working Group for Aim 1.

## **Aim 2: Detecting zoonotic disease exposure at scale**

Animal-human contact is the necessary condition for spillover of potential pandemic, directly-transmitted viruses. While a small fraction of such encounters result in actual exposure or infection, such exposures are frequent given the total sum of encounters. Most such infections are never reported and rarely spread widely, and only a very rare subset become widespread in the human population<sup>42</sup>. Other viruses such as Lassa spill over thousands of times per year<sup>43</sup>. In areas of frequent spillover, the eco-evolutionary dynamics of "stuttering chains" of infection are what give rise to epidemics and pandemics<sup>44</sup>. Identifying populations where frequent exposure occurs is critical for deploying preventative measures and following viruses upstream to their wildlife hosts. Yet even large-scale surveillance projects cover too small populations and produce far too few detections to determine the most exposed geographic, demographic, or occupational groups at an actionable scale [REF<sup>2</sup>, showing PREDICT sampling efficiency]. This is for two reasons: the field and laboratory cost of surveilling populations interacting with wildlife interface and, and the low detection rates of the widely-used, molecular PCR or metagenomic approaches.

We aim to drastically increase the scale at which populations can be monitored for exposure to animal-origin viruses by developing and piloting novel tools and analyses needed to implement large-scale serological surveys. While metagenomic methods have been favored for their ability to capture genetic sequences of previously unknown viruses, serological methods can be used to detect exposure to known and unknown viruses using multiplex assays tailored with a mixture of sensitivities and specificities<sup>45</sup>. Serological tools can detect antibodies for months or years after viral infection, rather than the limited window of days or weeks using molecular methods, and thus can provide a much richer profile of populations where pandemics may emerge<sup>46</sup>. In this planning period, we will begin pilots to test the feasibility of two complementary approaches

Our work under PREDICT is relevant here, working with local community leaders to distribute results and the 'Living Safetly with bats book'. But how do we scale this? One idea is through a network of local leaders across the landscape, like a "Community One Health Volunteer" network.

Number: 2 Author: Kevin Olival Date: 10/1/2021 3:27:00 AM

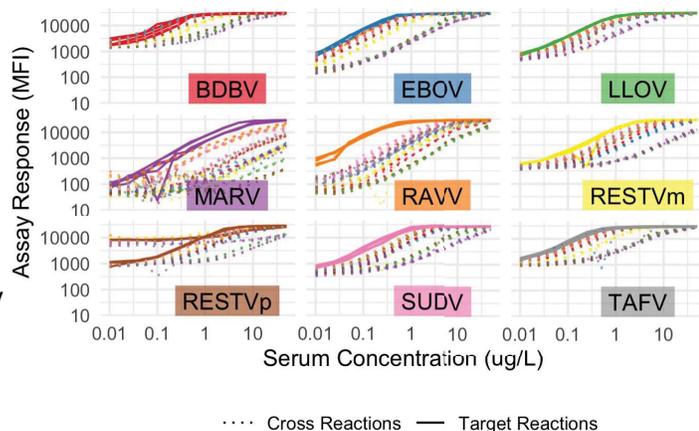

Noam, can you find a good one?

to enabling serological screening at large scales: 2a) the creation of rapid bioinformatics pipelines to interpret high-dimensional serological data from large streams of surveillance data, and 2b) the development of rapid field serological tests for wildlife-origin diseases.

## Aim 2 Pilot Research Projects

### 2a. Rapid bioinformatics for high-throughput, multiplex serology

Members of our team (SP Laing, Broder) have developed multiplex serology tests that can be used to screen for exposure for many species and variants of filo-, henipa-, and coronaviruses simultaneously, and screening pipelines that can process samples at the scale of tens of thousands of samples. However, these tests pose challenges for interpretation, as high-dimensional results from multiplex bead or chip assays frequently contain signals of cross-reaction and autocorrelation (**Fig 3**). Through cross-disciplinary research between molecular virologists, serologists, mathematical modelers and data scientists on our team, we will create models to interpret this high-dimensional data and integrate them into a rapid bioinformatic pipeline that identifies individuals and populations to known viruses as well as flagging serological signals indicative of novel viruses. We will make use of data collected under our ongoing NIH and DTRA funded biosurveillance activities (Laing, Broder, Ross, Olival, Daszak) to develop detailed reaction/cross reaction profiles of a broad panel of zoonotic viruses to serological tests. We will build mechanistic, hierarchical Bayesian models that allow us to determine whether serological “profiles” are more likely to represent antibodies of known viruses, mixtures of multiple known viruses, or previously uncharacterized viruses. We will extend techniques of antigenic mapping,<sup>47</sup> using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential. Using simulation experiments, we will test reduced-form, simple models against fully structured models so as to develop statistically robust procedures to interpret these data without high-performance computation.

**Fig 3.** Preliminary data: Reaction-cross reaction plots of multiplex Luminex assay response to antibodies for closely-related filoviruses.

**Scaling center operations:** This pilot project will produce methods and a proof-of-concept pipeline for high-throughput analyses. We will leverage EHA’s Emerging Infectious Disease – Southeast Asia Research Hub (EID-SEARCH) project, a NIH-funded Center for Research in Emerging Infectious Diseases (PI Daszak) who’s partners include USU, Duke NUS, Chulalongkorn University in Thailand, and various clinics and institutions in Malaysia – currently screening large numbers of human samples (>10K/yr) for various coronavirus, filovirus, and paramyxovirus antibodies. In the future the CSI will implement surveillance studies screening these sample streams using multiplex serology, and utilize the analytical and bioinformatic tools we develop in the next 18 months. As part of our planning activities, we will establish protocols and approvals for this work.

## **2b. Development of a field-ready semi-quantitative lateral flow assays for an emerging zoonotic viruses (Nipah virus)**

Lateral flow assays (LFAs), are low-cost tests where reagents printed on cellulose strips react with a sample that flows via diffusion. LFAs are capable of providing quantitative results (in proportion to antibody titer) using a combination of high-quality manufacturing and carefully designed, calibrated optical scans<sup>48</sup>. LFAs can be used to provide diagnostics at low cost at the point of care and by consumers. Lack of commercial-scale applications has prevented LFAs from being used for serological testing for novel or emerging disease. To our knowledge, no studies have used LFAs for zoonotic virus serosurveillance in the field.

We will develop a proof-of-concept LFA for Nipah Virus (NiV). NiV has a high mortality rate and is considered to have pandemic potential that is ranked by CEPI as one of 7 high pandemic risk pathogens<sup>49</sup>. The range of NiV's primary wildlife hosts (*Pteropus spp*, fruit bats) cover South and Southeast Asia but human cases have only been detected in Malaysia, Bangladesh, and the Philippines. Spillovers occur regularly in Bangladesh, but are rarely reported in large portions of the country<sup>50</sup> and reporting is strongly associated with health care accessibility<sup>51</sup>. Broad-scale serological monitoring has the potential to identify populations from which pandemic strains may emerge. Through previous work, members of our working group (Laing, Broder) have developed multiplex serological assays for NiV<sup>52</sup> and the soluble proteins and reagents required for an LFA. We have also added experience in engineering, quality control and commercialization of LFAs (Busa, industry consultant) to our working group. For the pilot, we will engage with commercial manufacturers to create and test a prototype Nipah LFA and a protocol for smartphone-based optical reading of quantitative responses.

**Scaling center operations:** The pilot will create a prototype LFAs. As part of full center operations under CSI, we will aim to scale up production and test LFAs efficacy using control sera and field deployment as part of EID-SEARCH. We will additionally assess feasibility and cost of deployment, and compare performance against current laboratory-based assays.

**Working Group 2 Activities:** In addition to the two pilots above, working group members will contribute to the our CSI monthly seminar series, presenting on topics including high-dimensional data models, field serology, serological assay development, laboratory product design, and public-private partnerships and commercialization. We will conduct two online workshops on serological data analysis, jointly with undergraduate, masters, and doctoral students at USU and UR, leveraging partnerships with field researchers currently working in serological surveillance. Our working group will lead a 3-day intensive workshop, where we will recruit additional participants with expertise in serological assay design and surveillance, immunology, emerging zoonoses, and focus discussion on key barriers to scaling serological surveillance for known and unknown zoonotic viruses.

**Partners, Initial Working Group 2 Members, and Roles:** EHA (coPI Ross): Model and pipeline design, software optimization. Uniformed Services University (SP Liaing, SP Broder): data and model interpretation, reagent manufacture, assay design. SP Busa: device manufacturing, quality control, industry outreach and partnership development. We will recruit additional participants from our partner network engaged in serological field studies as well as industry representatives to be part of the Working Group for Aim 2.

### **Aim 3: Rapidly Identifying Anomalous Health Events**

In early stages of epidemic spread, novel contact and mobility-induced behavioral data as well as communication patterns may provide a signal of e.g., health-seeking activity indicative of an outbreak cluster. We contend that these signals may be detectable in large-scale data streams of population mobility and contact, or disease reporting available through telecommunications and health care providers. Timely detection requires approaches that can manage data at scale,

analyze high-dimensional, spatio-temporally correlated streaming data in (pseudo) real time, and distinguish between known signals (e.g., typical influenza-related activity) and novel spillover-related signatures that we wish to unveil, characterize, and explain in order to trigger the necessary public policy responses.

This desideratum calls for fundamental methodological and computational advances, to go along with epidemiologically-relevant data sources that describe how humans are moving and interacting across physical space, with unprecedented temporal resolution and geographical coverage. Traditional flow-based mobility datasets used to parameterize epidemiological models have been aggregated and formatted in the form of origin-destination (OD) matrices. While valuable towards understanding population flows between regions of interest, OD matrices lack information on how much time a traveler spends in any given location. Naturally, when it comes to epidemiological studies the duration of time spent in potentially risky geographical areas is key towards deciphering actionable contact and exposure patterns<sup>53</sup>. Moreover, recent studies have shown that flow counts between pairs of geographical areas can be loosely correlated with, and not representative of, epidemiology-relevant mixing patterns<sup>54</sup>. Instead, these couplings among subpopulations are measured by effective contact rates, meaning how often people from each region come into contact in a way that is sufficient to transmit a disease. To address these challenges, our consortium will partner with the Facebook Data for Good team and leverage two recently assembled global-scale datasets - Activity Space Maps and Colocation Maps<sup>53,54</sup>.

Different from existing approaches that have focused on measuring the causal impact of mobility-oriented interventions, **our ambitious goal in this aim is to markedly advance the surveillance infrastructure available to predict anomalous health-related events before a major outbreak occurs.** While undoubtedly a multi-faceted endeavor, in this planning grant we will take initial, but significant steps with an emphasis on network-centric, computational analyses of dynamic mobility and interaction data at a global scale. By developing the appropriate statistical tools, we will support the ultimate goal of characterizing early pandemic “fingerprints” or signatures that can be extracted from these global datasets.

**Aim 3 Pilot Research Projects:** Working closely with Facebook Data for Good (see Letter of Collaboration from Alex Pompe), this working group will pilot data-driven research activities to explore the feasibility of extracting early (post spillover) signals of epidemic onset from Activity Space Maps and Colocation Maps. Our multi-disciplinary working group brings together leading experts in systems engineering, AI for healthcare, data science, mathematical epidemiology, graph signal and information processing, privacy-preserving mobility data generation and management, human behavioral modeling, and environmental science. We believe the current team, consisting of a wide array expertise and partnership, will instigate the cross-pollination of ideas leading to center-level activities while making significant inroads towards addressing our grand challenge. We propose two specific pilot projects:

### ***3a. Spatio-temporal monitoring of spillover-induced activity anomalies in Southeast Asia***

*Activity Space Maps (ASMs)* are a novel global-scale movement and mobility data set which describes how people distribute their time through geographic space.<sup>53</sup> They are designed to complement existing digitally-collected mobility datasets by quantifying the amount of time that people spend in different locations. Accordingly, this information is valuable for estimating the duration of contact with the environment and the potential risk of exposure to disease -- something critical especially early after spillover. More germane to the theme of this aim, it also offers the unique possibility of developing and testing sequential change-point detection algorithms to monitor multiple spatial grid cells of interest (informed, for instance, by outcomes

of the image-recognition effort under Aim 1). We will target areas known to include health care facilities in pursuit of abnormal trends of (increased) activity. Moreover, using ASMs we will examine flow and temporal activity anomalies around expert-annotated wildlife and wet market locations. Said events are expected if there are human infections, or significant associated changes in behavior around these sites early after spillover. Our initial efforts during this planning grant will be focused on Southeast Asia, which on top of its epidemiological relevance is one of the regions where Facebook ASMs have the most coverage. We will target Indonesia, where EHA has extensive on-the-ground efforts tracing networks of wildlife trade as well as market sites.<sup>55</sup> We will also tap into the resources stemming from EHA's Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) to identify clinics and market sites of interest in Thailand and Malaysia. Some key challenges we will address include accounting for the implicit biases in data collection associated with the construction of ASMs,<sup>53</sup> and their subsequent effects on the statistical algorithms that we will develop. Our Working Group will address additional challenges of data interpretation of anomaly detection analyses with input from emerging disease experts and epidemiologists. To calibrate our models, we will bring to bear recent activity data before and after the SARS-CoV-2 outbreak in those locations, in addition to historical influenza seasonal trends that go further back in time. With the exciting prospect of ASM data being officially released in the last quarter of 2021, *we are in a privileged position to be the first multi-disciplinary team that leverages this invaluable global-scale resource to advance our understanding of zoonotic spillover risk and its immediate effect on human mobility.*

### **3b. Online network change-point detection in dynamic, global-scale Colocation Maps**

Activity data are complemented by *Colocation Maps (CMs)*, which estimate how often people from different regions worldwide are colocated. In particular, for a pair of geographic regions  $i$  and  $j$  (e.g., counties in the US), CMs estimate the probability that a randomly chosen person from  $i$  and a randomly chosen person from  $j$  are simultaneously located in the same place during a randomly chosen minute in a given week.<sup>54</sup> In other words, CMs are global-scale, dynamic network datasets with colocation probabilities encoded as edge weights. Thus, they are well suited to parametrize metapopulation models of disease spread,<sup>56</sup> or to measure temporal changes in interactions between people from different regions.<sup>57</sup> To monitor said changes as part of our second pilot activity in this aim, we will build on our recent advances in online (i.e., sequential) algorithms for anomaly and change-point detection from network streams<sup>58,59</sup>; see also.<sup>60-62</sup> The envisioned statistical methods are in stark contrast with most existing graph change-point detection approaches, which either rely on extensive computation,<sup>63</sup> or they would require storing and processing the entire observed CM time series.<sup>64</sup> We will prototype and test a lightweight online change-point detection algorithm with quantifiable performance guarantees, that is also explainable since it relies on interpretable node embeddings.<sup>58,65</sup> The latter desirable feature will be leveraged to construct dynamic anomaly maps for user-friendly visualization of post-spillover events; see also our recent network-scientific visualizations of spatio-temporal COVID-19 contagion patterns across the US.<sup>66</sup> Moreover, the sheer-size of the CM graphs calls for algorithmic and modeling innovations we will investigate as part of our research agenda, e.g., seamlessly integrating graph subsampling or dimensionality reduction techniques to the analytics pipeline. We will team up with computer vision experts affiliated to the University of Rochester Goergen Institute for Data Science (GIDS, see attached Letter of Collaboration from institute director Mujdat Cetin), to also explore the exciting prospect of integrating geo-tagged multimodal data such as video and imagery in our studies, for instance as nodal attributes embedded to the CMs.

**Working Group 3 Activities: *Recruitment and diversity:*** We will recruit 6 students from the GIDS-run master’s program in data science, which attracts students from multidisciplinary backgrounds and significant computational proficiency to contribute in the aforementioned pilot research activities. *The CSI leadership and broader community are committed to providing research training and educational experiences for those traditionally under-represented in STEM, including women and underrepresented minority students.* The PI team has a solid track-record in actively recruiting and supervising such students at the undergraduate, masters and doctoral level, with demonstrated efforts towards broadening participation in STEM. As examples of the commitment to diversifying the field, co-PI Mateos serves as founding faculty advisor to the UR’s SACNAS chapter and regularly organizes diversity, equity and inclusion panels to highlight challenges and successes of UR’s Hispanic and Latino STEM community. We plan to prioritize engaging women and minority students in the research and working group activities proposed here. ***Coursework:*** These students will be on the existing health and bio track with an opportunity to take classes in immunology, microbiology and virology programs as well as data ethics at the University of Rochester Medical Center (URMC) as well as the college of engineering. Through the planning grant, we plan to establish a special MS track on ‘zoonotic surveillance’ in order to train and mentor the students to lead center level activities. ***Seminar and workshop series:*** The students will be part of the large cohort of all the participating institutions and participate in the CSI monthly seminar series. The co-PIs (Mateos and Hoque) will conduct two workshops (and invite additional faculty members from UR as guest speakers) with hands-on lessons in mobility and human behavior modeling. ***Hackathon:*** The students will be encouraged to participate in the yearly hackathon, Dandyhacks (<https://dandyhacks.net/>), organized every fall by the University of Rochester Computer Science Department and work with the dataset from Facebook. Additionally, co-PIs Mateos and Hoque will work with the organizers of Dandyhacks to release some of the public dataset from Facebook for other teams to explore, model and mine the data.

***Data visualization meetups at the University of Rochester’s VISTA Collaboratory:*** To get acquainted with the different data resources at our disposal, over the first 3 months of the project the Rochester team (along with Facebook and EHA collaborators via Zoom) will hold bi-weekly team meetings with the MSc students at the UR’s VISTA Collaboratory. This is a 1,000 square-foot visualization lab equipped with an interactive (20 ft. wide x 8 ft. tall) tiled-display wall, that renders massive data sets in real time, giving team members the ability to visualize and analyze complex data instantaneously and collaboratively; see Fig. 4. As we dissect what dataset components are central for the aforementioned pilot activities, our graduate students will develop customized data visualization tools, maps and dashboards to facilitate downstream analyses. Updates and progress reports will be shared in these meetings, giving the students a unique opportunity to develop their communication skills. The whole team will provide feedback and share ideas, making this a truly collaborative activity. Moving forward, the VISTA Collaboratory offers a unique resource that we will fruitfully leverage as we scale up to full center operation.

**Fig. 4.** UR’s Vista Collaborative will serve as a spillover intelligence “situation room” for training UR and CSI exchange students on analysis of real-time epidemiologically relevant datasets.

**Partners, Initial Working Group 3 Members, and Roles:** University of Rochester (co-PIs Hoque and Mateos): coordination of working group activities, development and testing of computational tools for early detection of post-spillover signatures, dissemination of research products and educational materials, recruiting and mentoring of master students, liaisons to

GIDS. Facebook Data for Good (OP Pompe and Maps for Good team members Iyer and Citron): data ethics, quantification of privacy protections, data scientific support for Activity Space and Colocation Maps, mathematical epidemiology expertise for data and model interpretation. EHA (SP Mendelsohn and Ross): identification of target spatial locations in Southeast Asia, epidemiological interpretation of anomaly detection analyses and validation of detected early pandemic fingerprints.

*Scaling center operations:* First, our working group intensive 3-day workshop are designed to lead to new partnerships and synergies for expansion of Aim 3 activities. Second, we will expand our pilot anomaly detection-- mobility data project to new geographies by including new data on georeferenced clinics, wildlife markets and other relevant locations by engaging with our in-country network of partners. Third, we test new streams of predictive data, e.g. mobile phone datasets, via expanded partnerships with public and private stakeholders to access and ingest these data. We will expand our policy engagement via EHA's *Alliance* and existing connections with WHO, FAO, the World Bank and others to develop behavioral risk interventions in the regions and populations we identify as high risk for zoonotic diseases.

**Associated Risks and Mitigation Plans:** We envision two primary risks associated with our proposed work 1) data access and privacy violations and 2) biosafety concerns inherent with emerging zoonoses research. For data related risks, we have already established a strong collaborative relationship with FB's Data for Good team in developing this proposal and have access to all the relevant datasets for our pilots. Data privacy concerns are taken seriously by our group, including deidentification of any personal identifying information, and we will adhere to strict protocols on using human subject data as outlined in our already approved IRBs as part of NIH-funded work. For biosafety related risks, there will be no active sample collection under our proposed NSF project, although we will use data leveraged from EHA's NIH-funded research. We have already secured appropriate approvals (IRB, IACUCs) that outline safety and PPE use and have established biosafety monitoring plans for this work. Our lateral flow assay development will be undertaken in laboratories designate at the appropriate Biosafety Level following US regulations (partner labs to be confirmed upon award).

### Results from Prior NSF Support

**Kevin J. Olival** has not had prior NSF support, but is co-PI on NIH-funded "EID-SEARCH" (NIAID-CREID U01AI151797, 2020-25 PI Daszak). Previously co-PI on "Understanding the risk of bat coronavirus emergence" (NIAID R01 AI110964, 2014-2019, PI Daszak). **Intellectual merit:** Identified >50 SARSr-CoVs in bats, showed evidence of ability to infect human cells, humanized mouse models, and people in China, and used evolutionary and mammalian biodiversity patterns to analyze spillover risk for use in public health control. Produced 18 peer-reviewed papers<sup>20,34,67-79</sup>, including two papers in *Nature*<sup>80,81</sup>, and a review in *Cell*<sup>82</sup>, and others submitted. **Broader impacts:** 2 PhD and 6 MS students trained; disease risk and potential management strategies shared with US agencies, WHO, OIE, FAO, and the public.

**Ehsan Hoque: Project IIS-1750380.** PI: Hoque. Period (2018-23). Amount: \$511,453 "CAREER: A collaboration coach with effective intervention strategies to optimize group performance". **Intellectual merit:** Developing and validating the efficacy of automated mediation strategies in online meetings. **Broader Impacts:** >6 research papers<sup>83-88</sup>. **Project NRT-DESE-1449828.** PI: Hoque (2015-21). Amount: \$2,965,341.00 "Graduate Training in Data-Enabled Research into Human Behavior and its Cognitive and Neural Mechanisms". **Intellectual merit:** Chartering a new traineeship program to train Ph.D. students at the University of Rochester to advance discoveries at the intersection of computer science (cs),

brain and cognitive sciences (bcs), and neuroscience. **Broader Impacts:** Supported over 50 PhD students in cs and bcs, several won interdisciplinary research positions at R1 institutes.

**Gonzalo Mateos** (a) Project: CCF-1750428. PI: Gonzalo Mateos Buckstein. Period: 4/1/18 - 3/31/23. Amount: \$407,944. (b) Title: CAREER: Inferring Graph Structure via Spectral Representations of Network Processes. (c) **Intellectual Merit:** We investigate how to use information available from graph signals to estimate the underlying network topology through innovative convex optimization approaches operating in the graph spectral domain. **Broader Impacts:** We prepared a feature article on identifying network structure via GSP,<sup>89</sup> presented tutorials in EUSIPCO'19, CAMSAP'19 and SSP'20, organized the 2019 IEEE SPS Summer School on Network- and Data-driven Learning. (d) Research products are available in.<sup>66,89-96</sup>

**Emily Mendenhall** (a) National Science Foundation Doctoral Dissertation Improvement Grant, \$10,000; Stories at the Border of Mind and Body: Mexican Immigrant Women's Narratives of Distress and Diabetes. **Intellectual merit:** Led to crucial insights studying syndemics - the interactions of social, environmental, psychological, and biological factors that are synergies of epidemics. Papers in *The Lancet*<sup>29</sup>, *Medical Anthropology Quarterly*<sup>97-99</sup>, and as a full-length book<sup>100</sup>. **Broader Impacts:** Understanding diabetes, trauma, and broader socio-political factors with infectious diseases in India, Kenya, South Africa, and Ethiopia.

---

Dear ALL,

See page 15 on the attached. I accepted Gonzalo's minor edits and revised the scaling operations section on p15 and added in a "Associated Risks and Mitigation Plans" section... but now we're a bit more over length, so need to cut back more. How does this new section look?? Missing any big risks?

**Associated Risks and Mitigation Plans:** We envision two primary risks associated with our proposed work 1) data access and privacy violations, and 2) biosafety concerns inherent with emerging zoonoses research. For data related risks, we have already established a strong collaborative relationship with FB's Data for Good team in developing this proposal and already have access to all the relevant datasets for our pilots. Data privacy concerns are taken seriously by our group, including deidentification of any personal identifying information following strict protocols on using human subject data from FB and our already approved IRBs as part of EHA's NIH-funded work. We will amend or apply for additional IRBs as needed. For biosafety related risks, there will be no active sample collection under our proposed NSF project. We have already secured appropriate approvals (IRB, IACUCs, sampling permits) that outline PPE use and biosafety monitoring plans for our NIH-funded work. Our lateral flow assay development will be undertaken in laboratories designate at the appropriate Biosafety Level following US regulations (USU and other partner labs to be confirmed upon award).

## PROJECT DESCRIPTION

### Introduction and Background

The spillover and spread of novel, zoonotic pathogens can have tragic societal and economic impacts, as is evidenced by the ongoing COVID-19 pandemic. Unfortunately, the emergence of SARS-CoV-2 (the virus that causes COVID-19) is just the latest in a series of viral emergence events that have been accelerating over the last several decades. In just the last year, as the world continues to respond and adapt to COVID-19, we have seen several deadly zoonotic (animal origin) viruses re-emerge in the human population, including Ebola and Marburg in Guinea<sup>1,2</sup>, Nipah virus in India<sup>3</sup>, Rift Valley Fever virus in Kenya<sup>4</sup>, and novel strains of influenza in China [REF]. Most emerging infectious diseases (EIDs) originate in wildlife reservoir hosts and are transmitted across species boundaries, or (“spill over”), when livestock or human populations increase contact with wildlife through factors including land use change, agricultural intensification, and the wildlife trade<sup>5-7</sup>. Zoonotic spillover is a dynamic process determined by many steps including ‘pre-emergence’ viral evolution, diversification, and transmission among wildlife hosts; ‘human exposure’ via direct or indirect contact between humans, livestock, and wildlife; ‘post-exposure’ limits to cell entry, host range, human-to-human transmission; and population level virus amplification and spread. Once efficiently transmitted, EIDs can spread rapidly through globalized travel and trade networks, threatening countries with high population growth, urbanization and international trade (Fig 1).

**Fig 1.** Four stages of zoonotic disease emergence and spread, with gaps in knowledge at each stage. Our proposed project will develop and pilot novel, multidisciplinary and technological advances to address critical gaps in the first three stages of emergence, when pandemic prevention is possible.

Novel human EIDs are typically only discovered when they cause severe or unusual symptoms, when astute clinicians are linked with laboratories capable of pathogen discovery research, and after they have been transmitted from person to person (in which case control options become more difficult).<sup>7,8</sup> The emerging human viruses characterized to date likely represent just the tip of the iceberg given the hundreds of thousands of predicted zoonotic viruses that exist in nature and limited surveillance capacity globally<sup>9</sup>. New research has disrupted the paradigm that zoonotic disease spillover is a rare event. A combination of more advanced molecular and serological assays, improved laboratory capacity around the world, and targeted surveillance of “high risk” human populations have led to evidence of zoonotic virus transmission and infection, even in the absence of notable disease outbreaks. Often these spillover events lead to “dead end” infections in people or limited ‘stuttering’ chains of transmission, a phenomenon referred to as “viral chatter”<sup>10</sup>. Community-based serological surveys from our group and others have illuminated relatively frequent and previously-unknown instances of zoonotic virus spillover

including Henipaviruses in bat hunters from Cameroon<sup>11</sup>, SARS-related CoVs in rural communities living near caves in China (pre-2019), and Ebola virus exposure in DRC<sup>12</sup> and even Southeast Asia<sup>13</sup>

It is during these early stages of emergence, i.e. “viral chatter” with limited human transmission and even further upstream to include pre-emergence risk analyses at the human-animal interface, where innovative convergent research approaches are most needed for pandemic prevention. While we have made significant scientific advances over the last ~15 years in understanding where and through what mechanisms novel zoonotic viruses spill over into the human population<sup>5,14-17</sup>, there **are still fundamental knowledge (and implementation) gaps that stymie our ability to preempt and prevent future disease emergence events.**

### **Our Grand Challenge Problem**

Prior to 2019, EcoHealth Alliance (EHA) and colleagues demonstrated that SARS-related coronaviruses (SARSr-CoVs) in China pose a clear and present danger for a future human outbreak. We conducted extensive viral discovery in wildlife from China and Southeast Asia, phylogenetic analysis, and host-range experiments to show that certain bat species harbor a diverse assemblage of SARSr-CoVs<sup>18,19</sup>, as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics<sup>20-23</sup>. We conducted behavioral risk factor surveys and serological sampling from human populations living close to caves and found serological evidence of SARSr-CoV spillover in people exposed to wildlife<sup>24</sup>. Building on this body of knowledge, our recent models suggest that bat-origin SARSr-CoVs may be infecting 400,000 (median 50,000) people in Southeast Asia each year<sup>25</sup>. While confidence intervals around these estimates are large, our sensitivity analyses importantly identified key area for future research to improve these spillover risk models - notably, quantification and better contextual understanding of human-bat contact, the role of wildlife farming and livestock hosts, scaling up human serological surveys, and better data on sero-dynamics following novel SARSr-CoV exposure.<sup>25</sup>

**Despite this strong body of evidence for SARSr-CoV spillover risk (prior to the emergence of SARS-CoV-2), surveillance and research on these potential pathogens, their hosts, and their interface with humans was not conducted across a wide enough geography, nor at a temporal or spatial scale to inform actionable disease mitigation.** Even for large-scale efforts to strengthen zoonotic virus early warning systems, like the 10-year, 30 country USAID PREDICT program<sup>26</sup>, led by a global consortium including EHA, it's nearly impossible to capture enough data and disseminate that quickly enough to lead to widespread prevention measures at a national scale using existing methods – especially when considering multiple potential viral threats at once. This is especially true for large countries with heterogeneous human populations, diverse wildlife fauna, and known ecological and societal risk factors for emergence. Approaches to massively scale up zoonotic spillover surveillance are needed.

**Our grand challenge problem: "How can we capture actionable data about the risk of zoonotic spillover (and early spread) at the scale and speed required to prevent outbreaks?"** Can we leverage tools developed by computer scientists, data engineers, and technology companies to collect data from diverse populations and geographies to advance zoonotic spillover intelligence to a global scale? Can we incorporate new insights from medical anthropology, sociology, wildlife biology, disease ecology, molecular virology, biomedical assay design, and data science and use these to pioneer new methods in data collection and interpretation for zoonotic disease prediction and prevention? In this development proposal, we propose to build a collaborative research and training network to confront this challenge, designed at the start to scale up to a future Center for Spillover Intelligence (CSI). Our network will deeply integrate computer scientists, engineers, and data scientists using machine learning and other novel technological approaches together with experts in emerging disease and social-

behavioral research. New insights from social, behavioral, and anthropological research make it clear that the emergence and future trajectory of human epidemics require that we recognize potential biological risks alongside risks posed by cultural and societal factors<sup>27-29</sup>. Our cross-disciplinary, multi-institution project will combine synergistic research activities with training and education programs to facilitate new innovations to scale-up the collection and interpretation of data to inform where, how, and what zoonotic viruses are poised to emerge – a field we collectively refer to as *Spillover Intelligence*. Our inclusion of social-behavioral researchers, data ethicists, and inter-governmental EID policymakers will ensure that our aims and approaches are culturally and locally relevant, and align with our ultimate goal of improving global health.

**Our Vision:** We envision a world where diffuse data streams can be combined and interpreted in near real-time to disrupt the spillover and spread of future zoonotic viruses. We envision diverse leaders and scientific disciplines coming together to advance spillover intelligence and transform the ways we think about, monitor, and respond to global viral threats.

### **Our Team**

We have assembled a multidisciplinary team of experts to lead our development project and to create and grow the Center for Spillover Intelligence (CSI). Our **Leadership Team (PI, coPIs, Senior Personnel)** includes a mixture of established scientists and early career leaders working across the fields of: emerging infectious diseases, computer and data science, engineering, mathematical modeling, virology, technology and biotechnology, data ethics, social science, and medical anthropology. Our project will be led by EHA (PI Olival) building off the foundational pandemic prediction work our institution has developed over the last decade, but expanding to new partnerships and collaborations we have not previously been able to explore – including with computer scientists and engineers from University of Rochester (UR) and behavioral anthropologists from Georgetown University (GU). We will develop and pilot new technologies for field biosurveillance and data interpretation with Uniformed Services University (USU). Our Leadership Team is ethnically, culturally, and geographically diverse, including US-based researchers who originate from and/or currently conduct their primary research in global EID hotspot regions<sup>5,14</sup>, e.g. South Asia (Hoque); Latin America (Mateos); Africa (Mendenhall); and Southeast Asia and the Pacific (Olival). Our geographic and disciplinary diversity, including long-standing international collaborators from each region make our team well equipped to address spillover at a global scale, while understanding the importance of local context.

**PI Olival** (EHA) is a disease ecologist and evolutionary biologist with a primary interest in developing novel analyses to target zoonoses surveillance and viral discovery. He currently leads two regional biosurveillance projects in Southeast and Western Asia, and recently served as Modeling & Analytics Coordinator for the USAID PREDICT project<sup>26</sup> overseeing a multi-institution team developing pandemic prediction strategies using public and project-specific data from 30 countries<sup>5,15,30-35</sup>. **coPI Mendenhall** (GU) is a medical anthropologist and Professor at the Edmund A. Walsh School of Foreign Service. Mendenhall works at the intersection of social, psychological, and biological lives, attempting to understand what makes people sick, why, and where. Mendenhall is currently a PI of NIH Fogarty International Center grant “Soweto Syndemics”, the first ever study to evaluate a syndemic from the ground up. **coPI Hoque** (UR) is an Associate Professor of Computer Science working at the intersection of Human-centric Computing (HCC) and Artificial Intelligence with a focus on multimodal machine learning with applications in health and wellness. Hoque is currently a PI of NSF NRT grant, and received NSF CAREER and CRII grant. Hoque has been identified as an ‘emerging leader of health and medicine’ at the National Academy of Medicine (NAM). **coPI Mateos** (UR) is Assoc. Professor of Electrical and Computer Engineering and a Data Science Fellow, his research focuses on algorithmic foundations, analysis, application of (graph) signal processing tools to the study of large-scale and dynamic networks. He has pioneered foundational work in network topology

inference, online learning from graph streams, and interpretable representation learning for unstructured data. **coPI Ross** (EHA) is Principal Scientist for Computational Research. His research includes model development to interpret complex spatio-temporal disease surveillance data in heterogeneous populations, including from serological surveys, real-time community and hospital testing, and simulating and forecasting epidemic dynamics over populations, space, and networks. He is PI on awards from DHS Science & Technology Directorate and the Defense Threats Research Agency (DTRA) for designing disease forecasting systems. **SP Mendelsohn** (EHA) is a research data scientist specializing in the development and application of machine-learning models to draw insights into the occurrence and spread of emerging infectious diseases. With a focus on reproducible research methods and data management, she has been the lead analyst on data driven disease forecasting and behavioral survey-based projects characterizing animal-human contact patterns. **SP Daszak** (EHA) is an EID expert who has studied the process of disease emergence for decades and pioneered groundbreaking work in “hotspot” risk mapping to target surveillance. **SP Broder and Laing** (USU) are experts in the design of multiplex serological assays, molecular virology, and implementation of field-based human and wildlife biosurveillance strategies. **OP Busa** is a biotechnology consultant with a specialty in developing lateral flow assays and optical readers. **OP Pompe** is the Research Manager for Facebook Data for Good, who specializes in applying human mobility datasets from social media feeds and data privacy and ethical issues.

### Intellectual Merit

The primary intellectual merit of our proposed project is in **developing and piloting innovative approaches to pandemic prediction across previously siloed scientific domains** including biology, computer science, electrical engineering, and social-behavioral research. We apply new theoretical advances and convergent research to address our grand challenge of capturing actionable data about the risk of zoonotic spillover and early spread at a scale and speed required to prevent outbreaks. We will identify existing gaps and next-generation solutions for step-level changes in zoonotic spillover prediction via multi-day intensive workshops with thought-leaders organized by each of our three multidisciplinary Working Groups. Our pilot research projects will serve as a test bed for new theoretical frameworks to advance spillover intelligence. For example, in Aim 1 we will transform decades-old anthropological approaches and pilot a cost-effective, scale-up of quantitative and qualitative behavioral data collection through a unique public-private partnership Facebook; and use image recognition and artificial intelligence to quantify and map human-wildlife contact globally. In Aim 2 we will develop hierarchical Bayesian models to interpret rich, multiplex serology datasets and test these on real surveillance data as part of EHA’s NIH-funded work; and develop the first field-forward lateral-flow assay for Nipah virus antibody detection. In Aim 3 will use cutting edge theoretical advances in network science, anomaly detection, and machine learning to detect changes in human mobility patterns that may portend spillover (e.g. increase congregation around wildlife markets) or signal early epidemic spread after the point of spillover.

### Broader impacts

This proposal could potentially transform our understanding of zoonotic spillover risks using survey, multimedia, and mobility data on a global scale, including aggregated and anonymized data from ~3B active Facebook users. Insights and intellectual outputs from our working group activities will have direct benefits to public health by informing disease mitigation strategies for pandemic prevention. We will synthesize our three working group outputs and prepare a special joint publication for the National Academies of Science’s Forum on Microbial Threats for wide distribution, and write popular press articles to accompany our peer-reviewed manuscripts. EHA’s *Alliance*, includes a network of over 70 partner institutions in 30+ countries, presents a unique opportunity to work with local stakeholders in emerging virus ‘hotspots’ and validate

Peter, Ehsan, sound good?

models using data sets obtained through our long-standing collaboration with government partners including human health, agriculture, and environmental sectors.

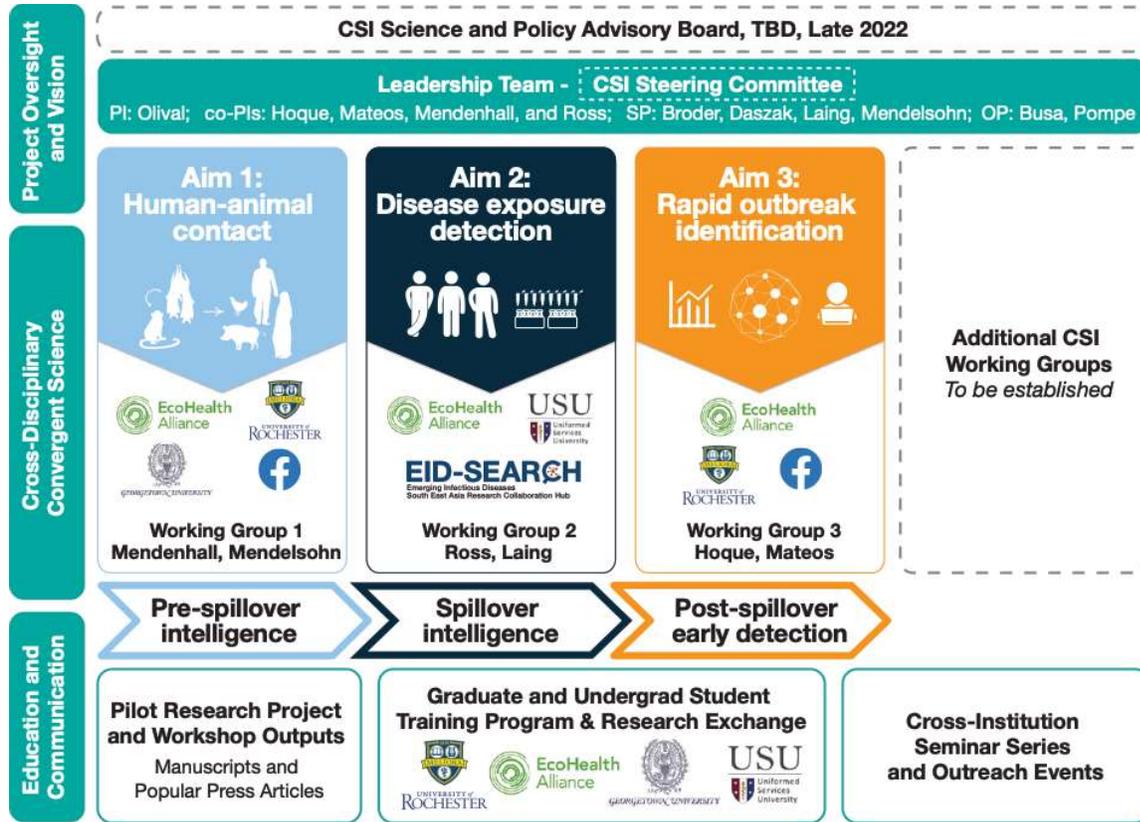

Our education mission consists of multiple workshops, hackathons, monthly seminar series, and access to state-of-the-art visualization facilities. We will begin to train a new generation of graduate and undergraduate students who will be prepared to harness the burgeoning power of data science to make novel inroads into understanding human-animal contact, serological surveillance, and aggregated mobility data and their interaction. Our proposal builds on a unique partnership between the academic (UR, GU, USU), non-profit (EHA), and private sector (FB), allowing students to apply lessons learned from classroom settings to the real-world, and our recruitment will focus on including >50% women and underrepresented minorities in science and engineering. This planning grant will be a path towards structuring interdisciplinary education, cross-training courses across institutions, followed by hands-on experience via internships and research exchanges – with options for international work via existing programs at our institutions. Through the planning grant, a new MS data science track on ‘zoonotic surveillance’ will be established at UR, the first step in our plans to expand our Education and Training plan should we move towards a Center-level award in the future.

### **Education and Training Plan**

Our Leadership Team will serve as mentors for our **CSI Student Training Program** that will offer a fellowship stipend to cross-train 20 Master’s level graduate students via semester-long projects associated with proposed pilot research activities (3-4 students per project) and 3-week research exchanges between our institutions (UR, GU, EHA, USU, 4-8 students from each). The research exchange builds off EHA’s successful NSF-funded EcoHealthNet training program (2011-21) and will take place in either the Summer of 2022 or 2023. We will link with currently-funded international programs at our respective institutions (e.g. Gui<sup>2</sup>de in Nairobi, Kenya run by GU; and the NIH funded CREID research pilot program with EHA’s EID-SEARCH project in Southeast Asia) to support students who desire to gain international, hands-on research experience as part of their research exchange. The focus of each research exchange will be on cross-disciplinary training to think ‘big’ about the future of pandemic prediction and ensure the next generation of spillover intelligence researchers gains valuable hands-on experience working with experts outside their area of study. Students will be drawn from respective departments across our institutions, i.e. students with a computational background and with interests in interdisciplinary work will be recruited from UR’s cross-department Goergen Institute for Data Science, Anthropology and International Affairs students from GU, and Emerging Disease and Virology students from USU. As EHA is a non-profit and does not have an active student body, we will recruit Ecology, Evolutionary Biology, and Environmental sciences students from universities in the NYC area, including Columbia University’s E3B department where PI Olival, coPI Ross and SP Daszak serve as adjunct faculty. We will explore specific mentorship opportunities with data scientists from Facebook. If awarded, we will additionally apply for funds through NSF’s Research Experiences for Undergraduates (REU) program, with the goal of supporting summer stipend for 1 undergraduate per institution or the maximum allowable. We will host a joint monthly virtual seminar series (2 semesters long) open to graduate and undergraduate students from our respective institutions, with a dedicated student “lab meeting” before each seminar. Two CSI students from diverse disciplines will lead each lab meeting discussion based on a deep read of relevant publications that each speaker will distribute in advance. We envision the first semester of the seminar series will be led by our Leadership Team and Working Group experts, and the second semester will be for CSI Graduate students to present results or current challenges related to their pilot research projects. We hope to encourage these students to pursue Ph.D. studies. If we are successful at establishing a center through our planning grant, we should have access to a trained cohort of students with appropriate multidisciplinary skillset.

## Project Overview

Our 18-month research agenda aims to understand how new methods and technologies can improve the efficiency, intensity, speed, and scope of zoonotic disease surveillance. **We have structured our development grant around three primary research aims** that will guide our interdisciplinary research and training activities. We will establish a working group composed of multi-disciplinary experts for each primary aim that will be co-led by members of our Leadership Team. We will develop pilot research projects that capture different parts of the disease spillover process focused on specific geographies, lead 3-day intensive workshops, monthly student seminars, and student training activities that cut across our inter-linked research aims.

**Fig 2. Project overview schematic** showing our project management; three primary aims with graphical representation of pilot research activities to scale up and advance spillover intelligence; institutional partners leading activities for each aim including designated working group leads, and student education and communication activities, including pilot research projects, graduate student research exchanges, seminars, and other outreach activities. Our development level project was built to scale to a Center level award (the Center for Spillover Intelligence, CSI) as noted with the dashed outline boxes, including the future addition of other CSI Working Groups, a Science and Policy Advisory Board, and transitioning our current Leadership Team (PI, coPIs and SP) into a more formal Steering Committee for oversight.

### Aim 1: Measuring human-animal contact at scale

Interactions among humans, wildlife, and livestock create interfaces for pathogen spillover and are proximate risk factors for the emergence of all directly-transmitted zoonotic diseases.<sup>14,36</sup> Human-animal contact is commonplace around the world, with many factors mediating the type and frequency of contact, including cultural practices, environmental conditions, food security, and occupational demands.<sup>36</sup> In regions of the world considered prone to spillover--forested tropical landscapes with high biodiversity and recent land-use changes--understanding human-

animal contact is crucial to pandemic prevention.<sup>5</sup> To measure these interactions and characterize associated behaviors, beliefs, and knowledge, researchers often implement resource-intensive surveys in key communities.<sup>37,38</sup> While crucial to understanding human-animal contact dynamics, on-the-ground surveys cannot yield scalable data that is comparable across populations. Often, in place of surveys, researchers conducting analyses at broad scales rely on coarse estimates of contact such as the joint density of human and animal populations. **Our working group will uniquely combine social scientists, disease ecologists, and computational scientists to increase the scale at which we can directly measure human-animal contact.** We will develop and implement two pilot research projects. The first will use novel, social-media-based survey approaches to reach larger populations at higher frequencies while maintaining the cultural sensitivity and relevance of on-the-ground surveys. Working collaboratively with cross-disciplinary researchers, we will design surveys to understand social behaviors, cultural perceptions, and occupational hazards that may pose zoonotic spillover risk to individuals and communities. We will target geographies based on our existing spatial risk modeling work that maps infectious disease spillover potential and the ecological distributions of key reservoir host species.<sup>5,15,25</sup> Second, we will conduct pilot research on the use of social-media-based image recognition algorithms to identify locations of human contact with key species known to host high pathogen diversity. This pilot will include a collaboration effort to test the efficacy of such technology for understanding taxon-specific contact patterns globally, and to bring multidisciplinary context to meaningfully interpret the outputs (including species validation with taxonomic experts). If successful, will use these data on frequency of animal contact from image data to identify locations for additional survey data collection.

**Aim 1 Pilot Research Projects:** We will develop two pilot projects to assess the potential of 1a) social-media dispensed surveys and 1b) passive surveillance using artificial intelligence for image recognition to capture information about human-animal contact. We will target populations at wildland interfaces where contact with wildlife is likely high but internet penetration may be mixed.

***1a) Social-media dispensed surveys to quantify and contextualize human-animal contact***

We will pilot social-media dispensed, large scale population surveys about perceptions of and interactions with animals. We will optimize the design of these surveys for mobile platforms to facilitate higher response rates, and will also explore the possibility of longitudinal sampling respondents (either individuals or populations) to understand changes in conditions and responses over time. Survey questions will be based on a combination of EHA's past experience designing on-the-ground human-animal contact surveys<sup>37,39,40</sup> and ideas generated from our proposed working group activities involving anthropologists, data scientists, and disease ecologists who have worked extensively in the geographic and societal contexts in which we focus our work. We will aim to design surveys that account for populations and individuals holding different beliefs, carrying different histories, and living in different ecologies. We will attempt to survey demographically and geographically diverse populations to capture direct and indirect animal-contact patterns and behaviors, and will attempt to capture the role that international, state, and local policy plays in individuals' lives. Further, we will aim to recognize particular hesitations among individuals to interact with certain technologies or other public health interventions.

We will explore various online platforms at the start of our project for survey administration. Given our unique public-private partnership with Facebook for many components of this project, using the Facebook platform to disseminate our pilot survey is likely to be a strong option, especially given Facebook's global reach (nearly half of the world's population, ~3 billion users), which introduces opportunities for digital interaction across class, gender, ethnicity, and cultural

divides. Facebook has extensive experience administering surveys, either directly on its platform (e.g. Yale Climate Change opinion survey) or off-platform (e.g. Carnegie Mellon University COVID-19 surveys) that we will leverage. Facebook also has extensive privacy infrastructure and data-review policies to ensure anonymity and data security.

We will also explore creating games that users will be encouraged to play online to enable us to learn more about how they think about host species, viral threats, environment, and health/disease. For example, users may be given a list of 30 images and will be asked to put them into categories and describe what each category means. Adapting these “pile sorting” anthropological methods<sup>41</sup> to an online interface and for spillover risk, will be a novel application with potential for a massive scale-up of data around cultural and conceptual dimensions of zoonotic disease risk. Data generated from this exercise will generate a more ethnographic understanding of people's experiences and thought processes, which tend to be locally mediated. We understand that there are geographic and demographic gaps in internet and social media use, and will incorporate bias corrections into our study design. We will initially focus on Southeast Asia, a region with a high likelihood of future zoonotic disease emergence and where EHA has good coverage of on-the-ground surveillance programs to ground truth online data collection.<sup>5</sup>

### **1b. Image recognition of zoonotic disease host species**

We will pilot image-based surveillance of Facebook and Instagram feeds to attempt to identify human contact with key zoonotic disease host species and to explore the limits of taxonomic and behavioral recognition in images. We will work with Facebook Data for Good (see **Letter of Collaboration**) to adapt and refine their existing machine vision algorithms to target key taxa and to assess the efficacy of different approaches, working within strict guidelines and ethical standards for data de-identification. While data will be de-identified, we will only use photos with full location meta-data, allowing us to not only quantify the type of species and contact, but where it occurred. There are multiple image libraries that may serve as AI training datasets, including iNaturalist, the American Society of Mammologists, and Integrated Digitized Biocollections (iDigBio). We will iteratively implement and test algorithms starting with broad taxonomic groups (e.g., bats) and will explore the extent to which our approaches can identify finer taxonomic resolutions down to the genus or species level. In addition to taxa identification, we will explore image recognition of features that may suggest specific types of human-animal contact, such as cages or market settings. Further, we will use text and image metadata and explore using hashtags associated with images to boost the ability of our algorithms to identify key taxa.

This work will involve collaboration between machine learning scientists, biologists/ecologists, and social scientists. We will follow all data anonymity and privacy guidelines from Facebook and will also discuss data handling ethics in our working group. We will assess the ability of passive surveillance with image recognition to be used to target surveys to populations that may have higher frequency of contact with wildlife, and ultimately to target biological surveillance of human and animal populations. We will consider both the accuracy of the image recognition algorithms as well as implications for survey distributions, results interpretation, and ethical data practices. We will also compare the spatial distribution of human-animal contact patterns derived from image recognition with previously generated spillover risk maps based on joint occurrences of animal and human distributions (e.g., SARS-related CoV spillover risk from Sanchez et al. 2021 preprint).<sup>25</sup>

**Working Group 1 Activities:** Our working group will convene 12-15 experts from the social sciences, disease ecology, and computational sciences for an intensive, 3 day workshop. We will structure the workshop to focus first on data ethics in human behavioral surveying and image recognition surveillance and secondly on survey design and analysis planning, with specific attention to accounting for gaps or biases in survey distributions. We will center the workshop around the understanding that technological quick fixes are never enough and that data collection must address long term social, ecological, and economic realities to understand how people perceive, experience, and interact with the risk of and repercussions from spillover events. We will also address experiences and challenges in engaging longtime ethnographers and local leaders to understand what's at stake for communities engaging with online and field surveillance programs. Our working group will help mentor students part of the CSI Student Training Program, to facilitate information sharing and idea generation among undergraduate and master-level students. Working group 1 will also contribute to the CSI Seminar Series with cross-disciplinary topics such as AI image recognition (lead by a data scientist and bat biologist) and human-behavioral survey design (lead by an epidemiologist and medical anthropologist).

**Partners, Initial Working Group 1 Members, and Roles:** EHA (SP Mendelsohn): survey design and implementation, image recognition algorithm development and testing, novel data analyses. Facebook Data for Good (OP Pompe): survey implementation, image recognition algorithm development and testing, data ethics. University of Rochester (coPI Hoque): Image recognition algorithm development and testing. Georgetown University (coPI Mendenhall): Survey design with focus on ethnography and anthropology; online free listing/pile sorting game design; help lead expansion of WG to include emerging international leaders in social-behavioral science (e.g. Dr. Edna Bosire from Kenya). We will invite additional leaders from our extensive funded collaborations to be part of the Working Group for Aim 1.

## **Aim 2: Detecting zoonotic disease exposure at scale**

Animal-human contact is the necessary condition for spillover of potential pandemic, directly-transmitted viruses. While a small fraction of such encounters result in actual exposure or infection, such exposures are frequent given the total sum of encounters. Most such infections are never reported and rarely spread widely, and only a very rare subset become widespread in the human population<sup>42</sup>. Other viruses such as Lassa spill over thousands of times per year<sup>43</sup>. In areas of frequent spillover, the eco-evolutionary dynamics of "stuttering chains" of infection are what give rise to epidemics and pandemics<sup>44</sup>. Identifying populations where frequent exposure occurs is critical for deploying preventative measures and following viruses upstream to their wildlife hosts. Yet even large-scale surveillance projects cover too small populations and produce far too few detections to determine the most exposed geographic, demographic, or occupational groups at an actionable scale [REF<sup>2</sup>, showing PREDICT sampling efficiency]. This is for two reasons: the field and laboratory cost of surveilling populations interacting with wildlife interface and, and the low detection rates of the widely-used, molecular PCR or metagenomic approaches.

We aim to drastically increase the scale at which populations can be monitored for exposure to animal-origin viruses by developing and piloting novel tools and analyses needed to implement large-scale serological surveys. While metagenomic methods have been favored for their ability to capture genetic sequences of previously unknown viruses, serological methods can be used to detect exposure to known and unknown viruses using multiplex assays tailored with a mixture of sensitivities and specificities<sup>45</sup>. Serological tools can detect antibodies for months or years after viral infection, rather than the limited window of days or weeks using molecular methods, and thus can provide a much richer profile of populations where pandemics may emerge<sup>46</sup>. In this planning period, we will begin pilots to test the feasibility of two complementary approaches

Our work under PREDICT is relevant here, working with local community leaders to distribute results and the 'Living Safetly with bats book'. But how do we scale this? One idea is through a network of local leaders across the landscape, like a "Community One Health Volunteer" network.

Noam, can you find a good one?

to enabling serological screening at large scales: 2a) the creation of rapid bioinformatics pipelines to interpret high-dimensional serological data from large streams of surveillance data, and 2b) the development of rapid field serological tests for wildlife-origin diseases.

## Aim 2 Pilot Research Projects

### 2a. Rapid bioinformatics for high-throughput, multiplex serology

Members of our team (SP Laing, Broder) have developed multiplex serology tests that can be used to screen for exposure for many species and variants of filo-, henipa-, and coronaviruses simultaneously, and screening pipelines that can process samples at the scale of tens of thousands of samples. However, these tests pose challenges for interpretation, as high-dimensional results from multiplex bead or chip assays frequently contain signals of cross-reaction and autocorrelation (**Fig 3**). Through cross-disciplinary research between molecular virologists, serologists, mathematical modelers and data scientists on our team, we will create models to interpret this high-dimensional data and integrate them into a rapid bioinformatic pipeline that identifies individuals and populations to known viruses as well as flagging serological signals indicative of novel viruses. We will make use of data collected under our ongoing NIH and DTRA funded biosurveillance activities (Laing, Broder, Ross, Olival, Daszak) to develop detailed reaction/cross reaction profiles of a broad panel of zoonotic viruses to serological tests. We will build mechanistic, hierarchical Bayesian models that allow us to determine whether serological “profiles” are more likely to represent antibodies of known viruses, mixtures of multiple known viruses, or previously uncharacterized viruses. We will extend techniques of antigenic mapping,<sup>47</sup> using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential. Using simulation experiments, we will test reduced-form, simple models against fully structured models so as to develop statistically robust procedures to interpret these data without high-performance computation.

**Fig 3.** Preliminary data: Reaction-cross reaction plots of multiplex Luminex assay response to antibodies for closely-related filoviruses.

**Scaling center operations:** This pilot project will produce methods and a proof-of-concept pipeline for high-throughput analyses. We will leverage EHA’s Emerging Infectious Disease – Southeast Asia Research Hub (EID-SEARCH) project, a NIH-funded Center for Research in Emerging Infectious Diseases (PI Daszak) who’s partners include USU, Duke NUS, Chulalongkorn University in Thailand, and various clinics and institutions in Malaysia – currently screening large numbers of human samples (>10K/yr) for various coronavirus, filovirus, and paramyxovirus antibodies. In the future the CSI will implement surveillance studies screening these sample streams using multiplex serology, and utilize the analytical and bioinformatic tools we develop in the next 18 months. As part of our planning activities, we will establish protocols and approvals for this work.

## **2b. Development of a field-ready semi-quantitative lateral flow assays for an emerging zoonotic viruses (Nipah virus)**

Lateral flow assays (LFAs), are low-cost tests where reagents printed on cellulose strips react with a sample that flows via diffusion. LFAs are capable of providing quantitative results (in proportion to antibody titer) using a combination of high-quality manufacturing and carefully designed, calibrated optical scans<sup>48</sup>. LFAs can be used to provide diagnostics at low cost at the point of care and by consumers. Lack of commercial-scale applications has prevented LFAs from being used for serological testing for novel or emerging disease. To our knowledge, no studies have used LFAs for zoonotic virus serosurveillance in the field.

We will develop a proof-of-concept LFA for Nipah Virus (NiV). NiV has a high mortality rate and is considered to have pandemic potential that is ranked by CEPI as one of 7 high pandemic risk pathogens<sup>49</sup>. The range of NiV's primary wildlife hosts (*Pteropus spp*, fruit bats) cover South and Southeast Asia but human cases have only been detected in Malaysia, Bangladesh, and the Philippines. Spillovers occur regularly in Bangladesh, but are rarely reported in large portions of the country<sup>50</sup> and reporting is strongly associated with health care accessibility<sup>51</sup>. Broad-scale serological monitoring has the potential to identify populations from which pandemic strains may emerge. Through previous work, members of our working group (Laing, Broder) have developed multiplex serological assays for NiV<sup>52</sup> and the soluble proteins and reagents required for an LFA. We have also added experience in engineering, quality control and commercialization of LFAs (Busa, industry consultant) to our working group. For the pilot, we will engage with commercial manufacturers to create and test a prototype Nipah LFA and a protocol for smartphone-based optical reading of quantitative responses.

**Scaling center operations:** The pilot will create a prototype LFAs. As part of full center operations under CSI, we will aim to scale up production and test LFAs efficacy using control sera and field deployment as part of EID-SEARCH. We will additionally assess feasibility and cost of deployment, and compare performance against current laboratory-based assays.

**Working Group 2 Activities:** In addition to the two pilots above, working group members will contribute to the our CSI monthly seminar series, presenting on topics including high-dimensional data models, field serology, serological assay development, laboratory product design, and public-private partnerships and commercialization. We will conduct two online workshops on serological data analysis, jointly with undergraduate, masters, and doctoral students at USU and UR, leveraging partnerships with field researchers currently working in serological surveillance. Our working group will lead a 3-day intensive workshop, where we will recruit additional participants with expertise in serological assay design and surveillance, immunology, emerging zoonoses, and focus discussion on key barriers to scaling serological surveillance for known and unknown zoonotic viruses.

**Partners, Initial Working Group 2 Members, and Roles:** EHA (coPI Ross): Model and pipeline design, software optimization. Uniformed Services University (SP Liaing, SP Broder): data and model interpretation, reagent manufacture, assay design. SP Busa: device manufacturing, quality control, industry outreach and partnership development. We will recruit additional participants from our partner network engaged in serological field studies as well as industry representatives to be part of the Working Group for Aim 2.

### **Aim 3: Rapidly Identifying Anomalous Health Events**

In early stages of epidemic spread, novel contact and mobility-induced behavioral data as well as communication patterns may provide a signal of e.g., health-seeking activity indicative of an outbreak cluster. We contend that these signals may be detectable in large-scale data streams of population mobility and contact, or disease reporting available through telecommunications and health care providers. Timely detection requires approaches that can manage data at scale,

analyze high-dimensional, spatio-temporally correlated streaming data in (pseudo) real time, and distinguish between known signals (e.g., typical influenza-related activity) and novel spillover-related signatures that we wish to unveil, characterize, and explain in order to trigger the necessary public policy responses.

This desideratum calls for fundamental methodological and computational advances, to go along with epidemiologically-relevant data sources that describe how humans are moving and interacting across physical space, with unprecedented temporal resolution and geographical coverage. Traditional flow-based mobility datasets used to parameterize epidemiological models have been aggregated and formatted in the form of origin-destination (OD) matrices. While valuable towards understanding population flows between regions of interest, OD matrices lack information on how much time a traveler spends in any given location. Naturally, when it comes to epidemiological studies the duration of time spent in potentially risky geographical areas is key towards deciphering actionable contact and exposure patterns<sup>53</sup>. Moreover, recent studies have shown that flow counts between pairs of geographical areas can be loosely correlated with, and not representative of, epidemiology-relevant mixing patterns<sup>54</sup>. Instead, these couplings among subpopulations are measured by effective contact rates, meaning how often people from each region come into contact in a way that is sufficient to transmit a disease. To address these challenges, our consortium will partner with the Facebook Data for Good team and leverage two recently assembled global-scale datasets - Activity Space Maps and Colocation Maps<sup>53,54</sup>.

Different from existing approaches that have focused on measuring the causal impact of mobility-oriented interventions, **our ambitious goal in this aim is to markedly advance the surveillance infrastructure available to predict anomalous health-related events before a major outbreak occurs.** While undoubtedly a multi-faceted endeavor, in this planning grant we will take initial, but significant steps with an emphasis on network-centric, computational analyses of dynamic mobility and interaction data at a global scale. By developing the appropriate statistical tools, we will support the ultimate goal of characterizing early pandemic “fingerprints” or signatures that can be extracted from these global datasets.

**Aim 3 Pilot Research Projects:** Working closely with Facebook Data for Good (see Letter of Collaboration from Alex Pompe), this working group will pilot data-driven research activities to explore the feasibility of extracting early (post spillover) signals of epidemic onset from Activity Space Maps and Colocation Maps. Our multi-disciplinary working group brings together leading experts in systems engineering, AI for healthcare, data science, mathematical epidemiology, graph signal and information processing, privacy-preserving mobility data generation and management, human behavioral modeling, and environmental science. We believe the current team, consisting of a wide array expertise and partnership, will instigate the cross-pollination of ideas leading to center-level activities while making significant inroads towards addressing our grand challenge. We propose two specific pilot projects:

### ***3a. Spatio-temporal monitoring of spillover-induced activity anomalies in Southeast Asia***

*Activity Space Maps (ASMs)* are a novel global-scale movement and mobility data set which describes how people distribute their time through geographic space.<sup>53</sup> They are designed to complement existing digitally-collected mobility datasets by quantifying the amount of time that people spend in different locations. Accordingly, this information is valuable for estimating the duration of contact with the environment and the potential risk of exposure to disease -- something critical especially early after spillover. More germane to the theme of this aim, it also offers the unique possibility of developing and testing sequential change-point detection algorithms to monitor multiple spatial grid cells of interest (informed, for instance, by outcomes

of the image-recognition effort under Aim 1). We will target areas known to include health care facilities in pursuit of abnormal trends of (increased) activity. Moreover, using ASMs we will examine flow and temporal activity anomalies around expert-annotated wildlife and wet market locations. Said events are expected if there are human infections, or significant associated changes in behavior around these sites early after spillover. Our initial efforts during this planning grant will be focused on Southeast Asia, which on top of its epidemiological relevance is one of the regions where Facebook ASMs have the most coverage. We will target Indonesia, where EHA has extensive on-the-ground efforts tracing networks of wildlife trade as well as market sites.<sup>55</sup> We will also tap into the resources stemming from EHA's Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) to identify clinics and market sites of interest in Thailand and Malaysia. Some key challenges we will address include accounting for the implicit biases in data collection associated with the construction of ASMs,<sup>53</sup> and their subsequent effects on the statistical algorithms that we will develop. Our Working Group will address additional challenges of data interpretation of anomaly detection analyses with input from emerging disease experts and epidemiologists. To calibrate our models, we will bring to bear recent activity data before and after the SARS-CoV-2 outbreak in those locations, in addition to historical influenza seasonal trends that go further back in time. With the exciting prospect of ASM data being officially released in the last quarter of 2021, *we are in a privileged position to be the first multi-disciplinary team that leverages this invaluable global-scale resource to advance our understanding of zoonotic spillover risk and its immediate effect on human mobility.*

### **3b. Online network change-point detection in dynamic, global-scale Colocation Maps**

Activity data are complemented by *Colocation Maps (CMs)*, which estimate how often people from different regions worldwide are colocated. In particular, for a pair of geographic regions  $i$  and  $j$  (e.g., counties in the US), CMs estimate the probability that a randomly chosen person from  $i$  and a randomly chosen person from  $j$  are simultaneously located in the same place during a randomly chosen minute in a given week.<sup>54</sup> In other words, CMs are global-scale, dynamic network datasets with colocation probabilities encoded as edge weights. Thus, they are well suited to parametrize metapopulation models of disease spread,<sup>56</sup> or to measure temporal changes in interactions between people from different regions.<sup>57</sup> To monitor said changes as part of our second pilot activity in this aim, we will build on our recent advances in online (i.e., sequential) algorithms for anomaly and change-point detection from network streams<sup>58,59</sup>; see also.<sup>60-62</sup> The envisioned statistical methods are in stark contrast with most existing graph change-point detection approaches, which either rely on extensive computation,<sup>63</sup> or they would require storing and processing the entire observed CM time series.<sup>64</sup> We will prototype and test a lightweight online change-point detection algorithm with quantifiable performance guarantees, that is also explainable since it relies on interpretable node embeddings; see e.g., *Hamilton\_Book*.<sup>58,65</sup> The latter desirable feature will be leveraged to construct dynamic anomaly maps for user-friendly visualization of post-spillover events; see also our recent network-scientific visualizations of spatio-temporal COVID-19 contagion patterns across the US.<sup>66</sup> Moreover, the sheer-size of the CM graphs calls for algorithmic and modeling innovations we will investigate as part of our research agenda, e.g., seamlessly integrating graph subsampling or dimensionality reduction techniques to the analytics pipeline. We will team up with computer vision experts affiliated to the University of Rochester Goergen Institute for Data Science (GIDS, see attached Letter of Collaboration from institute director Mujdat Cetin), to also explore the exciting prospect of integrating geo-tagged multimodal data such as video and imagery in our studies, for instance as nodal attributes embedded to the CMs.

**Working Group 3 Activities: *Recruitment and diversity:*** We will recruit 6 students from the GIDS-run master's program in data science, which attracts students from multidisciplinary backgrounds and significant computational proficiency to contribute in the aforementioned pilot research activities. *The CSI leadership and broader community are committed to providing research training and educational experiences for those traditionally under-represented in STEM, including women and underrepresented minority students.* The PI team has a solid track-record in actively recruiting and supervising such students at the undergraduate, masters and doctoral level, with demonstrated efforts towards broadening participation in STEM. As examples of the commitment to diversifying the field, co-PI Mateos serves as founding faculty advisor to the UR's SACNAS chapter and regularly organizes diversity, equity and inclusion panels to highlight challenges and successes of UR's Hispanic and Latino STEM community. We plan to prioritize engaging women and minority students in the research and working group activities proposed here. ***Coursework:*** These students will be on the existing health and bio track with an opportunity to take classes in immunology, microbiology and virology programs as well as data ethics at the University of Rochester Medical Center (URMC) as well as the college of engineering. Through the planning grant, we plan to establish a special MS track on 'zoonotic surveillance' in order to train and mentor the students to lead center level activities.

***Seminar and workshop series:*** The students will be part of the large cohort of all the participating institutions and participate in the CSI monthly seminar series. The co-PIs (Mateos and Hoque) will conduct two workshops (and invite additional faculty members from UR as guest speakers) with hands-on lessons in mobility and human behavior modeling.

***Hackathon:*** The students will be encouraged to participate in the yearly hackathon, Dandyhacks (<https://dandyhacks.net/>), organized every fall by the University of Rochester Computer Science Department and work with the dataset from Facebook. Additionally, co-PIs Mateos and Hoque will work with the organizers of dandyhacks to release some of the public dataset from Facebook for other teams to explore, model and mine the data.

***Data visualization meetups at the University of Rochester's VISTA Collaboratory:*** To get acquainted with the different data resources at our disposal, over the first 3 months of the project the Rochester team (along with Facebook and EHA collaborators via Zoom) will hold bi-weekly team meetings with the MSc students at the UR's VISTA Collaboratory. This is a 1,000 square-foot visualization lab equipped with an interactive (20 ft. wide x 8 ft. tall) tiled-display wall, that renders massive data sets in real time, giving team members the ability to visualize and analyze complex data instantaneously and collaboratively; see Fig. 4. As we dissect what dataset components are central for the aforementioned pilot activities, our graduate students will develop customized data visualization tools, maps and dashboards to facilitate downstream analyses. Updates and progress reports will be shared in these meetings, giving the students a unique opportunity to develop their communication skills. The whole team will provide feedback and share ideas, making this a truly collaborative activity. Moving forward, the VISTA Collaboratory offers a unique resource that we will fruitfully leverage as we scale up to full center operation.

**Fig. 4.** UR's Vista Collaborative will serve as a spillover intelligence "situation room" for training UR and CSI exchange students on analysis of real-time epidemiologically relevant datasets.

**Partners, Initial Working Group 3 Members, and Roles:** University of Rochester (co-PIs Hoque and Mateos): coordination of working group activities, development and testing of computational tools for early detection of post-spillover signatures, dissemination of research products and educational materials, recruiting and mentoring of master students, liaisons to

GIDS. Facebook Data for Good (OP Pompe and Maps for Good team members Iyer and Citron): data ethics, quantification of privacy protections, data scientific support for Activity Space and Colocation Maps, mathematical epidemiology expertise for data and model interpretation. EHA (SP Mendelsohn and Ross): identification of target spatial locations in Southeast Asia, epidemiological interpretation of anomaly detection analyses and validation of detected early pandemic fingerprints.

**Scaling operations:** Our programs and pilot research are designed to scale. First, we aim to expand on successful pilots by expanding the geographies of our work, engaging with more in-country partners. Second, we test the development of each of these new streams of predictive data, we plan to develop partnerships with local, national, and global agencies to ingest these data, expand into programs to develop behavioral interventions and testing in response to identifying regions and populations at high risk of contracting zoonotic diseases.

Working groups are really about bringing our project to scale, our intensive 3-day workshop will also lead to new partnerships and synergies for expansion.

### Results from Prior NSF Support

**Kevin J. Olival** has not had prior NSF support, but is co-PI on NIH-funded “EID-SEARCH” (NIAID-CREID U01AI151797, 2020-25 PI Daszak). Previously co-PI on “Understanding the risk of bat coronavirus emergence” (NIAID R01 AI110964, 2014-2019, PI Daszak). **Intellectual merit:** Identified >50 SARSr-CoVs in bats, showed evidence of ability to infect human cells, humanized mouse models, and people in China, and used evolutionary and mammalian biodiversity patterns to analyze spillover risk for use in public health control. Produced 18 peer-reviewed papers<sup>20,34,67-79</sup>, including two papers in *Nature*<sup>80,81</sup>, and a review in *Cell*<sup>82</sup>, and others submitted. **Broader impacts:** 2 PhD and 6 MS students trained; disease risk and potential management strategies shared with US agencies, WHO, OIE, FAO, and the public.

**Ehsan Hoque: Project IIS-1750380.** PI: Hoque. Period (2018-23). Amount: \$511,453 “CAREER: A collaboration coach with effective intervention strategies to optimize group performance”. **Intellectual merit:** Developing and validating the efficacy of automated mediation strategies in online meetings. **Broader Impacts:** >6 research papers<sup>83-88</sup>. **Project NRT-DESE-1449828.** PI: Hoque (2015-21). Amount: \$2,965,341.00 “Graduate Training in Data-Enabled Research into Human Behavior and its Cognitive and Neural Mechanisms”. **Intellectual merit:** Chartering a new traineeship program to train Ph.D. students at the University of Rochester to advance discoveries at the intersection of computer science (cs), brain and cognitive sciences (bcs), and neuroscience. **Broader Impacts:** Supported over 50 PhD students in cs and bcs, several won interdisciplinary research positions at R1 institutes.

**Gonzalo Mateos** (a) Project: CCF-1750428. PI: Gonzalo Mateos Buckstein. Period: 4/1/18 - 3/31/23. Amount: \$407,944. (b) Title: CAREER: Inferring Graph Structure via Spectral Representations of Network Processes. (c) **Intellectual Merit:** We investigate how to use information available from graph signals to estimate the underlying network topology through innovative convex optimization approaches operating in the graph spectral domain. **Broader Impacts:** We prepared a feature article on identifying network structure via GSP,<sup>89</sup> presented tutorials in EUSIPCO'19, CAMSAP'19 an SSP'20, organized the 2019 IEEE SPS Summer School on Network- and Data-driven Learning. (d) Research products are available in.<sup>66,89-96</sup>

**Emily Mendenhall** (a) National Science Foundation Doctoral Dissertation Improvement Grant, \$10,000; Stories at the Border of Mind and Body: Mexican Immigrant Women’s Narratives of Distress and Diabetes. **Intellectual merit:** Led to crucial insights studying syndemics - the interactions of social, environmental, psychological, and biological factors that are synergies of epidemics. Papers in *The Lancet*<sup>29</sup>, *Medical Anthropology Quarterly*<sup>97-99</sup>, and as a full-length

book<sup>100</sup>. **Broader Impacts:** Understanding diabetes, trauma, and broader socio-political factors with infectious diseases in India, Kenya, South Africa, and Ethiopia.

**BIOGRAPHICAL SKETCH**

Provide the following information for the Senior/key personnel and other significant contributors.  
 Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Jonathan H. Epstein

eRA COMMONS USER NAME: (b) (6)

POSITION TITLE: Vice President for Science and Outreach

**EDUCATION/TRAINING**

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Brandeis University, MA	BA	1996	Biology
Tufts University, Sch. Vet. Med., Boston, MA	DVM	2002	Wildlife Med., Intl. Med.
Tufts University, Sch. Vet. Med., Boston, MA	Cert Intl Med	2002	Zoonotic Diseases
Tufts University, Medical School, Boston, MA	MPH	2002	Epidemiology
Columbia University, NY	Fellowship	2006-2009	Molecular Virology
Kingston University, UK	PhD	2017	Disease Ecology

**A. Personal Statement**

The goal of this research is to improve our understanding of why Nipah virus outbreaks seem to be restricted to a specific region in western Bangladesh despite the host, virus, and route of transmission being present in eastern Bangladesh. This project builds on more than 15 years of NIH-funded Nipah virus research conducted by myself and our organization in Malaysia and Bangladesh. This work will involve field surveillance of bats and people, serological, molecular, and virological testing to detect and characterize Nipah virus strains in bats, and BSL-4 animal model experiments at the NIH Rocky Mountain labs to identify phenotypic differences among NiV strains. I am well positioned to lead this work, having spent 15+ years conducting epidemiological studies of bat-origin viruses and having spent the last 10 years managing large-scale multidisciplinary surveillance in wildlife and humans in Bangladesh and four other countries for viral zoonoses, including henipaviruses under the USAID funded EPT RPEDICT project. I have trained teams and led fieldwork in Malaysia, India, Bangladesh, Saudi Arabia, Cambodia, The Philippines, China, and Liberia and conducted ecological and epidemiological studies of zoonotic viruses in bats, including Nipah, Hendra, MERS-CoV, SARS-CoV and Ebola virus. My work has led to the discovery of bats as the reservoir for SARS CoV, the identification of MERS-CoV in bats and camels in Saudi Arabia, the identification of Reston ebolavirus in bats in The Philippines and the detection of Zaire ebolavirus for the first time in bats in West Africa (Liberia). I have also conducted and coordinated data analyses from field and lab activities including identifying novel viral agents (the first bat pegivirus), and confirming that *Pteropus* fruit bats are reservoirs for henipaviruses. I spent five years working as a visiting research fellow at Columbia University’s Center for Infection and Immunity conducting Nipah virus and pathogen discovery research, including molecular and serology techniques, bioinformatics, phylogenetic analyses, all of which has given me a strong understanding of the challenges of conducting viral surveillance in wildlife and the constraints of molecular and serological diagnostics. I have extensively collaborated with each of the co-investigators and key personnel on this proposal and continue to collaborate under currently active projects. Under this proposal, we bring strong partnerships and preliminary data from prior NIH R01 and K08 awards.

## **B. Positions and Honors**

### **Positions and Employment**

- 1999 Intern, Brisbane South Public Health Unit & DPI Queensland Animal Research Institute, AUS.
- 2002 Extern, Division of Viral and Rickettsial Diseases, CDC, Atlanta, GA
- 2003-09 Senior Research Scientist, EcoHealth Alliance, New York, NY.
- 2003 - Adjunct Clinical Associate, Tufts University Cummings School of Vet. Med., MA.
- 2006-10 Research Fellow, Center for Infection and Immunity, Columbia University, NY,
- 2009-16 Associate Vice President, Conservation Medicine Program EcoHealth Alliance, NY  
Executive Director, Consortium for Conservation Medicine, EcoHealth Alliance, NY
- 2016- Adjunct Associate Professor, Columbia University Mailman School of Public Health, NY
- 2016 - Vice President for Science and Outreach, EcoHealth Alliance

### **Other Experience and Professional Memberships**

- 2003 - Member, IUCN Veterinary / Wildlife Health Specialist Group
- 2004 Invited speaker, *WHO, Emerging Zoonotic Diseases Working Group* meeting
- 2006 Member, Delta Omega Public Health Honors Society
- 2010- Invited speaker, Institute of Medicine Forum on Microbial Threats, National Academies of Science
- 2011- Admissions Committee, Tufts University Masters in Conservation Medicine degree program

### **Honors**

- 2002 Certificate of International Veterinary Medicine, Tufts University Sch. Vet. Med. (1<sup>st</sup> recipient)
- 2002 Hills award for excellence in veterinary clinical nutrition
- 2002 Sylvia Mainzer Award for Outstanding Achievement in Public Health
- 2006 Inductee & Keynote speaker, Delta Omega Honor Society for Public Health (Alpha Rho Chapter)
- 2007 Outstanding Alumnus award, Tufts Cummings School of Veterinary Medicine
- 2012 Young Alumni Achievement Award, Tufts University
- 2013 Named one of the ten “Distinguished Alumni” by Tufts University School of Medicine
- 2014 Commencement speaker, Tufts University Medical School Graduate Programs in Public Health

## **C. Contribution to Science**

**1. Research on the epidemiology of emerging zoonotic viruses, including Nipah virus.** A range high impact emerging viruses appear to have bat origins (e.g. SARS-CoV, Ebola viruses, NIV, HeV, MERS-CoV). My research has focused on identifying bat reservoirs and the epidemiology of Nipah and Hendra virus, Ebola Reston virus, SARS-CoV, and MERS-CoV. I have trained field teams in Asia and Africa to conduct surveillance for zoonotic viruses in bats and other wildlife, as well as humans and livestock. In Malaysia, my work helped identify the agricultural drivers of NiV emergence. In Bangladesh, I helped characterize NiV infection dynamics and the ecology of its bat reservoir including patterns of habitat use as they relate to spillover to humans and livestock. In China, I led initial fieldwork that identified Horseshoe bats as the natural reservoir for SARS-like CoVs and collaborated on the identification of SL-CoVs in bats that

that use the same receptor as SARS-CoV. Under the USAID-funded Emerging Pandemic Threats: PREDICT program, I currently manage field and laboratory teams in Liberia, Malaysia, India, and Bangladesh that conduct human and wildlife surveillance for novel viruses as well as important viral zoonoses such as Nipah virus, MERS-CoV, Ebola, and HPAI. We recently identified Zaire ebolavirus in a bat in Liberia, the first detection of Ebola in a bat in the region. This work has been instrumental in advancing our understanding of viral dynamics and diversity in wildlife reservoirs and how environmental change and human behavioral factors drive zoonotic virus emergence.

Dis.* 2018

**2. Identification of novel pathogens in bats and other wildlife with zoonotic potential.** My work on the ecology of viruses in bats led to my discovery of a novel flavivirus (GB virus) in the Bangladesh fruit bat *Pteropus medius*, related to the hepatitis C virus, and now classified as a *Pegivirus*. An additional 55 novel viruses, some related to Nipah, and serological evidence of filoviruses have been identified in these samples, demonstrating the importance of livestock surveillance in rural South Asia to discover potential zoonoses. Under the USAID PREDICT project, I lead work in Liberia, Bangladesh, India, and Malaysia. As a collaborative group, we have discovered more than 1200 novel viruses in 30 countries. I have as a senior technical lead since the project inception in 2009 designing SOPs for wildlife surveillance, and training dozens of scientists and government officials from wildlife and agricultural ministries in more than 30 countries, leading.

**3. Studies of bat ecology and immunology to understand emerging zoonoses.** Over the last few years, I have worked to integrate wildlife ecology and immunology into viral epidemiological studies. I have helped

pioneer the use of satellite telemetry and mark-recapture studies on bat Nipah virus reservoirs to help define geographic range of these viruses. My work has helped show that in Malaysia, Nipah virus bat reservoirs have long-range, international migratory movements that explain how viral maintenance at low incidence and drivers of viral diversity. I have integrated immunological experiments into Nipah virus studies in an effort to generate actual data about antibody persistence in bats, which has informed mechanistic models of viral dynamics. This work has enhanced our ability to understand how Nipah virus circulates in bat populations and how cohorts of juveniles contribute to viral outbreaks within bats.

---

Hello, all!

I am hoping that everyone can create or update a NIH-formatted biosketch and forward it to me for inclusion in our CEPI proposal.

A recent version of Jon's biosketch is attached as an example. Section A, the personal statement, should be adjusted to be relevant to the CEPI proposal and your Nipah virus work. We've also removed Section D (funding/financial information).

For those whose biosketches we already have, from previous recent proposals, I will follow up separately in response to this email and ask that you update your biosketch as necessary. (Arif, Zia, Prof. Tahmina, Chris, and Vincent.)

Please let me know if you have any questions, and have a great weekend!

Madeline

**Abstract**

Hendra virus (HeV) and Nipah virus (NiV) are bat-borne zoonotic paramyxoviruses identified in the mid- to late 1990s in outbreaks of severe disease in livestock and people in Australia and Malaysia, respectively. HeV repeatedly re-emerges in Australia while NiV continues to cause outbreaks in South Asia (Bangladesh and India), and these viruses have remained transboundary threats. In people and several mammalian species, HeV and NiV infections present as a severe systemic and often fatal neurologic and/or respiratory disease. NiV stands out as a potential pandemic threat because of its associated high case-fatality rates and capacity for human-to-human transmission. The development of effective vaccines, suitable for people and livestock, against HeV and NiV has been a research focus. Here, we review the progress made in NiV and HeV vaccine development, with an emphasis on those approaches that have been tested in established animal challenge models of NiV and HeV infection and disease.

## INTRODUCTION

Nipah virus (NiV) and Hendra virus (HeV) are bat-borne viral zoonoses that were discovered in the mid- to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia [NiV-Malaysia (NiV-M)] (1). They are the prototype members of the genus *Henipavirus* in the family *Paramyxoviridae* (2). NiV outbreaks have also been recorded in Bangladesh and India by a closely related strain, NiV-Bangladesh (NiV-B) (3). Three other henipaviruses are also recognized: Cedar virus (CedV) as an isolate and Ghana virus (GhV) and Mojiang virus (MojV) known only from sequence data (4–7). Both NiV and HeV are highly pathogenic in a broad range of mammalian hosts that are capable of infecting and causing severe disease in humans, monkeys, pigs, horses, cats, dogs, ferrets, hamsters, and guinea pigs and that span six mammalian orders including bats, although bats do not exhibit disease when infected (8–21). In contrast, CedV is nonpathogenic in well-characterized models of HeV and NiV disease including ferrets and hamsters (4, 22). The pathogenic potential of GhV and MojV is unknown.

Several species of *Pteropus* fruit bats are the natural reservoir hosts of NiV, HeV, and CedV (4, 23–27). NiV- or HeV-mediated disease has not been reported in wild or experimentally infected bats (13, 28–30). NiV and HeV infections in people and many animals manifest as severe systemic and often fatal neurologic and/or respiratory diseases (31–33). Both NiV and HeV are regarded as transboundary biological threats to both human and animal health and are classified as biosafety level 4 (BSL-4) select agents (34, 35). NiV and henipaviral diseases are included in the World Health Organization (WHO) R&D Blueprint list of priority pathogens with epidemic potential that need research attention (36). This review summarizes the important characteristics of the NiV and HeV pathogens, the modes of virus transmission, and the immunization strategies being developed against them.

### Emergence and Outbreaks of Hendra and Nipah Viruses

In 1994 in the Brisbane suburb of Hendra, Australia, an outbreak of severe respiratory disease resulted in the deaths of 14 horses and their trainer, along with the nonfatal infection of 7 other horses and 1 other person. This led to the discovery of a novel paramyxovirus initially termed equine morbillivirus, now known as HeV (37–39). The first known cases of HeV in horses and a human actually occurred a few months prior, where one person became ill after assisting in the necropsies of two horses later shown to have died from HeV (40, 41). This individual experienced a relapsed fatal encephalitis caused by HeV 13 months later (42). HeV has since re-emerged in Australia 62 times with a total of 104 horse deaths (fatal or euthanized), along with 4 human fatalities of 7 cases (43). Every recorded occurrence of HeV in Australia has involved horses, all resulting in a severe or fatal disease, and all cases of human infection were acquired from virus-shedding horses (31, 44).

In 1998, an outbreak of encephalitis among pig farmers in Peninsular Malaysia occurred and a virus was isolated from samples of cerebrospinal fluid (CSF) of two patients who had died; cells infected with this virus cross-reacted with antibodies against HeV (45). Genetic studies revealed a new paramyxovirus that was closely related to HeV, and it was named Nipah after the village in Malaysia where one of the patients had lived (45). There were 265 cases of human infection with 105 fatalities in Malaysia and 11 cases and 1 fatality among abattoir workers in Singapore (46, 47). This outbreak was controlled through the culling of more than 1 million pigs, resulting in significant economic impacts to the region (48, 49).

A genetically similar but distinct strain of NiV was identified as the causative agent of fatal encephalitis in people in Bangladesh (NiV-B) (3, 50). Since 2001, nearly annual occurrences of human NiV-B infections have occurred in Bangladesh, and there have been three outbreaks in

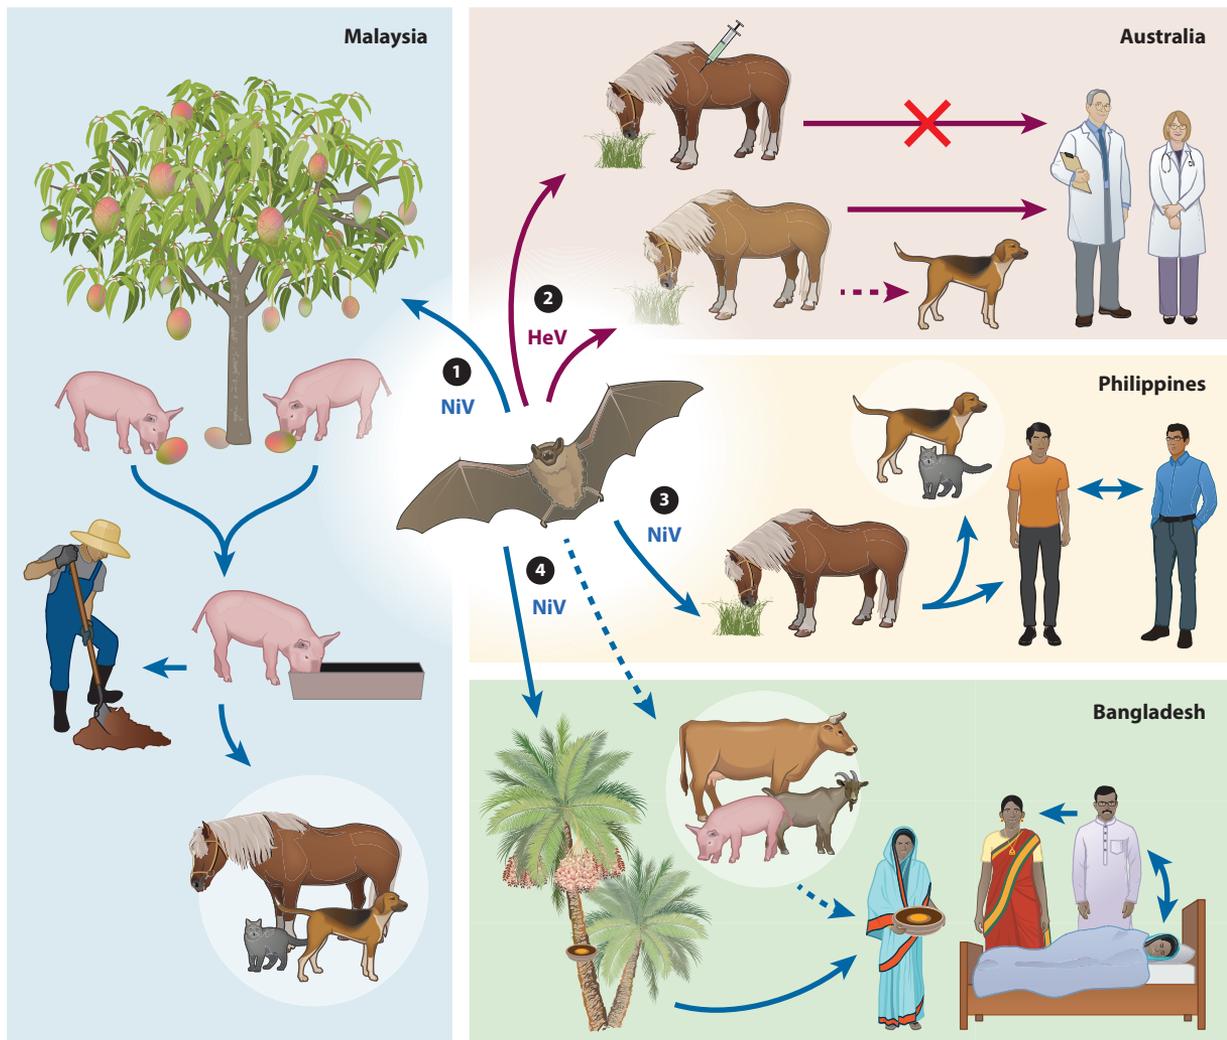

India (51–54). The recent 2018 NiV outbreak in Kerala, India, was significant, having occurred in a new geographic region far from locations in Bangladesh and India where all prior outbreaks had occurred and with a case fatality rate of 91% (51). In 2014, an outbreak of NiV-M encephalitis occurred in the Philippines with 9 fatalities of 11 human cases of acute encephalitis and influenza-like illness or meningitis in another 6 individuals (55). Altogether, there have been over 650 cases of human NiV infection (combined ~60% fatality rate) in South Asia and Southeast Asia in five countries (54, 56).

### Transmission of Hendra and Nipah Viruses

The routes of transmission of virus infection to humans from animals are different for HeV and NiV, with horses the only spillover host of HeV in Australia, while for NiV it was pigs in Malaysia and horses in the Philippines (**Figure 1**). However, human NiV infections in Bangladesh, India, and the Philippines also include bat-to-human and human-to-human transmission (57–60). Transmission routes of HeV and NiV to animals are likely urine from infected bats contaminating pastures or pigsties and/or virus-contaminated fruit spat from bats that is ingested (61, 62) (**Figure 1**). Recoverable virus is shed in the urine of experimentally infected bats and can also be detected in throat and rectal swabs (13, 28–30). Pooled urine samples from flying foxes are also routinely used to detect and isolate henipaviruses (4, 13, 23, 27, 63–65).

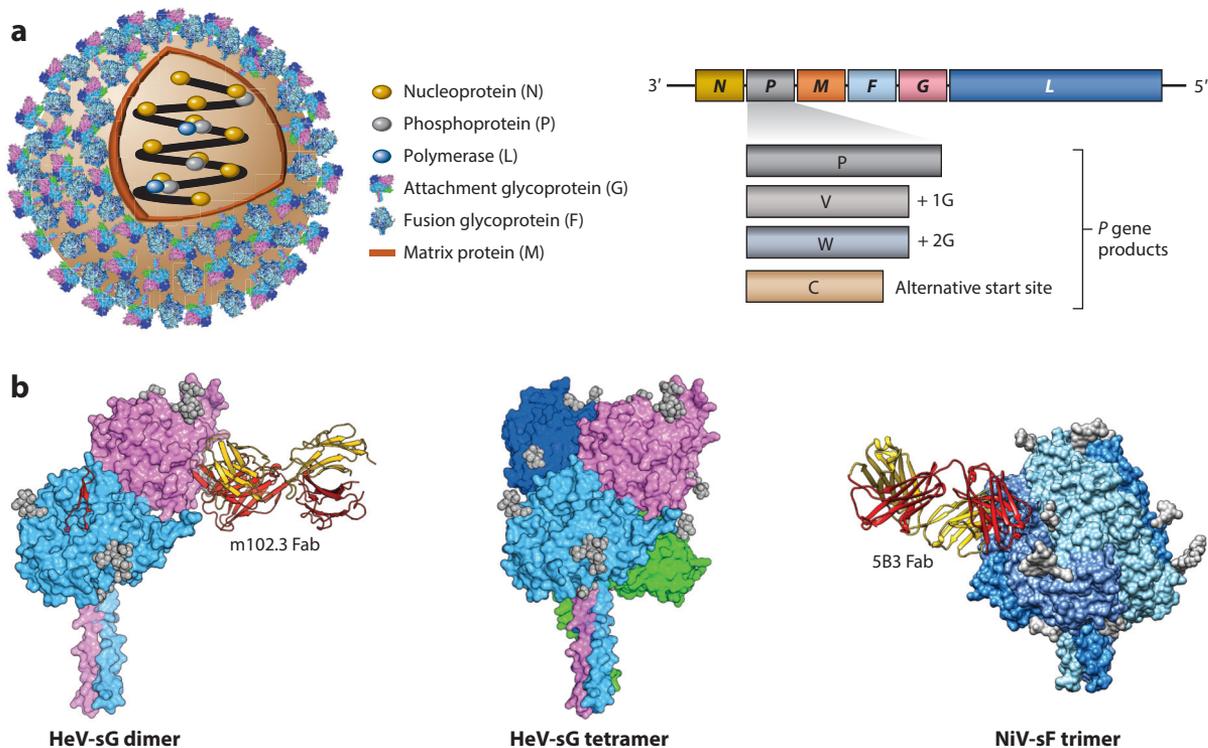

It was previously suggested that infected horses could transmit HeV to people during the feeding of ill animals (38). Also, the majority of all HeV-infected horse cases have involved a single animal, suggesting that HeV is not readily transmitted between horses, and multiple horse outbreaks are likely via contamination of fomites (43, 66). The transmission risk of HeV from infected horses to humans appears to be virus-contaminated fluids or tissues during examination procedures and/or the necropsy of horses (31, 67) (**Figure 1**). Indeed, all cases of human HeV infection have been associated with postmortem examination of horses or close contact with ill horses (31, 38, 42, 68). In Malaysia, it was contact with infected pigs or fresh infected pig products that was required for transmission of virus to humans (45, 69, 70) (**Figure 1**). NiV shedding in respiratory fluids of infected pigs suggested that it probably spread among farmed animals by aerosol droplets or direct contact (16, 71, 72). In Bangladesh, the transmission of NiV from bats to people has been linked to the consumption of virus-contaminated fresh date palm sap, and bats will consume sap during its collection (57, 73, 74). Domestic animals have also been linked to NiV infection in people in Bangladesh from unwell animals (cows and goats) and pigs (50, 59). Human-to-human transmission of NiV has been well documented in Bangladesh and India (52, 58–60, 75) (**Figure 1**). A study of human NiV-B cases in Bangladesh spanning 14 years reported that of 248 cases studied, one-third were caused by human-to-human transmission (56). Human-to-human transmission of NiV-M was not apparent in Malaysia (76, 77), whereas in the Philippines' NiV-M outbreak, human cases were linked to horse slaughtering and horse meat consumption or exposure to other human patients, indicating both horse-to-human and human-to-human transmission (55) (**Figure 1**). The NiV-B outbreak in Kerala had a very high rate of human-to-human transmission (22 of 23 cases) at three different hospital locations (51).

Naturally acquired NiV infections were also recorded in cats, dogs, and horses in the initial Malaysian outbreak (**Figure 1**), and serological evidence of natural NiV infection in dogs was linked to outbreak farms (11, 61, 78). In the Philippines, both dogs and cats were linked to NiV-M infection, with cats dying after eating horse meat and dogs having NiV-neutralizing antibodies (55) (**Figure 1**). In Australia, a dog was found to be seropositive for HeV and later euthanized but showed no signs of disease, and a second HeV-positive dog was identified in 2013 following exposure to blood from an infected horse (79) (**Figure 1**). Dogs are susceptible to experimental HeV infection and shed virus but show little evidence of clinical illness (80).

**Figure 1**

Nipah virus (NiV) and Hendra virus (HeV) modes of transmission in different countries. The transmission routes of NiV in Malaysia (*left*), Philippines (*middle right*), Bangladesh (*bottom right*), and HeV (*top right*) are depicted. Solid lines represent transmission that has been observed and documented, and dashed lines represent suspected transmission in natural conditions. Fruit bats are the natural reservoirs of NiV and HeV. (1) Pigs are infected by consuming partially eaten or contaminated fruit from infected bats (urine, saliva) and transmit NiV to other pigs, pig farmers, or other animals (dogs, cats, and horses) through close or direct contact. (2) Horses can be infected from grazing in contaminated pastures and transmit HeV to humans and on occasion domestic dogs through close contact. A One Health vaccine approach was developed for vaccination of horses in Australia with the dual purpose of saving horses from lethal HeV infection and preventing HeV transmission from horses to humans. (3) NiV is transmitted to humans through close contact with infected horses. NiV transmission to humans, cats, and dogs appears to have occurred following close contact with or consumption of infected horse meat. Human-to-human NiV transmission can occur through close contact. (4) Bat-to-human NiV transmission occurs through consumption of contaminated date palm sap. Human-to-human transmission can occur through close contact with infected patients. Humans may also become infected through contact with infected animals. Figure adapted with permission from Reference 171.

**Figure 2**

Henipavirus structure and genome organization and models of the G and F glycoprotein soluble ectodomains, Hendra virus (HeV-sG) and Nipah virus (NiV-sF), respectively, and their complexes with respective NiV and HeV cross-reactive neutralizing monoclonal antibodies m102.3 (anti-G) and 5B3 (anti-F). (a) Schematic representation of a henipavirus particle with the structural proteins depicted in different colors (left) and the henipavirus genome (right). HeV and NiV *P* genes encode 3 nonstructural proteins: The C protein is expressed from an alternative start site, and the V and W proteins are expressed following the addition of one or two G residues at the messenger RNA editing site, respectively (right). (b, left) HeV-sG shown as a dimer solvent-accessible surface view with one monomer (cyan) overlaid with the monoclonal antibody m102.3 CDR-H3 loop (red) at the receptor binding site, and the other monomer (magenta) in complex with m102.3 Fab, which has an identical heavy chain and a similar light chain, that was used in place of the m102.4 monoclonal antibody (mAb) in the structural solution of the complex (109). The HeV-sG consists of amino acids 76–604, and the structures of the two globular head domains of HeV-sG are derived from the crystal structure (103, 172). The stalk regions of each G monomer (residues 77–136) are modeled (173). The light chain of m102.3 Fab is colored in yellow, and the heavy chain is colored in red. (b, middle) The HeV-sG tetramer surface view is modeled with one dimer (cyan and magenta) in front and the other dimer (blue and green) in back. N-linked glycans are gray spheres. (b, right) Structural model of the NiV-sF trimer in complex with the 5B3 Fab derived from the cryo-electron microscopy structure (110). The NiV-sF consists of amino acid residues 1–494 with a FLAG tag (DYKDDDK) introduced between residues L104–V105 and a C-terminal GCN4 motif. Each monomer of NiV-sF is in a different shade of blue, 5B3 heavy chain is in red, and light chain is in gold. N-linked glycans are illustrated in gray.

## Entry and Tropism of Nipah and Hendra Viruses

NiV and HeV are enveloped viruses containing an unsegmented, single-stranded, negative-sense RNA genome (2). **Figure 2a** is an illustration of the viral particle and the associated viral proteins. The genomes of HeV and NiV, and also CedV, GhV, and MojV, are considerably longer than the genomes of other paramyxoviruses, at greater than 18 kb. Henipavirus genomes encode 6 structural proteins: nucleoprotein (N), phosphoprotein (P), matrix protein (M), fusion glycoprotein (F), attachment glycoprotein (G), and the polymerase protein (L) (**Figure 2a**). The N, P, and L proteins comprise the replication complex. The *P* gene undergoes RNA editing

to produce 2 additional nonstructural proteins, V and W, that are interferon (IFN) antagonists (81–84). The C protein is transcribed from a second open reading frame in the *P* gene (**Figure 2a**). NiV has been central to understanding the V, W, P, and C protein roles in antagonizing the innate immune responses via a diverse set of mechanisms (85, 86). Recent in vivo studies with recombinant NiV variants have further defined the varying importance of these nonstructural proteins in pathogenesis, but only a lack of the V protein results in a nonlethal infection (87–89).

The henipavirus virion bears surface projections composed of the F and G glycoproteins that are anchored in the viral membrane and together mediate infection of host cells, and they are the major antigens of vaccine strategies (1) (**Figure 2a**). The F glycoprotein facilitates membrane fusion between the virus and host cell. The G glycoprotein consists of a characteristic stalk with a globular head that engages entry receptors on host cells, leading to the fusion activation of F and virus infection. The native structure of G is a tetramer while F is a trimer, and together they are the key determinants of infection and tropism (90–92). Models of the soluble ectodomain of the HeV G (HeV-sG) as a dimer and tetramer and the soluble ectodomain of the NiV F (NiV-sF) as a trimer are shown in **Figure 2b**. NiV and HeV utilize the host cell proteins ephrin-B2 and ephrin-B3 for entry (93–96). Ephrin-B2 and ephrin-B3 are members of a large family of ligands that bind to Eph receptors and are highly sequence conserved among mammals (97, 98). Ephrin-B2 expression is prominent in the vasculature of multiple organs, whereas ephrin-B3 is found predominantly in the nervous system (99–101). The ability of HeV and NiV to use these ephrins as receptors provided explanations of their broad host and tissue tropism (32, 33, 102). The NiV and HeV G head domain structures alone and in complex with ephrin-B2 and ephrin-B3 receptors have been determined (103–106). The structures of both the NiV and HeV F in their prefusion conformation have also been determined (107, 108). These studies have provided insights into understanding the virus entry receptors and host tropism features of the viruses on the molecular level and also facilitated further structural studies of henipavirus G and F glycoproteins in complexes with specific virus-neutralizing antibodies, providing valuable information that has aided vaccine design and choice (109, 110).

### Nipah Virus and Hendra Virus Infection in Humans and Animals

Human NiV and HeV infections are generally accepted to occur via the oronasal route, and the incubation periods for both have been estimated to be 1 to 2 weeks (31, 51, 111). Acute infection in people is a systemic infection likely via hematogenous spread of the virus from the respiratory system (112). In general, HeV and NiV disease onset is characterized by fever, myalgia, shortness of breath, and cough (38, 111). Human HeV infections have resulted in both fatal respiratory or encephalitic disease and also recovery from infection (31, 38, 42, 68). The predominant clinical feature in the NiV-M outbreak in Malaysia was encephalitis, but respiratory symptoms were also common with fever, cough, and headache (47, 111, 112). The clinical presentation of NiV-B infections in Bangladesh also includes severe respiratory disease. In the 2018 NiV-B outbreak in Kerala, 83% of cases presented with acute respiratory distress syndrome (ARDS) (51, 113). Central findings of human NiV and HeV infection are a widespread endothelial cell tropism and systemic vasculitis, with prominent parenchymal cell infection in most major organs with the brain and lung significantly affected (45, 112, 114). Human NiV and HeV infections can also take a protracted course following apparent recovery, and some patients can experience late-onset encephalitis or relapsed encephalitis can occur in patients who previously recovered (42, 115). Relapsed encephalitis caused by NiV appears to result from a recrudescence of virus replication in the central nervous system (CNS), with cases presenting from a few months to as long as 11 years later (116–118). Recrudescence of virus has important implications for vaccine development.

The development of animal models of NiV and HeV infection and pathogenesis has been a major focus since the late 1990s and an essential component of vaccine development and testing. Also, the approval process of countermeasures for NiV and HeV would fall under the animal rule requirement set forth by the US Food and Drug Administration (FDA) in 2002 as an alternative licensing pathway for countermeasures against highly pathogenic agents when human efficacy studies are not feasible or ethical (119, 120). Several animal models of NiV and HeV infection have emerged that well reflect the pathogenesis seen in infected people, which includes a systemic vasculitis with both respiratory and neurological diseases. Detailed reviews of NiV and HeV infections of a variety of mammalian species have recently been published (33, 121–123). It is generally accepted that the pathogenic processes of NiV and HeV infection in the hamster, ferret, and African green monkey (AGM) best reflect the pathogenesis observed in humans, whereas the most appropriate models for livestock are the horse and pig themselves.

## VACCINATION

The attachment and fusion glycoproteins of paramyxoviruses such as measles, mumps, and parainfluenza viruses are the viral antigens to which virtually all neutralizing antibodies are directed (124–126). Likewise, immunization strategies for NiV and HeV have largely targeted their G and F glycoproteins.

### Passive Immunization Strategies

Early passive immunization studies in the hamster model demonstrated that polyclonal antisera or mouse monoclonal antibodies (mAbs) to NiV F or G could provide complete protection against NiV-M or HeV when administered before and immediately after virus infection (10, 127, 128). These studies demonstrated a major role of a viral glycoprotein-specific antibody in protection.

Recombinant human antibody technology was used to generate a potent cross-neutralizing mAb against NiV and HeV (m102.4) (129, 130). The m102.4 mAb epitope maps to the ephrin receptor binding site of G and blocks virus infection (see the left side of **Figure 2b**), and it can neutralize NiV-M, NiV-B, and HeV (8, 109). The m102.4 mAb provided complete protection from NiV-M-mediated disease in ferrets as a single 50 mg dose administered 10 h post-challenge (8). In the AGM model, m102.4 administered as two 20 mg/kg doses, intravenously, at 10 h and again on day 3, on days 1 and 3 (days 1/3), or on days 3/5, after HeV challenge [ $4 \times 10^5$  50% tissue culture infectious dose (TCID<sub>50</sub>)] by intratracheal (i.t.) administration, protected 100% of treated subjects (131). All treated subjects seroconverted against HeV F glycoprotein with a rise in antibody titer over time, indicating all animals had become infected with HeV and recovered, whereas untreated control subjects succumbed to HeV disease and failed to mount a protective immune response. No clinical signs were evident at any time in the early treatment groups; although neurological symptoms were observed in subjects in the late treatment group (days 3/5), all later recovered from infection. There was no HeV antigen or virus-specific histopathology detected in the lung or brain at the conclusion of the study in any treated subject, and infectious virus could not be recovered from any tissue. A similar study evaluated m102.4 against NiV-M disease in the AGM model at several time points following virus challenge ( $5 \times 10^5$  PFU), including a late cohort where treatment was initiated at the onset of clinical illness (day 5) (132). All subjects became infected after challenge, and all subjects that received m102.4 survived infection and all controls succumbed to disease. Subjects in the late day 5/7 treatment group exhibited disease, but all recovered. A comparative study in AGMs using NiV-M and NiV-B [ $5 \times 10^5$  PFU divided by i.t. and intranasal (i.n.) administration] revealed that NiV-B caused a more aggressive disease, with a

shortened time to death and higher virus loads in tissues and fluids (133). When m102.4 was tested in this model, all subjects in the days 1/3 and days 3/5 post-infection treatment groups survived NiV-B challenge, but subjects in the days 5/7 treatment group succumbed, indicating a shorter therapeutic window in treating NiV-B infection (133). Another well-characterized, humanized mouse mAb, 5B3 (h5B3.1), that is cross-reactive to the F glycoprotein of NiV and HeV and binds a prefusion conformation epitope on F, preventing membrane fusion, was recently tested (110, 134) (**Figure 2b**). The h5B3.1 mAb was given to ferrets in 20 mg/kg doses by intraperitoneal (i.p.) injection, at 1 to several days post-challenge, with either NiV or HeV ( $\sim 5 \times 10^3$  PFU) delivered i.n. (135). All subjects that received h5B3.1 after infection were protected from disease and had increasing neutralizing antibody titers, whereas all controls died. No pathology was observed, and no infectious virus could be isolated at the study endpoint. Altogether, these studies demonstrate that passive immunization with mAbs can provide therapeutic benefit and allow the infected host an extended period to mount a protective immune response. The findings from these experiments were also important because they suggest that vaccine approaches designed to induce adequate neutralizing antibody responses to NiV and HeV should be effective.

The m102.4 mAb producing cell line was provided to the Queensland Government, Australia, to produce the mAb for compassionate use in future cases of high-risk human HeV infection. To date, 14 individuals exposed to either HeV in Australia ( $n = 13$ ) or NiV in the United States ( $n = 1$ ) have been given high-dose m102.4 therapy (15–20 mg/kg) by emergency use protocols, and all have remained well. In Australia, m102.4 was used in a randomized, controlled phase I study in healthy adults (136). The study included four single and one repeat dosing groups, and the m102.4 mAb was found to be safe and well tolerated, with a half-life ranging between  $\sim 16.5$  and 27 days, and no observed immunogenicity was reported. Two doses of 20 mg/kg (days 1/3) were as well tolerated as a single dose. This study's findings will aid in the design of future dosing regimens of mAbs for evaluating their ability to prevent and/or treat HeV and NiV human infections.

### Active Immunization Strategies

A variety of immunization strategies have been developed to prevent NiV and HeV infection including several live-recombinant virus vectors, protein subunit, and virus-like particle (VLP) approaches, and all target the virus attachment and entry steps of infection by employing the G and/or F glycoprotein antigens. Here we summarize these various vaccination countermeasure approaches to NiV and HeV infection (**Tables 1** and **2**).

**Poxvirus vectored.** Poxviruses have a long history as a platform for the expression of heterologous genes to study protein function and serve as vaccine candidates as a live-attenuated viral vaccine platform capable of inducing both cell-mediated and humoral immune responses (137). The F and G glycoproteins of NiV and HeV were functionally characterized using recombinant vaccinia viruses in the early 2000s (138, 139). The first NiV vaccine tested used a highly attenuated vaccinia virus strain (NYVAC) encoding either the F or G glycoproteins from NiV-M (127). Hamsters were vaccinated by subcutaneous (s.c.) injection in a prime-boost strategy with NYVAC-NiV-F or NYVAC-NiV-G, individually and in combination, and then 3 months later challenged i.p. with NiV-M. Vaccination yielded complete protection from NiV-M with no detection of viral RNA, and control subjects succumbed 7–10 days after challenge (127) (**Table 1**). Another poxvirus-based approach was examined as a vaccine for pigs using canarypox (ALVAC) vaccine vectors encoding either NiV-M F or G glycoprotein (140). A prime-boost strategy with ALVAC-NiV-F or ALVAC-NiV-G vectors was tested alone or in combination in pigs. The animals were then challenged 28 days later with NiV-M via i.n. administration. All vaccinated animals survived NiV-M challenge

**Table 1** Virus vectored vaccine strategies for NiV and HeV

Approach	Name(s)	Animal model	Vaccination dose, route, schedule	Adjuvant	Challenge	Challenge dose, route, schedule	Survival	Correlate(s) of immunity/ protection	Reference
Poxvirus	NYVAC-NiV-F and/or -G	Hamster	2 doses at $1 \times 10^7$ PFU, s.c., 1 month apart	None	NiV-M	$1 \times 10^3$ PFU, i.p., 3 months later	100%	NAb response, viral RNA	127
	ALVAC-NiV-F and/or -G	Pigs	2 doses at $1 \times 10^8$ PFU, i.m., 2 weeks apart	None	NiV-M	$2.5 \times 10^5$ PFU, i.n., 28 days later	100%	NAb response, viral RNA, infectious virus, viral shedding, cytokine production	140
	ALVAC-HeV-F and/or -G	Hamster	2 doses at 7.4 or 5.4 log <sub>10</sub> CCID <sub>50</sub> , s.c., 3 weeks apart	None	HeV	$1 \times 10^3$ LD <sub>50</sub> , i.p., 21 days later	89% and 63%	NAb response, viral RNA, viral antigen, viral shedding	141
		Ponies	2 doses at 6 log <sub>10</sub> CCID <sub>50</sub> , i.m., 3 weeks apart	None	NT	NA	NA	High NAb titers	
MVA-NiV-sG and/or MVA-NiV-G	IFNAR <sup>-/-</sup> mice	1 or 2 doses at $1 \times 10^8$ PFU, i.m., 3 weeks apart	None	NT	NA	NA	High serum IgG titers, NiV-G-specific CD8 and CD4 T cells	142

All NiV glycoprotein vaccines employ the NiV-M strain.

Abbreviations: AGM, African green monkey; CSIRO, Commonwealth Scientific and Industrial Research Organisation; F, fusion glycoprotein; G, attachment glycoprotein; HeV, Hendra virus; i.m., intramuscular; i.n., intranasal; i.p., intraperitoneal; i.t., intratracheal; IgG, immunoglobulin G; LNP, lipid nanoparticle; M, matrix protein; MPLA, monophosphoryl lipid A; mRNA, messenger RNA; NA, not applicable; NAb, neutralizing antibody; NiV, Nipah virus; NiV-B, Nipah virus Bangladesh; NiV-M, Nipah virus Malaysia; NT, not tested; o.n., oronasal; PFU, plaque forming unit; s.c., subcutaneous; sG, G glycoprotein soluble ectodomain; TCID<sub>50</sub>, 50% tissue culture infectious dose; VLP, virus-like particle.

as determined by the lack of NiV RNA and infectious virus from nasal washes, pharyngeal swabs, and a variety of sampled organs (140).

ALVAC-vectored vaccines encoding HeV F or G glycoprotein for potential use in horses were also examined (141). ALVAC-HeV-F or ALVAC-HeV-G vectors were combined and first used to vaccinate hamsters at a high or low dose of each vector, by s.c. injection, and then challenged with HeV by i.p. administration. Vaccination did not result in complete protection, with 8 out of 9 subjects in the high-dose group and 5 out of 8 subjects in the low-dose group surviving challenge. No signs of disease were noted, and viral antigen or viral RNA could not be detected in survivors. Nine ponies vaccinated using the same prime-boost regimen were able to develop high cross-neutralizing antibody titers to HeV and NiV-M at day 28 after vaccination. Although ponies were not challenged, most animals yielded titers of at least 1:32 and were considered likely protective (141).

More recently, a modified vaccinia virus Ankara (MVA) vector encoding NiV-M G glycoprotein and a soluble version of G (NiV-sG) were examined in interferon receptor  $\alpha$  and  $\beta$  (IFNAR $^{-/-}$ ) knockout mice (142) (**Table 1**). IFNAR $^{-/-}$  mice were immunized once with MVA-NiV-G or MVA-NiV-sG or prime-boosted. IFNAR $^{-/-}$  mice developed high serum immunoglobulin G (IgG) titers to NiV-G and also generated NiV-G-specific CD8 and CD4 T cells following vaccination. MVA-NiV-sG vaccination induced rapid and significantly higher amounts of NiV-G epitope-specific CD8 T cells compared with the MVA-NiV-G candidate vaccine, suggesting superior immunogenicity. Together, these immunization studies with poxvirus vectors highlight that both T cell and B cell responses play a role in an adaptive immune response to NiV and HeV. However, detailed studies on the adaptive immune responses in animal experiments with henipaviruses have been limited. Future studies evaluating the role of NiV-specific T cells will be important because two human survivors of NiV-B infection in the 2018 outbreak in Kerala showed marked elevation of activated CD8 $^{+}$  T cells, which coincided with virus clearance (143).

**Vesicular stomatitis virus vectored.** Recombinant vesicular stomatitis virus (rVSV) vectors as a vaccine platform suitable for single immunization strategies to potentially meet emergency use requirements have been tested by several groups (**Table 1**). A method of using two defective VSV $\Delta$ G vectors each expressing only the NiV G or F glycoprotein was devised using VSV G glycoprotein complementation that can generate replication-defective VSV vectors that could elicit NiV-neutralizing antibodies (144). Using this technique, researchers tested rVSV vaccines expressing either NiV-M F or G glycoproteins (VSV- $\Delta$ G-NiVG, VSV- $\Delta$ G-NiVF) in hamsters by intramuscular (i.m.) vaccination (145). Hamsters were then challenged 32 days later with NiV-M by i.p. administration. All vaccinated animals survived lethal infection with no clinical signs of disease. No viral RNA or viral antigen could be detected in the sampled tissues when compared with controls, and there was a lack of an anamnestic immune response in vaccinated subjects following challenge, suggesting the induction of sterilizing immunity.

Another study used rVSV- $\Delta$ G vectors expressing NiV-B F or G glycoprotein and also tested them as single-injection vaccinations in NiV-M-challenged ferrets (146). Ferrets were vaccinated i.m. with rVSV-NiV-B F or rVSV-NiV-B G complemented with VSV G or a mix of both vectors, rVSV-NiV-B F/G, that was generated as a complementing pair in the absence of VSV G and then challenged at 28 days with NiV-M by i.n. administration. All vaccinated ferrets were completely protected against NiV-M challenge. Although viral RNA was detected in blood at day 6 post-challenge in 2 of 5 animals in each group, those levels were 100 times lower than in the unvaccinated controls, and by day 21 no viral RNA was detected (146). In a second study, rVSV-NiV-B F and rVSV-NiV-B G were assessed separately and in combination in AGMs (147). Cohorts were

vaccinated with the rVSVs by i.m. injection and challenged 28 days later with NiV-B divided between the i.t. and i.n. routes (147). Complete protection was recorded from NiV-B disease with no gross pathology and no detectable NiV antigen in lung or spleen tissues. Viral RNA was detected in nasal and oral swabs of the vaccinated groups, but no viral RNA could be detected in blood samples.

Replication-competent rVSV-NiV-M F or G vectors, generated by the retention of the envelope glycoprotein from *Zaire ebolavirus* (ZEBOV-GP), which allowed virus stocks to be propagated (rVSV-ZEBOV-GP-NiVF, rVSV-ZEBOV-GP-NiVG, and rVSV-ZEBOV-GP-NiVN), have also been tested (148). These rVSVs were used to immunize hamsters by i.p. administration and were challenged 28 days later with NiV-M. All subjects vaccinated with either the NiV F or G glycoprotein encoding rVSV vectors were completely protected with no clinical disease or pathology, whereas those vaccinated with the NiV N protein were only partially protected (2 of 6 animals) with no clinical signs of disease and the other subjects succumbed to infection. The protective efficacy of the rVSV-ZEBOV-GP-NiVG was also tested in AGMs, where vaccinated subjects were challenged with NiV-M by i.t. administration 29 days later (149). All vaccinated subjects were protected from lethal challenge and showed no signs of clinical disease, no viral RNA was detected in the blood or oral and nasal swabs, and no infectious virus could be recovered. Another study using a rVSV vector expressing a codon-optimized HeV G gene together with an inactivated counterpart was evaluated in mice for humoral immune responses only as a comparator to a recombinant rabies virus vaccine encoding HeV G as a HeV vaccine candidate (150). Here, the live rVSV vectors induced greater levels of HeV G-specific antibodies and higher levels of HeV-neutralizing antibodies than did the recombinant rabies virus vectors (see the section titled Rabies Virus Vectors).

**Adeno-associated virus and adenovirus vectored.** Adeno-associated virus (AAV) vectors as a vaccine platform against infectious diseases, particularly viral pathogens, have been explored. AAV is a small, single-stranded DNA virus in the family *Parvoviridae*. Immunization of hamsters with an AAV vector expressing NiV-M G glycoprotein (AAV8 NiV.G) by i.m. injection demonstrated complete protection from a challenge of NiV-M by i.p. administration, and no signs of clinical disease were recorded (151) (Table 1). Neutralizing antibodies to NiV were induced, no viral RNA or viral antigen was detected in any of the sampled tissues, and there was only a moderate anamnestic response observed in a single subject, suggestive of potential sterilizing immunity. However, in a cross-protection study, AAV8 NiV.G protected only 50% of hamsters challenged with HeV.

Chimpanzee adenoviral (ChAd) vectors circumvent issues of the preexisting immunity observed with human adenovirus vectors (152). Adenoviruses are double-stranded DNA viruses in the family *Adenoviridae*. An engineered replication-deficient ChAd vector, Oxford 1 (ChAdOx1), was tested as a NiV/HeV vaccine (153). Here, ChAdOx1 encoding NiV-B (ChAdOx1 NiV-B) G glycoprotein was used to vaccinate hamsters by i.m. injection, either as a single dose or as a prime-boost protocol. Hamsters were challenged by i.p. administration with NiV-B 42 days following the booster or the single vaccination. Neutralizing antibodies were detectable, and all vaccinated hamsters were protected against lethal disease with no lung pathology, suggesting that a single dose of ChAdOx1 NiV-B was sufficient to completely protect against NiV-B. No viral RNA in the lung tissue and no viral shedding in oropharyngeal swabs could be detected, and no infectious virus could be isolated. A second cohort using a single dose of ChAdOx1 NiV-B to vaccinate hamsters was trialed, and these animals were challenged 28 days later with NiV-M or HeV. All vaccinated animals were protected from lethal NiV-M challenge, but 4 out of 6 hamsters succumbed to HeV disease between days 5 and 7 post-challenge. Neither virus shedding in oropharyngeal swabs nor

infectious virus was detected in the lung or brain tissues of NiV-M-challenged vaccinated hamsters. In contrast, infectious virus was detected in the lung tissues of 75% of the HeV-challenged vaccinated animals. The lower cross-protection observation using NiV G vaccination followed by HeV challenge was not unexpected, as it was previously shown that when the G glycoprotein (as a recombinant soluble subunit immunogen) of either HeV or NiV was used to vaccinate cats, both could completely protect against lethal NiV-M challenge, and that the HeV-sG elicited greater heterologous neutralizing antibody responses in comparison to NiV-sG (14).

**Measles virus vectored.** Recombinant measles virus vectors based on the HL (rMV-HL) and Edmonston (rMV-Ed) measles virus strains have also been explored in which they encoded the NiV-M G glycoprotein (rMV-HL-G and rMV-Ed-G) (154) (**Table 1**). Hamsters were immunized twice by i.p. administration of rMV-HL-G or rMV-Ed-G. All vaccinated animals produced NiV G-specific antibody titers after the booster immunization. Animals were challenged 1 week after the second immunization with NiV-M by i.p. administration. All immunized hamsters exhibited no clinical symptoms and survived challenge. The study was extended to non-human primates (NHPs), where 2 AGMs were immunized twice by s.c. injection with rMV-Ed-G. Subjects were challenged 2 weeks after the second immunization with NiV-M by i.p. administration. Here, immunization completely protected the AGMs with no observed clinical disease and no detectable pathological changes, and no viral RNA could be detected in sampled tissues. Although this was a small study, the safety profile and success of the live-attenuated measles virus vaccine suggests that a recombinant platform encoding the NiV G glycoprotein as a NiV vaccine candidate is promising and should induce a balanced and long-lasting immune response against NiV.

**Rabies virus vectored.** A rabies virus (RABV) SAD B19 vaccine strain, BNSP333, expressing HeV or NiV G glycoproteins has been evaluated (150, 155). Recombinant BNSP333 encoding either the wild-type or a codon-optimized HeV G gene, together with their inactivated counterparts, was used in mice (150) (**Table 1**). Mice were immunized by i.m. injection with a single dose of the RABV-based vectors or with 3 doses of their inactivated versions. The inactivated RABV-based vectors induced higher and more rapid HeV G-specific antibody responses and higher neutralizing antibody titers than their live counterparts. The inactivated RABV-coHeV-G induced cross-neutralizing antibodies against NiV. A similar study used the BNSP333 vector expressing NiV-B G glycoprotein (RABV-NiV-BG) (**Table 1**) and elicited NiV G-specific neutralizing antibodies (155).

Recently, the recombinant RABV Evelyn-Rokitnicki-Abelseth (ERA) strain (rERAG<sub>333E</sub>) expressing either NiV-M F or G glycoproteins was evaluated in mice and pigs (156) (**Table 1**). This vector, rERAG<sub>333E</sub>, serves as an oral vaccine in dogs. Here, mice were orally immunized with RABV-NiV-F or RABV-NiV-G either individually or in combination. Pigs were also immunized in a similar manner but with 2 doses of each vector either alone or in combination. RABV-NiV-F and/or RABV-NiV-G immunization induced NiV F- and G-specific IgG antibody responses and neutralizing antibodies in both mice and pigs with the combination vaccine inducing higher titers. Although not suitable for human use, the live-attenuated rERAG<sub>333E</sub> vector is of interest as a potential veterinary vaccine for NiV because it is already approved for use in some animals and could be adapted for emergency use to protect against NiV infection in livestock, particularly swine.

Many of these virus-vectored vaccines for NiV are promising candidates because of their established safety profiles and ease of genetic modification. Several of these virus-vectored vaccines also require no adjuvants, and some are clearly efficacious as a single immunization strategy, suitable features for emergency use circumstances. In addition, several of these platforms are able to induce both cell-mediated and humoral immune responses, which may also be desirable but as yet

are not fully explored in the development of vaccines for NiV and HeV. Although animals immunized with viral vectors encoding the NiV G glycoprotein and challenged with the homologous virus were completely protected, cross-protection studies with some of these vaccines against a HeV challenge were less effective. For example, only 50% of AAV8 NiV.G-immunized hamsters or 33% of ChAdOx1 NiV-B G glycoprotein-immunized hamsters were protected from a lethal HeV challenge (151, 153). In addition, the ALVAC-HeV-F and ALVAC-HeV-G vaccination studies showed that these vectors did not provide 100% protection in hamsters challenged with HeV, perhaps due to either a suboptimal immunization dose or the immunization route (141).

**Virus-like particles.** VLPs have been explored as a vaccine platform because of the resemblance of their surface structure, dimensions, and compositions to authentic virus yet are of high safety because of the lack of viral genetic material. Earlier studies revealed that the M protein of NiV was capable of orchestrating the formation and budding of NiV VLPs when expressed in cells that appeared structurally similar to authentic NiV virions, and these VLPs could also incorporate other viral proteins such as the F and G glycoproteins (157, 158). VLPs composed of NiV M, F, and G were used to vaccinate mice s.c. at weeks 0, 2, and 4 and demonstrated they could induce high neutralizing antibody titers by day 35 (159) (Table 2). NiV VLPs were later used in NiV-M challenge studies either alone or in combination with adjuvant, monophosphoryl lipid A (MPLA) and Alhydrogel<sup>TM</sup> (15 µg/50 µg) or CpG and Alhydrogel (40 µg/50 µg) (160). Hamsters were vaccinated i.m. either as a single dose or as a 3-dose regimen and then challenged via i.p. administration of NiV-M at 28 days or 58 days, respectively. In all cohorts, 100% of the vaccinated animals survived with no clinical signs of disease and no detection of viral RNA in any of the sampled tissues, regardless of the presence of adjuvant. VLPs are thus an alternative means, with inherent safety, of producing an inactivated whole virus vaccine from an otherwise highly pathogenic virus.

**Subunit vaccine.** The HeV-sG subunit vaccine has been extensively evaluated in several studies. Here, a brief summary of earlier reports is made, but the focus is on studies in NHPs and livestock. Recombinant HeV-sG and NiV-sG can elicit a potent neutralizing antibody response and were first tested as vaccine immunogens in the feline model (14, 161) (Table 2). Both HeV-sG and NiV-sG vaccination of cats completely protected against lethal NiV-M challenge, and HeV-sG elicited greater heterologous neutralizing titers than did NiV-sG, demonstrating that a single subunit vaccine may be effective against both NiV and HeV (14). Other studies using lower doses of HeV-sG (Table 2) demonstrated that a pre-challenge neutralizing titer of 1:32 could protect against NiV-M (162). Additional studies in ferrets showed that low doses of HeV-sG could protect against HeV and NiV-B (163, 164) (Table 2). Also, a longevity study showed that vaccinated ferrets challenged with NiV-B at 14 months post-immunization, with pre-challenge neutralizing titers of 1:16 to 1:128, were also protected (164).

The HeV-sG vaccine has been extensively evaluated in AGMs (Table 2). In a cross-protection study, 100 µg, 50 µg, or 10 µg doses of HeV-sG in combination with Alhydrogel and CpG were administered i.m. as a prime-boost, on days 0 and 21. Pre-challenge 50% neutralization titers ranged from 1:28 to 1:379. All subjects were challenged with NiV-M by i.t. administration on day 42. All vaccinated subjects were completely protected, displaying no clinical signs of disease, and no viral RNA could be detected in blood and tissues and no infectious virus was isolated (165). Similarly, HeV-sG vaccination HeV challenge in AGMs has also been performed. Using a prime-boost regimen, AGMs were vaccinated twice, 3 weeks apart, by i.m. injection with 100 µg HeV-sG with Alhydrogel or HeV-sG with Alhydrogel and CpG, and then challenged 3 weeks later with HeV by i.t. administration (166). All vaccinated animals were completely protected from clinical

disease, and no HeV RNA or viral antigen could be detected in swabs, blood, or tissues, and notably HeV-sG formulated in only Alhydrogel protected (166).

The efficacy and inherent safety of the HeV-sG subunit led to its development as an equine vaccine to prevent HeV infection of horses and also reduce the risk of HeV transmission to people, as a One Health concept (**Figure 1**). HeV-sG, formulated in an approved equine adjuvant (Zoetis, Inc.), was evaluated in two efficacy studies; the first tested 50  $\mu\text{g}$  and 100  $\mu\text{g}$  doses of the same HeV-sG used in prior animal studies to vaccinate horses, and the second used 100  $\mu\text{g}$  doses of HeV-sG produced in Chinese hamster ovary cells (Zoetis, Inc.). Two vaccinations were given by i.m. administration 3 weeks apart. All horses in these efficacy studies were challenged by oronasal inoculation with HeV (**Table 2**). Seven horses were challenged at 28 days and 3 horses were challenged at 194 days after the second immunization. All vaccinated horses remained clinically healthy following challenge; pre-challenge neutralization titers ranged from 1:128 to more than 4,096 in horses challenged 21 days after vaccination and only from 1:16 to 1:32 in horses challenged at 6 months. There was no gross or histologic evidence of infection in any of the vaccinated horses at study completion, and all tissues examined were negative for viral antigen, with no viral genome detected in any tissue. In 9 of 10 vaccinated horses, HeV nucleic acid was not detected in daily nasal, oral, or rectal swab samples or from blood, urine, or fecal samples collected before euthanasia, no recoverable virus was present, and no rise in antibody titer was detected in any vaccinated horse following challenge (167). The HeV-sG horse vaccine (Equivac<sup>®</sup> HeV) was launched by Zoetis, Inc., in November 2012 on a minor use permit by the regulatory authority, the Australian Pesticides and Veterinary Medicines Authority (APVMA), and is the first commercially developed and deployed vaccine against a BSL-4 agent. All vaccinated horses are microchipped, and a database is maintained. Equivac HeV received full registration by the APVMA in 2015. To date, more than 765,000 doses of Equivac HeV vaccine have been administered to more than 179,000 unique horses, and laboratory-confirmed HeV infections in horses have since occurred only in unvaccinated animals.

Studies showed HeV-sG as a NiV vaccine in the pig model (which is a non-lethal challenge model) was much less effective in comparison to results observed in the cat, ferret, NHP, and horse, and HeV-sG was only partially protective against HeV challenge and unprotective against NiV-M in the pig (168). These experiments also indicated that both humoral and cellular immune responses were required for protection of swine against NiV and HeV. Here, pigs were immunized with HeV-sG in a proprietary adjuvant (Zoetis, Inc.), and subjects were challenged with HeV or NiV via i.n. administration (**Table 2**). HeV-sG-vaccinated pigs developed neutralizing titers ranging from 1:160 to 1:320 to HeV, but only partial protection was achieved with reduced viral RNA in tissues and no recoverable virus, and there was no reduction of viral shedding in nasal washes. These HeV-sG-vaccinated pigs did not develop neutralizing antibodies to NiV-M that were considered protective (low), nor did they have measurable activation of cellular immune memory. Only a comparative group of pigs that were first orally infected (vaccinated) with NiV (and recovered) were subsequently protected against an i.n. rechallenge with NiV. This group of pigs developed protective antibody levels and cell-mediated immune memory responses (168).

**Single-dose lipid nanoparticle mRNA, HeV-sG vaccine.** More recently, messenger RNA (mRNA)-based vaccines have emerged as an attractive vaccine strategy because of safety, efficacy, and rapid implementation features. In a recent study, the efficacy of an mRNA vaccine approach was assessed in a NiV-M animal challenge model (169). mRNA transcripts encoding HeV-sG were complexed with lipid nanoparticles (LNPs) to generate HeV-sG mRNA LNP. Two groups of 10 hamsters were vaccinated with a single dose of HeV-sG mRNA LNP at either 10  $\mu\text{g}$  or 30  $\mu\text{g}$  by i.m. injection. Subjects were challenged with NiV-M by i.p. administration 30 days

post-vaccination (**Table 2**). The HeV-sG mRNA LNP was only partially protective, with 3 hamsters from the low-dose group and 7 hamsters from the high-dose group surviving challenge. Of the surviving animals, signs of clinical disease were observed in 2 low-dose group and 6 high-dose group hamsters; however, disease symptoms were gone by study termination. NiV *N* gene RNA levels in the blood and a variety of tissues in surviving hamsters were lower compared with nonsurvivors, but NiV RNA copy levels were not different compared with controls. No anti-NiV IgG or virus-neutralizing activity was detected in vaccinated animals prior to challenge; however, all post-challenge survivors were positive for anti-NiV IgG antibodies, and all survivors (in both groups) had similar neutralizing titers ranging from 1:160 to 1:640. Euthanized animals had little to undetectable neutralizing activity, highlighting the correlation of this immune response to protection. Although promising, the partial efficacy of HeV-sG mRNA LNP observed in this study suggests that further optimization of vaccination route, addition of an adjuvant, and/or a prime-boost regimen is needed.

## SUMMARY AND FUTURE PERSPECTIVES

The frequency of henipavirus outbreaks and human infections is a significant global health concern. A promising passive immunization strategy has been developed using a human mAb, m102.4, shown effective in the NHP challenge model, which has also been administered numerous times to people by compassionate use protocol and has successfully completed a phase I safety trial in Australia. In addition, the Equivac HeV vaccine is available, targeting the protection of horses and also people by breaking the chain of HeV transmission to people, and is an example of a One Health approach to counter an infectious disease threat. Over the past 15 years, nearly a dozen NiV and HeV vaccine approaches have been trialed in animal challenge models, and many show promise as effective human-use vaccines. Recently, the formation of the Coalition for Epidemic Preparedness Innovations (CEPI), a global partnership between public and private organizations, was undertaken with the goals of developing vaccines against emerging infectious diseases and offering equitable access to those vaccines (170). Indeed, without the support of CEPI, the prospects of having a NiV or HeV vaccine suitable for use in people, at a deployable stage in the event of a significant outbreak, would have remained academic. Research teams can now capitalize on the large body of basic and preclinical vaccine development data on a half-dozen important emerging viral threats including NiV and, with the support of CEPI, can develop vaccine candidates for clinical use and future licensure. Several of the NiV human vaccine candidates described in this review are now supported by CEPI.

## DISCLOSURE STATEMENT

C.C.B. is a US federal employee and co-inventor on US and foreign patents pertaining to soluble forms of HeV and NiV G and F glycoproteins and monoclonal antibodies against HeV and NiV whose assignee is the United States as represented by the Henry M. Jackson Foundation for the Advancement of Military Medicine (Bethesda, Maryland). The soluble forms of the HeV and NiV G glycoproteins are licensed to Zoetis, Inc., and Aurobindo Pharma USA Inc. M.A. declares no competing interests.

## ACKNOWLEDGMENTS

C.C.B. is supported by National Institutes of Health (NIH) grant AI142764 and Coalition for Epidemic Preparedness Innovations grant to Aurobindo Pharma USA Inc. The authors thank

Dr. Kai Xu, NIH, Bethesda, Maryland, and Ha V. Dang and Dr. David Veesler, University of Washington, Seattle, Washington, for providing the glycoprotein models in **Figure 2**.

hi Raúl

Sure, that's fine.

Sorry but what I meant before on the last question, was "we" Jon, myself and Eric **do not** know who could address all 3 workflows easily .

I guess my HeV point is:

If the goal of the RFP is aimed at gathering genetic data in support of vaccine development, why is the RFP focused only on Nipah virus isolates, all of which are highly similar (92-99.9% identical), when we know now that the Hendra G glycoprotein (only 78% identical to Nipah G) can completely protect against Nipah Malaysia and Nipah Bangladesh in multiple animal models?

Nipah from Thailand being essentially identical to Bangladesh and all Bangladesh isolates essentially identical amongst themselves (99,9%), and Nipah Malaysia to Bangladesh >92% identical among all proteins with G being 95.5% identical. Any vaccine using G as the immunogen of choice delivered in a way to induce a broad polyclonal response will be effective against all the isolates of Nipah virus we know of.

Importantly, Nipah G does not provide complete protection against a Hendra virus challenge; this has been done with ChAdOx1 and AAV.

We settled on HeV-sG as the vaccine of choice in 2004, because the first test in the cat model showed it to be superior in eliciting higher cross-reactive neut titers to Hendra and Nipah, as compared to Nipah sG

What if a new Nipah virus emerges in SEA or Oceania that is more related to Hendra? Those Nipah G vaccines based on the Bangladesh G will likely not be as effective, whereas the Hendra G vaccine will be.

Chris

Eric will inquire with his partners in a soon to be funded DTRA project for virus surveillance in the Philippines. But we do not think there are any human samples available. Jon has active surveillance projects in India and Bangladesh and Malaysia now, but most of these activities target wildlife/livestock but some human sampling, and are serology based.

best wishes  
Chris

Hello Chris,

Thank you for your email – always good to hear from you!

This RfP was prepared and launched by CEPI's Epidemiology group, which is primarily responsible for its contents. I disseminated the RfP to our Task Force members as a courtesy, and I will be supporting the Epi team tangentially by reviewing applications and by ensuring that we engage external stakeholders in a coordinated fashion.

On that note, you raise questions and comments along the lines of others who have replied. Would it be OK with you if your questions highlighted in yellow are logged to be followed up in CEPI's public response to questions raised? The questions would be anonymized. If you have additional questions to these, please let us know. The HeV point is an important one and I would suggest framing into a question for public follow up.

Best wishes,

Raúl

**Abstract:** The ongoing coronavirus disease 2019 (COVID-19) pandemic has had devastating health and socio-economic impacts. Human activities, especially at the wildlife interphase, are at the core of forces driving the emergence of new viral agents. Global surveillance activities have identified bats as the natural hosts of diverse coronaviruses, with other domestic and wildlife animal species possibly acting as intermediate or spillover hosts. The African continent is confronted by several factors that challenge prevention and response to novel disease emergences, such as high species diversity, inadequate health systems, and drastic social and ecosystem changes. We reviewed published animal coronavirus surveillance studies conducted in Africa, specifically summarizing surveillance approaches, species numbers tested, and findings. Far more surveillance has been initiated among bat populations than other wildlife and domestic animals, with nearly 26,000 bat individuals tested. Though coronaviruses have been identified from approximately 7% of the total bats tested, surveillance among other animals identified coronaviruses in less than 1%. In addition to a large undescribed diversity, sequences related to four of the seven human coronaviruses have been reported from African bats. The review highlights research gaps and the disparity in surveillance efforts between different animal groups (particularly potential spillover hosts) and concludes with proposed strategies for improved future biosurveillance.

## 1. Introduction

In the past two decades, four novel coronaviruses of public and veterinary health importance have emerged. These include the three agents originating from China; severe acute respiratory syndrome coronavirus (SARS-CoV) in 2002 [1,2], swine acute diarrhoea syndrome coronavirus (SADS-CoV) among localized pig farms in 2017 with re-emergence in 2019 [3,4], and SARS-CoV 2 towards the end of 2019 [1,4–6]. The fourth emergent coronavirus, Middle East respiratory syndrome coronavirus (MERS-CoV), emerged in the Arabian Peninsula in 2012 [7,8]. These events show that coronaviruses have the potential to spillover from natural hosts into different species and cause severe diseases with devastating consequences. Dromedary camels are considered the reservoirs of MERS-CoV,

though the original source and transmission routes from animals are still uncertain for SARS-CoV and SARS-CoV 2 [9–13], with related viruses identified in bats. Different amplification hosts are considered to be involved in all three human coronavirus (HCoV) outbreaks.

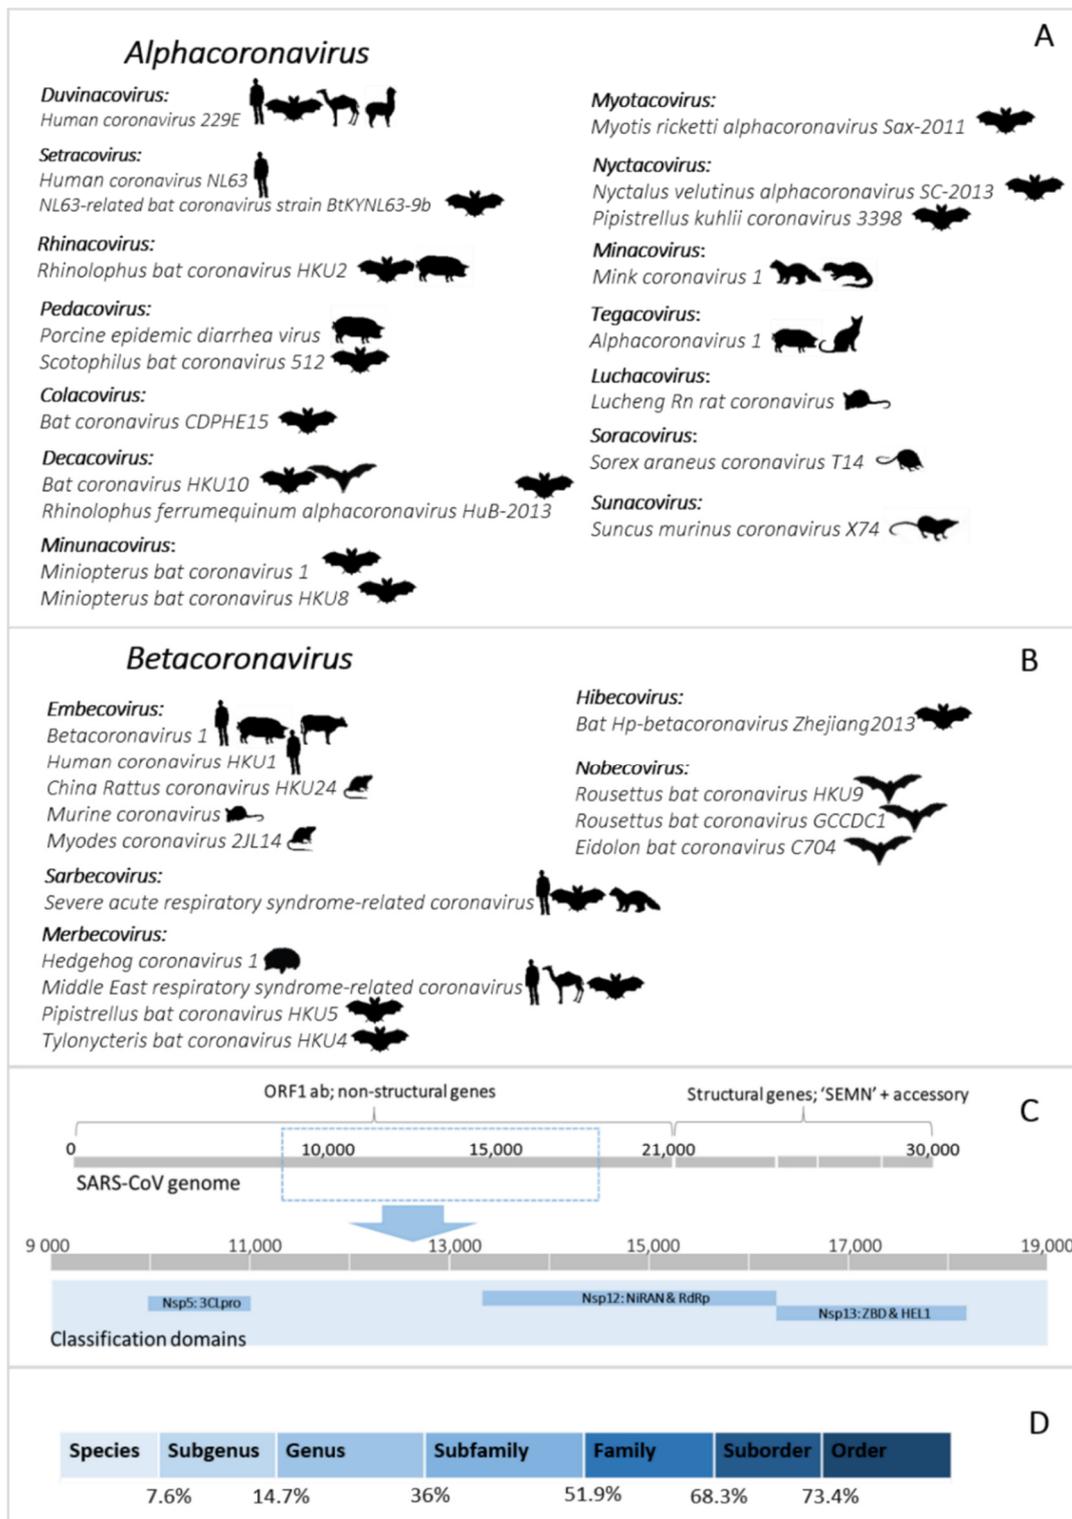

The link between bats and emerging coronaviruses was first considered in 2005 following the identification of coronaviruses related to SARS-CoV in specific Asian rhinolophid bat species [14–16]. Since then, a high diversity of coronavirus nucleic acids has been detected in bats, several of which are related to coronaviruses infecting human and domestic animals, with hundreds of unclassified sequences pending characterization. The expanding knowledge of coronavirus diversity has additionally allowed for novel insights into their evolutionary history, including linking bats as the ancestors of specific mammalian coronavirus lineages [17,18]. More specifically, bat coronaviruses with genetic similarity to known coronavirus species, such as HCoV229E and HCoVNL63, are suggested to have acted as ancestors of these human viruses from previous spillover events [19].

Biosurveillance of wildlife hosts, including bats, are one of the first steps towards understanding how viruses emerge [20,21] and include identifying viral diversity, host species, and distribution ranges. However, several factors have been implicated in spillover events, including genetic, ecologic, epidemiological, and anthropological elements [22]. Unless the underlying factors are also identified and mitigated, coronaviruses are likely to continue to emerge in the future.

The high biodiversity on the African continent supports viral species richness, which has been correlated with disease hotspot mapping and novel viral diseases that have emerged or re-emerged in Africa to date [22]. Many communities in Africa live in close contact with wildlife, domesticated animals, and livestock. Some surveillance for bat coronaviruses has been performed in Africa. A recent review by Markotter et al. [23] provides a comprehensive summary of potentially zoonotic coronaviruses reported from Africa (relatives of HCoV229E, HCoVNL63, MERS-CoV, and SARS-CoV), focusing on the distribution of the host bat species, and concluding that inferences on zoonotic potential based on the genetic relatedness is limiting. This review focuses in greater detail on the total coronavirus diversity identified among African animal species. We review published literature concerning bat species targeted, sample sizes, viral genetic diversity, and evolutionary links to specific host species. The review was also expanded to include the currently available surveillance data among non-bat wildlife and domesticated livestock as hosts of coronavirus diversity. We highlight surveillance approaches from previous studies, important findings, and gaps in current surveillance and propose a surveillance framework to guide the design of future biosurveillance studies.

## 2. The Importance of Viral Taxonomy

The hierarchical levels of the coronavirus taxonomy are well described [24]. There are currently four genera in the *Orthocoronavirinae* subfamily: the *Alphacoronavirus*, *Betacoronavirus*, *Gammacoronavirus*, and *Deltacoronavirus*. The *Alphacoronavirus* and *Betacoronavirus* genera predominantly infect mammals and are further divided into subgenera (Figure 1A,B). Human coronaviruses group within either the *Duvinacovirus*, *Setracovirus*, *Sarbecovirus*, *Merbecovirus*, or *Embecovirus* subgenera (Figure 1A,B). Coronavirus genomes consist of several non-structural genes in open reading frame (ORF) 1 (encoding the replicase polyprotein pp1ab), followed by four structural genes and several accessory genes depending on the species (Figure 1C). Current classification criteria for coronaviruses (ICTV code 2019.021S) rely on comparative amino acid sequence analysis of five domains within the replicase polyprotein pp1ab: 3CLpro, NiRAN, RdRp, ZBD, and HEL1 [6,25]. Computational approaches are used to estimate genetic divergence, and thresholds are utilized as demarcation criteria at various taxonomic levels (Figure 1C,D) [24]. Moreover, only complete genomes are considered for formal taxonomic placement.

**Figure 1.** (A,B) Current coronavirus subgenera (bold) and species of the *Alphacoronavirus* and *Betacoronavirus* genera. The images indicate host species associated with the virus species. Figure constructed with the species listed on the 2019 Release of the ICTV Virus Taxonomy 9th Report MSL#35: (Available at [https://talk.ictvonline.org/ictv-reports/ictv\\_9th\\_report/positive-sense-rna-viruses-2011/w/posrna\\_viruses/222/coronaviridae](https://talk.ictvonline.org/ictv-reports/ictv_9th_report/positive-sense-rna-viruses-2011/w/posrna_viruses/222/coronaviridae) accessed on 12 December 2020). (C) Representation of the coronavirus genome (based on the reference genome NC\_004718.3 SARS coronavirus Tor2) depicting the locations of important domains for classification of species (NSP5 (3CLpro), NSP12 (NiRAN and RdRp), and NSP13 (ZBD and HEL1)). (D) Thresholds of the taxonomic demarcation criteria [24]. Novel viruses are part of a taxonomic level if the divergence within the five concatenated replicase domains is less than the indicated amino acid percentage.

Since the initial identification of bat coronaviruses in 2005, a total of 16 formally recognized coronavirus species have been described from bats. Biosurveillance research mainly report on partial sequences of the coronavirus genome and can only be described to a limited extent by their phylogenetic grouping or similarity percentages. Sequences are considered ‘related’ to genetically similar sequences in a phylogenetic cluster, pending the viral diversity included in the inference. This ‘related’ terminology has become widely misrepresented. It is frequently used to indicate the relatedness of sequences to the closest human coronavirus (HCoV) in a phylogeny, even if these sequences may be significantly distant. For example, SARS-CoV belongs to the *Sarbecovirus* subgenus; and the *Hibecovirus* subgenus forms a sister-clade to the sarbecoviruses (Figure S2). Sequences with low similarity to sarbecoviruses, and which should be part of the hibecoviruses, have (even recently) been deemed as ‘SARS-related’. Erroneous conclusions may be readily avoided by including all representative diversity of the current taxonomy in phylogenies. In this review, we will employ the convention of limiting the use of ‘related’ only to describe bat coronaviruses deemed sufficiently similar to known species according to demarcation criteria (e.g., MERS-related, SARS-related, 229E-related, and NL63-related). All others will be described in relation to phylogenetic clusters, using sequence similarities where possible, or indicating possible grouping within a subgenus (Figure 1A).

### 3. Biosurveillance Studies Based on Nucleic Acid Detection in Africa

Table 1 stipulates the selection criteria utilized to identify and classify publications included in the review. Several surveillance studies focused on bat species were identified [19,26–47], though few studies were found in regards to surveillance among other wild animals or livestock [40,48–51] (Table 1). This may be due to the ‘reactive’ nature of surveillance among livestock, domestic animals, and non-bat wildlife in response to outbreak events among farmed animals or human populations; such events have not been regularly reported in Africa. Global examples include studies involving farmed civets following the first SARS-CoV outbreak, surveillance in camel herds after identifying MERS-CoV and detecting SARS-CoV 2 among mink farms in Europe [9,52,53]. Coincidentally, the use of passive unbiased metagenomic next-generation sequencing among illegally smuggled pangolins identified sarbecoviruses with overall genome similarity of 85.5% to 92.4% to SARS-CoV 2 in Asia [10,54,55].

**Table 1.** Selection and classification criteria of studies included in the review.

<b>Search criteria:</b>	Google scholar searches with keywords: “bat, bats, fruit bats, insectivorous bats, animal, mammal, livestock, domestic, domesticated, wildlife, coronavirus, coronaviruses, detections, Africa, Sub-Saharan, Southern Africa, Eastern Africa, nucleic acid, molecular detection, serology, serological, surveillance, survey” were used to search for peer-reviewed publications documenting surveys for coronaviruses in mammals from Africa (mainland Africa as well as islands associated with Africa such as Madagascar, Reunion Island, Seychelles).
<b>Selection criteria:</b>	For a suitably thorough synopsis of the findings, publications were limited to research available until the end of December 2020 and excluded dissertations, theses, or non-peer-reviewed publications. Sequences included in phylogenetic analyses in this review also excluded sequences from dissertations, theses, or unpublished sequences on GenBank that are not linked to available publications. However, PREDICT surveillance data (‘PREDICT 1 and 2 surveillance and test data’) linked to a 2017 publication was accessed online from Healthmap.org [56] and included both surveillance among bats and other wildlife and livestock.
<b>Criteria for ‘primary surveillance reports’:</b>	Reports containing a description of the collection and testing of samples from animals for coronavirus surveillance. For bat surveillance, we focused on surveillance strategies using nucleic acid detection methodologies such as family-wide consensus PCR analysis or unbiased high throughput metagenomic sequencing. This includes re-testing samples from an earlier report with a different assay and reporting additional coronaviruses detected. Primary surveillance reports may contain varying levels of characterization for detected viruses. We expanded this criterion for livestock and non-bat wildlife to include both nucleic acid and serological surveillance.
<b>Criteria for ‘secondary characterization reports’:</b>	Refers specifically to studies based on a primary surveillance report that does not describe new sample collection but a detailed characterization of viral sequences identified in a previous publication or more in-depth analysis of data obtained from primary surveillance reports.

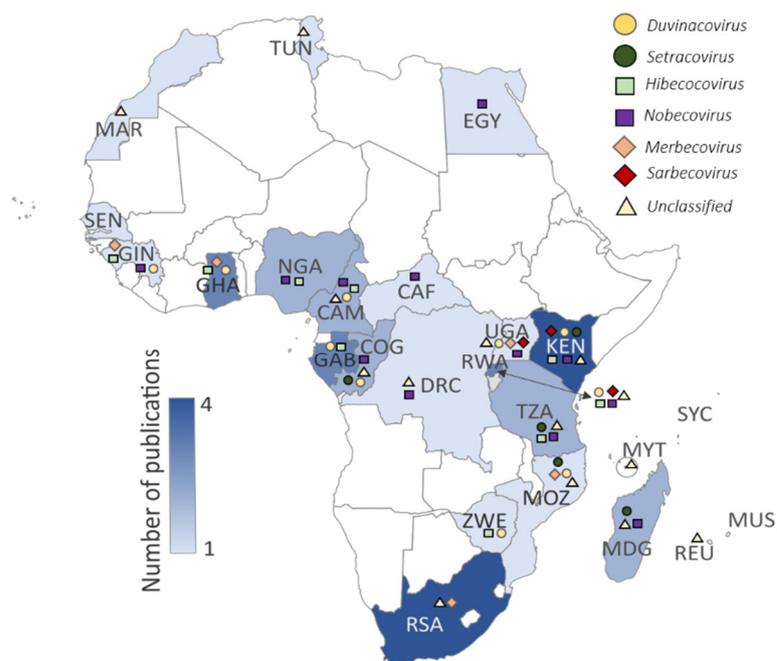

### 3.1. Surveillance in African Bats

Several surveillance studies focused on bats have been performed in Africa since the first reports in 2009 [26,37]. We identified 23 primary surveillance reports and four subsequent secondary characterization reports [57–60] (Table 2 and Figure 2) that included sampling in 24/54 African countries ([www.un.org](http://www.un.org), accessed on 6 September 2020). Several reports originate from Kenya, Ghana, Gabon, and South Africa (Table 2, Figure 2), with limited surveillance in Morocco and Tunisia [33]. Most studies focused on one or more sites within a single country (Table S1), though few studies include once-off sampling from multiple African countries [30,33,38,45]. Anthony et al. [30] describe the PREDICT surveillance performed over a 5-year timespan in more than 20 countries, seven of which took place in Africa (with Rwanda surveillance further detailed in Nziza et al. [36]). Furthermore, nine reports identified coronaviruses while conducting broader virological surveillance [29,31,32,34–36,39,45], whereas others were coronavirus specific. Supplementary Tables S1–S4 summarize the different reports in terms of approach, species and sample numbers, nucleic-acid detection strategy, and overall findings, including when the information was omitted or not sufficiently described.

**Table 2.** Bat coronavirus surveillance performed in Africa, per country.

Country (3 Letter Country Code)	References [Primary Surveillance]/(Characterization Report) *

\* References in square brackets indicate primary surveillance reports; Round brackets refer to 'secondary characterization reports'.

**Figure 2.** Published bat coronavirus surveillance studies per country (shading denoting the number of publications). Symbols in the key above the map represent different coronaviruses detected in the respective countries: Duvinacovirus as a yellow circle (HCoV229E-related viruses), Setracoronavirus as a dark green circle (HCoVNL63-related viruses), Sarbecoviruses as a red diamond (HCoV-SARS-related viruses), Merbecoviruses as an orange diamond (HCoV-MERS-related viruses), Nobecoviruses as a purple square, Hibecoviruses as a green square, and unclassified viruses as a black triangle. Further details on coronaviruses identified can be reviewed in Table S4. Three-letter ISO country code abbreviations are shown on the map.

### 3.1.1. Sampling Approaches and Methodologies of Bat Coronavirus Surveillance

Overall, the primary aim of most of the reports was to detect the presence of coronavirus RNA in bat species, with limited subsequent genetic characterization. Bat species and sample numbers were opportunistically sampled at roosts in mainly cross-sectional once-off sampling focused on a targeted population, region, or species. The frequency of sampling was generally poorly described (Table S1). Exceptions include reports from Madagascar, Nigeria, and Zimbabwe, where multiple sampling events (2 or more) were performed at the same roosts [28,31,47]. Figure 3 provides a graphical summary of the approaches employed by surveillance efforts for bat coronaviruses (Tables S1 and S2).

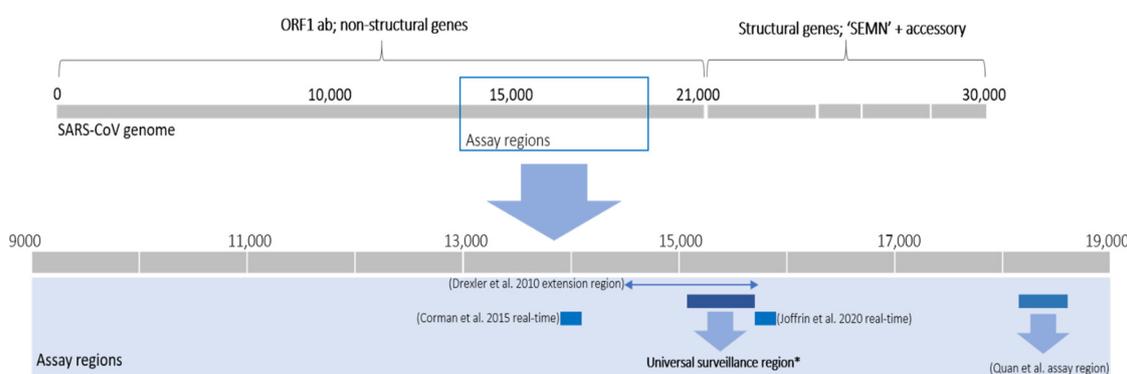

**Figure 3.** A summary of coronavirus sampling approaches and methodology. (A) The sampling approaches of the 23 primary surveillance reports. Combination studies are split into those employing new or archival destructive sampling. (B) Sample preservation methods. (C) Sample types selected for surveillance and samples testing positive. (D) Biosurveillance methodology for nucleic acid testing, percentage of studies using conventional, real-time, or metagenomic approaches. The conventional assays were further split into existing assays from the literature, updated existing assays, or whether new assays were developed. The percentages of studies targeting the ‘universal surveillance region’ (see text for an explanation) contrast to those using different genome regions, and whether specific or random primers were chosen for cDNA preparation.

It is well established that coronaviruses display a gastrointestinal tropism in bats [61], and fecal material or other gastrointestinal sample types such as rectal swabs (non-destructive) or intestinal tissue (destructive) is the preferred sample types for surveillance (Figure 3). Sample collection was mostly non-destructive (52% of studies), including fecal material collected beneath roosting bats in caves and trees [28,29,31,33,37] or fecal material and rectal swabs from individual bats [19,26,27,30,32,34,35,37,42–44,46,47]. For this review, we are assuming fecal swabs are the same as rectal swabs. Only 13% of studies solely implemented destructive sampling (collection of organ tissues), and 35% of studies (Figure 3) combined both methodologies to collect sample material for multi-pathogen surveillance [27,30,35,41,43,45] or were tested due to availability within archival tissue banks [32,39,42]. Along with gastrointestinal samples, oral (or throat) swabs were also collected [19,26,27,30,47], but infrequently contained coronavirus RNA [19,27,30,36,39]. Due to limited reporting information provided per study, coronavirus detection among oral swabs can only be roughly estimated. Of all reports investigated, only 35% tested oral swabs (Figure 3). From these reports, 62.5% identified coronavirus RNA, representing positive

oral swabs from only 14% of studies overall (Table S1). Coronaviruses were also opportunistically detected within lung and liver tissues [27,38,45], though it is unclear what other positive individuals' organs were also tested.

The basic methodology implemented in all but two studies [32,34] involved RNA extraction of samples followed by nucleic acid detection targeting a conserved region of the genome. A region of the RNA dependent RNA polymerase (RdRp) gene within the open reading frame (ORF) 1b of the coronavirus genome (Figure 4) is mostly targeted and corresponds to approximate nucleotide position 15,200–15,600 in the coronavirus genome (using reference NC\_004718.3 SARS coronavirus Tor2) (Figure 4, Table S2). Targeting of this “universal coronavirus surveillance region” enables comparison between studies, though 74% of the African bat surveillance studies utilized assays based on the region (22% either used a non-universal region or combination of both; Table S2). The addition of a nested step is generally essential for the detection of low concentration viral RNA. A small number of studies in Africa quantified viral concentrations of positive samples, obtaining as little as 50–450 RNA copies/mg fecal material for some low concentration samples, or between 323 to  $1.5 \times 10^8$  RNA copies/g of fecal material [37,44].

**Figure 4.** Representation of the coronavirus genome (based on the reference genome NC\_004718.3 SARS coronavirus Tor2) depicting the assay regions. The assays corresponding to this universal region included in Tong et al. [26], de Souza Luna [62], Geldenhuys et al. [42] and Geldenhuys et al. [32] (based on primers from Woo et al. [63]), Razanajatovo et al. [47] (based on Poon et al. [14]), Shehata et al. [27], Waruhiu et al. [29] (based on Watanabe et al. [64]), Chu et al. [65], Gouilh et al., [33]. The RdRp grouping units (RGU) amplification region by Drexler et al. [66] is indicated with the line and arrows.

The majority of surveillance studies (52.2%) implemented a one-step kit approach (i.e., utilizes RNA templates in a single reaction with target-specific primers for cDNA followed directly by PCR amplification), with seven (30.4%) implementing an unbiased methodology for the preparation of cDNA with random hexamers before PCR amplification [31–33,35]. An unbiased approach is more beneficial where only limited sample material is available and multi-pathogen surveillance is done. Suitable assays were either selected from the literature (with the assay from de Souza Luna et al. [62] most frequently employed), constitute newly developed assays (included if no reference was provided for assay modifications), or were updated/modified from the literature (Table S2 and Figure 3). Assays selected from the literature were constructed using the available sequence information known at that point in time. The expanding genetic diversity of coronaviruses is high, and even though these assays target a conserved region, existing primers may be less sensitive toward the detection of more diverse viruses. For example, primers developed before the 2012 emergence of MERS-CoV might not be sufficiently sensitive to detect diverse coronaviruses from the Merbecovirus subgenus. Developing new assays or updating available primers have the added advantage of ensuring that some of the expanding sequence diversity of emerging human coronaviruses and newly detected animal coronaviruses can be incorporated; reducing the probability of highly diverse clades going undetected.

Exceptions to this ‘universal CoV surveillance’ region are represented mainly by the nested RT-PCR assay developed by Quan et al. [41], targeting a region downstream of the universal CoV surveillance region, corresponding to the approximate nucleotide position 18,300–18,700 (Figure 4). Sequences amplified with the assay from Quan et al. [41] cannot be directly incorporated in phylogenies using the short universal CoV surveillance region and may only be compared to viruses for which this corresponding genome region is available or with full genomes. The PREDICT surveillance described in Anthony et al. [30] and Nziza et al. [36] utilized two surveillance assays to test samples; that of Watanabe et al. [64] based on the universal region and Quan et al. [41]. In total, the Watanabe assay detected 950 coronavirus sequences compared to the 654 sequences from the Quan assay, with only a 27% overlap [30].

Overall, it is not possible to directly compare methodologies to conclude best practices for coronavirus surveillance. However, non-destructive sampling methodologies (swab collection or fecal material from underneath roosting bats) associated with a gastrointestinal origin allow for successful coronavirus identification with minimal injury to the hosts or ecosystem. Proper preservation of sample material is good practice (cold chain or using preservation media), and unbiased cDNA preparation approaches allow for the conservation of reagents and sample material. The use of appropriate assays and overlapping target regions are essential to enable comparisons between studies.

### 3.1.2. Summary of Sample Sizes and Bat Species Tested

The surveillance data from the 23 publications were compared to the 2019 African Chiropteran Report (comprehensive report of the current taxonomy with data based on museum records from bats collected across the continent) to determine an estimate of total bats sampled per species (Table S4; [67]). There are 13 extant bat families in Africa, with an estimated 324 species [67]. Eleven families have been included in coronavirus surveillance reports (Table 3). Several publications provided the total bats sampled within a study though may not have specified per species or country, and thus 1966 sampled bats could not be included [29,41]. The sample numbers (per species per country) were not specifically indicated in Anthony et al. [30], but total PREDICT surveillance data for the seven African-surveyed countries was accessed online from Healthmap.org and included in the analyses. We acknowledge that the data likely exceeds the sample size for the countries used for the analysis in the 2017 publication; however, we felt that including the data in our assessment greatly contributes to the total bats sampled in Africa per species—by over 10,000 individuals. Moreover, this data was also used in Tables 2 and S1–S3. Of the approximate 127 total bat species included in studies, bat coronaviruses were identified in 59. Nearly 26,000 bat individuals are estimated to have been tested for coronaviruses in African surveillance studies using one or more assays. However, this number comprises mainly pteropid and hipposiderid bats (41.8% and 33%, respectively) and varies per family. The table below highlights the need for additional surveillance in several families, such as the Vespertilionidae. These are abundant bats, and increasing the sample size tested of species in this family may provide a greater understanding of the host ecology of coronavirus species such as MERS-related viruses.

**Table 3.** Coronavirus detections according bat host taxonomy.

Bat Families Tested	Number of Species	Species Tested	Bat Species Positive	Number of Individuals Tested Per Family *	Positive Individuals #
Pteropodidae	44	22	14	10,851	881 (8.1%)
Hipposideridae	21	10	8	8563	257 (3%)
Molossidae	44	16	8	2144	286 (13.3%)
Miniopteridae	22	12	5	1464	120 (8.2%)
Vespertilionidae	114	37	9	918	41 (4.5%)
Rhinolophidae	38	14	9	728	68 (9.3%)
Emballonuridae	11	4	0	678	0
Nycteridae	15	6	3	299	51 (17.1%)
Rhinonycteridae	6	3	2	250	74 (29.6%)
Megadermatidae	2	2	1	25	3 (12%)
Rhinopomatidae	3	1	0	1	0
Myzopodidae	2	0	0	0	-
Cistugonidae	2	0	0	0	-
Totals	324	127	59	25,921	1779 (6.9%)

\* Counts for number of individuals tested reflect individuals from publications reporting total individuals tested per species per country, or total positive individuals in reports where total sampled are not provided. These counts exclude 1966 bats tested in [29,41] from which species totals were not provided, and studies testing colony-level fecal samples [28,31].

# Approximate number of positives from Table S5.

Coronavirus RNA has been detected in nine of the eleven families sampled, excluding the Emballonuridae and Rhinopomatidae. The Rhinopomatidae represents only one tested individual; approximately 678 bats from four species in the Emballonuridae family have been investigated (*Coleura afra*, *Taphozous perforates*, *Taphozous mauritanus*, and *Taphozous hildegardeae*). This includes surveillance from eight countries with sample sizes varying from 1 to 172 (Tables S4 and S5). Comparatively, coronaviruses have been identified from families like the Megadermatidae, Rhinonycteridae, or Nycteridae, from which far fewer individuals were analyzed (25–299). The lack of viral detection from the Emballonuridae family could be due to insufficient sample sizes, extremely low prevalence, time of sampling, highly diverse viruses missed by consensus primers, or the absence of coronaviruses. The remaining unsampled Myzopodidae and Cistugonidae families are small (two species each), with limited distributions in Madagascar and Southern Africa, respectively.

Primary surveillance reports investigating one or two species/genera typically focus on abundant hosts that may form large populations with frequent opportunities for contact with human communities [28,31,32,34]. Studies sampling many diverse genera/species (83% of primary surveillance reports) mostly sample species opportunistically present at one or more surveillance sites (Table S3). To estimate sample sizes per species, we looked at the total and average number of individuals per species tested in these reports and specifically noted sample sizes of less than ten individuals (Table S3). For some species, below ten individuals were tested, whereas several hundred [19,27,30,36,45,47] or even thousands of individuals from other species were sampled [44,46]. It was more common for less than 100 individuals to be sampled per species, though a few reports averaged 100–150 per species [19,27,30,36,45,47]. The percentage of species within a report for which less than ten individuals were sampled ranged between 18.5 to 100% of species (Table S3). This constituted more than 50% of species sampled from 11 of the reports and likely represented opportunistically caught individuals. This could not be determined for a further four reports, as sufficient detail was not specified, or samples collected represent colony or population-level sample collection.

A guideline for optimal sample sizes per species was proposed by the meta-analysis of coronavirus surveillance in 20 countries by Anthony et al. [30], with the optimal sampling number being approximately 397 individuals. This was calculated to detect the av-

average number of unique coronavirus groups relating to probable viral species (2.67) estimated to be present in each bat species. Their findings identified that sampling less than 154 individuals per species constituted poor returns on investment and sampling effort [30]. The percentage of species per report from which coronavirus nucleic acids were detected varied between 8.3% to 66.7% (excluding when only one species was sampled). Overall, the percentage positivity of coronaviruses per total samples ranged from below 1% to 25.7% (excluding pools) (Table S3). As expected, increasing either sample sizes or number of species tested show correlation with increased positivity percentages (Pearson's product correlation  $t = 8.9289$ ,  $df = 21$ ,  $p < 0.001$  and  $t = 5.4952$ ,  $df = 20$ ,  $p < 0.001$ , respectively). The differences in positivity can be attributed to many factors, including the nucleic acid detection assay, the methodology for sample collection (preservation of nucleic acids), time of sampling coinciding with coronavirus excretion, species sampled, and sufficient sample numbers per species. Tables S4 and S5 highlight species commonly detected to host coronaviruses; a detailed description of 'high-risk' viruses identified from host species is described below.

### 3.1.3. Importance of Accurate Bat Species Identification

Correct identification of bat species is essential to conclude potential virus-host associations and estimation of host-viral distribution ranges. This is especially important for complex bat species with similar morphological markers, such as members of the Hipposideridae, Rhinolophidae, and Vespertilionidae. Since the start of coronavirus nucleic acid surveillance among bat species in Africa in 2009, several bat species have undergone species reassignments and name changes. We could not update all new species names for this review and used the taxonomy described in the 2019 African Chiropteran report [67]. However, recent changes of note are among the Hipposideridae, Rhinolophidae, Miniopteridae, and Vespertilionidae families, with additions of new genera (*Afronycteris*, *Pseudoromicia*, *Vansonia* (elevated to genus)) and the reassignment of species to existing and new genera [68–71]. Some of these include *Hipposideros* species reassignments to the genus *Macronycteris* and the resolution of some *Neoromicia* species with reassignments to *Laephotis*, *Afronycteris*, and *Pseudoromicia* genera [68,69]. Currently recognized species may be accessed at [www.batnames.org](http://www.batnames.org) (accessed 18 November 2020) [72], and new species need to be correctly correlated to geographical distributions.

We investigated the methodologies for host identification implemented by the primary surveillance reports (Table S3). No identification methodologies for bat species were stipulated in seven (30%) of the bat coronavirus surveillance studies; five (22%) report the use of keys to determine morphological identities by either field teams, veterinarians, or experienced chiroptologists; and two (9%) report the use of molecular means of species confirmation. Only nine reports (39%) describe both morphological and molecular methods to identify and confirm host species (Table S3). Molecular methods include either mitochondrial cytochrome B gene or cytochrome C oxidase subunit I sequencing [73,74]. Not only is this good practice in ensuring accurate determination of host species identity, but if deposited on public reference databases, it ensures that the records of these sequences for sampled species are expanded. However, depositing sequences of individuals lacking accurate morphological identification and failure to update taxonomic changes generally leads to confusion and incorrect host reporting. Thus, reference material on these databases must be associated with correctly identified individuals where morphological identification was conducted by highly trained individuals or experienced bat taxonomists.

### 3.1.4. Characterization of Bat Coronavirus Genomes and Virus Isolation Attempts

Bat coronavirus surveillance in Africa primarily focused on amplifying and sequencing short amplicon sequences and subsequent diversity determination. The majority of African bat coronaviruses are therefore unclassified and are only represented by a short-sequenced region. Further characterization of the detected coronaviruses is essential for

improved phylogenetic placement and comparisons of various genes/proteins for phenotypic analyses. Studies aiming to further characterize identified coronaviruses employed diverse methodologies (Table S2). Sequence-specific primers have been successful in extending the sequenced regions of the ORF1ab [28,47] or recovering complete coding regions of structural genes like the nucleoprotein gene [27,37]. Sequencing these regions generally involved primer-walking strategies with conventional Sanger sequencing or even high throughput sequencing platforms to overcome the length limit of conventional sequencing. The informal RdRp gene grouping units (referred to as RGU; Figure 4) developed by Drexler et al. [66] amplifies an 816 nucleotide amplicon of the RdRp gene. The pairwise distances of the translated 816 nucleotide fragments (272 amino acids) have been used to delimit different groups as a surrogate system for taxonomic placement of detected bat coronaviruses that lack complete genomes. Grouping units of alphacoronaviruses differ by 4.8% and betacoronaviruses by 5.1% [61]. These grouping units have been used as an extension assay by 22% of African bat coronavirus studies [32,35,43,44,46]. It is worth noting that these units are an unofficial estimate of possible species groupings and may be subject to revision as new diversity is detected (as evident by previous decreasing betacoronavirus thresholds from 6.3% to 5.1%) [61].

The number of bat coronaviruses that can correctly be assigned to a viral species is limited to those with available complete genomes. From African studies, there are over 1840 partial coronavirus gene sequences available among public domains (such as NCBI's GenBank), though only 13 complete genomes and 12 near-complete genomes [19,32,34,41,46,57–59]. The MERS-related *Pipistrellus* bat coronavirus from Uganda was recovered with unbiased sequence-independent high throughput sequencing on the MiSeq platform [59] and a near-complete genome of Zaria bat coronavirus from Nigeria using 454 pyrosequencing [41]. Sanger sequencing with classic primer-walking spanning the entire genome with 70 overlapping hemi-nested PCR assays was implemented to recover a MERS-related *Neoromicia* bat coronavirus from South Africa [58], with a second variant from the same host sequenced using 11 overlapping hemi-nested PCR assays on the MiSeq platform [32]. For more novel viruses, amplification of more conserved coronavirus genome segments with nested consensus degenerate primers are frequently required before being able to sequence more diverse regions with long-range PCRs [19,46,57].

The limited number of complete African bat coronavirus genomes are reflective of the challenges involved. These include the limited scope of certain studies, low viral RNA concentrations, unavailability of sufficient material, lacking related reference genomes for primer design, availability of high throughput sequencing platforms, expertise, and cost [32,37,46]. To overcome some of these constraints, such as limited availability of material, virus culturing can be attempted. However, coronaviruses are notoriously difficult to isolate in vitro, with various methodologies utilized (reviewed in Geldenhuys et al. [75]). Only bat coronaviruses closely related to SARS-CoV have thus far been successfully isolated in Vero cells because the bat viruses could use the same receptors as SARS-CoV [76,77]. This challenge and limited sample material available after nucleic acid extraction and high-biocontainment requirements are likely contributing factors to why none of the 23 primary surveillance publications or secondary characterization reports attempted cultivation of coronaviruses in cell culture (nor described attempts).

It is important to note the formats of naming conventions among bat coronavirus studies, with only some providing sufficient information on the origins of sequences (Table S2). The Coronavirus Study Group of the ICTV recommends adopting a standardized format for nomenclature that has been used for Influenza viruses and avian coronaviruses [6]. Namely, the reference to a host organism from which the viral nucleic acid was derived, the place of detection, a unique strain identifier as well as mention of the time of sampling (e.g., virus/host/location/isolate/date or as an example BtCoV/Neoromicia/RSA/UP5038/2015). This format also allows rapid identification of inter-genus viral sharing in phylogenetic trees and highlights similar clades of viruses occurring in related

species independent of geography. More importantly, this naming convention makes no inference of belonging to a particular species, as species assignments may only be performed once the requirements have been met (i.e., sequencing the genome according to species demarcations).

### 3.1.5. Coronavirus RNA Identified in African Bats

Global coronavirus surveillance in bats has established several generalizations, with which African studies are in agreement. Namely, bat coronaviruses generally display host specificity, which is usually evident at the genus-level [19,61,78–80]. As a result, certain viral species or even subgenera may be predominantly associated with specific host genera (e.g., rhinolophid bats and *Sarbecovirus*). This association has been observed to be independent of the geographical isolation of the bat hosts [38,81,82]. The evolution of coronaviruses has been suggested to involve a combination of two mechanisms, co-evolution between viral and host taxa and frequent cross-species transmission events [78]. Co-evolution is evident by genus-specificity and the large diversity of bat coronaviruses globally sampled, though many taxa host more than one species/group of coronaviruses [37,78]. Meta-analyses of publicly available bat coronavirus sequences confirmed long-term evolution among bats and determined that frequent cross-species transmissions occur, particularly among sympatric species, though often result in transient spillover among distantly related host taxa [19,30,78]. Such transmissions potentially create viral adaptation opportunities to new hosts and increase overall genetic diversity [83]. Uniquely for Africa, the genetic information of bat coronaviruses sharing similarity to human coronaviruses have been identified in four of the five subgenera associated with human coronaviruses—*Duvinacovirus*, *Setracovirus*, *Merbecovirus*, and *Sarbecovirus* (Figure 1A,B). Such findings suggest opportunities for transmission from bats to other animals or directly to humans may have occurred in the past. Though these viruses are still circulating among these hosts, discerning current risks of spillover is limited by available evidence.

Together with highly variable mutation rates [84,85], coronaviruses are also known for recombination events, where homologous recombination between similar coronaviruses is the most likely. However, recombination between different co-infecting coronaviruses from different subgenera/genera has also been documented [86–88]. Opportunities also increase when bats are co-infected by more than one species of coronavirus. Moreover, heterologous recombination between viral families has also led to the assimilation of novel genes in certain coronaviruses [86,87]. Recombination hotspots within the spike gene have been identified for diverse coronaviruses originating from humans, domestic animals, and bats [89]. Some of the new resultant variants may have improved fitness advantages within their native or new hosts, and new recombinants may be more suited to the usage of new receptor molecules.

Phylogenies were constructed with the sequences from the 23 primary surveillance reports and secondary characterization research studies, representing the sequence diversity of African bat coronaviruses compared to formally classified species and relevant reference sequences (see Appendix A and complete phylogenies in Figures S1 and S2). The following sections summarize the information available regarding detected bat coronaviruses associated with known human coronaviruses and highlight the importance of recombination in the emergence of novel viruses. We also discuss the large diversity of unclassified and unstudied viruses in some highly abundant host species and consider possible interaction opportunities between humans and bat hosts.

### Alphacoronaviruses—*Duvinacovirus*, *Setracovirus*, and Unclassified Virus Relatives of Human Alphacoronaviruses

Several African bat coronaviruses share genetic similarity with the two human alphacoronaviruses, HCoV229E (*Duvinacovirus*) and HCoVNL63 (*Setracovirus*). As seen in Figure 5A, hipposiderid bats (genus *Hipposideros*) are associated with coronavirus se-

genomes, including gene losses (e.g., ORF8 within human viruses) and deletions within the spike gene [46]. Several of the bat viruses with similarity to HCoV229E for which no complete genomes are available indicate that there are sequence divergences of approximately 13.5% among RdRp partial gene segments, suggesting circulation of highly diverse HCoV229E-related viruses. The scenario would suggest that HCoV229E may have originated from the large diversity of *Hipposideros* HCoV229E-related bat coronaviruses in the past 200 years (based on the current sequence diversity), with camelids (alpacas, camels, etc.) as possible intermediate hosts [46].

Similarly, several African bat sequences cluster around HCoVNL63 (Figure 5A) and originate from the genus *Triaenops* (Rhinonycteridae family). *Triaenops afer* is the only mainland Africa species currently recognized within the genus after it was split from *T. persicus*, which only occurs in the Middle East [67,90] (with *Triaenops menamena* from Madagascar). Partial and complete genomes were first reported in Kenya [19] with additional partial genomes from the Republic of the Congo, Tanzania, Mozambique, and Madagascar [30,38] (Table S4). Three full genomes were recovered from Kenyan *T. afer* bats and compared to HCoVNL63 [19]. Much like 229E-related bat viruses and HCoV229E, comparisons of the bat viruses to HCoVNL63 identified additional ORFs (ORFx) in bat viral genomes that were absent in HCoVNL63 [19]. The new species, *NL63-related bat coronavirus strain BtKYNL63-9b (Setracovirus)*, comprised of *Triaenops* coronavirus strains, has been recognized. *Triaenops* virus 9a shares the closest similarity to HCoVNL63 with 78% overall nucleotide identity. The spike was the most divergent gene, with gene phylogenies showing the spike gene of HCoVNL63 grouping with *Hipposideros* 229E-related bat viruses detected in the same study [19]. Recombination analysis of HCoVNL63 indicates multiple breakpoints within the spike gene and suggests a history of recombination between the *Triaenops* NL63-related viruses and *Hipposideros* 229E-related viruses giving rise to the lineage of HCoVNL63 before its introduction into human populations [19]. As with HCoV229E, an intermediate host (and not bats directly) may likely have been involved in introducing progenitor HCoVNL63 viruses into the human populations. Such intermediate hosts are often domesticated livestock animals (such as camelids in the case of HCoV229E) as they have more frequent contact with people, underscoring the need for expansive surveillance within domestic animals to complement surveillance in wildlife.

Bats from the *Hipposideros*, *Myonycteris* and *Triaenops* genera are all small insectivorous bats and have many overlapping ecological features in terms of habitat. *Hipposideros* and *Myonycteris* primarily roost in caves, though certain species have been known to roost in rock crevices, under bridges, and in tunnels [67]. *Triaenops* have been found roosting in small trees and certain shrubs and mines and caves [91]. Moreover, bats from all three genera are sensitive to human activities that lead to habitat loss and roost disturbance [67]. The surveillance findings show that these viruses continue to circulate in these hosts, with the potential to recombine and create new variants. Establishing whether these viruses pose possible zoonotic risks is limited due to lacking evidence. In vitro studies can assist with determining permissivity or pathogenicity in different cell lines, and protein modeling can suggest the likelihood of receptor binding of bat viruses in spillover hosts. There is also a lack of nucleic or serological investigations into potential spillover animal species that overlap with the bat hosts' geographical distributions and ecological niches.

#### Alphacoronaviruses—Molossids and a Large Diversity of Uncharacterized Bat Coronaviruses

The diversity of bat alphacoronaviruses from Africa is high. Much of the reported sequences share genetic similarity to members of described subgenera, such as *Rhinacovirus*, *Pedacovirus*, and *Minunacovirus* (Figure 5B). Many of the other sequences represent undescribed diversity and may possibly belong to new subgenera. A large number of unclassified alphacoronaviruses have been identified from molossid bats (Figure 5B). Generally, these sequences form three clades, with sequences similar to a species of

*Colacovirus* detected in *Chaerephon* and *Tadarida*; a sister clade of the *Mycotacovirus* subgenus that split into an *Otomops*-specific species clade from Kenya; a predominantly *Mops/Chaerephon* group of alphacoronaviruses from several countries (Cameroon, Kenya, Tanzania, South Africa and the Republic of the Congo). The latter group also contains a large volume of sequences from various pteropid species (as well as a few vesper species) from Cameroon [30], making it a mixed family clade or a group of viruses frequently prone to host switching. Sequence information on these viruses largely constitutes short sequences from surveillance assays as well as a few partial genomes (HQ728486/BtCoV/*Chaerephon*/KEN/2006/KY22 and HQ728481/BtCoV/*Chaerephon*/KEN/2006/KY41) [57]. These coronaviruses were detected from molossid species such as *Chaerephon pumilus*, *Mops condylurus*, *Otomops martiensseni*, and *Tadarida aegyptiaca*, with only 16 of the 44 species from the Molossidae family having been included in surveillance studies. Of note are recent taxonomy changes among this family [72]. Moreover, as indicated in Table S4, large numbers of molossid bats tested are only specified to genus level, with nearly 171 *Chaerephon* spp., 30 *Mops* spp., and 64 *Tadarida* spp. reported. This again reiterates the need to identify hosts down to species level. These species are highly abundant with widespread distributions throughout Africa and are often encountered in urban settings. They are frequently found to be roosting in large populations (several hundred) in the rafters or roofs of buildings such as houses or public institutions like schools, universities, and libraries [67]. As a result, opportunities for contact arise between bat excreta and people (and domestic animals). Though there is no current zoonotic association with these coronaviruses, their abundance among a commonly encountered bat species, with possibly frequent exposure opportunities warrant investigation. Significant characterization of these viral groups is required to better understand this diversity and investigate the zoonotic potential of these alphacoronaviruses.

#### Betacoronaviruses—Merbecoviruses and Vespertilionid Bats

MERS-CoV emerged on the Arabian Peninsula in 2012 and is now considered endemic to the region due to the presence of the primary reservoir, the dromedary camel [7,92,93]. According to reports from Africa, Europe, Asia, and even South America, viruses sharing similarities to MERS-CoV (*Merbecovirus*) are associated with more than one bat host genus or family [32,43,44,59,83,94,95]. The MERS-related coronaviruses genomes currently sharing the highest similarity to human and camel MERS-CoV were detected in Africa from *Neoromicia capensis* (South Africa) and *Pipistrellus hesperidus* (Uganda) [32,58,59]. Both *Neoromicia* and *Pipistrellus* are small insectivorous bats belonging to the Vespertilionidae family, with several species reassignments occurring in 2020 [68]. Due to taxonomic rearrangements, the genera *Laephotis*, *Afronycteris*, and *Pseudoromicia*, necessitate inclusion into future MERS-related coronavirus surveillance due to possible intra-host sharing of coronaviruses. Sampling efforts into the previously recognized *Neoromicia* species include approximately 238 individuals and only 100 individuals among *Pipistrellus* species (Table S4), warranting intensified surveillance. According to published reports, very few individuals have been found to harbor MERS-related viruses from these bats sampled.

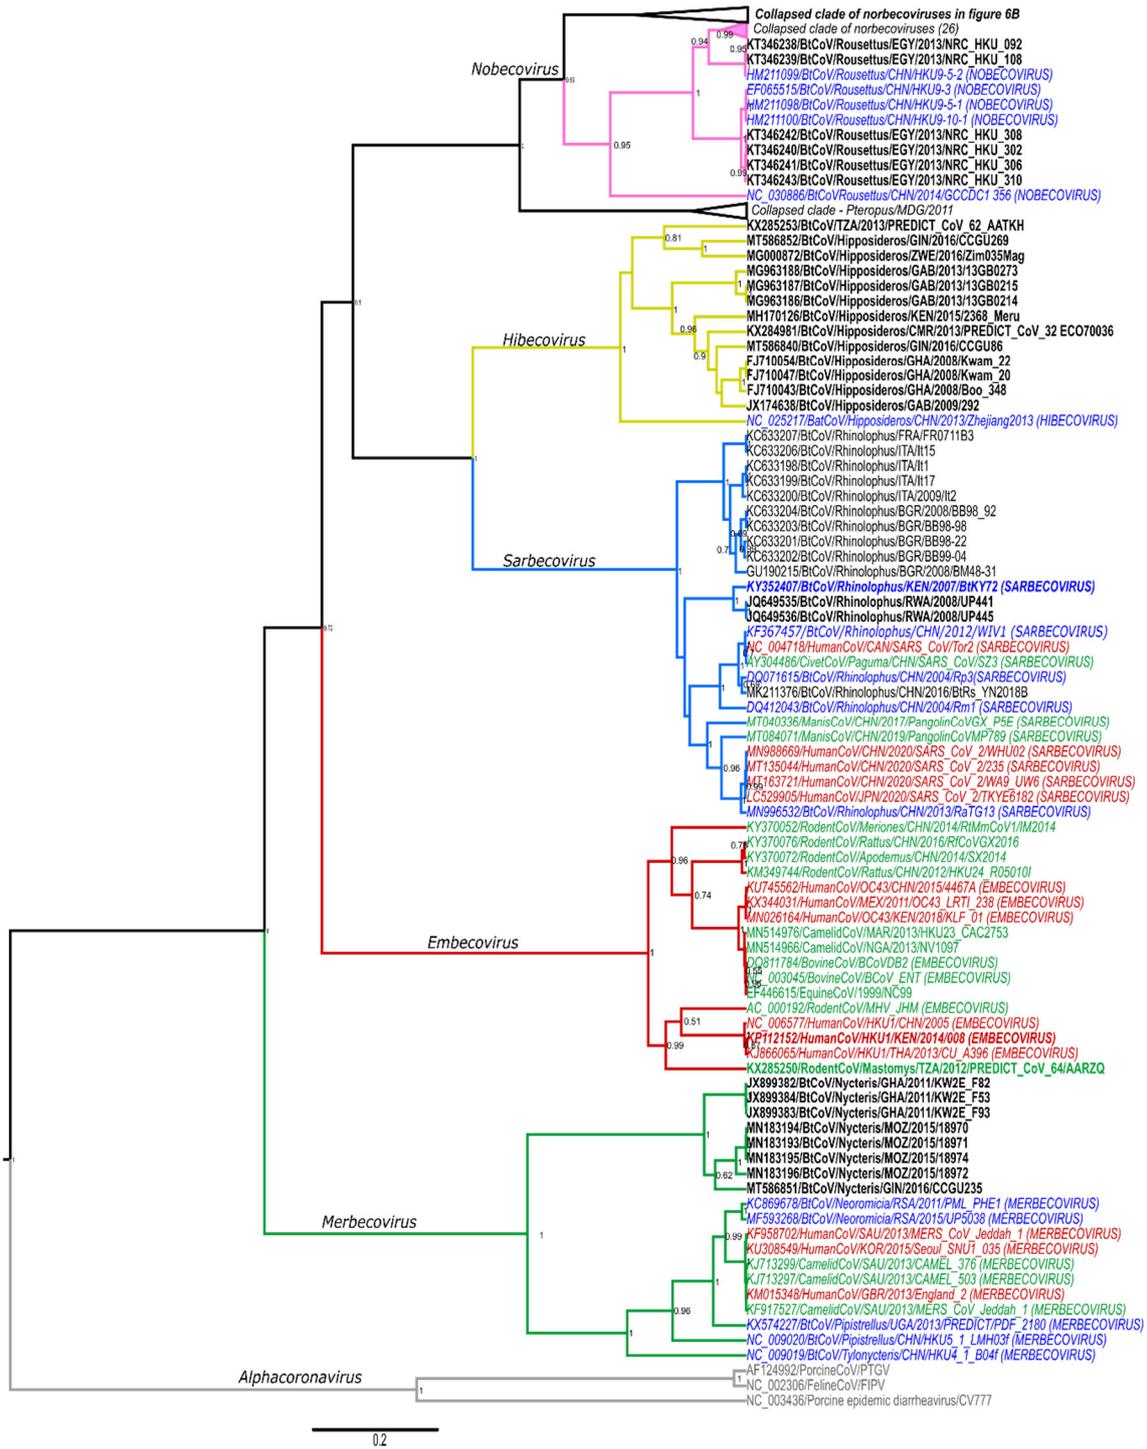

The three available viral full genomes recovered from *Neoromicia* (*Laephotis*) and *Pipistrellus* were used to classify the viruses as belonging to the same viral species as human and camel MERS-CoV. Within the bat-borne MERS-related viral genomes, the spike genes shared the lowest similarity to human and camel MERS-CoV spike genes (approximately 63–64% nucleotide identity) [32,58,59]. The latter viruses utilize the DPP4 (Dipeptidyl peptidase 4) as an entry receptor. Using homology models based on the crystalized structure of the spike protein of the *Pipistrellus* MERS-related virus, Anthony et al. [59] determined that the bat virus spike was unlikely to utilize DPP4 due to insufficient similarities among the required residues to facilitate binding of the spike to the receptor. This was practically demonstrated when recombinant MERS-CoV particles containing the spike from the *Pipistrellus* MERS-related virus were unable to enter Vero cells (unlike wild-type

MERS-CoV) [59]. Moreover, recombination analysis also identified potential breakpoints within the spike gene for *Neoromicia (Laephotis)* MERS-related virus PML/PHE1 and *Pipistrellus* MERS-related virus PREDICT/PDF-2180 [58,59]. The data thus suggests that the identified bat-borne MERS-related viruses have not served as direct progenitors of MERS-CoV detectable in camels and humans, though whether recombination occurred in a bat host or an intermediate host is uncertain.

Depending on the species, both *N. capensis* (reassigned as *Laephotis capensis*) and *P. hesperidus* have widespread distributions in various parts of Africa [67,68]. *N. capensis* (*L. capensis*) is an abundant and adaptable species distributed from sub-Saharan Africa to South Africa. They typically roost under bark or rock crevices that limit roost sizes to a few individuals [96]. However, these bats have adapted to occupy increasingly available urban roost sites such as cracks in walls and the roofs of houses, which allow populations over 50 individuals to congregate [96,97]. As a result, *N. capensis* (*L. capensis*) is a common species in urban areas that beneficially aid in decreasing insect populations attracted by city lights. Conversely, *P. hesperidus* is not very abundant and sparsely populated within its distribution from sub-Saharan Africa (Ethiopia down) to South Africa [98].

#### Betacoronaviruses—Sarbecoviruses with African Rhinolophids

Bat coronavirus sequences sharing similarity to human sarbecoviruses (SARS-CoV and SARS-CoV 2) have been identified throughout the geographic distribution of rhinolophid bats in Asia, Europe, and Africa. The highest genetic similarities between human and bat sarbecoviruses (Rp3, HKU3, WIV1, WIV16, ZXC21, ZC45, RaTG13, RmYN02) originate in Asia [5,76,77,82,99]. Bat species from the *Rhinolophus* genus are considered the main hosts for the genetic diversity of bat sarbecoviruses [16,66,88]. Some species occurring in Europe have also been reported from Northern Africa, such as *Rh. ferrumequinum* and *Rh. euryale*; and are known hosts of sarbecoviruses [66], but very few sequences with similarity to members of the *Sarbecovirus* subgenus have been identified in Africa (Figure 6A). Reports include partial RdRp sequences from two species (*Rh. hildebrandtii* and *Rh. clivosus*) from Kenya, Rwanda, and Uganda (non-universal surveillance region) with similarity to SARS-CoV [19,35,36,100]. Further sequencing of the complete genome of BtCoV KY72 detected from a *Rhinolophus* sp. from Kenya identified the virus as a member of the *Severe acute respiratory syndrome-related coronavirus* species within the *Sarbecovirus* subgenus [100].

(A)

**Figure 6. (A,B):** Bayesian *Betacoronavirus* phylogeny of a 294-nucleotide sequence region of the RdRp gene. Shorter sequences were omitted. Clades collapsed in A are shown in B (and vice versa), and the collapsed clade of *Eidolon* nobecoviruses may be viewed in Figure S2). Sequences in italics indicate formally recognized species (subgenera are indicated in capital letters at the end of sequence names); sequences in bold originate in Africa; red highlights human viruses; green indicate non-bat animal hosts; blue/italics indicate formally recognized bat species; orange indicate viral detections from hosts not typically associated with a particular group of coronaviruses. All sequence names were edited to conform to the correct convention, with the modification of the unique sequence identifier listed last due to convenience. Only posterior probabilities of greater than 0.5 are indicated. No unpublished sequences were included.

This limited detection of sequences similar to sarbecoviruses may be due to lacking surveillance of individuals within the *Rhinolophus* host genus. There are 38 extant *Rhinolophus* species in Africa, with approximately 728 individuals from 14 species included in published surveillance efforts from 11 countries (Table S4). However, very small sample sizes averaging between 1–62 individuals have been tested per species. To our knowledge, no bat coronaviruses sharing high similarity to the SARS-CoV 2 clade sarbecoviruses have been identified from African bats. In addition to betacoronaviruses, unclassified alphacoronaviruses have also been identified from four *Rhinolophus* species, suggesting large diversities of coronaviruses to be present in these bats [19,29,33].

Rhinolophids are taxonomically challenging to identify with frequent revisions to species due to highly convergent morphology [67]. Certain species are widespread and have distributions spanning into other continents, such as *Rh. clivosus* from Africa and into South West Asia [101]. These bats generally roost in caves, unused mines, and buildings [67] and are threatened by disturbances to roosts such as mining and the use of pesticides and insecticides [102], though provide valuable ecosystem services by decreasing the populations of crop-damaging insects [102].

Sequences with similarity to sarbecoviruses have also been reported from non-rhinolophid genera, including *Chaerephon* spp. in Kenya and hipposiderids in Rwanda, Cameroon, and the Republic of the Congo [26,30,36]. The latter hosts' detections were few and may represent transient spillover between hosts (*Rhinolophus* and *Hipposideros*), possibly co-roosting. In addition, some other studies have reported the detection of viruses with homology to SARS-CoV in hipposiderid bats, though these viruses were part of a more distant sister clade than rhinolophid SARS-related viruses. Moreover, this sister-clade was later formally classified as the *Hibecovirus* subgenus. Due to the thorough surveillance of hipposiderid bats, these viruses have been reported from various countries, including Ghana, Gabon, Nigeria, Kenya, Rwanda, Zimbabwe, Guinea, and Rwanda (Tables S4 and S5).

#### Betacoronaviruses—Nobecoviruses and Fruit Bats

Members of the *Nobecovirus* subgenus are not currently associated with any known zoonotic diseases, though much like the aforementioned molossid alphacoronaviruses warrant further investigation due to their widespread occurrence in several abundant fruit bat species [79]. Nearly two-thirds of all the unclassified sequences in Figure S2 likely represent members of this subgenus. Described species in this genus include two Asian bat viruses, *Rousettus bat coronavirus HKU9* and *Rousettus bat coronavirus GCCDC1* detected in species such as *Rousettus leschenaultia* [80,103], as well as *Eidolon bat coronavirus C704* in Cameroon [34]. The African detections sharing similarities to members of the *Nobecovirus* subgenus are indicated in Table S5. These detections have been widespread and predominantly reported from fruit bat genera such as *Rousettus*, *Eidolon*, *Micropteropus*, *Epomophorus*, *Pteropus*, *Epomops*, *Myonycteris* (formerly *Lissonycteris*), and *Megaloglossus* [19,26–30,34,36,39,47]. Additionally, similar sequences have been reported from several insectivorous bat species, though whether these represent active maintenance of the virus in these hosts or transient spillover is unclear. Recombination events have been detected between species of the *Nobecovirus* subgenus identified in *R. leschenaulti* in Asia and rotaviruses (*Reoviridae*; double-stranded RNA viruses) co-infecting the same species, leading to the acquisition of the P10 orthoreovirus fusogenic gene [86].

*E. helvum* migrates over large distances throughout much of sub-Saharan Africa (Senegal to Ethiopia and down to southern Africa) and are tree-roosting fruit bats that form aggregates of thousands to millions of individuals. Large urban colonies have been recorded in trees of various cities (e.g., Accra in Ghana) [67]. Excreta from these urban colonies would provide ample opportunities for human contact with contaminated fecal and urine. *E. helvum* is also heavily harvested for bushmeat, with estimates of 128,000 bats being sold per year in markets in Ghana alone [67,104]. *R. aegyptiacus* also has a broad

distribution throughout sub-Saharan and parts of Northern Africa, as well as South East Asia and the Western Palaearctic region [67]. This species is a cave-dwelling fruit bat that forms large colonies in the thousands (e.g., 5000 to 50,000), and may co-roosts with multiple insectivorous bat species. Opportunities for contact and possible viral sharing may thus arise between different bat genera, though possible exposure events to humans are more infrequent and generally arise due to human activities. These bats are often threatened by farmers who view fruit-eating bats as destructive to their crops as well as due to mining and other cave disturbances [67,105].

### 3.1.6. Investigating Factors Affecting the Maintenance of Bat Coronaviruses

Understanding how bat coronaviruses are maintained in their host populations allows determination of infection duration and times that may be at 'higher risk' for coronavirus spillover opportunities. 'High risk' periods coincide with increased excretion of viruses from bats in a colony and may be associated with reproductive or seasonal factors affecting the viral infection dynamics of the colony. For example, an increase of mating activity and accompanying hormonal changes may affect the susceptibility of hosts to infection, or the increase in immunologically naive juveniles at the start of a birthing pulse creates a large population of bats susceptible to infection [106–108]. Understanding these dynamics allows the formulation of management plans to mitigate risks and facilitate engagement with communities at risk of frequent contact with particular bat populations. Behavioral changes may assist in reducing the associated risks of exposure and possible spillover interactions [109].

Limited African studies (only 5) expanded data analyses to include correlations between bat biology, ecology, and viral status of hosts [30,36,38,40,44]. Those investigating increased infection among age classes agree that subadults are more likely to host coronaviruses than adults [30,36,44], consistent with reports from other continents [109]. A higher frequency of infection was also identified among lactating females [44], though also males [30]. Most disagreements center around seasonality, with either no correlation identified [36] or a higher chance of detecting coronaviruses in the dry seasons [30]. Longitudinal surveillance projects would be able to assist with such interpretations in the future.

Bats occupy a wide range of niches, including diverse roost preference (e.g., cave-dwelling or tree-roosting), eating habits (frugivores, nectivores, insectivores, etc.), population sizes (less than 10 to thousands), and level of social interaction between the same and different species (gregarious or non-gregarious). It may also be possible that factors affecting the maintenance of coronavirus infection among bat species may not be universal to all bat species. Thus, combining coronavirus data from different species may result in biased conclusions. For example, it has been suggested that bat coronaviruses may amplify within maternity colonies [108], though the reproductive seasons of diverse bat species do not all overlap, and certain species are capable of reproducing more than once a year, depending on the geographic regions. For example, *Rousettus aegyptiacus* displays two birthing pulses among populations along the North of Africa [110], while populations in Southern Africa have only one [111]. Thus, if coronavirus maintenance is linked to its host species' reproductive biology, viral shedding may be predictable for certain species in particular climate zones.

A recent study predicted high-risk periods for different host species utilizing available surveillance data from three countries (Rwanda, Uganda, and Tanzania) and Bayesian modeling [30,60]. Though several assumptions were made regarding the duration of lactation and weaning, they determined that juveniles recently weaned were 3.34 times more likely to shedding coronavirus RNA than juveniles that were not recently weaned. Even adults were nearly four times more likely to be shedding coronaviruses when juveniles were being weaned [60], possibly due to increased coronavirus excretion levels within the colony. As described in Wacharapluesadee et al., [109], increased coronavirus shedding

among juvenile bats may be due to vertical transmission from mother to pup, which coincides with studies describing viral shedding from lactating females with increased frequency compared to non-lactating females [112]. The higher frequencies observed in recently weaned juveniles may be due to the loss of maternally received antibody protection following weaning [60,108]. These conclusions require confirmation with longitudinal surveillance among investigated bat species as well as serological studies determining changing antibody levels between lactating mothers, weaning and non-weaning juveniles, as well as other adults in the colony.

### 3.2. Surveillance in Other Wildlife and Domestic Animals (Livestock)

Coronavirus nucleic acid surveillance among non-bat wildlife, livestock, or other domestic animals in Africa is very limited, both in the frequency of research, sample sizes of animals tested, locations targeted, and are frequently investigated for only specific coronaviruses. Nucleic acid testing in animal populations where the prevalence of infection may be very low would yield limited data, provided that sampling was performed at a time when animals are infected or actively excreting viruses [113]. We only identified four reports in which other animals were tested for coronavirus nucleic acids, including anthroponoses of HCoVOC43 between humans and chimpanzees in Côte d'Ivoire [48], MERS-CoV specific surveillance among 4248 livestock animals from Ghana (cattle, sheep, donkeys, goats, and pigs) [50], general surveillance among 731 wildlife animals (rodents, non-human primates, and ad hoc samples of other wildlife) in Gabon [40], as well as just over 27,000 animals (birds, domestic animals, carnivores, pangolins, swine, rodents, and non-human primates) as part of the PREDICT surveillance initiative (accessed via Healthmap.org) (Table 4). Though this seems like a significant number of individuals tested, the total species diversity among all 16 countries sampled is much larger than the fraction represented by this surveillance. Moreover, not all hosts listed were surveyed in all countries (Table 4), with mostly opportunistic sampling from accessible individuals. However, even though the total positives detected in relation to the total number sampled is <1%, it still shows the presence of coronaviral RNA from among non-human primates (14 chimpanzees), ungulates (1 bush duiker), carnivores (1 African palm civet) and rodent species (13 individuals) from opportunistic surveillance [48,56].

Two of these sequences, publicly available and corresponding to the universal surveillance region (excluding the anthroponoses of HCoVOC43 from the chimpanzees), were included in the phylogenies in Figures 5A and 6A (KX285508 and KX285250). Most of the detected African rodent coronavirus partial sequences are phylogenetically placed in the *Embecovirus* subgenus, with human coronaviruses OC43 and HKU1 and other rodent coronaviruses from Asia [18,30]. Divergent rodent alphacoronavirus virus RNA was also identified (KX285508), as well as highly divergent shrew coronaviruses [30]. The sequence information confirms surveillance data from Asia and Europe, namely that rodents and shrews likely harbour additional undiscovered diversity of coronaviruses. Improved systematic and longitudinal surveillance of wildlife and domestic populations will provide more data on the presence of coronaviruses among these animal groups. The research is too limited to make any conclusions regarding the absence of viral sharing between animal groups. Additionally, serological surveillance would complement nucleic acid surveillance by providing data on hosts not actively infected with coronaviruses.

Not included in Table 4 is the expansive surveillance of dromedary camel populations for MERS-CoV. MERS-CoV is not only endemic to the dromedary camel populations of the Middle East but also populations in Northern Africa (Burkina Faso, Ethiopia, Kenya, Mali, Morocco, Nigeria, Somalia, Sudan, Tunisia) [93,114]. Seroprevalence of adult dromedaries is high (80–100%) and may result in respiratory disease with viral shedding via nasal discharge [93,115]. Despite this widespread occurrence, MERS infections among people from camels have only been reported from the Arabian Peninsula [114,115]. Viruses from African dromedaries form a separate basal lineage to the two clades of MERS-CoV identified from infected people and camels on the Arabian Peninsula [114,116],

though still share antigenic similarities through cross-neutralization [114]. Furthermore, within this African clade, genomes from the West and North African dromedary populations (Nigeria, Burkina Faso, Morocco) display deletions in specific accessory genes [114,117,118]. It has been suggested that these accessory genes are not required for the adaptation of the virus to dromedary camels and may have been necessary for a more historical host [114]. Whether bat-borne MERS-related viruses established in dromedary camel populations can only be addressed with better surveillance of African bat and dromedary populations, especially where bat and camelid distributions overlap [32].

#### 4. Coronavirus Serosurveillance

Coronavirus serology is complex and faces several challenges—even among human coronaviruses [113]. Serological targets include the immunogenic nucleoprotein that is abundant during infections and the spike protein that allows for the detection of more specific antibody responses and neutralizing antibodies [119]. Targeting a more conserved protein (such as the nucleoprotein) may yield high seropositivity levels due to potential cross-reactivity of conserved epitopes among related coronaviruses, without being able to discern between different viral species (or genera). Depending on the assay target, cross-reactivity could complicate human coronavirus assays due to conserved motifs between seasonal human coronaviruses, SARS-CoV, and MERS-CoV [113], as well as between SARS-CoV and SARS-CoV 2 [120]. Serosurveillance among animal populations is similarly hampered with cross-reactivity as they may be exposed to unidentified coronaviruses. Due to the challenges of cultivating certain animal coronaviruses, virus neutralization tests to exclude cross-reactions are not readily feasible. A lack of specific animal coronavirus assays often leads to the use of human coronavirus assays (generally based on the spike protein). However, interpreting the results should be made with caution as cross-reactivity to unknown epitopes and modifications to validated assays may allow for false assumptions [113]. There is a great need to develop suitable assays for serological surveillance of diverse coronaviruses in wildlife and domestic animals. The lack of well-

characterized reference sera to determine cut-off thresholds and limited species-specific biologics also challenges new assay development.

Bat coronavirus serology is demanding for all the aforementioned reasons and is further complicated by the large diversity of bat coronaviruses. Of note is that not all bat coronaviruses utilize the same receptor molecules. Angiotensin-converting enzyme two or ACE2 is the known receptor for SARS-CoV, SARS-CoV 2, and only the most closely related bat sarbecoviruses. The receptor-binding regions and important motifs even differ greatly between SARS-CoV and SARS-CoV 2 (see Andersen et al. [13]). The spike receptors for the larger majority of bat sarbecoviruses lack the required binding sites and are largely incompatible with human ACE2. The spike proteins of BtCoV/422 only share 68–72% amino acid similarity to the spike proteins of SARS-CoV and SARS-CoV 2 and their most closely related bat viruses (unpublished data). Though, protein similarity alone cannot be used to determine if cross-reaction will occur due to the glycosylation and conformational folding of spike proteins [113].

In comparison to the number of studies investigating bat coronavirus nucleic acid surveillance, minimal serosurveillance studies have been performed on the continent. These include mainly Muller et al. [121], wherein a SARS-CoV ELISA kit with minor modifications was used to test bat sera from the Democratic Republic of the Congo (DRC) and South Africa, as well as a MERS-CoV pseudo-particle neutralization assay to test *Rousettus* sera in Egypt and Lebanon by Shehata et al. [27]. Though no MERS-antibodies were detected in *Rousettus aegyptiacus*, antibodies reactive to SARS-CoV antigens were identified in 6.7% of bats tested (7 of 26 species) from the DRC and South Africa. These species include pteropid bats (*Rousettus*, *Myonycteris*, and *Hypsignathus*) as well as other insectivorous bat genera like *Mops*, *Miniopterus*, and *Rhinolophus*; many of these genera have since been identified to host either alpha- or betacoronaviruses. The results were confirmed with western blots, though no neutralizing antibodies were identified [121], cross-reactivity between potentially related bat coronaviruses. Increased bat coronavirus serological surveillance would provide better overall estimates of population exposure levels [119,122] and reduce false-negative assumptions from non-actively shedding hosts.

Wildlife, livestock or domestic animal serological surveillance in Africa is more frequent than serological surveillance among bats. A broad search of the literature found mainly studies focused on MERS-CoV serology and dromedary camel populations among various countries (reviewed in Dighe et al., [93]). Among domestic animals, several studies investigated livestock in Ghana [49–51]. Bovine coronavirus was determined to possibly be widespread among ruminants such as cattle and capable of spilling over into sheep and goats [51]. Cattle, sheep, goats, donkeys, and swineherds have been found lacking any serological response toward merbecoviruses like MERS-CoV or the similar *Nycteris* bat betacoronaviruses [50], or indeed HCoVNL63 and related bat viruses [49]. The authors highlight the need for such surveillance to be conducted in countries such as Kenya, where similar viruses to HCoV229E or HCoVNL63 were identified in bats.

Limited serosurveillance has been performed in wildlife. Though no feline coronavirus serological responses were identified among 13 lions from Botswana sampled between 2012 and 2014 [123], feline coronaviruses (particularly the highly pathogenic feline infectious peritonitis virus) have historically been shown to be actively circulating among captive cheetahs in the USA and free-living cheetah populations from Eastern and Southern Africa [124,125]. This lack of thorough surveillance in animals that may act as intermediate hosts and detecting spillover infections creates a gap in data not only for Africa but globally. Moreover, to our knowledge, no studies have investigated human populations in Africa for serological responses to bat coronavirus spillover [126].

## 5. Factors Associated with the Potential Emergence of Coronaviruses

Opportunities for potential pathogen exposure between humans and animals, including wildlife, are increasing. In Africa, the main factors include deforestation, agricultural intensification, and the collection, hunting, and butchering of bushmeat [22,127,128].

Interactions that are more specific to bats include ecotourism, mining, guano collection for fertilizer [128], or bat species that roost in man-made structures, such as houses, warehouses, schools, etc. Coronavirus nucleic acids are still detectable in guano fertilizer several days after collection, even if kept at room temperature (though viral isolation was not attempted) [129]. Although some factors may create opportunities for spillover, the exact routes of transmission are not yet clear. [130]. Research investigating potential interfaces in Africa is limited.

The bushmeat trade represents one of the most prominent points of contact between humans and bats on various continents [131], though it may practically represent a low risk of transmission for coronaviruses. Bushmeat serves as an important source of protein and household income in many African, Asian, and South American countries [132,133]. Large bats from the *Eidolon* or *Hypsignathus* genera are predominantly hunted, though smaller bats (*Hipposideros*, *Rhinolophus*, and *Myotis*, among others) are not excluded [133]. For sub-Saharan Africa alone, 52 African bat species (Table S4) are reportedly hunted in countries across their distribution [133]. *Alpha*- and *Betacoronavirus* sequences have been reported from at least 12 and 14 of these bat species, respectively (Table S4). Notably, viral sequences putatively grouping within the *Duvinacovirus*, *Sarbecovirus*, and *Hibecovirus* subgenera have been detected in one of the hunted bat species, namely *Hipposideros ruber* [30,36,37]. A large number of species deemed as bushmeat have, however, not been included in any coronavirus surveillance studies, and thus, their propensity as viral hosts and associated risk to humans remains to be determined.

Live animal markets have been labelled as an ideal interface for human exposure and disease emergence and have been scrutinized due to the ongoing global COVID19 pandemic [134]. As in specific regions of Asia where such markets are commonplace, live or cooked bats are sold in selected African countries [104,135,136]. These bats may also be used in traditional medicine. Additionally, festivals in Africa focused on bats, such as those in Buoyem (Ghana) and Idanre (Nigeria), may provide opportunities for viral spillover [137,138]. The emergence of SARS-CoV and the SARS-CoV 2 pandemic has led to the banning of wet markets from selling live animals in China [132]. Both bans were eventually lifted and remains a point of debate [139,140].

Human-bat interactions are motivated by social, economic and cultural drivers, which form an integral part of infectious disease research. Different cultures have multifaceted perspectives concerning bats, which may be shaped by the local beliefs, use in traditional medicine, knowledge of bat biology, disease risk, or change during periods of food shortages [141–144]. Though limited information is available in Africa, several recent studies have considered the risk perceptions of human populations to bats and their associations with zoonotic diseases [142–147]. Overall, the results suggest that communities have limited knowledge of bats and do not generally perceive bats as a threat [142,143,145]. These perceptions may likely have changed following the COVID-19 pandemic.

With the known diversity of coronaviruses in bat species from Africa and the association of a number of these bats in human activities, exposure to these viruses is inevitable. There have to date not been any reports of novel coronavirus-associated diseases speculated to be of bat origin on the African continent, contrary to the link between bats and sarbecoviruses from Asia [5,16]. There is a clear overlap between practices in Asian and African countries with regards to animal trade. An intricate relationship between the factors associated with disease spillover from bats to humans is likely involved. Identifying the synergistic effects of these factors is simply the first step in understanding their roles in disease emergence.

## 6. The Future of Coronavirus Surveillance

The majority of African coronavirus surveillance has been focused on nucleic acid detection, estimating the genetic diversity of coronaviruses from bats and largely excluding other wildlife. Very limited epidemiological information is available to understand

and support current assumptions regarding coronavirus maintenance among bat populations (effects of reproductive biology and ecologic impacts). Surveillance among other wildlife species and domesticated animals is so limited that no further conclusions can be reached on their risks. It is clear that bats host the genetic diversity of coronaviruses [17,18,78], but surveillance should be expanded to other species that share the same ecosystem as potential reservoir species and spillover hosts.

Longitudinal surveillance is essential towards understanding how bat coronaviruses are maintained within a species, as well as the occurrence and duration of shedding [109]. Identification of high-risk shedding periods can direct additional surveillance in other species and allow the formulation of preventative mitigation measures by decreasing possible interactions between human, livestock, and bat population. Determining possible increased shedding times can also allow better planning for surveillance studies to avoid sample collection of cross-sectional studies during the lowest shedding periods. This can be readily accomplished with non-destructive sample collection (colony-level fecal, swabs, or fecal collection). In addition, more basic research is also required for neglected species (Table S4), different animal groups (particularly rodents and livestock) [18] to expand surveillance regions and increase sample sizes.

The reliability of nucleic acid surveillance approaches would be much improved with standardized usage of updated, validated assays such as the recently published assay by Holbrook et al. [148], which updated the widely used Watanabe assay. There has also been an increasing shift away from only publishing short sequences to additional characterization of longer extended sequences or genes. This is both beneficial to the quality of research as well as disadvantageous to having basic surveillance data available. Better characterization of African bat coronaviruses will enable classification of more bat coronaviruses and identifying detectable recombination events. However, this requirement also hampers the frequency of newly published surveillance studies due to escalating costs and sequencing challenges leading to gaps of understanding and unreported diversity among different animal populations. A lack of such standardized approaches also results in technically challenging troubleshooting to be performed in resource-limited laboratories.

Moreover, the cost of fieldwork and sample collection in often remote regions of African countries, as well as the follow-up sample analyses, can be very high, with very little remaining for additional sequencing. Researchers should also be encouraged to publish data on the absence of coronavirus detections to assess species or regions of lower risk. Though not ideal, unpublished nucleic acid surveillance data can also be submitted to NCBI with all relevant collection data. As of August 2020, the user-friendly Database of Bat-associated Viruses (DBatVir) repository contained over 4600 bat coronavirus entries globally [149]. This repository is updated bimonthly, and accessing such a centralized source for bat coronavirus surveillance data (both published and unpublished) will allow for a more comprehensive comparison of detected viruses, assessment of surveillance coverage, and highlight areas where research is required.

We propose that surveillance studies publishing short sequences be bolstered by shifting from detecting viral presence alone to investigating questions concerning the epidemiology and maintenance of coronaviruses in selected populations of different species (Table 5). Bat surveillance in a specific region can be initiated, though it is important that surveillance of other species sharing the same ecological niche be done either concurrently or followed as soon as possible, including potential spillover hosts. Sampling of other animal groups and assessing anthropological and human behavioral risks should be included in the planning and implementation phase. Communities must be at the center of studies to understand societal and cultural issues. Initial surveillance at preselected sites may only provide an overall estimation of animal host species present (bat and non-bat), host movement patterns, and viral excretion, allowing informative planning decisions to be made for proper longitudinal surveillance appropriate sites. Surveillance using short

nucleic acid sequences from an updated assay is thus used to identify diversity and monitor changing excretion fluctuations of viruses in populations over time—either seasonally or based on a predetermined time frame (e.g., monthly). This would allow surveillance of both the presence and diversity of coronaviruses among bats and other sampled wild-life/domestic animals and investigate factors involved in viral maintenance with the collection of ecological data. Additionally, such data can be used for a basic assessment of risk regarding potential opportunities for spillover.

Further research is required to characterize detected coronaviruses, including recovery of complete genomes, incorporation of serological studies among bat populations and spillover hosts, or determination of host ranges and zoonotic potential with pathogenesis studies. Issues of cost or technical challenge may be overcome by collaborating with international institutions. In-country expertise and capacity building are essential to build sustainable surveillance programs and require an interdisciplinary approach.

**Table 5.** Framework for activity planning when implementing coronavirus surveillance in bat populations, other wildlife species, domesticated animals, and impacted human settlements.

Consideration	Activity
Formulate a strong research question around the aim of the research to be conducted.	Scope of the surveillance—only coronaviruses or broader surveillance. What will the primary focus of the project be? Assessment of risk for settlements near known colonies? Review the literature and determine important species to target.
Assemble an interdisciplinary team	Collaborate with experts in virology, taxonomists, field biologists, veterinarians, ecologists, specific community leaders, social sciences, and policy-makers. A large interdisciplinary team is essential for accurate long-term surveillance.
Identify high-risk species or animal populations based on a predetermined research question	As a starting point, collaborations can assist in identifying accessible locations of interests, such as specific roosts (day or maternity roosts, etc.) for bat host species considered higher risk (from literature). The roosts can be assessed for population presence over time to enable longitudinal surveillance planning. The region must be assessed for nearby human settlements and the occurrence of animals (farmed, free-roaming, or other wildlife).
Perform initial surveillance targeting either large roosts or multiple smaller roosts	Assess viral presence and diversity with once-off or seasonal surveillance (statistically significant). Population-level sampling of excreted samples such as fecal collection (beneath roosting bats) is simple and non-invasive. Proper species identification should be conducted with both barcodes and morphological identification.
Nucleic acid testing with a suitable assay	Review the literature and use a recently updated assay to ensure detection of all available diversity. Test the assay sensitivity for comparisons. Based on the scope of the project and resource

	conservation—consider a specific or randomly primed approach.
Plan longitudinal surveillance (duration, types of samples collected, measurement, and ecological data collection). Plan to survey animal species in the region preferably concurrently or sequentially following bat surveillance.	Based on initial findings, plan for longitudinal surveillance according to specified intervals (based on bat presence at roosts or species movements): seasonal or periodic (monthly). Sampling must occur across different reproductive stages. Surveillance can be done at the population-level (overall) and individual-level (to determine demographics of infection prevalence).
Serological surveillance	Review options for serological assays (commercial or developed assays). Collaboration with experts may be critical. Serological testing (bats, non-bat animals, and humans) is important to understand coronavirus antibody responses, duration of protection, and exposure—optimize suitable assays.
Viral characterization	Recover complete genomes of selected viruses for classification and functional studies. Assessing possible zoonotic potential with pathogenesis studies and protein modeling. Collaborate with specialists that can assist and help develop local capacity.
Investigate human-animal interactions	Perform observational and behavioural studies to assess human-wildlife-livestock interactions.

## 7. Conclusions

Surveillance of coronaviruses in wildlife and potential spillover hosts is complicated with logistical, technical, and practical challenges. Proper biosurveillance requires detailed planning ahead of time with well-formulated research questions [150] and essential resources such as highly skilled staff, funding, and operating within ethical and regulatory requirements. Availability of research tools such as appropriate diagnostic assays, standardized protocols, and correct species (specifically related to wildlife) identification is paramount. Studies based on nucleic acid detection have been more commonly used, given the lack of suitable or validated serological assays. The development of such assays is further complicated with issues concerning coronavirus culture in vitro and stringent biosafety Level III conditions. The latter limits research to only a few groups when additional characterization, pathogenicity investigations, and determination of the zoonotic potential of newly discovered bat, rodent, and wildlife coronaviruses is needed. The development of recombinant proteins for serological assays and reverse-genetics systems for coronavirus rescue, though technically complex, are some of the only available options at present.

Much of the coronavirus biosurveillance studies reported, particularly in wildlife, has been reactive to outbreaks/newly emerging viruses and very opportunistic. The current coronavirus research identified many coronavirus host species among bats and rodents and provided novel insights into the possible evolutionary origins of some human coronaviruses [25,35,54]. Moreover, specific groups of coronaviruses have been identified for further research due to lack of characterization and high coronavirus diversity among abundant host populations with opportunities for human contact. The studies mainly provided “snap-shots” of diverse coronaviruses among different species, time points, and geographical locations. Such approaches do not allow long-term monitoring of these viruses in host species toward understanding the factors involved in viral maintenance, nor

does it provide cues for interpreting increased risk of spillover. Systematic longitudinal investigations of both natural and potential spillover hosts are needed. Additional layers of investigation must include studying human behavior and anthropological influences and the roles of virus/host interactions, pathogenicity, and the natural ecology of the virus. Investigations of coronavirus diversity among other wildlife (particularly rodents) and livestock are at infancy, with much still unknown. As a result, the future of coronavirus research in African has many topics to cover and will expand continent-wide, requiring an interdisciplinary collaborative approach and significant resource investment.

**Author Contributions:** Conceptualization, M.G., M.M., W.M., J.W., J.T.P., J.H.E.; Data collection, M.G. and M.M.; Data curation, M.G. and M.M.; writing—original draft preparation, M.G., M.M., W.M.; Draft review M.M., W.M., J.W., J.T.P., J.H.E.; funding acquisition, W.M., J.W., J.T.P., J.H.E. All authors have read and agreed to the published version of the manuscript.

**Funding:** This work was financially supported in part by the National Research Foundation (NRF) of South Africa: the DSI-NRF South African Research Chair held by WM Grant No. 98339 (postdoctoral fellowship funding). The financial assistance of the National Research Foundation (NRF) towards this research is hereby acknowledged. Opinions expressed and conclusions arrived at, are those of the author and are not necessarily to be attributed to the NRF. The project or effort depicted was or is sponsored by the Department of the Defense, Defense Threat Reduction Agency (HDTRA1-20-1-0025). The content of the information does not necessarily reflect the position or the policy of the federal government, and no official endorsement should be inferred. MG and MM were also supported by the University of Pretoria's postdoctoral funding program.

**Institutional Review Board Statement:** Not applicable.

**Informed Consent Statement:** Not applicable.

**Conflicts of Interest:** The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript, or in the decision to publish the results.

## Appendix A

### *Details of Phylogenetics*

Short sequence lengths may hamper the resolution of a phylogeny, resulting in poor support for certain clades. The phylogenies in Figures S1 and S2 (and Figures 5 and 6) were constructed to include as many African bat coronavirus sequences as possible while still allowing for sequence lengths that would yield well-supported clades. Therefore, sequences that would have resulted in alignments of less than 200 nucleotides were omitted with final lengths between 260 and 294 nucleotides, respectively. For simplicity, all sequence names were converted to the standardized convention with the modification of listing unique sequence identifiers last. Sequences were obtained from Genbank (NCBI) by searching the accession numbers listed in the publications identified as described in Table 1, or manually searching for the publication title. The accession numbers of all sequences included are provided in the phylogenetic trees. Sequence alignments and editing were performed with ClustalW in Bioedit [151]. Maximum clade credibility trees were constructed using suggested models selected from jModelTest2.org [152]. Phylogenetic analyses were performed with Bayesian phylogenetics using BEAST v. 1.10 using the general time-reversible model (GTR) plus invariant sites and gamma distribution substitution

model [153]. The CIPRES Science Gateway was used to run computationally expensive analyses such as alignments, jmodeltest, and BEAST [154]. The Bayesian MCMC chains of the alphacoronavirus phylogeny was set to 20,000,000 states, sampling every 2000 steps, and the betacoronavirus phylogeny was set at 25,000,000 states (sampling every 2500 steps). Final trees were calculated from the 9000 generated trees after discarding the first 10% as burn-in. Trees were viewed and edited in Figtree v1.4.2.

# Bat identification workshop

## Ara Monadjem

UNIVERSITY OF  
ESWATINI

<b>Level</b>	<b>Numbers in Africa</b>
<b>Families</b>	13
<b>Genera</b>	57
<b>Species</b>	± 320

Can anyone identify this bat? Not easy!

*Laephotis capensis*

Lindy Lumsden

# How to proceed with identification?

- So, what can we do?
- A useful approach is to identify the bat to a higher taxonomic level
- Class: Mammalia, Order: Chiroptera
- **Family**, Genus, Species

# Southern African families

Pteropodidae

Hipposideridae

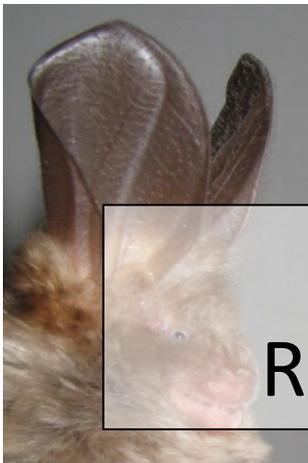

Rhinolophidae

Emballonuridae

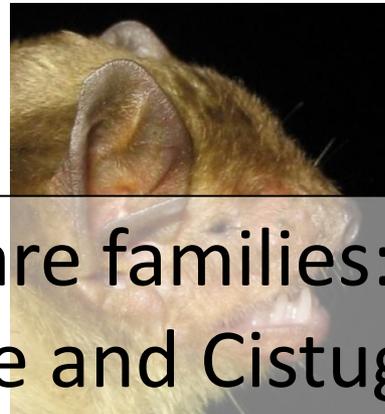

Nycteridae

Molossidae

Vespertilionidae

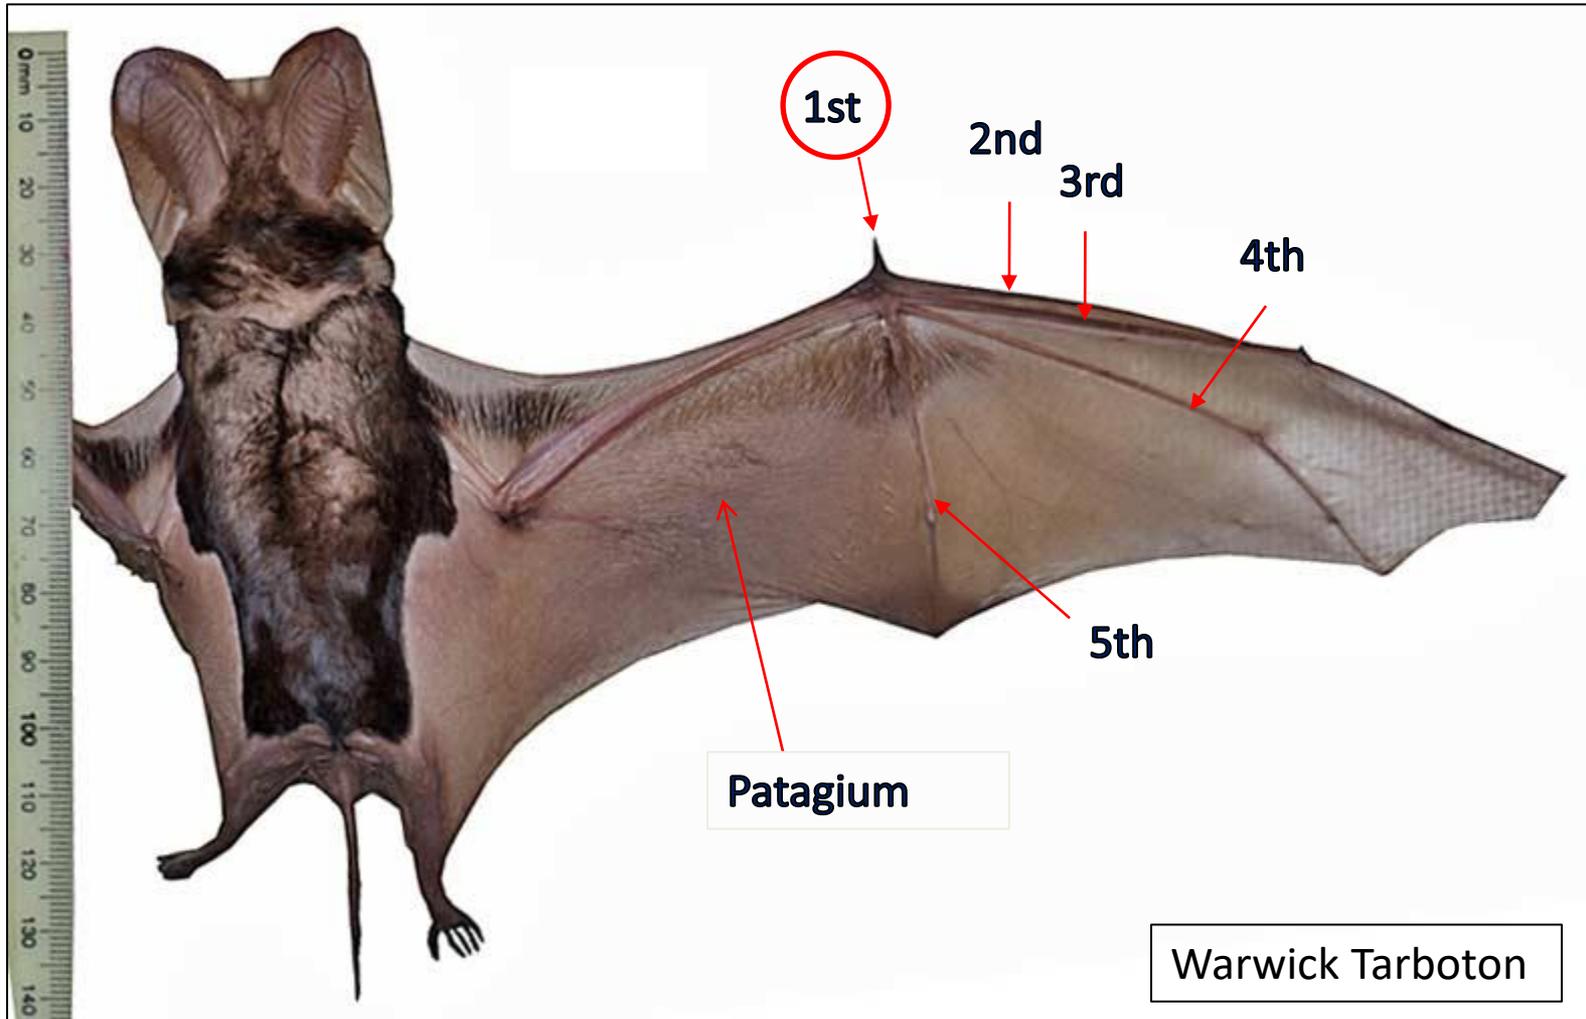

Miniopteridae

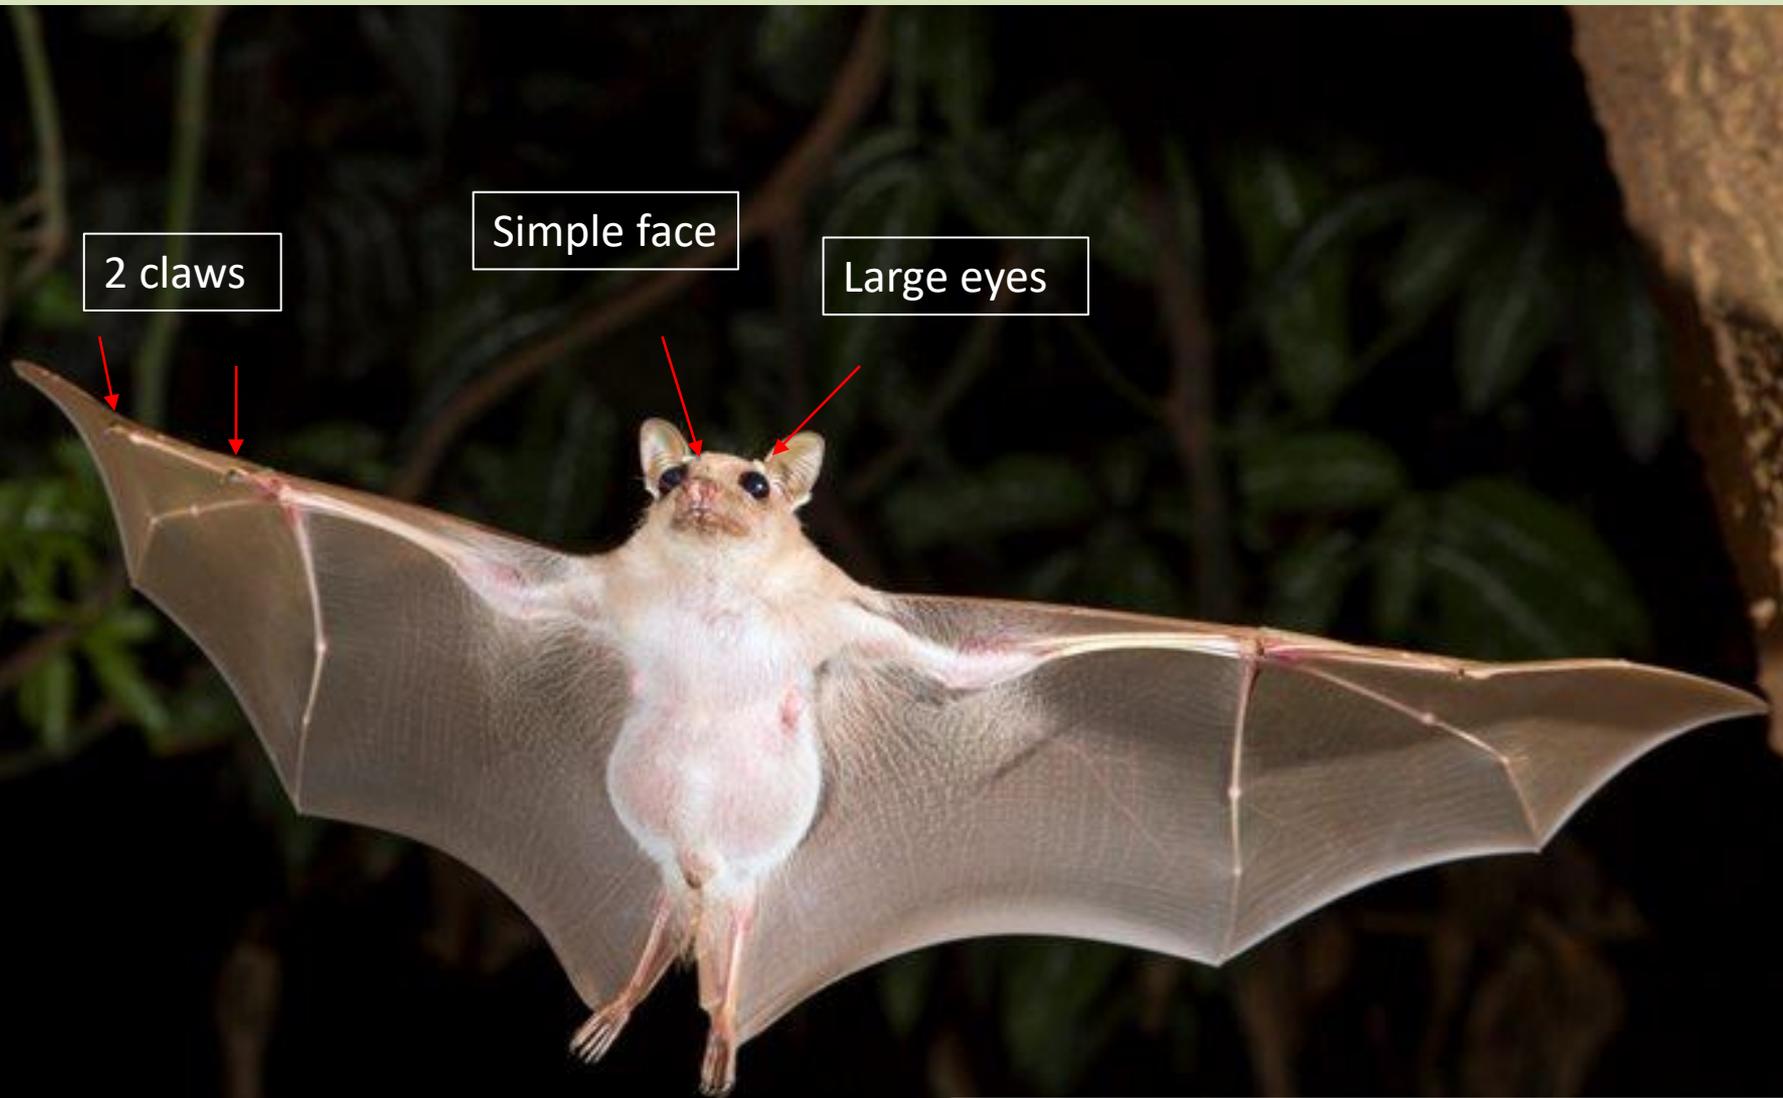

And two rare families:  
Rhinonycteridae and Cistugidae

# Note the claw on 1<sup>st</sup> digit

# Pteropodidae (fruit bats)

2 claws

Simple face

Large eyes

# Typical genera/species

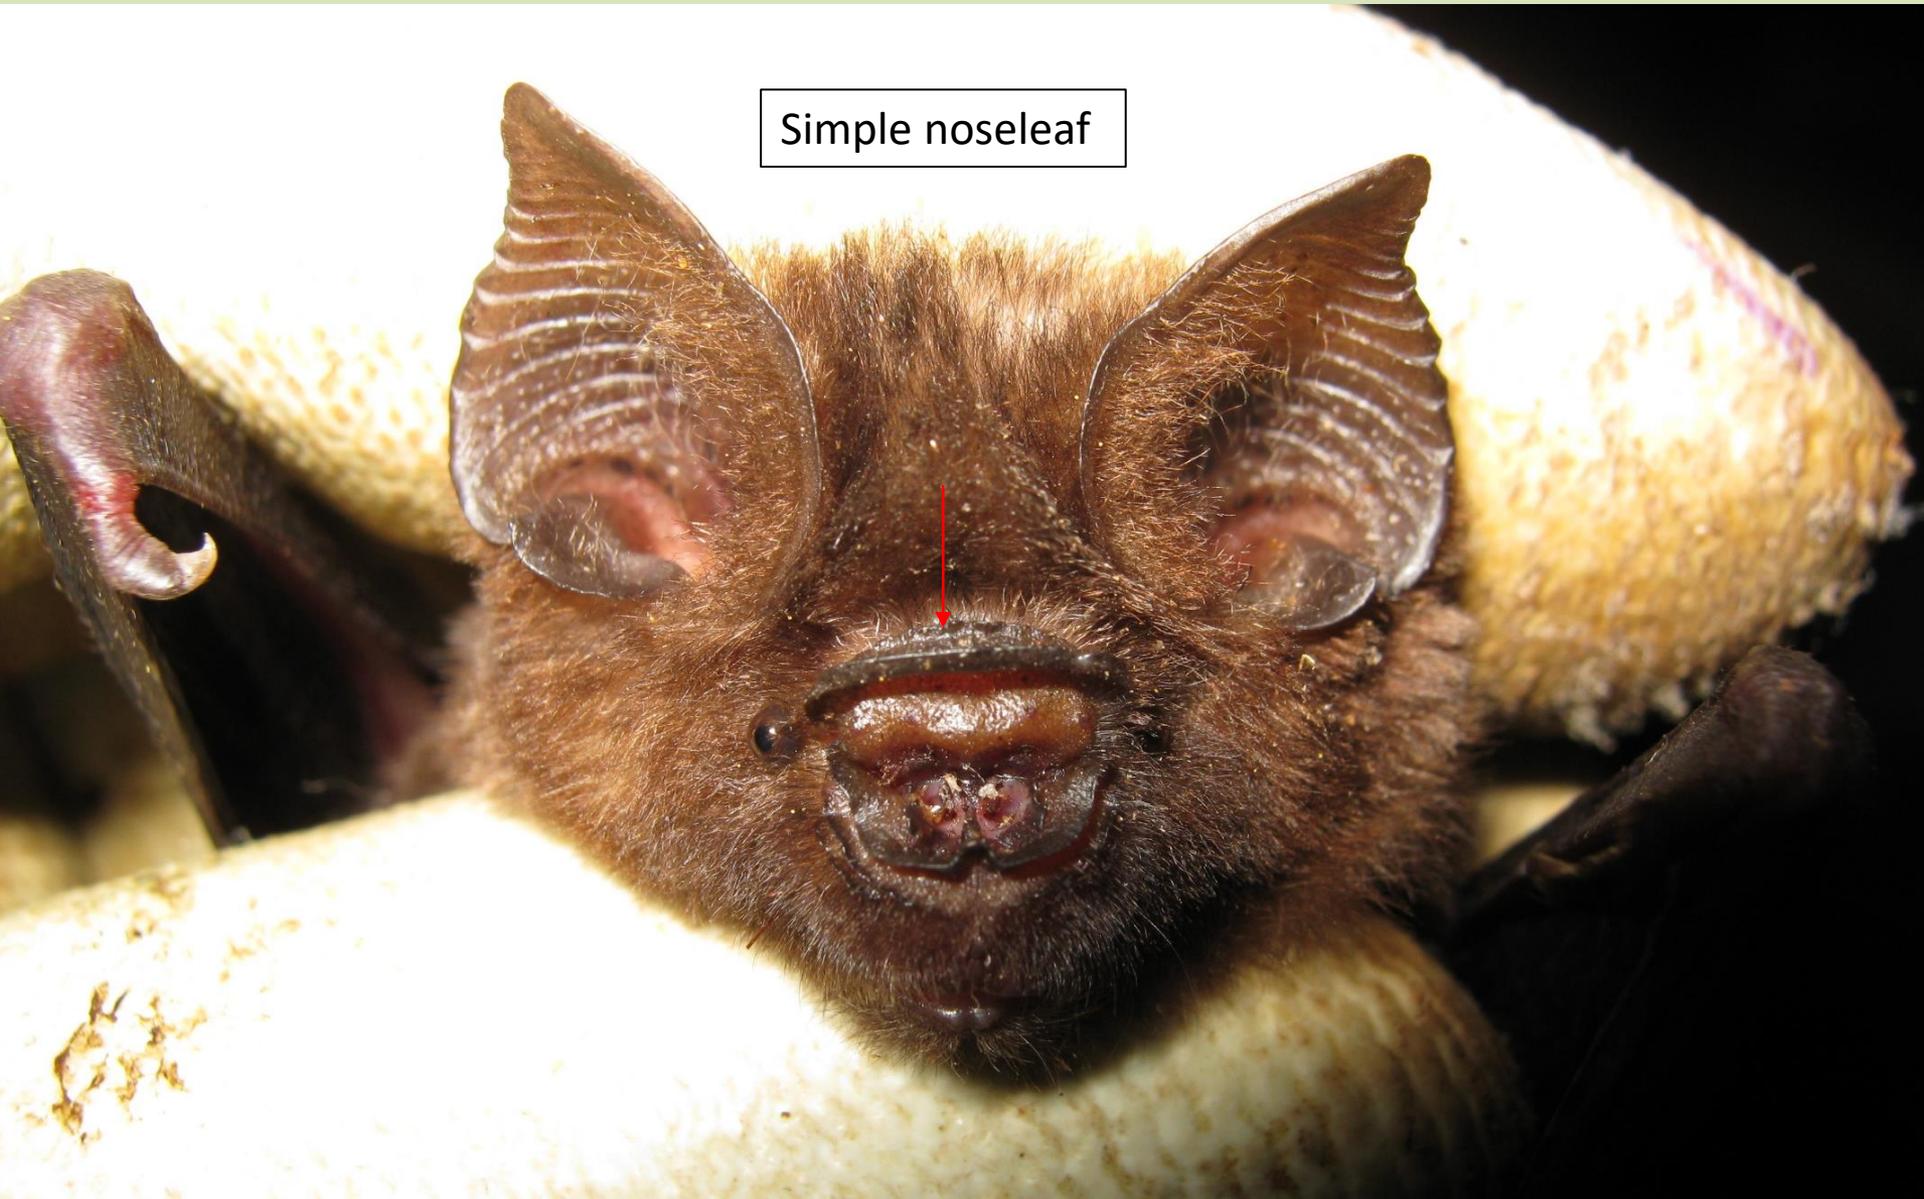

*Epomophorus wahlbergi*

*Rousettus aegyptiaca*

# Hipposideridae (leafnose bats)

Simple noseleaf

# Typical genera/species

*Hipposideros cafer*

*Macronycteris vittatus*

# Rhinolophidae (horseshoe bats)

Complex noseleaf

Just one genus: *Rhinolophus* but many species!

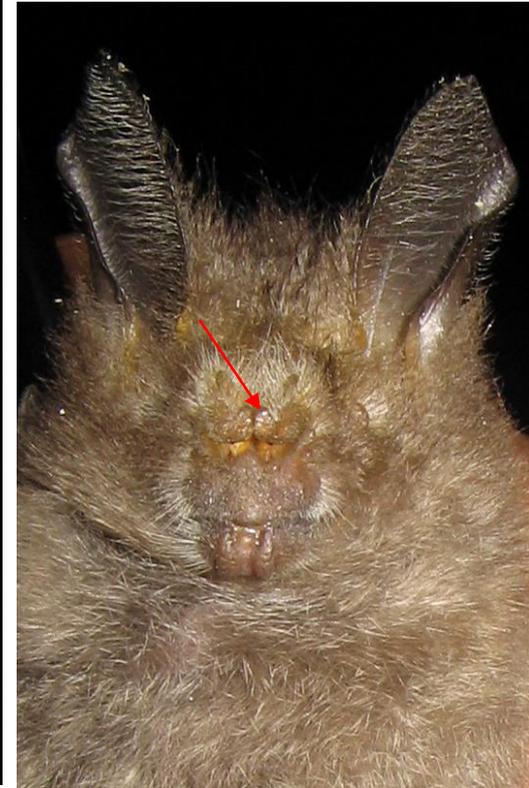

# Nycteridae (slit-faced bats)

T-shaped tail

Noseleaf covered

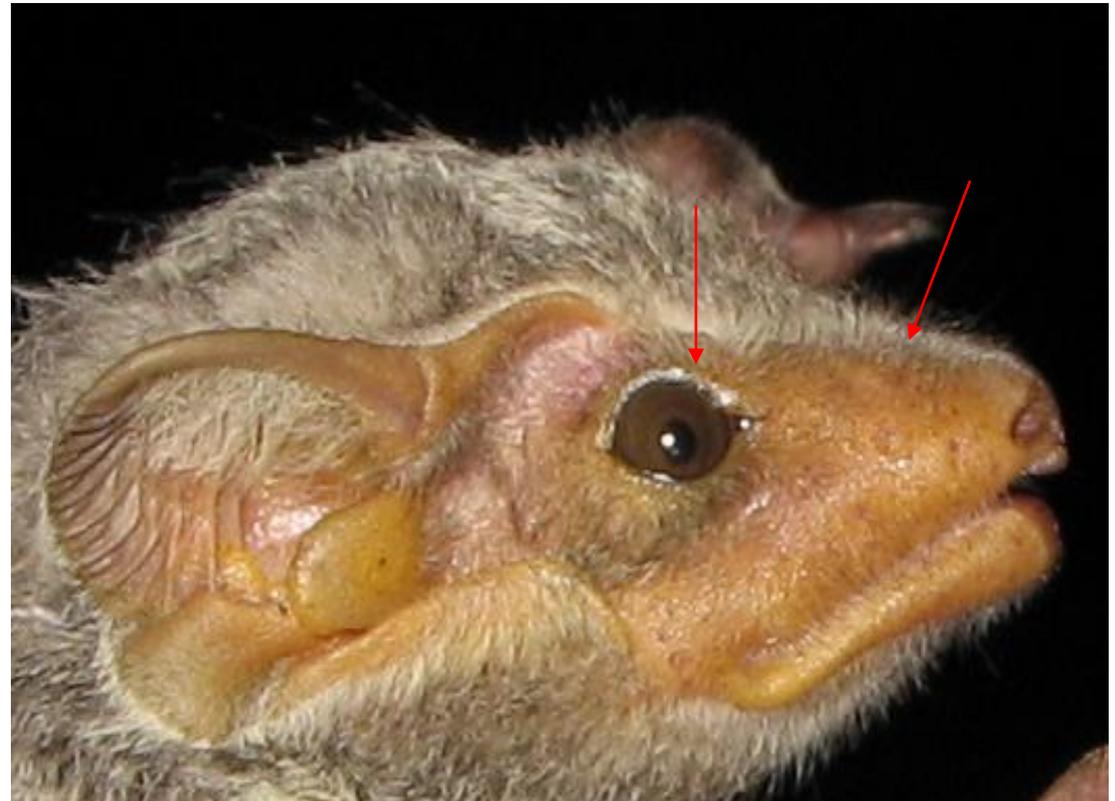

Just one genus: *Nycteris*

# Emballonuridae (tomb bats)

Tail protrudes above  
tail membrane

Large eyes

No noseleaf

Just one genus: *Taphozous*

# Molossidae (free-tailed bats)

Tail protrudes beyond membrane

Bulldog-like face

# Typical species (taxonomy not resolved)

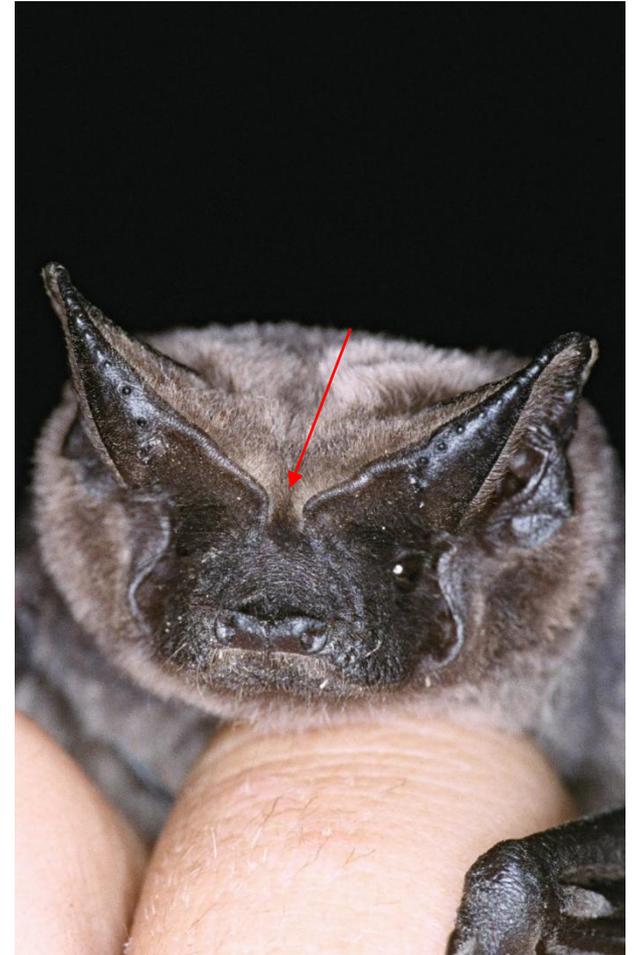

*Chaerephon  
pumilus*

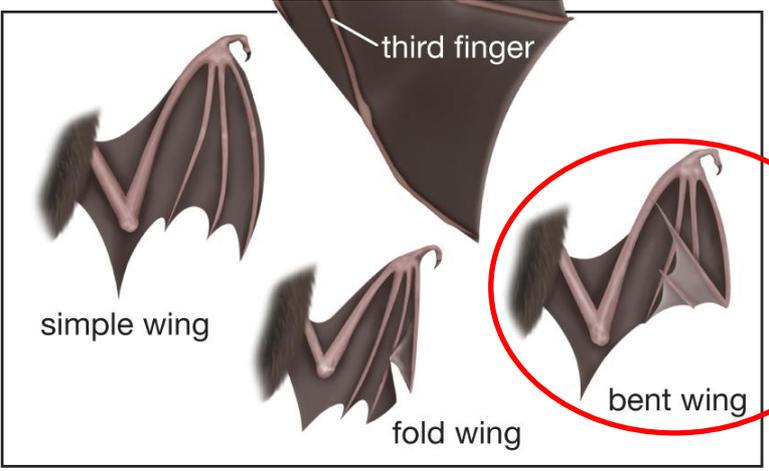

*Mops condylurus*

*Tadarida  
aegyptiaca*

# Miniopteridae (bent-winged bats)

'Bent' wings

No noseleaf

Domed head

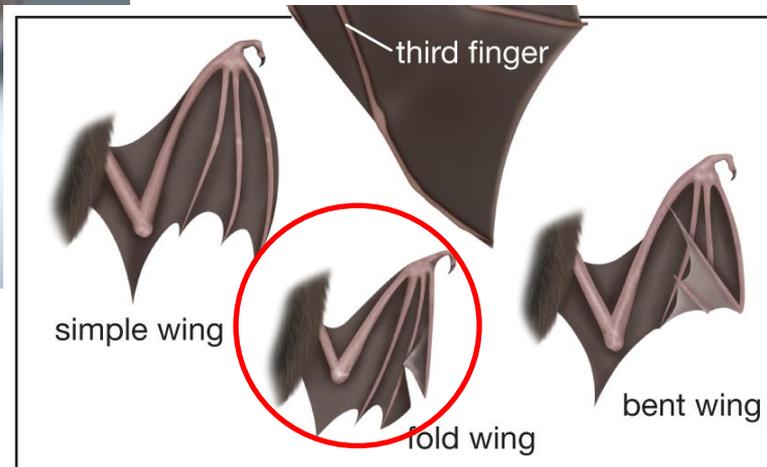

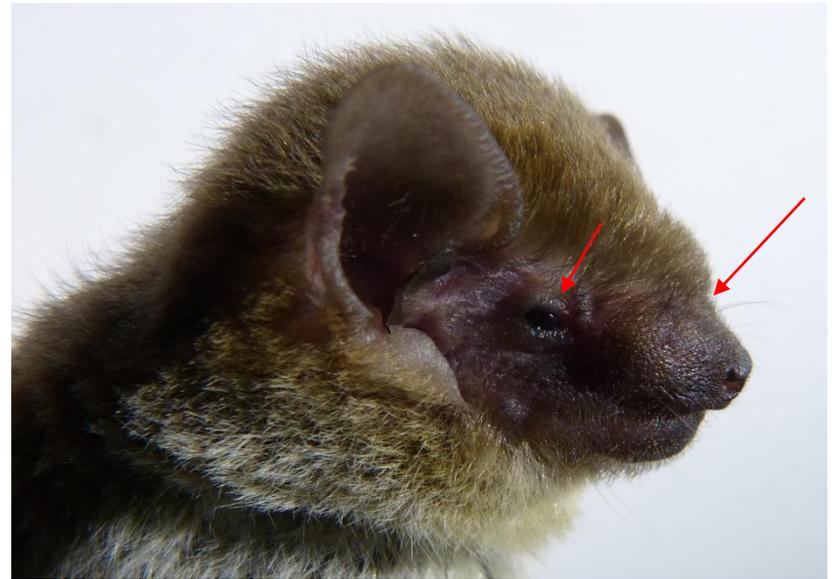

Just one genus: *Miniopterus*

# Vespertilionidae (vesper bats)

Folded wings

Small eyes

Simple face

# Many genera, and complicated!

*Laephotis capensis*

*Afronycteris nana*

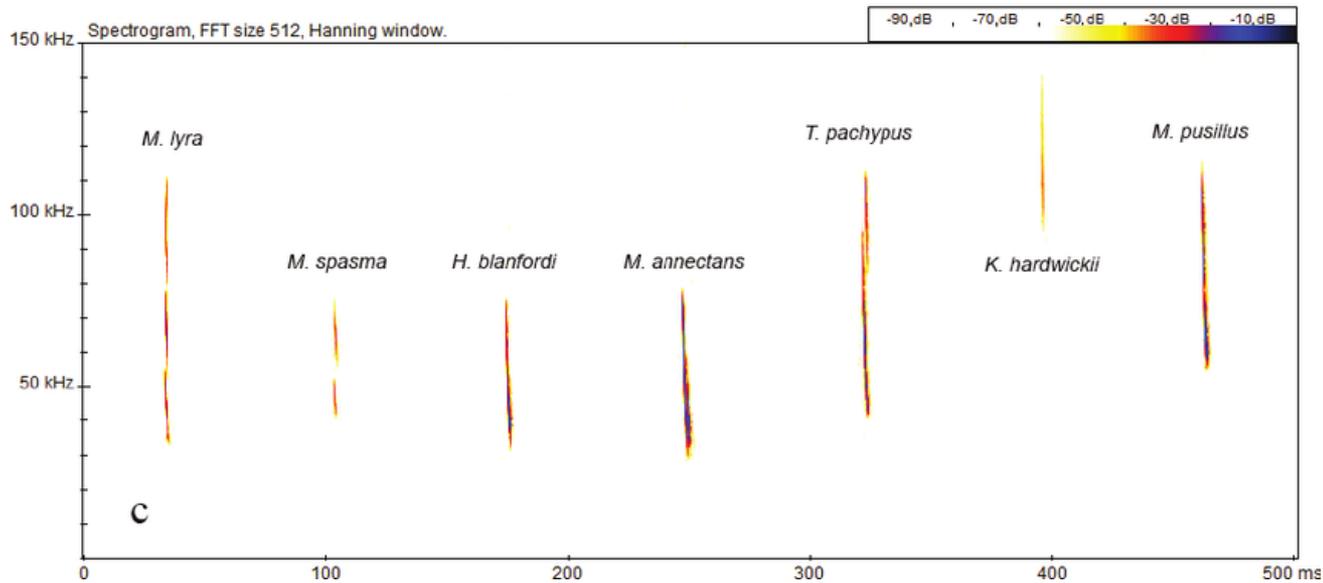

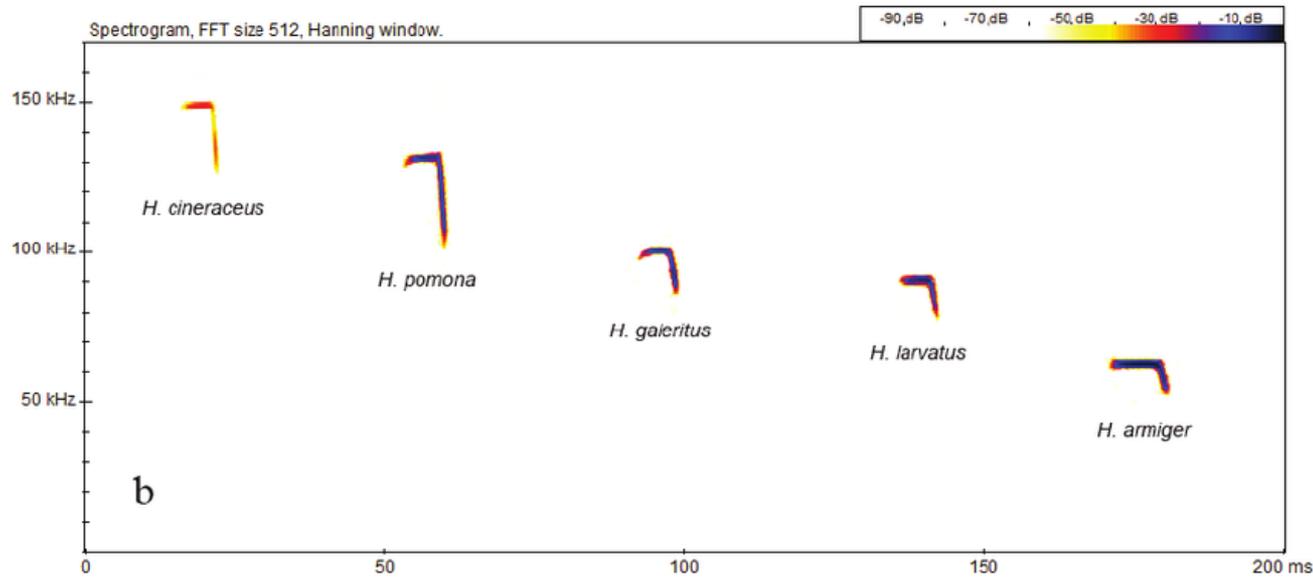

*Scotophilus dinganii*

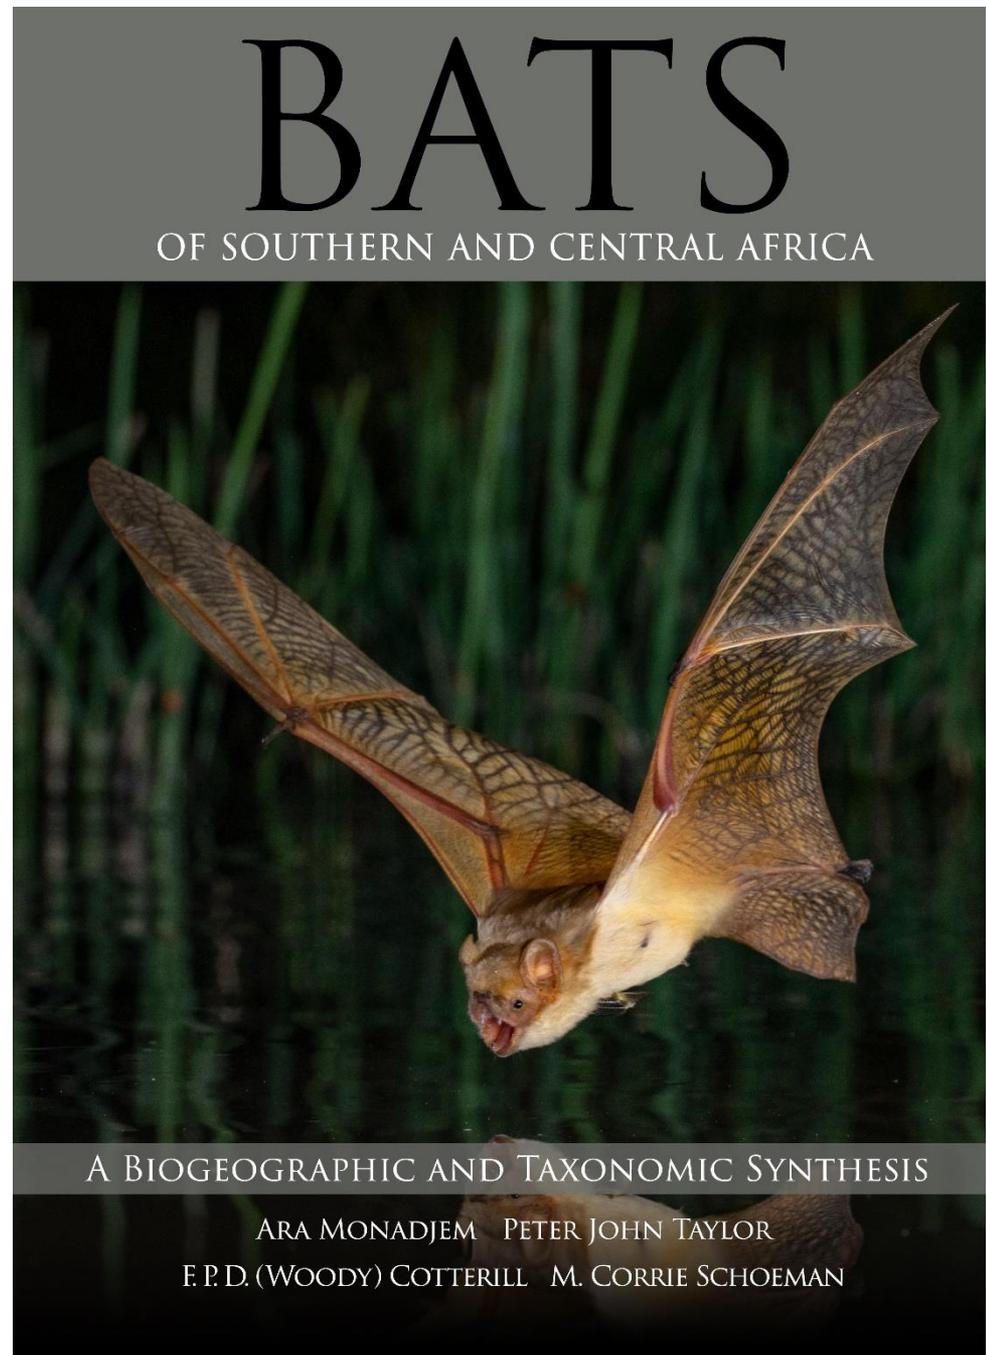

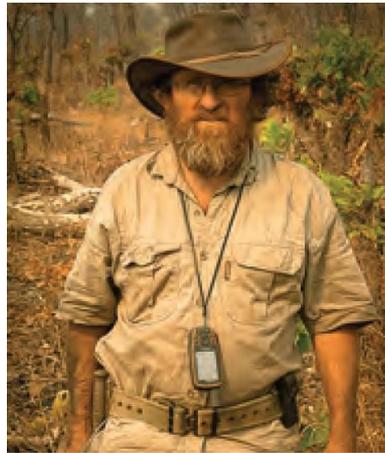

# Acoustic identification

# Different species have different calls

Fully revised 2<sup>nd</sup>  
edition now  
available

---

Dear all

Thank you for attending today's workshop. If you could not attend, the recording is on the drive at the following link;

  
I am also attaching a copy of Ara's slides

Attached is also our first official publication link to the DTRA project that was published today. It provides a good summary of coronavirus surveillance in Africa and suggestions for future work.

Kind regards

Wanda

## Specific Aims

About 60% of the known pathogens are zoonotic, and 75% are responsible for emerging outbreaks<sup>1</sup>. Spillover of zoonotic pathogens<sup>2</sup>, i.e. naturally transmitted between animals, including humans<sup>3</sup>, exists not only if pathogen and human populations inhabit the same region, but also if particular conditions enable transmission<sup>2</sup>. Changes in both land use and global climate are widely recognized to influence the risk and emergence of zoonotic pathogens<sup>1</sup>, driving shifts in the geographic distribution of habitat types and their biological communities<sup>4,5</sup>. The combination of these two forces creates new zones of contact between humans and wild and domesticated species, increasing the spillover risk of zoonotic pathogens to humans<sup>3</sup>. A result of this is the worldwide increase of spillover of zoonotic pathogens such as Zika, hantavirus lung syndrome, Nipah, Ebola, and coronavirus (CoV), including SARS-CoV-2<sup>6</sup>. When the first COVID-19 outbreak occurred in December 2019, public health officials asked: What is the disease agent? How does it spread? Has it been seen before? Natural history collections may hold the answers to these questions. Collections across the globe contain more than three billion specimens that represent largely overlooked sources of data for pathogen surveillance<sup>7-13</sup>. Besides being spatiotemporal distribution maps of biodiversity, natural history collections can also be a toolkit for characterizing, mitigating, and predicting zoonotic infectious diseases, offering the short-cuts that public health responders are looking for in understanding the origins and distribution of emerging pathogens<sup>7-11</sup>.

Bats are natural reservoirs for a variety of CoVs that cause serious disease in humans and animals<sup>14</sup>. Florida hosts 13 bat species, including *Eptesicus fuscus*, the big brown bat, a known reservoir of CoVs<sup>15</sup>. CoVs have been found previously in Florida<sup>16</sup>. Therefore, Florida faces the potential risk for spillback of SARS-CoV-2 from infected humans to wild animals, as occurred for both wild<sup>17</sup> and farmed<sup>18-20</sup> mink, and for the establishment of a new reservoir for SARS-CoV-2<sup>21</sup>. There is a need to determine what is the risk for Florida bat populations to be a suitable reservoir for SARS-CoV-2, as well as other pathogens. Animal-associated microbiomes are complex communities that play crucial functions for their hosts, including susceptibility to infections<sup>22</sup>, but they can also reflect animal population dynamics, allowing us to understand responses to pathogens or global ecological changes<sup>23</sup>. Moreover, bat species foraging in anthropogenic landscapes hold clues regarding increased contact with the human population<sup>24</sup> and the potential zoonotic spillover risk. We **hypothesize** that shifts in bat gut microbiota can be used as a predictor for a bat population to be a suitable reservoir for a zoonotic pathogen, and this, together with the ecological traits of the bat species – morphology, diet, and roosting habits – can determine the risk for zoonotic spillover to humans. Our **goal** is to identify biomarkers – gut microbiome and diet species – that can be used for prediction of host suitability to be a reservoir of zoonotic pathogen and spillover/spillback risk. Two specific aims have been designed to accomplish our goal:

### **Aim 1. To identify gut microbiome biomarkers of bat populations from museum collection specimens.**

An interpretable machine learning framework will be developed for the analysis of the gut composition of 183 bat specimens from Florida collected between 1920-2020 using publicly available bat gut metagenomic data as a training set to identify bacterial biomarkers and predict presence/absence of CoVs.

### **Aim 2. To predict the spillover/spillback risk of zoonotic pathogens, including SARS-CoV-2, from bats to humans.**

We will develop a metric for spillover/spillback risk based on the ecological traits of bats, including morphology, roosting and diet habits, with the latter obtained by inverse metabarcoding.

The proposed framework is feasible, as gut microbiota composition has been successfully determined from museum specimens before<sup>25</sup>, and microbiome as biomarkers was already proposed for cancer clinical investigations<sup>26</sup>. Moreover, this proposal is *significant* for several key reasons: 1) the findings will have immediate implications for public health during the ongoing pandemic as it will allow us to understand the potential of the bat population in the state to become a reservoir for SARS-CoV-2 or to be one for other CoVs; 2) the analyses can be partitioned according to roosting which is relevant because some species are more likely to be in close proximity to people, while others are colonial animals and transmission of viruses among the bats themselves may be higher; and lastly, 3) as the Florida Museum collection extends over many decades, it will give us unprecedented information on the spatiotemporal distribution and ecological changes in the Florida bat population and extrapolate evolutionary shifts that might be associated with climate change in the last century.

Other aspects of this proposal are also *innovative*: 1) this will be the first time that gut bat microbiome data will be used as a biomarker for identifying reservoirs of zoonotic pathogens; 2) the new framework will allow us to detect bacteria species linked to pathogen presence that can be used as biomarkers to develop field diagnostics and predict the risk for bat populations to become suitable reservoirs of human-emerging pathogens not only in Florida and the U.S., but also in other countries; and finally, 3) this framework has the potential to be applied to forensics and ecological microbiome investigations on a worldwide basis adjusting the information to the area or pathogen of interest.

Dear Chris

Sure, I'm attaching here a draft of the specific aims that Simone and I drafted a while ago. As the project is evolving, they will change, but the main idea is there.

And thank you so much for connecting us to Dr. Epstein.

Dr. Epstein,

It's a pleasure to e-meet you. I'm looking forward to your meeting next week!

Best,

Carla

Carla Mavian, Ph.D. (She/Her/Hers)  
Research Assistant Scientist  
Emerging Pathogens Institute  
Department of Pathology  
College of Medicine  
University of Florida

Southeast Asia is one of the world's highest-risk EID hotspots, and the origin of the SARS pandemic, repeated outbreaks of novel influenza strains and the spillover of dangerous viral pathogens such as Nipah virus. It is a wildlife 'megadiversity' region, where a rapidly expanding human population is increasing contact with wildlife, and increasing the risk of zoonotic disease outbreaks. The overarching goal of this proposal is to launch the **Emerging Infectious Diseases - South East Asia Research Collaboration Hub (EID-SEARCH)** to analyze the diversity of key viral pathogens in wildlife, the frequency and causes of their spillover, and to identify viral etiologies of undiagnosed 'cryptic' outbreaks in people. EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions, and in Thailand, Singapore, and the 3 major Malaysian administrative regions, whose collaborative networks span >50 clinics, laboratories, and research institutes across almost all SE Asian countries. This hub, and the network, will act as an early warning system for outbreaks - a way to exchange information, reagents, samples and technology, and a collaborative power-house for translational research. The long-term collaboration among the key personnel, and multidisciplinary skillsets from epidemiology, clinical management, lab analysis, through wildlife biology and data analysis **will act as significant assets when deployed to help counter outbreaks in the region**. The research goals of this EIDRC follow three specific aims:

**Specific Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife.** We will: 1) analyze some of the tens of thousands of archived wildlife samples at our disposal, conduct geographically- and taxonomically-targeted field surveillance in wild mammals (bats, rodents, primates), and use serological & PCR assays to identify known high-profile zoonotic pathogens, or close relatives with potential to infect people; 2) biologically characterize novel viruses that our analyses suggest have high spillover and pandemic potential; and 3) conduct *in vitro* receptor binding assays and cell culture experiments, and *in vivo* animal model infections using humanized mice and the collaborative cross mouse to assess their potential to infect people and cause disease.

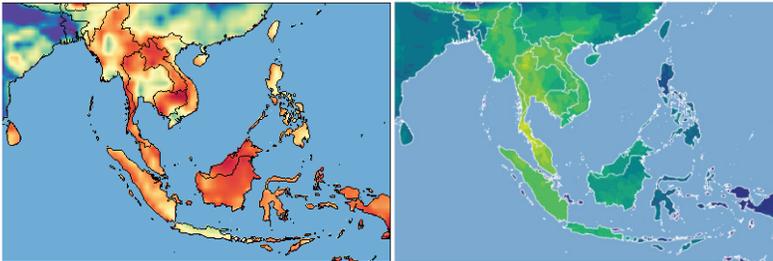

**Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.** Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities and approaches that can deal with the low statistical probability of identifying rare events. To achieve this, we will 1) conduct targeted cross-sectional serological surveys of human communities with extremely high geographic and cultural, occupational and behavioral exposure to wildlife-origin viruses; 2) design and deploy novel serological assays to identify baseline spillover of known or novel CoVs, PMVs and FVs in these populations; and 3) analyze and test hypotheses on the occupational, cultural and other risk factors for spillover (e.g. hunting wildlife).

**Specific Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts.** Our prior work provides substantial evidence of spillover leading to undiagnosed illness in people in the region. To test if these represent 'cryptic' outbreaks of novel viruses, we will conduct syndromic surveillance at regional clinics for the communities sampled in SA2. We will: 1) enroll and collect biological samples, and detailed survey data on risk factors, from patients presenting with influenza-like illness, severe respiratory illness, encephalitis, and other specific symptoms; 2) conduct molecular and follow-up serological diagnostic assays to test causal links between their syndromes and known and novel viral agents identified in SA1. Where viruses are identified, we will attempt to isolate and characterize them, then use the survey data, ecological and phylogenetic analyses to identify likely reservoir hosts/spillover pathways and inform intervention programs.

This research will advance our understanding of the risk of novel viral emergence in a uniquely important region. **It will strengthen in-country research capacity** by linking local infectious disease scientists **with an international collaborative network that has proven capacity to conduct this work and produce significant findings**. These include: testing of tens of thousands of samples from wildlife, humans and livestock in the region; discovery of hundreds of novel viruses from zoonotic viral families in wildlife; outbreak investigations in rural communities across SE Asia; discovery of the bat-origin of SARS-CoVs; discovery of a novel bat-origin SADS-CoV killing >25,000 pigs in S. China; and development of novel serological and molecular assays for high-impact viruses, and state-of-the-art *in vitro* and *in vivo* assays to characterize viral pathogenic potential. This body of collaborative research provides proof-of-concept that EID-SEARCH has the background, collaborative network, experience, and skillset to act as a **unique early warning system for novel EIDs of any etiology threatening to emerge in this hottest of the EID hotspots**.

## II. Research Strategy:

**1. Significance:** Southeast Asia is a critical hotspot for emerging diseases due to its high biodiversity of wildlife and their viruses, and the presence of key ecological and socioeconomic drivers of emergence (**Fig. 1**) (1). These include dense human populations living in networks of rural and urban communities, with strong cultural and occupational connection to wildlife and livestock farming and trading, and intimate connection to global travel networks (2). The region is undergoing rapid environmental and demographic change, both of which increase the risk of disease emergence and spread. Pathogens that emerge in this region often spread and sometimes enter the USA (e.g. prior influenza pandemics, SARS) and threaten global health security.

**Fig. 1:** Southeast Asia, and in particular, parts of Thailand and Malaysia are hotspots of risk for disease emergence (**left**), and predicted high diversity of 'missing' or as-yet undiscovered viruses, yellow = highest diversity (**left**). From (1-3).

Not surprisingly novel viruses, including near-neighbors of known agents, have emerged in the region leading to often unusual clinical

presentations (**Table 1**). This adds to a significant background burden of repeated Dengue virus outbreaks in the region (20), and over 30 known *Flavivirus* species circulating throughout S. and SE Asia (21). The events in Table 1 are dominated by three viral families: coronaviruses (CoVs), paramyxoviruses (PMVs - particularly henipaviruses) and filoviruses (FVs), which are initial examples of our team's research focus and capabilities. These viral groups have led to globally important emerging zoonoses (4, 5, 22-31), causing tens of thousands of deaths, and costing billions of dollars (32-34). Furthermore, near-neighbors of known pathogens in these families have been reported throughout the region, including by members of our consortium: henipaviruses in bats in Thailand, Cambodia, Philippines, Laos, Indonesia, China, Malaysia, Bangladesh and India (35-41); a novel henipavirus, Mòjiāng virus, in wild rats in Yunnan (14); serological evidence of FVs in bats in Bangladesh (42) and Singapore (43); Nipah- and Ebola-like viruses in *Hipposideros*, *Cynopterus* and *Rhinolophus* species in Malaysia (Hughes *et al.*, in prep.); evidence of novel FVs in bats in China (44-46), including Měnglà virus

Viral agent	Site, date	Impact	Novelty of event	Ref.
Nipah virus	Malaysia, Singapore 1998-9	~246 human cases, ~40% fatal	2 <sup>nd</sup> emergence of a zoonotic henipavirus, 1 <sup>st</sup> large outbreak	(4-6)
Melaka & Kampar virus	Malaysia 2006	SARI in family group, individual	1 <sup>st</sup> disease due to bat-origin reoviruses, also Singapore, Vietnam etc.	(7-10)
Reston filovirus	Philippines 2008	Seropositive people killed pigs,	No prior FVs in pigs	(11)
Thrombocytopenia Syndrome virus	E. Asia 2009	100s of deaths in people	Novel tick-borne zoonosis with large caseload	(12)
Reston filovirus	Shanghai 2011	PCR positive pigs	Further evidence of pig RESTV infection	(13)
Mòjiāng virus	Yunnan 2012	Death of 3 mineworkers	1 <sup>st</sup> evidence of rodent origin henipavirus in people	(14)
Nipah-like virus	Philippines 2015	Killed horses	No prior horse infection for NiV, known for HeV	(15)
SARSr-CoV & HKU10-CoV	S. China 2015	Seropositive people	1 <sup>st</sup> evidence human infection HKU10 & SARSr-CoV	(16)
SADS-CoV	China 2017	>25,000 pig deaths seronegative people	Novel emergence of bat-origin CoV	(17)
Nipah virus	Kerala 2018, 2019	Killed 17/19 people 2018, 1 infected 2019	1 <sup>st</sup> outbreak of NiV outside Bangladesh, W. Bengal focus	(18, 19)

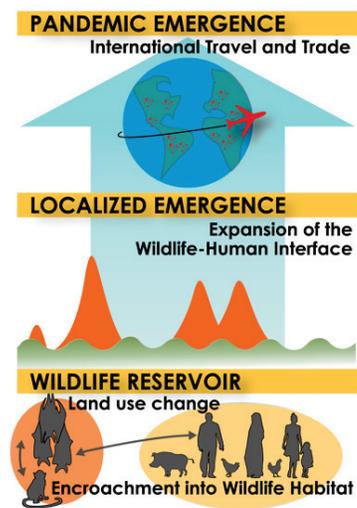

that appears capable of infecting human cells (47); novel PMVs in bats and rodents consumed as bushmeat in Vietnam (48); a lineage C  $\beta$ -CoV in bats in China using the same cell receptor as MERS-CoV to infect human cells *in vitro* (49); MERSr-CoVs in bat guano harvested as fertilizer in Thailand (50), and directly in bats (Wacharapluesadee *et al.*, in prep.); 172

**Table 1:** Recent emergence events in SE Asia indicating potential for novel pathways of emergence, or unusual presentations for known or

related viruses.

novel  $\beta$ -CoVs (52 novel SARSr-CoVs) and a new  $\beta$ -CoV clade (“lineage E”) in bats in S. China that occur throughout the region (24, 49, 51, 52); 9 novel wildlife-origin CoVs and 27 PMVs in Thailand, and 9 novel CoVs in Malaysia reported by us from USAID-PREDICT funding (51, 53). These discoveries underscore the clear and present danger of zoonotic events in the region. The wide diversity of potentially pathogenic viral strains also has significant potential use in broadly active vaccine, immunotherapeutic and drug development (49).

Most high-impact zoonotic viruses originate in wildlife reservoirs, sometimes spilling over first into livestock ‘amplifier’ hosts, or directly into localized human populations with high levels of animal contact (**Fig. 2**). Efforts to prevent emerging zoonoses have targeted these high-risk populations in regions prone to disease emergence (31, 54). However, these regions tend to be in the developing world, where nations often lack the resources to investigate novel zoonotic events, or wildlife reservoirs of zoonoses, and prioritize more immediate public health concerns such as Dengue virus or NTDs (20). Zoonotic disease surveillance and control is also hampered by inadequate information on basic disease ecology (e.g. range of wildlife reservoirs, risk factors for spillover) and pathogen biology (viral diversity, pathogenesis), and by logistical challenges sharing novel diagnostics, animal models, samples and reagents at sites where outbreaks begin (55). Countermeasure and vaccine development is challenged by the small number of isolates available, and the presence of closely-related strains, some with evidence of transmission to people but with unknown pathogenicity. For example, using NIH and other funding, we found serological evidence of exposure to African henipaviruses in 3-4% of a sample of people in Cameroon, with a significant risk factor being butchering of bats; and serological responses to bat SARSr-CoVs in 6/209 (2.87%) and bat HKU10-CoV in 2/412 (0.5%) people living close to a bat cave in Yunnan, all novel viruses with unknown clinical impact (16, 56). We discovered two novel bat-borne reoviruses, Melaka and Pulau viruses, and showed that 14/109 (13%) of people living in close proximity to bat roosts on Tioman Island, Malaysia were exposed to these viruses (7) as well as 12/856 (1.4%) of a random sample screened in Singapore (8). Previous studies in the Philippines found farmers and butchers who had contact with sick pigs tested positive for Reston ebolavirus antibodies but had not experienced illness (11), and it was our team that discovered Philippine bats as natural reservoir hosts for Reston virus (57). In preliminary screening in Malaysia with funding from DTRA we found serological evidence of exposure to henipaviruses (Hendra, Nipah and Cedar) in 14 bats and 6 human samples, and Ebola (Zaire and Sudan)-related viruses in 11 bats, 2 non-human primates (NHP) and 3 human samples (Hughes, in prep.).

Even when spillover leads to outbreaks of illness and mortality, they are often unreported, undiagnosed or misdiagnosed. We initiated targeted syndromic surveillance of encephalitis patients in Bangladesh clinics and showed that Nipah virus (NiV) causes repeated annual outbreaks with an overall mortality rate of ~70% (58). NiV has been reported in people in West Bengal, India, which borders Bangladesh (28), in bats in Central North India (59), and now in people in Kerala, South India in 2018 and 2019, raising the specter of future spillover at other sites in the region (18, 60).

**Fig. 2: Our Early Warning Approach:** Most zoonotic viruses emerge from wildlife hosts, sometimes via livestock (**lower panel**), to cause small scale outbreaks (green) or larger chains (red) of human-to-human transmission (**middle**). In some cases, these spread more widely via air travel (**upper**). Our EIDRC proposal targets each stage: SA1 examines the diversity and spillover potential of viral threats in targeted SE Asian wildlife; **SA2** seeks evidence of their spillover into focused high-risk human populations; **SA3** identifies their capacity to cause illness and to spread more widely. Figure from (54).

Under a current NIAID R01, we have shown that we can use analytical approaches to target surveillance of wildlife and people and identify likely sites of spillover. We used phylogenetic analysis of bat hosts and their CoVs to identify a key cave complex in SW Yunnan Province that harbors all the genetic elements of SARS-CoV (61), as well as a series of SARSr-CoVs that can infect human cells *in vitro*, cause SARS-like clinical signs in humanized mice, and evade vaccine treatment and therapeutics (24, 49, 51, 52, 62-64). We conducted risk factor surveys and biological sampling of human populations living close to this cave and found serological evidence of spillover in people highly exposed to wildlife (16). **This work provides proof-of-**

**concept for an early warning approach that we will expand in this EIDRC to target other viral groups in one of the world's most high-risk EID hotspots.**

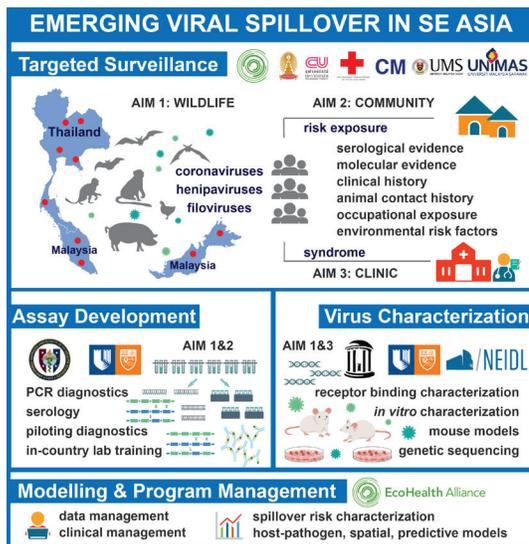

The overall premise of this EIDRC proposal is that there is substantial evidence that: 1) diverse CoVs, henipaviruses and FVs related to known human pathogens are circulating in wildlife reservoirs in Southeast Asia; 2) these viruses likely spillover regularly to people, are often unreported or misdiagnosed, and their clinical manifestations and potential to cause pandemics are unknown and underestimated; and 3) our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence. To scale-up this approach, we propose to launch EID-SEARCH (the **E**merging **I**nfectious **D**iseases - **S**outh **E**ast **A**sia **R**esearch **C**ollaboration **H**ub), to better understand, and respond to, the risk of zoonotic viral emergence in Southeast Asia. We will initially focus on the diversity of known and novel CoVs, henipaviruses, and FVs in wildlife reservoirs. We will use this work to build our center's interactive network throughout the region, bridge barriers, provide early focal point for basic and translational studies, develop sample handling and storage routines, communication networks, cohort management, infrastructure development, and cross-training in surveillance and novel diagnostic platforms. We will develop and transfer technology to test these viruses' capacity to infect human cells and mouse models, develop new specific and sensitive serological and molecular diagnostic tools, conduct surveillance of human communities with high risk of exposure to wildlife, and clinical cohorts to identify evidence of spillover of viruses causing previously 'cryptic' clinical syndromes in people. We will test the capacity of novel viruses to infect human cells and/or mouse models, and thus assess potential for spillover and spread which will feed into our risk models. Our group also has extensive experience in other viruses, including vector-borne flaviviruses, and alphaviruses, and will use this experience to provide robust long-term surveillance, diagnostics, and basic science opportunities. While the current proposal focuses its basic and applied research agendas on this group of viral EID, we note that the EID-SEARCH is poised to rapidly respond to any outbreak. **Thus, FVs, henipaviruses and CoVs are examples of sentinel surveillance systems in place that illustrate EID-SEARCH's capacity to identify and initiate a rapid response targeting any novel microbial pathogen that emerges in this region.**

**2. Innovation:** Previous work by our consortium has developed strategies to target surveillance in wildlife and people to better anticipate and identify early spillover events and pre-empt outbreaks of emerging viruses. In the EID-SEARCH we scale up this approach in a central research "hub" made up of leading laboratories, clinics and surveillance sites in three critically high-risk EID hotspot countries in SE Asia. EID-SEARCH's reach is expanded through its regional network of collaborators that covers nearly all of the greater SE Asia region. The innovation of the EID-SEARCH is in: 1) Its multidisciplinary approach that combines modeling to target geographic and taxonomic sampling targets with on-the-ground zoonotic disease surveillance in human and wildlife populations; 2) the biological characterization approach that identifies how likely viruses are to be able to infect people, and enables evaluation of existing countermeasure technologies; an approach that is grounded in our successful work on SARSr-CoVs; and 3) the strategic sampling of both high-risk communities with extensive animal contact at the front-lines of viral spillover and syndromic clinical cohorts that present with signs of novel viral emergence, to identify risk of viral spillover in an early warning system approach (**Fig. 2**). **In Aim 1, we will target viruses in archived and newly collected wildlife samples, and characterize their risk of spillover to people.** We will use spatial and phylogeographic analyses to identify the geography and species of wildlife to test samples from, and to further characterize viruses we have recently discovered. We will use *in silico* methods (novel ecological-phylogenetic risk ranking and mapping of receptor binding domains), cell culture, and animal models to assess their potential for spillover into high-risk human populations. **In Aim 2, we will conduct targeted cross-sectional serological surveys of human communities with high levels of animal contact to find evidence of viral spillover, and identify occupational and other risk factors for zoonotic virus transmission.** We will use serological tests targeting viruses identified in Aim 1 to identify the baseline spillover of known or novel CoVs, henipaviruses and FVs in these populations. Serological findings will be analyzed together with subject metadata (including a simple animal-contact survey, location data, viral sequence/isolates etc.) to identify zoonotic risk factors and routes of exposure from specific wildlife or vector species. **In Aim 3, we will use syndromic surveillance of clinical human cohorts to identify evidence of viral etiology for otherwise 'cryptic' outbreaks.** We will enroll and

collect biological samples from patients in local clinics and hospitals who present with syndromes previously linked to known viral agents and live within communities at high risk for disease emergence. We will conduct molecular and follow-up serological diagnostic assays to identify likely viral etiology of syndromes that may represent otherwise cryptic events. Where viruses are identified, we will attempt to isolate or molecularly re-derive them, and use survey data, ecological and phylogenetic analysis to identify likely reservoir hosts and inform intervention programs. Our US partner BSL-4 laboratory, NEIDL, will attempt isolation and characterization of viruses requiring BSL-4 of containment (e.g. novel filoviruses, close relatives of Hev/NiV).

**3. Approach: 3.1. Research team:** The EID-SEARCH builds on long-term collaboration among world leaders in emerging virus research with proven experience collaborating internationally on field, lab and human surveillance research (**Fig. 3**). Over the past two decades, our consortium partners have conducted high profile research on EIDs within the region and globally, including identifying the wildlife reservoirs for NiV and Hendra virus (HeV), MERS- and SARS-CoVs (24, 27, 59, 61, 65-67), discovering SADS-CoV (17), and developing an array of serological, molecular, *in vitro* and *in vivo* approaches to characterizing high-risk CoVs, henipaviruses, and FVs (62-64, 68-81). Our team has substantial experience conducting human surveillance in the community and during outbreaks (Sections 2.2.a., 2.2.b., 2.2.c, 3.2.a, 3.2.b), including: USAID-PREDICT, and DTRA-funded viral surveillance of indigenous communities in Peninsular Malaysia and syndromic surveillance of hospital patients in Sabah (Co-I Hughes); collection of >2,000 serum samples from healthy blood donors and sanitation workers, febrile and influenza like illness (ILI), and diarrheal stool samples from children under 5 years of age across Borneo Malaysia (Co-I Kamruddin); collaboration on the MONKEYBAR project with the

London School of Hygiene and Tropical Medicine to analyze risk and prevalence of the zoonotic malaria *Plasmodium knowlesi* through case control and cross-sectional studies in Sabah villagers (n=~800, 10,000 resp.) and clinical observational studies to determine the etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah. (Co-Is William, Rajahram, Yeo); and community-based surveillance of hundreds of bat-exposed villagers in Thailand (Co-Is Wacharapluesedee, Hemachudha). As a proof-of-concept of how our team can rapidly scale up resources for diagnostics and surveillance in the face of a new EID, in 2016, we discovered a novel bat-origin HKU-2 CoV (82, 83) killing >20,000 pigs in S. China, designed PCR and serological assays, surveyed pig farmers for evidence of exposure, and conducted experimental infections, pathogenesis and molecular studies, **all in the span of 3 months** (17, 84).

**Fig. 3:** EID-SEARCH scope, core institutions, and roles.

The administration of this center (**Section 4.1.**) will be centralized at EcoHealth Alliance (EHA) led by PI Daszak, who has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5-20 yrs on NIAID- and USAID-funded research. He will oversee all activities in this EIDRC, supported by Deputy lead, Dr. Olival – who has managed human and wildlife disease surveillance projects in SE Asia for >10 years, and a **Core Executive Committee (Section 4.1.a)**. Co-Is Olival and Zambrana are leaders infectious disease analytics, and head the modeling and analytics work for USAID-PREDICT. Co-Is Wang, Baric, Broder, Anderson, and Laing have developed a unique array of *in vitro* cell culture, serological and molecular reagents to identify and characterize emerging viruses in people and animals (henipaviruses and other PMVs, CoVs, FVs and many others). Co-Is Wacharapluesedee, Hemachudha, and Hughes and collaborators have coordinated clinical and community surveillance of people, and of wildlife and livestock within Thailand and Malaysia for the past 15 years, in collaboration with Ministries of Health, Agriculture and Environment. Finally, this consortium has extensive external funding from NIH, DoD, USAID, DHS and other USG agencies supporting laboratory, analytical and field studies directly related to the current proposal, and will bring substantial leverage to our EIDRC.

**3.2. Geographical focus:** The three core (hub) countries for this proposed EIDRC are Thailand, Malaysia and Singapore, three contiguous EID hotspot countries that stretch through one of the most significant foci of EID origins globally. Our proposed work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak and Sabah, and thus contains overlapping wildlife biogeography with India, Bangladesh, Myanmar, SW China, Laos, Cambodia, Vietnam, Philippines, and Indonesia. It encompasses diverse cultural and socioeconomic backgrounds which have correspondingly diverse and intensive interactions with wildlife reservoirs and the global travel network. We have already begun sampling of wildlife hunters, livestock workers, wildlife farmers and market workers, rural villagers living close to high risk wildlife species, people otherwise highly exposed to animals in these countries, and clinical cohorts, as part of current/prior NIH, DTRA, and USAID funding. Our core member's extensive network of collaborators in clinics, research institutes and public health laboratories in almost every other Southeast Asian country positions the EID-SEARCH within a much larger catchment area for emerging zoonoses and will allow us to rapidly scale up to include additional sites in response to an outbreak or shift in research priorities. We will conduct regular meetings with key research, public health and community leaders, including >50 leading laboratories/institutions in 10 countries (**Section 4.2**) to maintain these collaborative relationships with the core members of our consortium (**Fig. 4**).

We will use these, and our annual meetings, to share information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks across the region.

**Fig.4 :** Map of Southeast Asia indicating three hub countries for this proposed EIDRC (**Red**: Thailand, Singapore, Malaysia) and countries in which Key Personnel have existing collaborating partners via other funded work (**Green**), indicating that EID-SEARCH provides access to key collaborators and sites throughout the region.

**3.3. Capacity for linkage with other NIAID studies, and scaling up to respond to outbreaks:** EID-SEARCH US-based partners include senior scientists with significant experience on NIAID-funded projects, extensive collaborations with other NIAID-funded scientists, and previous experience working with NIAID leadership through workshops, review of programs (e.g. PI Daszak's role in NIAID CEIRS external review), and work on study sections. These contacts ensure that the EID-SEARCH senior leadership will be ready and able to rapidly set up data, sample and reagent/assay sharing protocols with NIAID researchers, the other EIDRCs, the EIDRC CC and other NIAID research centers. EID-SEARCH in-country partners include senior medical doctors and infectious disease specialists at national and regional hospitals in each country and administrative state in this proposal. On news of potential outbreaks, **EID-SEARCH will rapidly mobilize its core staff and their extensive collaborative network across almost all SE Asian countries (Fig. 4) (Sections 4.1.a, 4.2. 4.3)**. The core analytical approach can be used to rapidly identify sampling sites and targets to harvest vectors, vector borne arboviruses, birds and mammalian species that harbor most other viral threats. Through existing projects such as the USAID PREDICT Project and DTRA-funded biosurveillance projects, EHA is currently partnered with hospitals and researchers across South and Western Asia, West and Central Africa, and Latin America. Our partners already have capacity to conduct human and wildlife sampling and testing for novel viral agents, so expanding in geography or scale is readily achievable given sufficient resources.

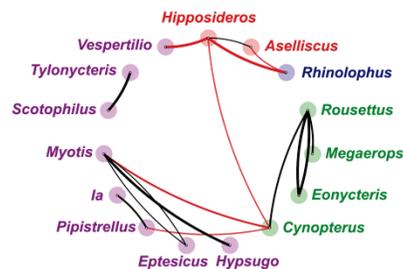

**Aim 1: Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife.**

**1.1 Rationale/Innovation:** The vast majority of emerging zoonotic pathogens are linked directly or indirectly to wildlife host, particularly from important mammalian groups like bats, rodents and NHPs (3). Our previous work on wildlife origin viruses demonstrates that zoonotic viral emergence tends to occur in specific regions with high diversity of wildlife that harbor viruses of zoonotic potential, and human populations that have close contact to these wildlife (**Fig. 1**) (2, 3). In Aim 1 (**see Fig. 9 for overview**), we will strategically conduct EID surveillance by applying risk analytics to prioritize the regions, wildlife species, and human populations that

have a particularly high risk of viral spillover. We will target high-risk zoonotic host reservoirs (bats, rodents and NHPs) in these regions and apply novel predictive models to estimate viral diversity and host range to identify wildlife species that have been ignored or under-sampled by previous zoonotic disease surveillance efforts. We will strategically collect specimens from these species and screen them, together with some of the tens of thousands of recently collected samples we have archived, for known and novel agents. We will begin screening using conserved PCR assays to identify known and novel viruses in high risk RNA viral families, *Coronaviridae*, *Paramyxoviridae*, and *Filoviridae*. We will expand to other groups of pathogens, including arboviruses, pending available resources and priorities established with the EIDRC coordinating center (EIDRC-CC) and other regional EIDRCs. Using risk ranking algorithms and a series of ecological and virological risk factors, we will triage the wildlife viruses we discover for further genomic characterization and viral isolation. On this subset of viruses, we will then use *in vitro* and *in vivo* approaches (viral rescue, cell lines, gene edited humanized transgenic mice and the collaborative cross genetic reference mouse population) previously developed and widely used by our team to predict capacity of novel viruses to infect people and spillover (63, 85-88). These high-risk viruses and their close relatives will be targets for human community serosurveys and clinical sampling in Aims 2 and 3, respectively.

**1.2 Preliminary data: 1.2.a. Geographic targeting:** EHA has led the field in analyzing where the highest risk of zoonotic spillover is across the globe, identifying SE Asia as a major EID hotspot (1, 2). These hotspots are sites where high wildlife biodiversity, human population density and rapid ecologic change collide (**Fig 1**). Using host and ICTV viral data for all known mammalian viruses, and generalized additive models to correct for sampling bias, we are able to predict the relative number of yet-to-be-described viruses that a species harbors (3). This demonstrates substantial undiscovered viral diversity in mammals across Southeast Asia, and particularly in regions of Thailand, Singapore and Malaysia (**Fig. 1**). Separately, we found that factors driving spillover (host diversity, climate) differ from those driving spread in human populations (population density, bushmeat hunting, livestock production) (89). We therefore analyze capacity for viral spread as a separate risk factor, using our unique demographic and air travel and flight data modeling software (90, 91). In the current proposed work, we will use all the above approaches to target wildlife sampling (archival and new field collections) in Aim 1, to inform sites for human sampling in Aim 2, and to assess risk of spread in Aim 3.

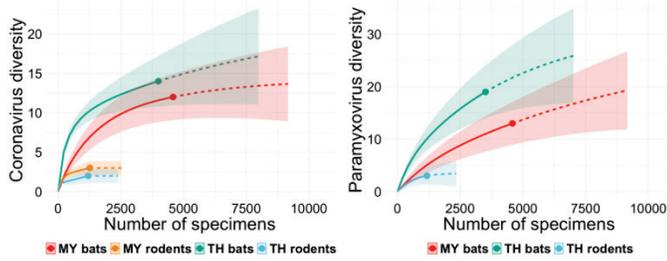

**1.2.b. Reservoir host species targeting:** Our analysis of all known mammalian host-viral associations demonstrates that bats, rodents and NHPs represent the three most important reservoirs for zoonoses, responsible for the highest proportion of known and predicted viral diversity of zoonotic potential (3). Thus, the bulk of our proposed wildlife sampling and testing will consist of these three taxa with a focus on bats, because this group is the known or hypothesized reservoir for the majority of high-impact zoonotic CoVs, PMVs and FVs (50, 92-94). Bats have the highest proportion of predicted zoonotic viruses in any mammalian group (2), and are exceedingly diverse in Southeast Asia (~500 species). To further prioritize taxonomic sampling targets within these diverse geographic hotspots, we used a novel Bayesian phylogeographic algorithm to identify host genera and species that are the most important centers of evolutionary diversity for a given viral group, e.g. bat genera for  $\beta$ -CoVs (**Fig. 5**) (51). This approach will be extended to other mammal taxa and viral families of interest, allowing us to identify the reservoir hosts of specific zoonotic viral groups, where viral diversity is likely highest.

**Fig 5:** Preliminary analysis of sequence data collected under prior NIH funding, identifying SE Asian bat genera with the highest  $\beta$ -CoV evolutionary diversity. We will apply this Bayesian discrete phylogeographic model to identify taxonomic and geographic centers of viral diversification and sharing for relevant PMV, CoV, FV and other virus clades. Line thickness proportional to probability of virus sharing between two genera. Inter-family switches in red.

Finally, we have designed a strategy to estimate sampling gaps, using a viral 'mark-recapture' approach we previously published (95, 96) (**Fig. 6**). Using prior data for bat, rodent and NHP viral discovery vs. sampling rates, we can identify the likely total viral diversity for specific host groups in a region, and use this to estimate sample sizes to discovering the majority of unknown viruses within a specific family or genus. **In the current**

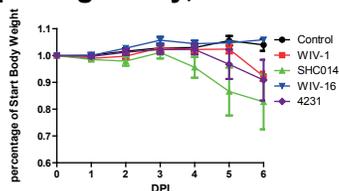

**proposal**, we will use these analyses to estimate geographic and species-specific sampling targets **to more effectively identify new strains to support experimental infection studies and risk assessment.**

**Fig. 6:** Estimated CoV (left) and PMV (right) diversity in bats and rodents from Thailand and Malaysia, using data from PCR screening and RdRp sequences from >10,000 specimens in bats and 4,500 in rodents. Bats have 4X more viral species than rodents, controlling for sampling effort. We estimate that additional collection of 5k-9k bat specimens and testing of our archived bat and rodent specimens alone will identify >80% of remaining CoV and PMV viral species in these key reservoirs, yielding >800 unique viral strains.

**1.2.c. Sample testing to identify known and novel viruses:** We have conducted extensive wildlife surveillance for novel viruses across Southeast Asia in prior NIAID funded work and as part of the USAID PREDICT project. Under the 10-year PREDICT program globally, we identified 912 novel and 210 known viruses, more than the total number of viruses previously recognized in mammals by the ICTV (97). This work included collecting nearly 300,000 individual mammal samples from 14 EHA-led PREDICT countries, and PCR-screening of more than 60,000 individual specimens (53). In southern China alone, we identified 178  $\beta$ -CoVs, of which 172 were novel, discovered a new  $\beta$ -CoV clade, “lineage E” (41), diverse HKU3r-CoVs (179 sequences) within a 'sister' clade to the SARS-CoV lineage, and a new bat-origin SADS-CoV, responsible for killing >25,000 pigs in Guangdong Province (17). We have collected 28,957 samples from bats, rodents and NHPs in Thailand and 47,178 in Malaysia, **but have only tested a minority of these using PCR.** We have identified 100 novel viruses in Thailand and 77 in Malaysia. **Furthermore, we have only sequenced a small segment of one gene for all novel viruses found. We have archived duplicate samples which are now available for use in this project**, including fecal, oral, urogenital, serum samples, and biopsies from bats, rodents, and NHPs. In the current proposed work, we will attempt to sequence, isolate and characterize those viruses that our analyses below suggest are most likely to be able to infect humans.

**1.2.d. In vitro & in vivo characterization of viral potential for human infection:** Using Coronaviridae as an example, we have conducted *in vitro* and *in vivo* experiments to characterize the pathogenic potential of novel SARSr-CoVs from bats. We isolated three SARSr-CoVs from bat feces: WIV1, WIV16 and Rs4874, with Spike (S) protein sequences that diverged from SARS-CoV by 3-7% (24, 61, 98). We conducted full-length genome sequencing of 12 other novel SARSr-CoVs, some highly similar to outbreak SARS-CoV in the most variable genes (61). Using our reverse genetics system we constructed chimeric viruses and rederived full length recombinant SARSr-CoV from in silico sequence. All 3 SARSr-CoV full length isolates and the two chimeric viruses replicated efficiently in Vero E6 cells and in HeLa cells expressing hACE2, civet and bat ACE2, but not in those without ACE2 (24, 61, 98). We used the SARS-CoV reverse genetics system (72) to generate a chimeric virus with a mouse-adapted SARS-CoV backbone expressing SHC014 S protein with 10% sequence divergence from SARS-CoV S. This and the other full length and chimera viruses replicated in primary human airway epithelium, using the human ACE2 receptor to enter into cells (62). Thus, **SARSr-CoVs with diverse variants of SL-CoV S protein without deletions in their RBD can use human ACE2 as receptor for cell entry.** The Baric lab has a well-established hACE2 and DPP4 transgenic mouse model that **we used to assess the capacity of novel SARSr-CoVs and MERS-CoV to infect humans and cause disease (85, 99).** Infection of bat SARSr-SHC014 or WIV1 caused SARS-like clinical signs in the transgenic hACE2 mouse model **that weren't reduced by immune-therapeutic monoclonals that attenuate SARS-CoV pathogenicity, nor after challenge following vaccination against SARS-CoV (62) (Fig. 7).** We repeated

this virus characterization approach with chimeras using HKU3r-CoV S proteins that are ~25% divergent from SARS-CoV S, **and found that they are unable to use the ACE2 receptor.** Additionally, we were unable to culture HKU3r-CoVs in Vero E6, or human cell lines.

**Fig. 7:** Body weight change in hACE2 transgenic mice after SARSr-CoV infection, demonstrating that bat-origin SARSr-CoVs cause similar clinical signs to outbreak SARS-CoV strain (4231) (62, 63).

A similar approach to the above pipeline for CoVs will be applied to novel henipaviruses we discover during our research. The broad mammalian tropism of HeV and NiV (68) is likely mediated by their usage of highly conserved ephrin ligands for cell entry (19, 100). A third isolated henipavirus, Cedar virus does not cause pathogenesis in animal models. **Co-Is Broder and Laing** have developed a reverse genetics system and rescued a recombinant CedV to test ephrin receptor usage/tropism and pathogenicity during henipavirus infections (77). CedV is unable to use the Ephrin-B3 receptor (77, 101) which is found in spinal cord and may underlie NiV encephalitis (102) and that pathogenesis also involves virulence factors V and W proteins. The putative henipaviruses, Ghana virus and Mòjiāng virus, predict V and W protein expression, with GhV able to bind to ephrin-B2, but not -B2 (103), and the receptor for MoJV remains unknown (104) but is likely ephrin-B2 (105). Our group has also used similar methods to test the hypothesis that novel Filoviruses discovered in wildlife are able to infect people. NiV, EBOV and MERS-CoV all infect primary microvascular endothelial cells, which are available at Co-I Baric's lab for EID-SEARCH collaborators (71, 106). Primary human lung endothelial cells are highly susceptible to Ebolavirus infection (107), and Huh7 cells can be used to isolate virus from clinical samples (108) offering advantages for reverse genetic recovery of novel FVs (109). The three filovirus genera, *Ebolavirus*, *Marburgvirus* and *Cuevavirus*, use Niemann–Pick type C1 (NPC1) protein as cell entry receptor (110). For novel filoviruses, cell culture would be carried out under BSL-4, however they can readily be characterized following identification of their encoded GP sequences which can be pseudotyped into recombinant GP-bearing vesicular stomatitis virus (VSV) pseudovirions (111). These pseudovirions can be safely used to characterize the tropism and entry filoviruses mediated by GP without a need for BSL4 containment. **Co-Is Wang and Anderson** used cells originating from various mammalian species to determine spillover and/or zoonotic potential of MLAV, a newly discovered Asian filovirus (47). Despite the low amino acid sequence identity (22–39%) of the glycoprotein with other filoviruses, MLAV is capable of using NPC1 as entry receptor. Cells from humans, monkeys, dogs, hamsters and bats were able to be infected with a MLAV pseudovirus, implying a broad species cell tropism with a high risk of interspecies spillover transmission.

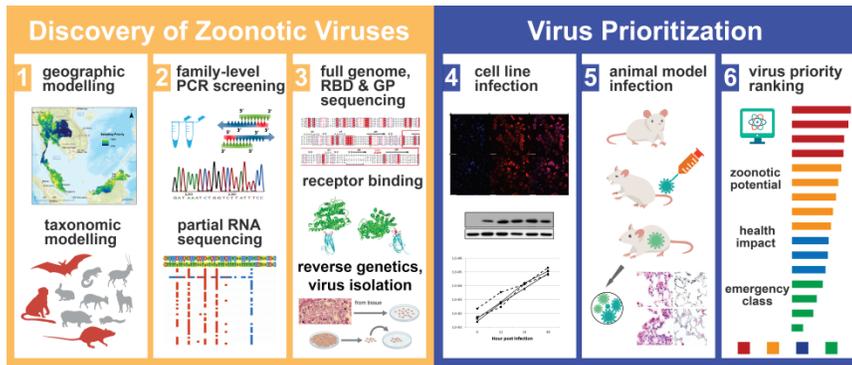

**Mouse models.** For novel viruses across all families, we will use the UNC collaborative cross mouse that captures 90% of the diversity within all mouse groups to assess the most suitable model for further experiments (112). We have used this model for CoV, FV (Ebola), Flaviviruses, and alphaviruses infections. Clinical signs such as weight loss, hemorrhage, encephalitis, and, acute or chronic arthritis were recapitulated in these mice following SARS, EBOV, West Nile virus and Chikungunya infections, respectively (86-88, 113-116). Note that CC OR3015 shows hemorrhagic disease phenotypes after EBOV infection (**Fig. 8**). **Bat Models.** Duke-NUS has developed two models for bat *in vivo* studies: a colony of *Eonycteris spelaea* (cave dwelling small fruit bat) and a bat mouse model, which contains the bat immune system in an immunodeficient mouse (117). In a proof of concept study, **Co-Is Wang and Anderson** infected *E. spelaea* bats with MERS-CoV to demonstrate their susceptibility and suitability for infection with a bat borne virus under BSL3 containment. These bats and the bat mouse model will serve to complement and expand studies from the UNC collaborative cross mouse, pending further funding from EIDRC CC.

Recombinant viruses, transgenic mouse models and experimental recombinant protein constructs described above will be made available to the EID-SEARCH consortium and other EIDRCs following standard procedures (**see Resource Sharing Plan**).

**Fig. 8:** EBOV Infection in Collaborative Cross Mouse. **Panel A/B:** Wt EBOV in two different CC lines demonstrate different disease patterns. **Panel C/D:** Hemorrhagic phenotypes on d. 6 (arrow) in spleen and liver, resp. From (86).

**1.3. General Approach:** We will conduct analyses to geographically- and taxonomically-target testing of samples from wild mammals that are most likely to harbor known high-profile zoonotic pathogens, or close relatives with potential to infect people. This includes selecting from tens of thousands of samples collected on recent projects and stored in freezers in our laboratories, and new sampling of wildlife in high risk locales. We will use viral family level PCR assays to identify and partially characterize viruses, then follow up sequencing of relevant receptor binding proteins to assess homology and predict binding affinity, then attempt to isolate and

biologically characterize viruses that phylogenetic and other data suggest have high spillover and pandemic potential. We will follow this with *in vitro* binding assays and cell culture experiments, and *in vivo* animal model infections to assess their potential to infect people and cause disease (**Fig. 9**). EHA will lead the study design, targeted sampling, and data analysis; Co-Is Hughes and Wacharapluesadee will lead field sampling and in-country testing; Duke-NUS, UNC, USUS will lead the serological and PCR diagnostic development and the *in vitro* and *in vivo* analyses, as well as cross-training and tech transfer to the hub labs in Thailand and Malaysia. This will include via support of one Malaysian Ph.D student, Mei-Ho Lee (CM Ltd.) who has worked with the EID-SEARCH collaborators for 9 years. The focus of her study will be infection potential of novel CoVs and PMVs already found in bats in Malaysia under preliminary data for this proposal.

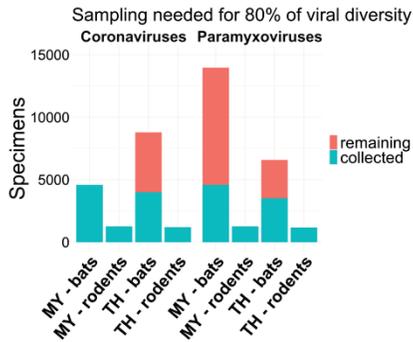

**Fig. 9:** Aim 1 will use analytical tools to target selection of archived and newly collected samples, conduct PCR and sequencing of novel viruses, recover by reverse genetics, and assess zoonotic potential using *in vitro* and *in vivo* models and analyses.

**1.4 Wildlife samples: 1.4.a. Geographic and taxonomic targeting for newly collected wildlife samples:** We will prioritize sites within each country that rank highest for both the risk of zoonotic

disease emergence (2) and the predicted number of 'missing' zoonotic viruses (3). Our preliminary analysis (**Fig. 1**) suggests priority areas include: the Kra Isthmus (S. Thailand) and adjacent forests in N. Peninsular Malaysia, NW Thailand (near the Myanmar-Laos border), and lowland rainforests of Sarawak and Sabah. In each of these 'hottest of the hotspots' regions, we will identify 2-4 distinct sampling sites based on the geographic distribution of key hosts we prioritize for additional wildlife sampling. We will priority rank bat, rodent, and NHP species using host trait-based models (3). We will also identify species predicted to be centers of evolutionary diversity for CoVs, PMVs, and FVs using ancestral host reconstruction of available sequence data and Bayesian discrete phylogeographic models (118-120). We will leverage our strong collaborations with wildlife experts in Malaysia and Thailand, including many of whom are based at our core partner institutions, to ground-truth geographic and taxonomic model outputs with local expert knowledge to ensure the sampling plan is realistic based on current species distributions, population size estimates, seasonality, and accessibility to sites. Most zoonotic viruses are naturally carried by multiple wildlife host species, and there are strong, predictable relations between host phylogeny and viral taxonomy (3). We will use a combined network analysis and phylogeographic model to rapidly predict and prioritize new (unsampled) hosts for important, novel viruses we discover during our research. We have shown this relatively simple model (using just wildlife species range overlap and phylogenetic similarity between host species) is both generalizable to estimate host range for all mammalian and avian viruses *and* robust – accurately predicting hosts 98% of the time when cross-validated using data from known viruses (121).

**1.4.b. Sample size justifications for testing new and archived wildlife specimens:** We calculate initial sample sizes targets using our preliminary data on average PCR prevalence from screening tens of thousands of bat, rodent and NHP specimens for CoV and PMVs based on previous studies in Malaysia and Thailand. We will refine these sample size targets, in real-time, over the course of our project using viral discovery curve analyses (**Fig. 6**) to either scale-up or scale-back new sampling and testing of archived specimens for each species depending on viral capture rates. We will only collect additional specimens projected from each prioritized taxa to achieve statistically robust sample sizes and to complement our archived specimens. For example, *Rousettus* spp. bats, known FV reservoirs, were not adequately sampled under PREDICT research in Thailand. Preliminary analysis indicates that, for all viral target families, we will require ~14,000 new samples to identify 80% of remaining viral species diversity in our study region, ~5,000 samples from Thailand and ~9,000 samples from Malaysia (**Fig. 10**). Viral strain diversity from a sampling effort this size is expected to number in the hundreds of strains. For example, given ~6% prevalence of CoVs in bat species previously sampled under the PREDICT project, a target of 14,000 individuals would yield ~800 PCR positive individuals,

representing, an estimated ~600 novel sequences/strains. Similarly, for PMVs, which have an average PCR detection prevalence of ~1.5%, sampling of 14,000 individuals would yield ~200 positives and an estimated 150 unique strains. Filovirus estimates are not feasible yet due to the small number of positive samples in prior

studies, but will be estimated as the project begins. From each mammal, we will collect serum, whole blood, throat swabs, urine and fecal samples or rectal swab using our previously-validated nondestructive methods. We will sample sites at different time-points throughout each year, and sample an equal number of males and females to account for seasonal or sex-specific differences viral shedding (See Vertebrate Animals) (122, 123). Dead or animals euthanized due to injury will be necropsied.

**Fig. 10:** Stacked bar plot showing number of currently-archived specimens (blue) and new specimens required (orange) to discover 80% of predicted number of CoVs and PMV species from high-risk bat and rodent taxa in Malaysia and Thailand.

**1.4.c. Sample collection, testing, viral isolation:** Wildlife will be captured and sampled using previously published techniques, by personnel wearing appropriate personal protective equipment (Tyvek suits or dedicated long external clothing, double nitrile gloves, leather gloves, an N95 or p100 respirator, and safety glasses) (53, 93, 95, 96, 122, 124). All samples will be placed in a vapor phase liquid nitrogen dry shipper immediately upon collection, and then transferred to a -80C freezer once back in the lab, until testing. Viral RNA will be extracted from bat fecal pellets/anal swabs. RNA will be aliquoted, and stored at -80C. PCR screening will be performed with pan-coronavirus (125, 126), filovirus (127) and paramyxovirus primers (128), in addition to virus specific primers where additional sensitivity is warranted in key viral reservoirs, i.e. Nipah virus or MERS virus specific primers (129, 130). PCR products will be gel purified and sequenced. We will attempt isolation on samples that contain viruses of interest (determined in Aim 1.5 below), using Vero cells and primary cell culture from the wildlife taxonomic order (bat, rodent and NHP cell lines). Over 70 bat cell lines are maintained at Duke-NUS from five different bat species. These include primary lung, brain, bone marrow, heart, kidney, intestine, liver, lymph node, muscle, spleen, PBMC and ovary/testes from *Eonycteris spelaea*, *Cynopterus bracyhotis*, *Rhinolophus Lepidus*, *Myotis muricola* and *Pteropus alecto* bats. In addition we have 8 immortalized cell lines, including those derived from lungs, therefore suitable for the isolation of respiratory viruses.

**1.4.d. Moving beyond RNA viruses:** To detect pathogens from other families, such as non-RNA viruses, we will combine conserved PCR assays with NGS. We will perform either unbiased NGS, or use a pan-viral enrichment library to sequence full-length genomes (131). We will conduct this work via EID-CC research projects or as part of outbreak detection/investigation in the region from DNA viruses or other agents.

**1.4.e. Sequencing Spike Glycoproteins:** Based on earlier studies, our working hypothesis is that zoonotic CoVs, FVs and henipaviruses encode receptor binding glycoproteins that elicit efficient infection of primary or continuous human cell lines (e.g., lung, liver, etc.) (16, 61, 62). Characterization these for SARSr-CoVs suggest that viruses up to 10%, but not 25%, different in the spike glycoprotein use human and bat ACE2 receptors for docking and entry. Uneven sampling gaps (e.g., no strains were found with 10-25% spike variation) prevent a thorough understanding of the transition point where the most divergent strains lose human ACE2 receptor usage. Our viral discovery curves (Fig. 6) suggest further sampling will reveal a rich diversity of as-yet-undiscovered SARSr-CoVs and strains of other viruses that fill in the phylogenetic tree between currently-described viruses. In this aim we will use phylogenetic and viral discovery analysis to specifically target bat species and regions that are under-sampled to allow sufficient power to identify and characterize missing strain diversity for potential zoonoses. We will sequence the S proteins of novel SARSr-CoVs to prioritize viruses for experimental work in Aim 3 to test this hypothesis. Likewise, we will test the hypothesis that phylogenetic related zoonotic receptor binding protein genes of MERS-related, Ebola-related and NiV/HeV-related viruses will also program efficient entry via human and ortholog receptors. For all novel virus strains, we will sequence the complete entry spike genes by amplifying overlapping fragments using degenerate primers as shown previously (24, 61). **Reverse Genetics:** Full-length genomes of selected CoVs, FVs or henipaviruses (representative across subclades) will be sequenced using NEBNext Ultra II DNA Library

Prep Kit for Illumina and sequenced on a MiSeq sequencer. PCR or Minlon sequencing will be performed to fill gaps in the genome. The full length spike gene sequences, including the amount of variation in the receptor binding residues that bind the appropriate human receptor will be used to select strains for Aim 3 experiments. We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-CoV cross neutralization, synthetically reconstruct a small subset (1-2) and evaluate growth in Vero, BHK and Huh7 cells (63, 132). From full length sequences, synthetic clones will be ordered to recover recombinant viruses using reverse genetics as described by our groups (62, 63, 77, 109, 133, 134). Recombinant virus growth will be accessed in Vero, BHK, Huh7 and select bat cells and recovered viruses used for downstream studies. Virus strain prioritization is described below.

**1.5. Assessing risk for spillover. 1.5.a. Capacity to infect human cells:** We will use a series of cell cultures to assess the capacity of target viruses to enter human cells. For CoVs, FVs and henipaviruses, we will use primary human ciliated airway epithelial cells (HAE) and lung endothelial cell cultures derived from the lungs of de-identified transplant recipients. HAE are highly differentiated and grown on an air-liquid interface for several weeks prior to use (62, 63, 132). We will prepare HAE and lung endothelial cultures from three different patient codes in triplicate in collaboration with the tissue procurement facility at the Cystic Fibrosis Center at UNC. Cultures will be inoculated with chimeric bat SARSr-CoVs or novel FVs or henipaviruses to assess efficient replication. At 72 hpi, cultures will be fixed for immunofluorescent staining using antisera to the SARS-CoV conserved nucleocapsid protein (N) or to structural genes of the other viruses (64, 71). SARSr-CoVs that differ significantly in S protein sequence (11-24%) from epidemic SARS-CoV yet replicate *in vitro*, will also be evaluated for sensitivity to neutralization in Vero cells by PRNT50 assays using broadly SARS-CoV cross reactive human mAbs S227.14, S230.15, S215.17, and S109.8 (63, 135) or monoclonal antibodies targeting the Ebola or Marburg E glycoprotein (Available through BEI), or NiV/HeV glycoproteins (136). As controls or if antisera is not available, the S genes of novel SARSr-CoV or spike entry genes of other novel viruses under investigation will be inserted into VEE 3526 replicon vectors (VRP3526-S), packaged and used to vaccinate mice (137). Polyclonal sera against test bat-SARS virus or other spike genes will be harvested and tested for ability to cross neutralize SARS-CoV, GD03, WIV-1, SHC014, WIV-16, other novel SARSr-CoV and HKU3-SRBD by PRNT50 assay (63, 138, 139). Using PRNT50 titers with sera (n=4 each) among these viruses, antigenic cartography (140) will allow comparison of antigenic vs. phylogenetic distance, identifying the transition at which SARSr-CoV strains escape SARS-CoV based vaccines, informing immunotherapeutic and vaccine design strategies (141-143). Similar approaches will be applied to novel MERS-related viruses, other CoV, FVs or henipaviruses. While most wildlife-origin viruses with unknown transmission potential or pathogenicity in people uncategorized, we use BSL-3 for isolation as standard, and cell culture for potentially BSL-4 pathogens will be undertaken at collaborating institute NEIDL. To facilitate this, duplicate samples in culture medium from animals PCR +ve for FVs and very close relatives of NiV or HeV will be shipped to NEIDL (**See letter of support**) for culture, characterization and sharing with other approved agencies including NIH Rocky Mountain Laboratories where PI Daszak and Co-Is Baric have ongoing collaborations. Similarly, some duplicate samples of animals PCR +ve for CoVs will be shipped to UNC for further characterization by Co-I Baric. Where feasible and appropriate, training opportunities at NEIDL and UNC for in-country staff will be given, thereby enriching hands-on collaboration across sites.

**1.5.b. Host ACE2, DPPR, Niemann-Pick C1 (NPC1) and EphrinB2/EphrinB3 receptors:** We will sequence relevant host receptors for select mammalian wildlife species we find positive for strains of high-priority CoV clades, and all new henipaviruses and FVs. Of particular interest is homology across 18 bat and human orthologue ACE2 contact interface residues that engage the SARS RBD as a potential indicator of SARSr-CoV cross species transmission potential and growth in human cells (70). Likewise, variation in the NPC1 receptor has been shown to alter EBOV ability to infect in humans and bats, so this can be structurally mapped for prediction and downselection of strains (144). Signatures of positive selection in bat NPC1 were concentrated at the virus-receptor interface, with the strongest signal at the same residue that controls EBOV infection in *Eidolon helvum* cells. Thus NPC1 is a genetic determinant of FV susceptibility in bats, and some NPC1 variations likely reflect host adaptations to reduce FV replication and virulence (145). NiV and HeV use ephrin B2 or ephrin B3 as a receptor, and variation affects its ability to use human vs bat receptor molecules (103, 146).

**1.5.c. Host-virus evolution and predicting receptor binding:** We will use Bayesian and Maximum Likelihood phylogenetic analyses of RNA-dependent RNA polymerase (RdRp) sequences from PCR screening, receptor binding glycoproteins, and/or full genome sequence data (when available) to reconstruct the evolutionary history of the novel bat SARSr-CoVs, bat MERSr-CoV, FVs and henipaviruses that we identify. We will run co-phylogenetic analyses to map out instances of host-switching (147, 148) and ancestral state reconstruction analyses (Fig. 4) to identify the most important species for shaping evolutionary diversity for these viruses (51, 149), allowing for more targeted future surveillance and spillover mitigation interventions. For receptor binding glycoprotein sequence data from characterized viruses, we will apply codon usage analyses and codon adaptation indices, as used recently on henipaviruses (150), to assess the relative contributions of natural selection and mutation pressure in shaping host adaptation and host range.

**1.5.d. Viral strain prioritization:** Of the expected 100-200 novel SARSr-CoV strains, and approximately 600 total CoV strains, we will down-select to prioritize for further characterization based on S genes that are: i) different from SHC014, WIV1, SARS-CoV with diversity ranges of 10-25%; ii) have virus S RBD that could use human/bat receptors; iii) have recombinant chimeric spikes indicative of gene flow between clade I and II strains; iv) have bat ACE2 or DPP4 receptors that might select for spike RBDs that can use human receptors for entry (15/18 conserved residues in human/bat ACE2 molecules that bind SARSs-CoV S RBD domains are likely more efficient receptors than 3/18 conserved sites). Using structural models based on the SARS S glycoprotein, the extent and location of antigenic variation will be annotated onto the structure, further resolving the locations of highly evolving and conserved structural motifs/epitopes that function in protective immunity (135, 151-153). For novel henipaviruses, we will examine the receptor-binding proteins (e.g. envelope attachment (G) proteins) for sequence and structural homology with particular attention to conservation of amino acids that mediate ephrin receptor binding. We will prioritize strains that are predicted to interact with ephrin-B2 and expression V/W proteins to determine whether these viruses represent zoonotic threats. Using the recombinant Cedar virus (rCedV) platform, we will be able to rescue rCedV that express heterotypic G proteins to explore receptor utilization and tissue dissemination in animal models. We will assess ability to infect human cells using a continuous lung epithelial cell line, Calu3, which our group has previously used to generate data on NiV and HeV growth curves and a variety of host expression changes after infection (154). We will also use primary human airway cultures and microvascular endothelial cells to assess human infection for FVs, henipaviruses and MERSr- and SARSr-CoVs (155) (156). There is some evidence for NiV and HeV replication in mouse lung, low level titers in young animals, 10 fold higher titers in aged mice (157, 158). Thus it is likely these models could be improved in the collaborative cross mouse resource at UNC. We have identified CC lines that are highly vulnerable to wildtype SARS and others that develop hemorrhagic disease following mouse adapted Ebola infections (86-88).

**1.5.e. Animal models:** We will use transgenic mouse models and the UNC Collaborative Cross model to assess spillover potential of viruses. For work on CoVs, we will follow the protocols in the transgenic mouse model used by the Baric lab previously. Briefly, in the BSL3 lab, 10- to 20-week old hACE2 or hDPP4 transgenic mice will be intranasally inoculated with  $5 \times 10^4$  PFU of full length wildtype rbat CoV, or chimeric SARSr-CoV or MERSr-CoV encoding different bat CoV spike proteins respectively, then monitored daily for weight loss, morbidity, and clinical signs of disease. Mice will be euthanized at 2, 4, and 6 dpi (endpoint of 14 dpi), organs harvested and virus quantified by plaque assay or genome (mRNA1) RT-PCR. After 7 days in formalin, tissues for histopathology will be removed from the BSL3 and stained with H&E, and for immunohistochemistry using polyclonal antibodies against the N protein. We will conduct limited evaluation of existing countermeasures using therapeutic monoclonal antibodies *in vitro*. Existing SARSr-CoV or MERS-CoV mAbs (159, 160) will be diluted in DMEM starting at 1:20, and serial dilutions mixed with an equal volume of 50 PFU of chimeric bat SARSr-CoVs encoding different spike proteins and RFP indicator genes, then incubated on Vero E6 cells at 37°C for 1 h. Antibody neutralization titers will be evaluated by plaque quantification at 4-5dpi. In select instances, hACE2 transgenic mice will be injected with SARS-CoV mAbs, and infected with chimeric bat SARSr-CoVs. Clinical signs and morbidity will be assessed and tissue pathology examined and compared with mice without treatment of mAbs to determine the therapeutic effect on SARSr-CoV infection, and protection of SARSr-CoV by wildtype SARS-S based vaccines assessed as described (132, 161). We will sequence full length genomes of high risk strains that are antigenically distinct and escape SARS or MERS-

CoV cross neutralization, synthetically reconstruct a small subset (1-2), recover full length viruses and evaluate the ability of nucleoside analogues to inhibit growth in HAE cultures and/or *in vivo* (63, 132). For the Collaborative Cross model, we will infect six to eight mice from 6-8 Collaborative Cross mouse lines (10 weeks of age) with six test viruses/yr, intranasally or by subcutaneous infection with  $1 \times 10^4$  virus. Animals will be followed for weight loss, morbidity, mortality and other clinical disease symptoms (e.g., hunching, hindleg paralysis). One half the animals will be sacrificed at day 3 and day 7 pi. to evaluate virus growth in various organs, and organ pathology. In highly vulnerable lines, additional experiments will be performed using more animals, evaluating virus growth, clinical disease symptoms, respiratory pathology, tropism and organ pathology through day 28 pi. We anticipate that some CC lines will prove highly vulnerable to select wildtype viruses, because of host susceptibility combinations that promote severe disease outcomes.

**1.6. Potential problems/alternative approaches: Challenges with logistics or obtaining permission for wildlife sampling in sites we select.** We have a >20-year track record of successful field work in Malaysia, and >10 years in Thailand, and have strong established partnerships with local wildlife authorities and communities to ensure access. We have existing permissions in place which will be renewed at the start of this project. Due to the abundance of wildlife habitats in the region, if access to a site is withdrawn, we will rapidly identify a suitable, complementary site with similar bat species composition and abundance. Finally, we have already collected tens of thousands of wildlife samples from the region and will focus on these while waiting for permission. **We may not identify novel viruses in our sample wildlife species due to seasonality of viral shedding or other factors.** We have calculated sample sizes based on realistic detection rates from our extensive preliminary data, and are confident that we will detect and identify large numbers of potentially zoonotic pathogens, particularly for CoVs and PMVs. We acknowledge that FV strain diversity may be harder to capture, given relatively low seroprevalence in bat populations – suggesting lower levels of viral circulation (42, 43). However, our team was the first and only group to sequence FV RNA from Asian wildlife species (46, 47, 57), and we are confident that with our targeted sampling and testing strategy offers the best chance globally to identify additional strains of Ebola and related viruses. The sampling regions we have selected are subtropical, and our previous data, and even published studies in temperate regions (162), do not suggest a strong pattern of seasonality in CoV shedding, and where seasonal patterns do occur, i.e. for henipaviruses in Thailand (163), or can be predicted from wildlife serology data, we will be sure to conduct sampling at different timepoints throughout the year to account for this.

**Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.**

**2.1 Rationale/Innovation:** Rapid response requires early detection. Assessing the spillover of rare or novel zoonotic agents will require targeted surveillance of high-risk communities that interface frequently with wildlife that harbor high risk emerging viral strains. To enhance the low statistical probability of identifying these rare events, In Aim 2 we will target rural human communities inhabiting regions identified in Aim 1 as having high viral diversity in wildlife, that also engage in practices that increase the risk of spillover (e.g. hunting and butchering wildlife). We will initially identify 4 subsites in each of Thailand, Peninsular Malaysia, Sarawak, and Sabah for sampling. We will design and deploy human risk factor questionnaires, and specific and sensitive serological assays to identify the baseline frequency, and causes of, spillover of known and related novel viral pathogens in these populations. **We will use the results to test a key hypothesis: that hunting wildlife increases the risk of exposure to novel viruses, compared to the rest of the community.** The alternative hypothesis is that seroprevalence in the general community is not statistically different to those who hunt and butcher wildlife, because exposure to wildlife pathogens is largely through inhabiting a biodiverse landscape where wildlife make indirect contact with people (e.g. via fomites). For participants who report symptoms related to 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever; or 6) unusual presentation of high fever with severe diarrhea; all within the last 10 days, an additional sample type will be collected, two nasal or oropharyngeal swabs. Samples will be marked for additional PCR-based assays to identify presence of known and novel CoVs, henipaviruses and FVs, and for isolation and biological characterization of potential pathogens, using the approach laid out in Aim 1.

**2.2 Preliminary data on high-zoonotic risk human community surveillance: 2.2.a Biological sample collection in SE Asia:** Our long-term collaboration in the region has included qualitative and quantitative survey data, and collecting large archives of banked human sera and other biological samples from high zoonotic-risk populations. For example, under the USAID-PREDICT project, EHA has collected 1,400 and 678 specimens in Malaysia and Thailand respectively from people living in zoonotic disease interfaces, all of which will be available for retrospective serological testing by EID-SEARCH which we have ensured is compliant with our existing IRB. Our core group has collected and tested many thousand additional specimens from other important community cohorts (**Table 2**), and some of these will continue under EID-SEARCH (**Section 2.4**).

Country, site	Lead	# enrolled, focus	Findings
Peninsular Malaysia	Hughes	9,800+ samples, Orang Asli indigenous pop., for PCR/serol.	25+ novel CoVs, influenza, Nipah ab+ve, FV ab+ve
Malaysia Sabah	Kamruddin	1,283 for serology	40% JE, 5% ZIKV ab+ve
Malaysia Sabah	William	10,800 for zoonotic malaria study	High burden of macaque-origin malaria
Malaysia Sabah	Hughes	150 bat cave workers	Ongoing
Malaysia Sarawak	Siang	500 Bidayuh and Iban people	8% PCR prevalence HPV in women
Malaysia PREDICT	Hughes	1,400 high zoonotic-risk communities for viral PCR, serology	Ongoing. Multiple known and novel CoVs, PMVs, others.
Thailand	Wacharaplu-esadee	100s of bat guano harvesters/villagers	Novel HKU1-CoV assoc. clinical findings
Thailand PREDICT	Wacharaplu-esadee	678 high zoonotic-risk communities for viral PCR, serology	Ongoing. Multiple known and novel CoVs, PMVs, others.
Singapore	Wang	856, for Melaka virus	7-11% MELV ab+ve

**Table 2:** Biological sample collection from healthy populations conducted by members of **EID-SEARCH** in our hub countries.

Of particular interest is the access to indigenous communities in Peninsular Malaysia (Orang Asli) and Sarawak (Bidayuh, Iban people), and the bat guano harvesters in Thailand. These communities hunt, butcher and eat wildlife daily, and work in supremely high-risk zoonotic interfaces (e.g. bat caves). One of our indigenous community sites is experiencing an ongoing outbreak of unknown etiology that we are investigating currently (Section 3.2.a).

**2.2.b Human Contact Risk Factors:** EHA is the lead organization across all 27 USAID-PREDICT project countries for collecting data on, and analyzing the human aspects of, zoonotic spillover risk (164, 165). We conducted exploratory studies using standardized one-on-one semi-structured interviews and site observation data with people living in hotspot areas or engaged in high-zoonotic spillover risk activities, using these data to assess local social and cultural norms underlying wildlife contact (165). We then developed a risk factor survey to accompany human biological sampling to evaluate the type and frequency of animal contact, wildlife exposure in daily life, occupational risk in markets and long the wildlife value chain, and unusual illnesses reported over the past 12 months. We conducted cross-sectional studies in high risk populations in 27 countries, and study participants provided biological samples (oral/oropharyngeal swab, nasal/nasopharyngeal swab, urine sample/urogenital swab, fecal sample/rectal swab, whole blood, serum, plasma). For example, survey and biological samples were collected from: 1,585 participants from 7 sites in Yunnan, Guangxi, and Guangdong provinces, China; 1,400 participants from 4 sites in Malaysia; and 678 participants from 4 sites in Thailand. Samples were tested with novel serological assays and results analyzed against risk factors from survey data (16). In China, CoV-seropositive individuals were mostly farmers/peasants (8/9), living in Yunnan province (7/9), 41-60 yrs old (7/9), with domestic contact with rodents (6/9), that are male (6/9). Although these results are preliminary and don't provide detailed information on routes of exposure, they identify key subpopulations to target that would likely increase the opportunity for identifying evidence of spillover for other CoVs, PMVs and FVs. Data from PREDICT surveys have been used to help identify target populations in Aim 2, identify strategies to better target at-risk people, and conduct focused **human risk factor surveys and serosurveys to produce statistically significant findings for henipaviruses, CoVs and FVs.** In Aim 2, we will use combined biological sampling and risk factor surveillance in targeted populations within the community to 1) test the hypothesis that occupational (i.e. wildlife hunting) risk factors correlate with seropositivity to henipaviruses, FVs and CoVs; 2) assess possible health effects of infection in people; and 3) where recent

illness is reported, obtain biological samples for PCR testing and potential viral isolation and characterization. Obtaining this information could be a significant step in understanding the likelihood of recent 'hidden' spillover events and their public health impacts, as well as the risk of future emergence of viral disease.

**2.2.c. Risk factors for illness:** Our preliminary data in Thailand, Malaysia and other SE Asian countries revealed that frequent contact with wild (e.g. bats, rodents, NHPs) and domestic animals (e.g. poultry, swine) among local communities was associated with a high percentage of self-reported severe/acute respiratory illness (SARI/ARI) and Influenza-like illness (ILI) symptoms (**Section 3.2.b**). In addition, people involved in crop production, hunting and butchering of wildlife reported statistically significantly higher SARI and ILI symptoms (Li *et al.*, in prep.). **These preliminary data suggest a target population and sites for current proposal with the correct targets for serological surveillance and risk factor surveys in Aim 2 to produce statistically significant findings.** Coupled with better serological tools from our team (**Section 2.2.d**), we will be able to identify the likely routes of exposure to known or novel coronaviruses, henipaviruses, and FVs in the study region, as well as build data on the illnesses they cause in people.

**2.2.d. Serological platform development:** Most emerging viruses produced a short-lived viremia in people so that large sample sizes are required to provide enough PCR-positive individuals to analyze infection patterns. For Aim 2, we will focus on serological sampling in the community, because antibodies are typically long-lived and can be used to assess prior virus exposure or infection with much smaller sample sizes (123). Most serological assays target a single protein, and for emerging viruses, it's often unclear which viral antigen will be immunodominant during human infection, and therefore which to target in developing serological assays. Co-Is Wang, Anderson (Duke-NUS) and Broder, Laing (USUS) have developed a series of approaches to deal with this problem, and which will be used in testing human biological samples in Aims 2 and 3. Henipaviruses, FV and CoVs express envelope receptor-binding proteins that are the target of protective antibody responses. Co-I Broder has led efforts to express and purify henipavirus native-like virus surface proteins for immunoassay application (166, 167), developing monoclonal antibodies (168, 169) and as subunit vaccines (170, 171), has developed a novel, multiplex microsphere immunoassay (MMIA) allowing serum samples to be simultaneously tested for antibodies reactive with henipaviruses, FVs and CoVs. This MMIA uses a Luminex-based multiplex platform and custom designed virus receptor-binding proteins expressed in a mammalian cell-culture system and purified as native-like oligomeric proteins. These oligomeric antigens retain post-translational modifications and quaternary structures, allowing capture of conformational-dependent antibodies raised during a natural infection, which represent the majority of the protective humoral response. The known diversity of henipaviruses includes five presently described viruses, NiV, HeV, CedV, GhV and MojV and this assay has been expanded to include all described species (**Fig. 11**). In the past, our collaborators have used NiV and HeV G protein antigens in a MMIA assay to identify a serological footprint of NiV-related African henipaviruses and exposure to virus(es) antigenically-related to NiV in livestock sampled in Bangladesh (78, 79). To strengthen serological data interpretation, the G protein from each virus is integrated into the MMIA so that virus-specific vs. henipavirus cross-reactive antibodies can be detected and address specificity of past virus exposure. Extensive cross-reactivity exists among ebolaviruses and between ebolaviruses and marburgviruses (172-174). We are validating the MMIA pan-FV assay for specificity, and as part of this, in collaboration with Duke-NUS, we have found serological evidence of past exposure to a filovirus(es) most antigenically-related to ebolaviruses (e.g. Ebola virus, Bundibugyo virus), but unreactive with Reston virus GP in three under-sampled fruit bat species, suggesting that novel FVs circulate within bat hosts in SE Asia (43). **This platform has now been set up for use in Malaysia and Thailand and will be available for use in this proposed work.** Co-Is Hughes, Broder, Laing have conducted initial screening of human, wildlife and livestock samples at high-risk interfaces in Malaysia, finding serological evidence of past exposure to viruses antigenically-related to NiV and EBOV in humans, bats and non-human primates (NHPs).

**Fig. 11:** Validation of multiplex microsphere immunoassay (MMIA) specificity and identification of immunologically cross-reactive viruses for A) NiV B) EBOV.

Co-Is Wang and Anderson (Duke-NUS) have developed a phage-display method to screen antibodies for all known and related bat-borne viruses, including henipaviruses, FVs and CoVs and have set up a similar Luminex-based assay. Additionally the Duke-NUS team has demonstrated capacity for rapid and cost-effective development of LIPS serological assays against novel viral agents (**Sections 2.6.a, 3.2.a**). These will be used for verification and expanded surveillance. For molecular investigation (Aim 2 & 3), we will combine targeted PCR with a discovery-driven enrichment NGS strategy to not only survey currently known viruses, but also to discover potential novel viruses. Both the phage-display serological and enrichment platforms can be rapidly updated to include new viruses identified.

**2.3 General Approach/Innovation: Our human sampling approach uses two approaches in Aims 1 & 2 (Fig. 12). In Aim 2 we will conduct community-based surveillance using a brief, focused questionnaire to**

identify the prevalence and frequency of risk-factors for viral spillover in tandem with collection of high quality biological samples to determine the seroprevalence of spillover viruses in at-risk human populations. We will use generalized linear models to analyze correlation between biological results and risk-factors for viral spillover. In Aim 3, we will conduct clinic-based syndromic surveillance and biological sampling at clinics/hospitals that are the catchment healthcare facilities for the communities sampled in Aim 2. Both community-based and clinic-based syndromic surveillance programs are cross sectional case-control studies designed with the sample sizes necessary to statistically quantify (with a power of 80%) risk factors and health impacts for viral spillover, linked to serological status and PCR prevalence in symptomatic patients. All human sampling conducted under Aims 2 and 3 will adhere to strict criteria for inclusion and recruitment and protection of human subjects from research risk (**see Human Subjects and Clinical Trials Information**).

**Fig. 12:** Human sampling approach. Aim 2 (left) focuses on serology in high-risk communities to identify evidence of population exposure to novel zoonotic viruses. Aim 3 (right) sets up clinical cohorts at hospitals serving these high-risk communities to conduct syndromic surveillance and identify the etiology of new viral syndromes

**2.4 Target population & sample sizes:** We will target populations in the same geographic regions as those identified in Aim 1 that harbor wildlife with high potential zoonotic viral diversity, that are EID hotspots, and that are well-connected through regional travel and trade hubs to the global travel network (**Fig 13**). Within each geographic region we will identify populations at four sub-sites, building on our preliminary data (Table 2). We will target specific communities based on our analysis of previously collected behavioral questionnaire data, and other publicly available data (e.g. wildlife hunting licenses sold in a region, number of guano caves accessed for fertilizer etc.) to identify key at-risk populations and occupations with high exposure to wildlife. We will conduct concurrent sampling trips at visits to sub-sites during which members of the community will be enrolled and wildlife surveillance activities conducted. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock, or slaughtering wildlife will be considered for enrollment. Participants will complete a consent form and questionnaire in addition to having biological samples collected. During these community trips after data collection the field research staff will conduct community meetings to help inform the public health risk of zoonoses. **Target populations:** Thailand (Co-I Wacharapluesadee): 100 subjects of healthy high-risk community from 2 study sites, Chonburi (NiV, other PMVs and CoVs found by PCR in bats in our previous work), and Ratchaburi (bat guano harvester villages where we found a MERSr-CoV in bat guano (50, 175) and serological evidence of α-CoVs, HKU1-CoV in people (175)). Peninsular Malaysia (Co-I Hughes, CM Ltd.): We will expand our sampling of the Orang Asli indigenous communities to include sub-sites in communities in Districts we have already sampled and

additional Districts in the States of Kelantan Perak, Pahang, and Kelantan all close to bat caves. Samples will be stored and tested at NPHL. Sarawak (Co-I Tan, Fac. Med. Hlth. Sci. UNIMAS): We will expand our sampling of the Bidayuh and Iban indigenous people to include the Dayak and Orang Ulu (“people of the interior”) because this group has a more intimate connection to remote wildlife-rich areas than the other two, albeit all are hunters. Human sampling will be led by UniMAS in collaboration with CM Ltd / EHA. Sabah: We will conduct sampling at the Madai bat and bird cave that has 200 permanent residents who harvest bird’s nests for soup, and >1,000 during the harvesting season and at Gomantong cave – one of the largest bat and cave swiftlet nesting sites in the world. Sabah: (Co-I Hughes): We will conduct sampling at the Madai bat and bird cave that has 200 permanent residents who harvest bird’s nests for soup, and >1,000 during the harvesting season and at Gomantong cave – one of the largest bat and cave swiftlet nesting sites in the world. Protocols follow those for Peninsular Malaysia Singapore: (Co-I Wang, Duke-NUS): Active human surveillance will be not be conducted in Singapore, but archived human specimens e.g. from our Melaka virus serosurvey (8), will be made available to conduct retrospective serosurveys for specific pathogens that are identified as high interest to the EIDRC, NIH, and EID-CC.

**Fig. 13:** Targeting high-risk sites for human zoonotic disease surveillance in Thailand and Malaysia. This map plots areas with high numbers of expected viruses in wildlife (3), greater spillover probability based on EID risk factors (2), and higher levels of connectivity (measured by road density data) that may facilitate person-person spread.

**Sample sizes:** From our previous work we conservatively anticipate that 10-30% of the community population will have had exposure to wildlife allowing us to capture highly exposed and non-exposure individuals at each site. Individuals living or working around wildlife habitats (e.g. bat caves/roosts), who hunt wildlife, work with wildlife or livestock farming, transportation, selling, or slaughtering wildlife in the surveyed areas will be targeted so that they make

up  $\geq 30\%$  of the sampled population in each community. We will stratify sampling to ensure appropriate representation of sex, demographic, and socio-economic factors at each community site. In each of our regions, we will conduct sampling at four sub-sites in populations with high prevalence of high occupational and environmental risk of exposure to wildlife populations, sampling 175 persons at each sub-site. We will target populations with, on average, 30% or higher prevalence of occupational or environmental exposures to wildlife based on data from previous studies. This design will give us >80% power to detect 5 percentage point differences in seroprevalence against any of our viral groups between baseline and high-risk subgroups. We conservatively assume 5% base seroprevalence, as well as assuming high spatio-temporal variance amongst sub-sites, with baseline varying 0-25% amongst sub-sites and the fraction of the population at risk varying from 20-40%. (Power calculation conducted by 500 simulations of a generalized linear mixed model (GLMM)). For community-based surveillance, we will enroll 700 individuals per study region, allowing us to make county/province-level comparisons of differing effects; the total sample will be 3,500 participants over 5 years.

**2.5 Data & sample collection:** Following enrollment, biological specimens (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max 500  $\mu$ L of whole blood and two 500  $\mu$ L serum samples) will be collected by locally certified healthcare professional proficient in phlebotomy techniques and a short questionnaire will be administered by trained project staff that speak appropriate local language to all participants. Through the serological findings and the survey we will investigate the details of five risk factors related to high risk wildlife exposure, to maximize the power of the analyses, based on continuing analysis of our previous work, and will focus on: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. For participants who report the symptoms relating to 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; or 5) hemorrhagic fever within the last 10 days, an additional sample type will be collected, nasal or oropharyngeal swab (2x). Blood of participants whose serum tests positive for emerging viral pathogens will be taken and Peripheral Blood Mononuclear Cells (PBMCs) frozen for future use.

These will be used for future harvesting of polyclonal and monoclonal antibodies as potential therapeutics/diagnostics (**see Letter of Support NEIDL**).

**2.6: Laboratory analysis: 2.6.a Serological testing:** We will screen all human specimens for henipaviruses, FVs and CoVs using our novel, multiplex microsphere immunoassay (MMIA) (**Section 2.2.d**). We will use ELISA and serum neutralization tests (SNT) as confirmatory, where feasible and appropriate for the biocontainment level given sensitivity and specificity variation, and the need for live virus for SNTs (**See Select Agent Research**). Serologic evidence of local spillover will be used to prioritize zoonotic strains for recombinant virus recovery from full length sequences. Preliminary data suggest ELISA will be effective for some viral groups. We previously developed a SARSr-CoV specific ELISA for serosurveillance using the purified NP of a bat SARSr-CoV (Rp3). The specificity of this assay was evaluated using polyclonal antibodies against HKU1, OC43, 229E, NL63, MERS-CoV and EBOV and no significant cross-activity detected (16). **This suggests that if we can expand our NP serology tests to cover other bat CoVs, and that doing so may identify many more seropositive individuals.** For CoVs, we will therefore use two serological testing approaches: 1) testing human sera collected from both community- and clinic- based sampling for a panel of bat CoVs that will include SARS-CoV, MERS-CoV, SADS-CoV and a range of bat SARSr-CoVs (16); 2) testing for antibodies to common human CoVs (HCoV NL63, OC43 – **Section 2.8**). We will test panels of NP and G recombinant proteins to assess if this approach will act as a comparison to MMIA for FVs and PMVs.

**2.6.b RT-PCR testing.** Specimens from individuals in the community who reported being symptomatic within the last 10 days (**Section 2.5**) will be screened using RT-PCR initially for CoVs, PMVs, and FVs following published protocols (**Section 1.4.c**). Positive samples will be subjected to full genome sequencing and RT-PCR amplification of the glycoprotein genes. Samples from the clinic-based syndromic surveillance will also be tested using RT-PCR for Influenza A & B, HCoV NL63, OC43, HKU1, SARS-CoV & 229E, NiV, HeV, Ebola (WHO PCR protocol) based on the symptom as rule-outs.

**2.6.c Biological characterization of viruses identified:** Novel viruses identified in humans will be recovered by cultivation or viruses re-derived from full length genome sequences using reverse genetic approaches. Viruses will be characterized for growth in primary human cell lines and in mouse models, including the Collaborative Cross Mice or humanized mice expressing human receptors from related strains. The approaches are discussed in more detail under Aim 1.

**2.7 Epidemiological analysis:** We will conduct a cross sectional case-control study to identify risk factors for Henipavirus, FVs, and CoVs spillover. “Cases” are defined as participants whose samples tested positive for Henipavirus, FVs, or CoVs by serological tests. “Controls” will be selected from the pool of participants admitted to the studies and whose samples tested negative for Henipavirus, FVs, or CoVs. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. We will use generalized linear models and least absolute shrinkage and selection operator (LASSO) regression analyses (176) to analyze correlation between biological results, serological/PCR status, and risk factors related to high risk wildlife exposure including: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) home or work proximity to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms lifetime and past 12mo. Additionally, we will use this procedure to determine how clinical presentation differs between Henipavirus, FVs, or CoVs in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms.

**2.8 Potential problems/alternative approaches: Rarity of spillover events** means it may be difficult to identify sufficient seropositives to statistically analyze human risk profiles. First, we will be targeting our community-based surveillance to subpopulations with high-levels of wildlife exposure, at sites selected for diverse and prevalent viruses to increase likelihood of finding positive individuals. Second, our serology testing will include a multi-plex panel of assays for a large diversity of viruses, increasing likelihood of positives. For example, in previous work our overall bat CoV PCR prevalence in the community was, 11.8%;  $\beta$ -CoV, 3.4%;  $\alpha$ -CoV, 9.1%). Thus, using this broad serological panel to screen individuals prone to contact with species of higher zoonotic risk increases the potential for detecting spillover with enough power for statistical analyses,

and will shed light on behaviors that predispose to spillover. Third, we will include common human CoVs, PMVs, and influenza viruses in our panel, so that even if low prevalence of wildlife viruses is found, we will be able to conduct a valuable cross-sectional study of the seroprevalence of more common human viruses. Finally, we will be able to assess relative measures of human-wildlife contact from our survey work. We will analyze intensity of contact with high-risk taxa against other risk factors to provide useful proxy information for spillover risk. **Serological testing may be difficult to interpret in the presence of known and novel viruses.** We will use the three-tiered serological testing system outline in **2.6.a** to try to identify exposure to these ‘novel’ viruses. However, we know exposure to a range of related viruses generates antisera that are cross-reactive with known, related virus antigens - a serious challenge to serological surveillance and diagnostics. Our collaborations have already demonstrated that SE Asia bat sera samples screened with our pan-filovirus MMIA have been exposed to an Ebola-like virus, that is antigenically-distinct from known Asiatic filoviruses, Reston virus and Měnglà virus (43). Using these three serological platforms we will address inherent challenges of indirect virus surveillance through antibody capture by testing multiple binding assay platforms and antigens, using positive control samples to establish serological profiles against known viruses that will aid in our interpretations of cross-reactive antisera responses likely representative of ‘novel’ viruses.

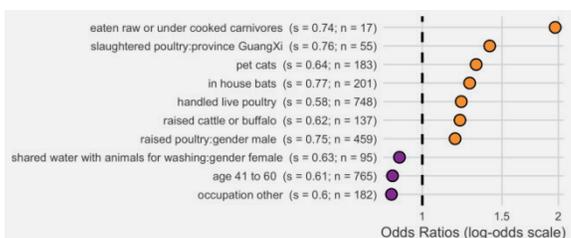

### **Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts.**

**3.1 Rationale/Innovation:** Our previous research (**Table 1**) and other data suggests that there are substantial numbers of outbreaks or clinical cases for which the etiologic agent is not diagnosed, e.g. (177, 178). To investigate this in SE. Asia, we have assembled a multi-disciplinary team that includes senior infectious disease doctors and clinicians and will work directly with local clinics and regional hospitals to identify the ‘cryptic’ outbreaks or cases that occur in the region. **In Aim 2, we will conduct serology in high zoonotic-risk communities to find evidence of prior exposure in people**, i.e. evidence of viral spillover into the community. In Aim 3 we identify members of these communities presenting at clinic with undiagnosed illness that may have high-impact zoonotic viral etiology. **Therefore, in Aim 3 we focus on PCR to identify the putative viruses that are replicating in these actively-infected patients (Fig. 12).** We will enroll, and collect high quality biological samples from patients who live in rural communities linked to Aim 2 and who present at regional clinics or hospitals with symptoms typical of high impact zoonotic viruses. We will collect detailed survey data to assess their contact type and frequency with wildlife and livestock and conduct molecular and serological diagnostic assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. We will conduct molecular viral discovery assays on patients who present with symptoms indicative of a high-risk zoonotic virus. If novel pathogens are identified by PCR, we will attempt to isolate, obtain full genome sequence and/or biologically characterize the wildtype or molecularly re-derived pathogen, using the *in vitro* and *in vivo* strategy laid out in Aim 1.

**3.2 Preliminary data clinical surveillance: 3.2.a. Clinical surveys and outbreak investigations:** Our longterm collaboration in the region has included the following activities investigating clinical syndromes: **Peninsular Malaysia: At the time of writing, an outbreak of suspected undiagnosed viral illness in the indigenous Batek Orang Asli (“people of the forest”) community living at Gua Musang (“civet cat cave”) district, in Kelantan, Malaysia, close to Taman Negara – a National Park containing the oldest known rainforest. This community is one where we have conducted prior routine surveillance and biological sampling, demonstrating proof-of-concept that our two-pronged high-risk community/clinic approach will work.** Dozens of people are affected and the outbreak is currently being investigated by our group in collaboration with the Malaysian NPHL. The Orang Asli continue to practice traditional subsistence hunting of wild animals (bats, rodents, primates). These communities are remotely located, in heavily forested areas, with limited access to medical services. **This outbreak, and others that will continue to emerge just like it, underscore the critical need for our EIDRC - to improve the technological tools, training, and human capacity for rapid EID surveillance, diagnosis, and response at the frontlines of disease emergence in SE Asia. Investigating this outbreak is a key priority if EID-SEARCH is funded.** **Sabah:** Co-I Kamruddin (BMHRC) is leading an asymptomatic leptospirosis study on sanitation workers, an ILI study in a Kota Kinabalu clinic and diarrheal study in children under 5 yrs. Co-Is William, Tan and others have conducted clinical observational studies to determine the etiology of central nervous system infections and acute undifferentiated febrile illness in Sabah.

Co-Is William and consultant Yeo have collaborated with Co-I Wang to enroll 90 adult and over 100 pediatric participants with central nervous system infections, negative tests for malaria and dengue from 3 district hospitals in Sabah to determine the various etiologies. While a proportion tested positive for rickettsial agents, the majority had no clear diagnosis. Co-Is William, Rajahram, and Yeo have conducted clinical studies of over 200 inpatients with acute febrile illness with negative tests for malaria and dengue from 3 district hospitals in Sabah to determine the various etiologies. While a high proportion tested positive for rickettsial agents, the majority had no clear diagnosis. **Sarawak:** Co-I Siang (UNIMAS) is conducting a survey of high-risk female Kelabit indigenous people and has found 8% with HPV52 as the dominant strain. He is working on clinical cohorts of hand, foot and mouth disease and will recruit patients from that study in the current proposed work. Finally, Co-Is Siang, Kamruddin are conducting a long-term study of rotavirus and other viral etiologies of acute gastroenteritis in Kuching, Sarawak that will include swine herders and farmers. The Baric lab is a global leader in norovirus VLP diagnostic reagents to detect serologic evidence of norovirus gastroenteritis, as well as RT-PCR detection of novel noroviruses in humans, and has identified novel bat noroviruses, suggesting further opportunities for expansion of this work (142, 179-181). This work is particularly relevant in Malaysia because pig farms are shunned by the government and local villagers to they are placed far away from town centers, deep in the forest, and it is this scenario that led to the emergence of Nipah virus in 1998-9 (6, 22). **Thailand:** Co-Is Hemachudha, Wacharapluesdee (TRC-EID, Chulalongkorn Univ. Hosp.) work in coordination with the Thailand Ministry of Health to investigate outbreak etiology, including the first case of imported MERS-CoV in Thailand, **for which we produced sequence confirmation within 24 hours from acquiring the specimen.** Three imported MERS cases have been detected in Thailand since 2015, and all cases were confirmed at the TRC-EID. We worked during the Zika outbreak to identify > 500 PCR-positive Zika patients with sequence confirmation. We have also worked on returning and suspected Ebola travelers, syndromic surveillance for SARI, encephalitis, Hand Foot and Mouth disease in children and viral diarrhea. Consultant Hickey (US CDC, Thailand), screened specimens collected between 1998 and 2002 from a large cohort of children from Kamphaeng Phet Province to examine Dengue virus and JE epidemiology (182, 183). Among the 784/2,574 convalescent sera henipavirus-specific antibodies were detected in 13 serum samples (1.7% seroprevalence), suggesting prior exposure to endemic henipaviruses or a related PMV in rural Thailand. **Singapore:** Duke-NUS has worked with the Ministry of Health to investigate Zika cases (184), and other EIDs. With EHA and others, Duke-NUS has developed novel CoV assays for clinical surveillance, and for expedited analysis during outbreaks. Our pipeline of novel virus detection, reservoir host identification, serological assay development, and serological testing is as rapid as several months, with the development of novel serological assays from sequence data in 7 days (17). **For example, with the discovery of SADS-CoV, we identified and fully sequenced a new virus, screened archived wildlife specimens to identify the natural reservoir host species (*Rhinolophus* spp. bats), developed LIPS serological assays, and tested human and swine samples to assess seroprevalence in less than 3 months (17).**

**3.2.b Analysis of self-reported illness:** We have developed a standardized approach for analyzing data from study participants on self-reported symptoms related to target illnesses: fever with cough and shortness of breath or difficulty breathing (severe acute respiratory illness - SARI); fever with muscle aches (fevers of unknown origin (FUO)); and, cough or sore throat (influenza-like illness - ILI). For all of our prior human clinical surveillance in 20+ countries, including in Malaysia and Thailand, we used a least absolute shrinkage and selection operator (LASSO) regression to identify associations between participants who reported ILI and/or

SARI symptoms and demographics, occupation, and contact with animals in the last year. Results have clear biological relevance. For example, in Yunnan, China, factors strongly associated with prior disease involve animal hunting and consumption (Fig. 14). We will expand this approach for all clinical syndromes in Aim 3, and use targeted questions to assess patient's exposure to wildlife in terms that are relevant to each specific country.

**Fig. 14:** Factors associated with self-reported ILI & SARI in prior 12 months (s = bootstrap support; n = #+ve out of 1,585 respondents). **Orange circles** = odds ratios > 1 (+ve association); **purple** = odds ratios < 1 (-ve association).

**3.3 General Approach:** Our previous research suggests that there are substantial numbers of outbreak cases for which the etiologic agent has not been identified. To capture these, we will expand on our current syndromic surveillance to enroll, and collect high quality biological samples from patients who present at regional clinics and live in rural communities linked to Aim 2. Case definitions and enrollment criteria include: 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever; or 6) high fever/diarrhea with unusual presentation. We will collect survey data to assess contact with wildlife, and occupational and environmental exposures, conduct molecular and serological assays to test causal links between their syndromes and the known and novel viral agents identified in Aim 1. If novel pathogens are identified by PCR, we will attempt to isolate and biologically characterize the pathogen, using the collaborative cross to identify an appropriate animal model to conduct preliminary pathogenesis work. We will then use behavioral survey data, ecological and phylogeographic analyses to assess the likely reservoir hosts to inform intervention programs.

**3.4 Clinical cohorts. 3.4.a Cohort selection:** We will initiate active clinic-based syndromic surveillance at 2 town-level level clinics and 2 provincial-level hospitals in each Thailand, Peninsular Malaysia, Sabah and Sarawak. These serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2 and are inclusive of wildlife sampling sites in Aim 1. Patients  $\geq 12$  years old presenting at the health facility who meet the syndromic and clinical case definitions above will be recruited into the study after completing a consent form. We will aim to enroll 300 participants per hospital, with that we will have a 95% probability of detecting live virus in patients in each hospital assuming a population prevalence of 1%. This sampling effort will total of 4,800 individuals for clinical syndromic surveillance. We assume up to 40% loss from follow-up, therefore yielding 2880 participants that will be available for follow-up blood sampling (**Section 3.4.b**). While enrollment is limited by the number of patients that come to the healthcare facility presenting with relevant clinical symptoms, in our work in the PREDICT project we enrolled an average of 100 participants per year, so we are confident this is an achievable enrollment target. Study data will be pooled across country regions, as clinical patients are limited by the number of individuals presenting at hospitals. “Cases” will be determined as participants whose samples tested positive for either CoVs, henipavirus, or FVs, PCR tests. “Controls” will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. Sites: Thailand: We will work with two primary hospital, Phanat Nikhom Hosp., Chonburi district (Key Pers. Dr. P. Hemachudha) & Photharam Hosp., Ratchaburi Province, and a large tertiary hospital, King Chulalongkorn Memorial Hospital, Bangkok Thailand (Co-I Dr. T. Hemachudha). Peninsular Malaysia: **Focusing immediately on the current outbreak in Orang Asli, we will work closely with the Malaysian Ministry of Health to support their investigation, and with 6 Orang Asli clinics which focus solely on this indigenous community.** Co-I Sellaran (Lintang Clinic, Kuala Kangsar) refers patients to Sungai Siput Hospital and Gen. Hospital, Ipoh. Key Pers. I Lotfi (Pos Betau clinic, Kuala Lipis) will continue collaboration with Co-I Hughes in the communities at that site. Sarawak: Key Pers. Diyana (Director, Bario Clinic) refers patients to Miri Hospital (Co-I Utap) and serves people from the Kelabit, and nomadic tribes in the region, as well as populations within a number of large towns. Sabah: We will continue our collaboration with Queen Elizabeth Hospital, QEH (Key Pers. Lee, Rajahram) and Hospital University Malaysia Sabah, HUMS (Co-I Lasimbang, Director). Both clinics include our targeted sites for **Aim 2** in their catchment, and both have ongoing collaboration with the Borneo Medical Health Ctr (Co-I Kamruddin, Director). Singapore: Currently, there are no plans to conduct clinic surveillance based on budget constraints. However, in the event that that is an evolving need for clinic surveillance, enrollment, and sampling, we have close working relationships with all hospitals in the country, and the central infectious disease reference lab (key clinicians at which are aware of our proposal). This would allow us to rapidly on-board a hospital based site.

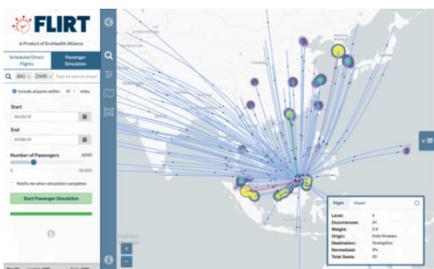

**3.4.b Clinic enrollment and follow-up:** We will recruit inpatients and outpatients to participate in the study after initial screening to determine if they meet our clinical case definitions. Once consented and enrolled, biological samples will be collected by trained and locally certified hospital staff and a questionnaire administered by trained hospital or research staff that speak appropriate local language. Every effort will be made to take samples concurrently when collecting samples for normative diagnostics. For both inpatients and outpatients, samples will be collected no more than 10 days of reported onset of illness to increase the chance

of PCR detection of viruses (185). Where possible, we will follow up 35 days after enrollment to collect an additional two 500 µL serum samples conduct a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. This gives adequate time for development of IgG, which occurs <28 days after onset of symptoms for SARS patients (186-188). Serum samples will be used to screen panels of high risk human and local zoonotic Filovirus, Henipavirus and Coronavirus strains as described in Aim 2. These samples may prove valuable to collaborators in that the PBMC could be used in production of therapeutic antibodies.

**3.4.c Sampling and clinical interview:** Biological specimens whole blood (5mL will be drawn for whole blood and serum collection, samples will be aliquoted, at least one max. 500 µL whole blood; two 500 µL serum samples) and two nasal or oropharyngeal swabs will be collected from all participants, and a questionnaire will be administered. We will investigate five risk factors, to maximize the power of the analyses, all related to high risk wildlife exposure, based on continuing analysis of our previous work, and will include: 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, in/around house; 3) proximity of residence or work place to environments of increased risks, e.g. nearby bat roosts; 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12mo and lifetime. With additional consent considerations for participants enrolled from clinical settings, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. Blood will be taken for future harvesting of Peripheral Blood Mononuclear Cells (PBMCs), as per **Section 2.5**.

**3.5 Sample testing:** The standard syndromic diagnostic PCR assays for common pathogens will be conducted and the results will be shared with the hospital with 48 hours. Specimens will be further tested for 3 viral families; CoV, PMV and filovirus by consensus PCR (**Section 1.4.c**). Necropsy samples from deceased patients will be further characterized by NGS if previous PCRs are negative and unable to identify the cause of infection. Co-Is Wang, Anderson will conduct a VirScan serological assay using paired serum samples at Duke-NUS that identifies antibodies with a four-fold rise in titer in the convalescent sample compared with the acute sample, thereby indicating a possible etiological agent. A PCR test with the specific primer from each virus antibody positive case will be further tested from acute specimens to confirm infection.

**3.6 Viral risk characterization and potential for pandemic spread:** We will use statistical models built from collated biological, ecological, and genetic data to assess the likelihood of pathogenicity for the range of diverse viruses we will characterize. The aim is to quickly identify and assess which viruses pose the most significant risk to human health and thus prioritize additional resources to more fully characterize, better understand pathogenicity, and invest in our animal model pipeline and ultimately therapeutic development for those pathogens. We will combine two independent but related statistical models to predict pathogen spillover risk and pathogenicity. First, we will expand a simple generalized additive modeling approach (3) to assess spillover risk probability to a new virus that is currently not known to infect people, when we have only limited genetic data from initial PCR screening and sequencing. Additional data from receptor binding protein homology and cell line infection experiments will be incorporated into the model framework as available. Second, given high likelihood to spillover and infect humans, or direct evidence of human infection from our clinical surveillance, we will then assess the likelihood of pathogenicity based on traits for phylogenetically related nearest neighbor viruses as a first approximation and incorporating more detailed data from genomic characterization and animal model experiments (Aim 1). Epidemiological trait data for ~300 viral species known to infect people (e.g. case fatality rate, global estimates of number of human cases per year or decade,  $R_0$ , infectious period, and primary symptoms) have been collated by recent studies and will be used as predictor variables (189). Thirdly, we will apply tools already developed, and being refined by EHA under DTRA and DHS supported research, to predict pandemic spread for viruses using global flight models, as well as additional datasets on human movement and connectivity across Southeast Asia (90, 91) (**Fig. 15**).

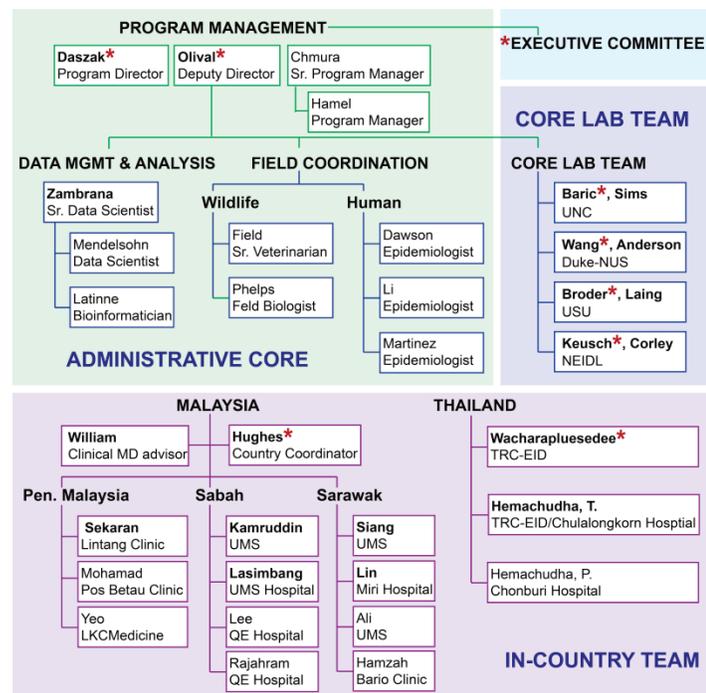

**Fig. 15:** Probability feed from EHA's Flight Risk Tracker tool (FLIRT). This image is of the likely pathways of spread and establishment for a Nipah-like virus emerging from Sabah, based on human movement and airline flight data (90, 91).

**3.7 Potential problems/alternative approaches: Patients visiting clinics may have cleared virus, but not yet developed IgG antibodies, reducing seropositive cases.** Our 35 day follow-up sampling should account for this because the maximum lag time between SARS infection and IgG development is ~28 days and Ebola virus infection and IgG approximately 20 days (185-188, 190). We also expect that patients in rural communities will only visit clinics when symptoms have progressed, likely coinciding with late illness and onset of IgG. We will also have data from our community study that can be analyzed in conjunction with, or in the absence of, clinical data from the hospital data to identify PCR- or seropositives. Finally, the risk of limited detection is outweighed by the potential public health importance of discovering active spillover of new henipaviruses, FVs or CoVs infection.

**4. Administrative Plan**

**4.1. Project management: 4.1.a. Administrative core:** The EID-SEARCH organizational partner roles are laid out by Specific Aim above (see Fig. 3). EcoHealth Alliance (EHA) will lead the administrative core of the EID-SEARCH, including: coordination and management of all human and animal research; communication with consortium partners, NIH, other EIDRCs, and the EIDRC-CC; data management and quality assurance; modeling and analysis; and compliance with all US, international, and institutional rules and regulations. The administration will be led by PI Daszak, who has >20 years' experience managing international research collaborations on emerging zoonoses, and has collaborated with all partners in the EIDRC consortium for 5-20 yrs on NIAID- and USAID-funded research (Fig. 16). He also has direct experience as one of two external reviewers of one of the CEIRS partners for NIAID (Program officer Diane Post). PI Daszak will be assisted by Deputy Lead, co-I Olival, who has overseen zoonotic disease research in Southeast Asia for >10 years and working directly with our partners in Thailand and Malaysia for 15 years. Senior program manager (Chmura) and full-time program assistant (Hamel) will provide administrative support. The EID-SEARCH data management, epidemiological analysis, and modeling activities will be led by co-Is Olival and Zambrana who have led all modeling and analytics on USAID USAID PREDICT for the last 10 years. They will oversee a programmer/data scientist (Mendelsohn), evolutionary biologist/bioinformatician (Latinne), and human epidemiologists (Dawson, Li, Martinez). Our human epidemiology team will work directly with country teams in Malaysia and Thailand to manage human surveillance, IRB applications and approvals, and ensure compliance with all human subjects work. EHA's senior veterinarian (Field) and wildlife field biologist (Phelps) have extensive experience working that bats, rodents, and primates in SE Asia and will coordinate all training and field research in Malaysia and Thailand and ensure compliance with IACUCs.

and full-time program assistant (Hamel) will provide administrative support. The EID-SEARCH data management, epidemiological analysis, and modeling activities will be led by co-Is Olival and Zambrana who have led all modeling and analytics on USAID USAID PREDICT for the last 10 years. They will oversee a programmer/data scientist (Mendelsohn), evolutionary biologist/bioinformatician (Latinne), and human epidemiologists (Dawson, Li, Martinez). Our human epidemiology team will work directly with country teams in Malaysia and Thailand to manage human surveillance, IRB applications and approvals, and ensure compliance with all human subjects work. EHA's senior veterinarian (Field) and wildlife field biologist (Phelps) have extensive experience working that bats, rodents, and primates in SE Asia and will coordinate all training and field research in Malaysia and Thailand and ensure compliance with IACUCs.

**Fig. 16: Administration and program management for the EID-SEARCH**

The EID-SEARCH core laboratory team includes global experts in virology, molecular pathogenesis, and the development of assays, reagents, and therapeutics for high consequence viral zoonoses (Co-Is Wang, Anderson at Duke-NUS; Baric, Sims at UNC; Broder, Laing at USU; Keusch, Corley at NEIDL). The core laboratory team will work with in-country diagnostic labs in Thailand (Wacharapluesedee, Hemachudha at the TRC-EID, Chulalongkorn University) and Malaysia (Hughes, Lee, CM Ltd.). Wacharapluesedee and Hughes will additionally serve as country coordinators for the EID-SEARCH, liaising directly with EHA on weekly conference calls, and working with in-country partners to ensure the smooth operation and coordination of clinical and community surveillance and wildlife research in Thailand and Malaysia, respectively. **A Core Executive Committee** comprising PI Daszak, Deputy Lead and Co-I Olival, and leads from each core partner and country: Co-Is Hughes, Wacharapluesadee, Baric, Wang, Broder, Keusch (or alternates), will conduct

regular conference calls and in-person meetings to facilitate rapid decision making within the EID-SEARCH. **This committee will also convene to manage EID-SEARCH response to outbreaks.**

**4.1.b Project Management in Thailand and Malaysia:** Wacharapluesedee and Hughes have collaborated directly with EHA for >15 years, including acting as country coordinators on the USAID PREDICT project for the last 10 years (project end date Sept. 2019). They maintain strong ties with Ministries of Health (MOH), Agriculture and Environment, multiple universities and research institutions, clinics, and hospitals, in their respective countries and across the region. The EID-SEARCH will use these connections to disseminate results, obtain permissions to conduct sampling, and also rapidly respond to and assist with outbreaks as they happen. Peninsular Malaysia, Sarawak, and Sabah are the three main Malaysian administrative regions, and effectively operate as three separate countries, with different regulations and government structures. We therefore provide specific details on the management of EID-SEARCH activities in each:

Coordination among Peninsular Malaysia, Sabah and Sarawak will be led by co-I Hughes (Conservation Medicine Ltd), and follow a successful model we implemented under USAID-PREDICT. **On Peninsular Malaysia** this project will be administered through the Zoonosis Technical Working Committee (ZTWC) established under the PREDICT project with a binding MOU among EHA, CM Ltd. and ZTWC, and including officers from MOH, Dept. of Veterinary Services, and PERHILITAN (the Govt. wildlife agency). EHA will communicate weekly with Co-I Hughes to coordinate and monitor implementation of research and reporting to ZTWC. Co-I Hughes will coordinate activities at all other Peninsular Malaysia institutions: NPHL, the National reference laboratory for diagnostic confirmation of pathogens, will manage molecular and serological screening (BioPlex) of Orang Asli samples, and serological screening of syndromic samples from Sabah and Sarawak; the PERHILITAN molecular zoonosis laboratory will store and conduct molecular and serological screening on wildlife samples; and Universiti Putra Malaysia (UPM) Faculty of Veterinary Medicine will conduct molecular and serological screening (BioPlex) of livestock samples, should these be required. **For Sabah & Sarawak**, work will be administered through the Sabah Zoonotic Diseases Committee (SZDC), a working technical committee comprising appointed and authorized officers from Sabah State Health Dept., Department of Veterinary Services, Sabah Wildlife Dept. (SWD), Universiti Malaysia Sabah (UMS) and EHA, all of which are also committed through a signed MOU. Co-I Hughes will oversee work at all other partners in Sabah, including: the Kota Kinabalu Public Health Lab (KKPHL) for molecular screening of syndromic samples from Sabah and Sarawak; the SWD Wildlife Health and Genetic and Forensics Lab for molecular screening of Sabah wildlife samples; The Borneo Medical Health Research Center (BMHRC) for screening some Sabah wildlife and livestock samples, if required, and human syndromic samples from Sabah and Sarawak. **In Thailand** all human community and wildlife research and testing will be coordinated by co-I Wacharapluesedee from the TRC-EID center. Clinical surveillance will be overseen by senior clinical physician and co-I T. Hemachudha.

**4.1.c. Approval and release of results:** In our experience, it is critical when working in resource-poor countries, on potentially important pathogens, to strictly adhere to protocols for release of results. EID-SEARCH will liaise with existing points of contact in the Ministries of Health, Environment, and Agriculture in each our administrative areas to approve and release project findings publicly. Results from human screening will be shared with participants when they become available, as per our IRB agreements ensuring no violations to anonymize data requirements (**see Protection of Human Subjects**).

**4.2. Flexibility to extend the EID-SEARCH to new sites as needed:** The EID-SEARCH consortium partners maintain extensive working relationships with leaders in EID outbreak control, clinical investigations and research at over 50 clinics, research institutes and public health laboratories across Southeast Asia. Due to space constraints, we haven't listed each of these, nor have we solicited >50 Letters of Support for this project. However, each core EID-SEARCH partner has contacted their networks and obtained permission for inclusion in the broader goals of the EIDRC. As examples of these contacts, our core partner, the Thai Red Cross Emerging Infectious Disease Health Science Centre (TRC-EID) at Chulalongkorn University, also serves as the WHO Collaborating Centre for Research and Training on Viral Zoonoses and has ongoing research collaborations across WHO SEARO countries including Bangladesh, Bhutan, Democratic People's Republic of Korea, India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, (Thailand), Timor-Leste; and has recently served as a training hub for scientists from Malaysia, Myanmar, Laos, the Philippines, and China to learn methods of wildlife sampling and diagnostic screening. Our Thai clinicians (Co-I T. Hemachudha and KP P.

Hemachudha) provide regular case consultations and clinical trainings for doctors across SEARO countries, including with Yangon General Hospital and the National Health Lab in Myanmar, 2018. To maximize leverage of this broad network, EHA has budgeted for annual meetings in SE Asia, in addition to regular smaller network meetings, with our core team and key public health experts from network labs in each of the 10 SE Asian countries. Additionally, we will set up a listserv and an internal communication network to facilitate collaboration and information exchange, including on the first reports of new disease outbreaks. Our annual and smaller network meetings will critically allow face-to-face meetings of the EID-SEARCH that will foster greater sharing of information on novel research and diagnostic approaches, pathogens that are of key pandemic potential, regions or populations at high risk of spillover, and information from the greater network on likely outbreaks of novel disease. This platform will coordinate sample sharing and diagnostic platforms and help build a rapid response to outbreaks in the region, guided by the PI, Deputy and the Executive Committee.

**4.3. Outbreak response:** EHA collaboration with expert networks around the world allows us to mobilize and enhance effective One Health response to disease emergencies (191), ranging from real-time situation updates and risk analyses to on-the-ground investigations (192-194). We will adopt management tools from Emergency Operating Center (EOCs) (195) and Incident Management Systems (IMS) (196), to shift resources where necessary to help respond to novel zoonotic outbreak events and other public health emergencies. EHA has extensive experience working with governments in low and middle income countries (LMIC) applying these principles of epidemic preparedness during outbreak responses we've been involved with under the USAID-PREDICT project. For example, at the request of the government of Bangladesh, we provided technical field and laboratory support for Nipah virus and avian influenza outbreak investigations, assisting with wildlife sampling as part of the outbreak response alongside human and domestic animal sampling. In India, we provided technical assistance in response to the Nipah virus outbreak in Kerala in 2018. Last month in Indonesia we assisted the Ministry of Health's Center for Health Laboratory in Makassar to provide technical assistance in a mysterious outbreak in a small village in South Sulawesi that killed 4 villagers and infected 72. Our network partners include the key government and govt. approved laboratories that would be directly involved in public health emergency response in their respective countries. The serological and PCR platforms that EID-SEARCH develops will be made available to the main government outbreak investigation teams for clinical work and research during the outbreak. EID-SEARCH will also offer assistance training and conducting animal sampling during an outbreak, epidemiological analysis and modeling to help identify likely reservoirs or likely pathways to spread. Technical and material support for lab, field and analytical activities during an outbreak will be provided by EHA, UNC, USU, Duke-NUS, and NEIDL, as well as in-country partners. Any clinical samples, viral isolates and sequence data will be shared among partners to promote the rapid development of new diagnostic assays, reagents, and therapeutics that can be deployed to the region or other regions as part of the larger NIH EIDRC network.

Finally, while the initial pathogen focus of our group is on CoVs, PMVs and FVs, our broad collaborative group has multidisciplinary expertise on a number of virus-host systems. For example: PI Daszak was PI on a subaward from PI Laura Kramer's U01 on Poxviruses and Flaviviruses, managing a multidisciplinary research project on West Nile virus ecology. He was also co-I on a 5-year NSF-funded project to understand West Nile virus dynamics and risk in the USA (197-201); Co-I Baric is a global leader in Norovirus research leading to the development of vaccines and therapeutics (202-205); Co-I Wang has conducted significant work on bat immunology, therapeutic, and reagent development, as well as being involved in a range of outbreak investigations, viral discovery programs and other research on a wide diversity of viral groups (206-215). Additionally, the serological and PCR-based diagnostic platforms being developed by Co-Is Wang and Broder are adaptable to other viral targets. The modeling tools developed by Co-Is Olival and Zambrana-Torrel can be used to predict the emergence and spread of diverse viral targets, including influenza, antimicrobial resistance, and vector-borne diseases (216-221). Our clinicians working in Thailand and Malaysia have a wide range of infectious disease investigations to adapt to any outbreak situation.

**4.4. Communications:** EHA will coordinate communication among all co-Is and key personnel, including:

- Multiple meetings per week with PI, Deputy Lead, Senior Program Manager (on project and task status)
- Weekly web/phone meetings between Program Manager and subawardee admin. staff
- Monthly web/phone conferences between EHA PIs and all subawardee PIs.

- Monthly web conferences between key personnel (research presentations/coordination)
- In-person Annual meetings with partner leads, key personnel at EHA and two in-person partner meetings annually between subawardees.
- Annual in-person meeting among all key personnel

**4.5. Problem identification and resolution:** Regular planning, monitoring, and evaluation meetings will be the primary mechanisms for problem identification. Minor problems (e.g. delays in sample availability or test results) will be dealt with internally through appropriate action and resolution monitored by PI Daszak and co-PI Olival, and our Senior Program Manager. In the event of significant problems, such as prolonged poor productivity, inadequate scientific collaboration, or major disputes regarding research direction or resource allocation, EHA will assist with resolving the problem through negotiation with relevant co-PIs and consultation with the Executive Committee. Should a resolution not be forthcoming, consultation with the EIDRC-CC, additional external technical advisors, and NIH staff may be warranted.

**4.6. Adaptive management and risk mitigation:** Maintaining a timeline and meeting milestones will require strict and continuous oversight of all project phases, frequent and regularly scheduled communication, and the ability to make decisions and implement strategies. To maintain our timeline on all projects, including the EID-SEARCH, we use an adaptive management approach to continually evaluate these trade-offs, to make decisions about when iteration is appropriate and when it is necessary to move forward with current information. Our ethos is that regular, scheduled communication among all staff, partners and collaborators will go a long way towards mitigating risks, especially if the process is collaborative and transparent.

## 5. Data Management Plan

EHA will house the Data Management and Analysis (DMA) team for EID-SEARCH, led by Co-PIs Olival and Zambrana-Torreilo and include Key Personnel Latinne and Mendelsohn. EHA has served as the data and analysis hub for numerous multi-institutional, multi-sectoral, international disease research groups, including acting as Modeling and Analytics lead for the PREDICT project (122), the Western Asia Bat Research Network (222) and EHA's Rift Valley Fever Consortium. We will leverage our experience and infrastructure from those projects to benefit the EID-SEARCH. **5.1. Project Database:** We will create a dedicated, centralized EID-SEARCH database to ingest, store, link, and provide for analysis all data associated with the proposed study and other expanded projects associated with the research network. The database will be SQL-based and use encrypted, secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations. The system will be designed to work with both with both paper- and tablet-based field data entry and with the Lockbox laboratory information management systems (**Section 5.2**) in place in individual partner labs. The database will use existing metadata standards, including NCBI standards for genetic and molecular data and Ecological Metadata Language (EML) for field and wildlife data, as well as other standards and formats designated by the EIDRC CC. This will enable rapid publication and deposition of data. Granular security and privacy controls will be applied so that specific expansion projects undertaken in the network may be managed while maintaining data confidentiality as needed.

**5.2. Biological Specimen Management:** Project laboratories will use the Lockbox Laboratory Information Management System (LIMS), to manage the security, traceability, and quality of biological specimens. The LIMS will support sample barcoding at creation, tracking through transport, storage/inventory, and use via portable scanners. Lockbox supports CLIA and ISO 17025 as well as direct export to NCBI formats such as Sequence Read Archive. We will use the Lockbox LIMS application programming interface (API) to link to the central project database and associated samples with field and ecological data. We note that the project focuses on highly pathogenic viruses, including select agents; Lockbox LIMS supports sample tracking and movement compliant with US Select Agent Regulations and US Department of Commerce Pathogen Import and Export Control Regulations, and includes all necessary encryption, security, and backup protocols.

**5.3. Training:** Members of the DMA team will team will develop documentation and provide training for field and laboratory teams at all partner institutions in data management, metadata standards and data hygiene best practices. The DMA team will act as trainers and consultants for partner institutions in experimental

design, power analysis, data analysis, and computational and reproducibility issues, and visit each partner institution and/or field team base for training workshops and analysis consultations.

**5.4. Data Identification and Privacy:** For human clinical data and questionnaires, data will be identified by a unique identification code assigned to each individual and only this, de-identified code will be accessible in the project database, and destroyed at the end of the project - as per details provided in the Clinical Management Plan and Protection of Human Subjects forms.

**5.5. Computing Resources:** EHA operates a cluster of high-performance servers for data analysis activities, as well as infrastructure to launch cloud-based computing environments (**see EHA Facilities**). Our servers host all necessary software for statistical and bioinformatics work that is available to the DMA and partners anywhere in the world. We use a mixture of cloud services (AWS, Azure, Backblaze, GitHub) to provide redundancy, backup, version control, and rapid post-disaster recovery, and will be available to all project partners for analysis and training.

**5.6. Data and Code Sharing:** See details provided in the **Resource Sharing Plan**.

## **6. Clinical Management Plan**

**6.1. Clinical site selection:** Our consortium partners have been conducting lab and human surveillance research, including during outbreaks, for >20 years and have developed strong relationships with local clinical facilities and processes in SE Asia and in LMIC globally. The plan for selection of clinical sites will begin in the same geographic regions as those identified in Aim 1 with high zoonotic viral diversity. Clinical sites will additionally serve as the catchment healthcare facilities for people in our community-based surveillance of Aim 2. We have already developed successful working relationships with the major healthcare facilities in Thailand and Malaysia and will use these established partners to rapidly gain appropriate permits and begin data collection quickly. Focusing on these EID hotspots in select biogeographic areas (see **Fig 13**) also reduces the number of additional sites needed to meet our goals within our geographic range. The capacity and capability requirements for clinical sites are fairly minimal, and include ability to enroll patients that meet the clinical case definitions of interest, collect and temporarily store biological samples, and follow standards for data management and subject protection with locked filing cabinets to store all paper records and an encrypted computer. We will be enrolling inpatient and outpatient participants within 10 days of the presentation of symptoms to increase the chance of PCR detection of viruses so we will not wait for advanced normative diagnostic tests, that are likely unavailable in the more remote sites, to be completed. We will work with clinical sites to determine the best process for project staff, in most cases supporting the time of currently hired staff at each site. We will recruit and train hospital staff in project-specific procedures including enrollment of patients, sample types to be collected, storage of samples, administration of the questionnaire, and data management plans. During the development and onboarding of new clinical sites we will assess the physical needs of the site and what supplies will be required for collection of data.

**6.2. Standardized approach, oversight, and implementation:** Management and oversight for all study sites will be undertaken by the local country coordinator with support from our Core Administrative team at EHA. Our research team has over 10 years of experience building capacity on human subjects' research and has developed training resources and materials for standardized implementation of community and clinical research and SOPs for screening, enrollment, and retention of participants. The country coordinator will conduct regular site visits to the clinical sites and annual visits to observe, monitor and evaluate the research process, and conduct follow-up training if required. Through our work with clinical sites under the USAID-PREDICT project we have developed culturally appropriate screening measures for clinical sites that do not disrupt the flow or quality of medical treatment received by the patient. This was done by working collectively with clinical staff to evaluate current procedures and patient flow at the site to determine the most efficient while minimal invasive inclusion of our study into the daily working of the clinical site. Most efficiently this was done by adding minimal basic screening questions to the current clinical intake forms, which allows the clinical research officer to quickly scan charts or logs for potential patients to enroll avoiding potential enrollees from being overlooked if staff are too busy or not on duty. Patients will be enrolled following established clinical criteria (**see Section 6.3**), samples collected and brief surveys conducted to assess the participants contact with wildlife through: 1) occupational exposures; 2) animal contact; and 3) the environment. With permission

from each clinic, and consent from participants, we will review clinical records to collect data on medical history, clinical syndromes, and patient etiology. Additionally, we will be following up with clinical participants to determine how clinical presentation differs between CoV, henipavirus, or FV in exposed and unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. The country coordinator will be continually monitoring the project database to ensure we hit target sample sizes. While patient's enrollment is limited by the number of individuals presenting at hospitals, in previous research we enrolled an average of 105 patients per year, ranging from 77-244.

**6.3. Clinical cohort setup, recruitment, enrollment:** We will recruit inpatients and outpatients from clinical sites to participate in the study after initial screening to determine if they meet the clinical case definitions for 1) severe/acute respiratory illness (SARI/ARI); 2) Influenza-like illness (ILI); 3) fever of unknown origin (FUO); 4) encephalitis; 5) hemorrhagic fever, of unknown etiology or severe diarrhea with unusual presentation for symptoms to increase the chance of PCR detection of viruses. Once enrolled, biological samples will be collected by trained hospital staff. When possible, samples will be taken concurrently with samples being collected for normative diagnostics. We will collect 5mL of blood for whole blood and serum collection, samples will be aliquoted, at least one max. 500  $\mu$ L whole blood; two 500  $\mu$ L serum samples and two nasal or oropharyngeal swabs will be collected. Controls who test positive for CoVs, FVs, or Henipaviruses will be selected from the pool of participants admitted to the studies and whose samples tested negative for coronaviruses, henipavirus, or filoviruses. We will follow up 35 days after enrollment to collect an additional 5mL blood draw for collection of two 500  $\mu$ L serum samples and a standardized questionnaire supplement to collect additional data on the course of symptoms in the interim period. Following up 35 days post initial collection gives adequate time for 1) development of IgG and IgM, which occurs <28 days after onset of symptoms to evaluate the immunological progression of disease and 2) further the risk assessment of the participants to monitor contact with wildlife, people, and to assess the likely reservoir hosts to collect information to inform potential intervention programs.

**6.4. Utilization of collected data:** Sampling of wildlife and the enrollment of community surveillance participants and a clinical cohort of participants give us the ability to assess the viruses that are circulating in each of the three populations in a similar geographic region. We will use phylogenetic analysis to compare the relationship between wildlife viruses found and viruses found in human participants. Additionally, the questionnaire data will allow us to assess relative measures of human-wildlife contact that we will analyze the intensity of contact with species known to be at a higher risk for spillover against other risk to provide useful proxy information for spillover risk. The clinical cohort will be split into cases and controls. "Cases" are defined as participants whose samples tested positive for either CoV, henipavirus, or FV via PCR tests. "Controls" will be selected from the pool of participants admitted to the studies and whose samples tested negative. We will use nearest neighbor matching to pair cases demographically (e.g. age, sex, location) with controls at a 1-to-3 ratio or greater. In clinical study, we will use this procedure to determine how clinical presentation differs between virus-exposed and -unexposed participants, as well as in the time course of illness, severity of symptoms, and type of symptoms. We will model the outcomes to analyze correlation between biological results and risk factors related to high risk wildlife exposure. With this collective data set we aim to quantify and detect novel viruses likely to spillover regularly to people, are often unreported or misdiagnosed as their clinical manifestations, and are unknown to detect cryptic outbreaks causing previously 'hidden' clinical syndromes in people. Our strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to conduct public health interventions and disrupt disease emergence.

**6.5. Development of reagents of value to the community.** Members of the EID-SEARCH consortium have substantial experience producing reagents, assays, and other products that are used widely by the clinical and research community, and some of which are on a pathway to commercialization. These include: PIs Daszak and Co-I Olival have produced software for analyzing the spread of novel viral agents through air travel networks; Co-I Baric has collaborated with a Norovirus surveillance collaboration with surveillance cohort at CDC and has developed therapeutics that have reached phase 2 and 3 clinical trials, He is currently working with Takeda Sanofi Pasteur on a Dengue therapeutic and with NIH on a tetravalent vaccine; Co-I Broder

developed a Hendra virus subunit vaccine that was commercially produced by Zoetis for horses and is labeled for human use under compassionate circumstances during outbreak situations.

**6.6. Potential expansion:** Expansion of the research project to other clinical sites or research areas could happen as new information is gathered, either through our research, the EID-SEARCH information network, or an outbreak being identified in the region by other organizations. If expansion is required we would rapidly shift research activities towards the clinical or community sites where the outbreak is active, using the same process we used to set up initial research locations. First, by working with local stakeholders to create a working relationship and on-boarding new clinical research staff through advanced trainings of project aims, SOPs on data collection and storage, and ethical guidelines. The network of infectious disease researchers in the community and hospital settings would allow for an accelerated response to any potential infectious disease outbreaks as staff are well trained on ethical guidelines for working with human subjects, data and specimen collection, storage, and transpiration, project staff would be on the front lines ready for the call to action. Ideally, our testing for viruses in priority viral families may lead to the discovery cryptic outbreaks before it spreads in the general public. Biological results coupled with survey data on key risk factors will provide necessary information for granular understanding of disease spread.

## **7. Statistical Analysis Plan:**

**7.1. Framework:** Statistical analyses across the project will be conducted under a common Bayesian framework. These models provide a unified, probabilistic approach best-suited for estimating effect sizes in heterogeneous populations of human clinical and wildlife subjects in observational studies. Within this Bayesian framework, we will use generalized linear mixed models to estimate population prevalences and seroprevalences, and estimate the effects of demographic, occupational and environmental factors affecting these. We will use occupancy models (223) to estimate total viral species and strain diversity and completeness of sampling within the human and wildlife sub-populations, and discrete phylogeographic models to identify taxonomic and geographic centers of viral diversification. All statistical analyses will be performed reproducibly using scripted, programmatic workflows (e.g., the R and Stan languages) and maintained under source code version control (git). As with data management, the DMA team will act as trainers and consultants for exploratory data analysis, power analysis, and study design with project partners, and the EHA computing cluster will be available for partners undertaking additional or expansion studies. Power analyses, current and expansion, are performed via simulation approaches allowing planning for complex, hierarchical variation in study populations. Power analyses and specific analytical components of this study are detailed under each Specific Aim.

**7.2. Data Quality Control and Data Harmonization:** All data will be examined at entry by field and lab teams upon data entry, followed by examination by DMA team members at upload and integration, for complete de-identification, completeness, accuracy, and logical consistency. The DMA will provide field and lab teams with reports, produced automatically, of data summaries, including aggregates, distribution, detected outliers and possible mis-entries. On a regular basis (quarterly or as-needed during data collection), DMA team members will review reports with field and lab teams to identify errors and update collection and entry procedures as necessary.

**7.3. Statistical Considerations for Behavioral Questionnaires and Clinical Metadata:** The data collected from the questionnaire will be analyzed to assess the reported measures of contact for each risk group under study, related to 1) occupation and occupational exposures; 2) observed or reported interactions with priority wildlife, especially bats, rodents, and primates in/around house and other livestock animals (e.g. farming, butchering, slaughtering); 3) proximity of residence or workplace to environments of increased risks (e.g. nearby bat roosts); 4) working or regular visitor to animal markets; 5) self-reported ILI/SARI clinical diagnosis or symptoms in the past 12 months and lifetime. Specific measures we are interested in are the proportion of respondents indicating they consume wildlife, where wildlife is obtained for consumption, have hunted wildlife, butchered or slaughtered live animals, seen wildlife in their homes, been bitten or scratched by animals, etc. Comparisons of measures of exposure contacts and types between men and women, children and adults, different study regions will be conducted in order to explore the occupational, environmental, and demographic factors (gender, age, socioeconomic status (SES)) that influence contact with animals and to determine who is

most at-risk. Statistical analysis will be employed to identify differences between groups with a 95% probability of detecting a difference. Measures of contact related to different activities within specific groups will be compared to determine the activities that put groups at most risk. As appropriate multivariate analysis (e.g. ordinary linear regression, logistic regression, non-normal distributions of outcome, least absolute shrinkage and selection operator (LASSO) regression, etc.) will be utilized to evaluate the relationship between the outcome variables, positive biological results (PCR or serology) key measures of contact and the factors that influence frequency and types of human-animal contact.

## 8. Project Milestones and Timelines

**8.1 Milestones: End of Year 1: Aim 1:** Sample targeting locations, species (for wildlife), sample size justifications completed for whole project and reported to in-country teams; Sample testing, viral isolation, NGS, glycoprotein sequencing begun for all archival and some newly-collected samples; *in vitro* work begun; host-pathogen dynamic analyses; animal model work begun. **Aim 2:** Target human community populations identified and sample sizes calculated for some sites in each country; Community data collection, serological testing and RT-PCR testing begun; first epidemiological analyses of data begin in last quarter. **Aim 3:** Clinical cohort selection underway; clinical enrollment, data collection and sample analysis begun. First Annual meeting in last quarter. First publications submitted by end of year, summary overview papers or reviews.

**End of Year 2: Aim 1:** No sample targeting or sample size justification analyses needed. All other aspects underway **Aim 2:** All aspects underway **Aim 3:** All sub-aims underway. Second Annual meeting in last quarter. Further 2 publications submitted by end of year, including first data papers.

**End of Year 3: Aim 1:** No sample targeting or sample size justification analyses needed. All other aspects underway **Aim 2:** All aspects underway **Aim 3:** All sub-aims underway. Third Annual meeting in last quarter. Further 3 publications submitted by end of year, largely data papers.

**End of Year 4: Aim 1:** No sample targeting or sample size justification analyses needed. All other aspects underway **Aim 2:** All aspects underway. Receptor binding work completed. **Aim 3:** No further cohort selection required; all other sub-aims underway. Fourth Annual meeting in last quarter. 3 further publications submitted, including first papers analyzing risk factors, pathogenic potential of novel viruses submitted.

**End of Year 5: Aim 1:** No sample targeting or sample size justification analyses needed. No receptor binding assays continuing. Serological and PCR testing completed end of 2<sup>nd</sup> quarter. Glycoprotein, *in vitro* and *in vivo* analyses, analysis of viral risk continue to end of project. **Aim 2:** No further community targeting or sample size work. Community data collection completed at end of 2<sup>nd</sup> quarter. All other aspects continue to end of project **Aim 3:** All sub-aims underway. Final Annual meeting in last quarter. Further 3 publications submitted.

### 8.2. Timeline:

ACTIVITIES	YEAR 1				YEAR 2				YEAR 3				YEAR 4				YEAR 5			
	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4
AIM 1	1.4.a. sampling targets																			
	1.4.b. sample size justifications																			
	1.4.c. sample collection & testing																			
	1.4.d. NGS																			
	1.4.e. sequencing Spike GP																			
	1.5.a. human cell infection																			
	1.5.b. receptor binding																			
	1.5.c. host-pathogen dynamics																			
	1.5.d. viral strain prioritization																			
	1.5.e. animal models																			
AIM 2	2.4 target population & sample sizes																			
	2.5 community data collection																			
	2.6.a serological testing																			
	2.6.b RT-PCR testing																			
	2.6.c virus characterization																			
	2.7 epidemiological analysis																			
AIM 3	3.4.a cohort selection																			
	3.4.b clinic enrollment & follow-up																			
	3.4.c clinical data collection																			
	3.5 sample testing																			
	3.6 risk characterization																			
	annual meeting

## PROJECT SUMMARY/ABSTRACT

Southeast Asia is one of the world's highest-risk EID hotspots, the origin of the SARS pandemic, Nipah virus, and repeated outbreaks of influenza. This is driven by high diversity of wildlife and rapidly expanding demography that brings human and wildlife populations closer. This proposal will launch the **Emerging Infectious Diseases - South East Asia Research Collaboration Hub (EID-SEARCH), a collaboration among leaders in emerging disease research in the USA, Thailand, Singapore and the 3 major Malaysian administrative regions. These researchers have networks that span >50 clinics, laboratories and research institutions across almost all SE Asian countries and will use the EID-SEARCH as an early warning system for outbreaks involving exchange of information, reagents, samples and technology, and a collaborative powerhouse for fundamental and translational research. The EID-SEARCH will also act as **a significant asset to scale-up and deploy resources in the case of an outbreak in the region**. This EIDRC will conduct research to: **1) Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife**, by analyzing previously-archived wildlife samples, conducting targeted wildlife surveillance, and using serology & PCR assays to identify novel viruses. These will be characterized to assess risk of spillover to people, and a series of *in vitro* (receptor binding, cell culture) and *in vivo* (humanized mouse and collaborative cross models) assays used to assess their potential to infect people and cause disease; **2) Collect samples and questionnaire data from human communities that live in EID hotspots and have high cultural and behavioral risk of animal exposure (e.g. wildlife hunting, bat guano collection). These will be tested with serological assays to identify evidence of novel virus spillover, and analyzed against metadata to identify key risk pathways for transmission**; **3) Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts**. We will conduct syndromic surveillance at clinics serving the populations in Aim 2, enroll patients with undiagnosed illness and symptoms consistent with emerging viral pathogens, and test samples with molecular and follow-up serological assays to identify causal links between these syndromes and novel viruses.**

This research will advance our understanding of the risk of novel viral emergence in a uniquely important region. **It will also strengthen in-country research capacity** by linking local infectious disease scientists **with an international collaborative network that has proven capacity to conduct this work and produce significant findings**. The large body of high impact collaborative research from this EIDRC leadership team provides proof-of-concept that EID-SEARCH has the background, collaborative network, experience, and skillset to act as a **unique early warning system for novel EIDs of any etiology threatening to emerge in this hottest of the EID hotspots**.

Hi everyone,

Could someone who has the technical proposal that was cleaned up and submitted easily on hand share it with me so I don't have to root through emails and drive folders?

**EDUCATION:**

1983 BS, Biological Sciences, with honors. Florida Institute of Technology, Melbourne, Florida.  
 1985 MS, Molecular Biology, Florida Institute of Technology, Melbourne, Florida.  
 1989 PhD, Microbiology and Immunology. College of Medicine, University of Florida, Gainesville, Florida.

**TRAINING / POSITIONS:**

1983 - 1985 Graduate student, Florida Institute of Technology, Melbourne. (Adv: Kenneth L. Kasweck, PhD)  
 1985 - 1989 Graduate student, Department of Immunology and Medical Microbiology, University of Florida. Gainesville. (Adv: Michael D.P. Boyle, PhD)  
 4/89 - 10/89 Postdoctoral Associate, Department of Medicine, University of Florida. (Adv: Richard Lottenberg, MD)  
 11/89 - 1/90 Microbiologist (GS-11), Laboratory of Viral Diseases (LVD), National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD. (Adv: Bernard Moss, MD)  
 1990 - 1992 National Research Council Research Associate, LVD, NIAID, NIH. (Adv: Bernard Moss, MD)  
 1993 - 1996 IRTA Fellow, LVD, NIAID, NIH. (Adv: Bernard Moss, M.D. and Edward A. Berger, PhD)  
 1996 - 2000 Assistant Professor, Department of Microbiology and Immunology; and Molecular and Cell Biology (secondary), USU, School of Medicine, Bethesda, MD.  
 2000 - 2005 Associate Professor (Tenured), Department of Microbiology and Immunology; and Emerging Infectious Diseases and Molecular and Cell Biology (secondary) USU, School of Medicine, Bethesda, MD.  
 2005-present Professor (Tenured), Department of Microbiology and Immunology, Joint appointment, Emerging Infectious Diseases Graduate Program, USU, Bethesda, Maryland.  
 2006-2018 Director, Emerging Infectious Diseases Graduate Program, USU, Bethesda, Maryland.  
 2018-present Chair, Department of Microbiology and Immunology, USU, Bethesda, Maryland

**HONORS / AWARDS:**

1987, 88 National Institutes of Health Training Grant Award.  
 1989 Medical Guild Graduate Research Award.  
 1990-92 National Research Council Research Associateship Award.  
 1993-96 National Institutes of Health Intramural Research Training Award Fellowship.  
 1996 The Fellows Award for Research Excellence, Office of Science Education, NIH.  
 1996 Breakthrough of the Year, Science; American Association for the Advancement of Science.  
 1997 Newcomb Cleveland Prize, American Association for the Advancement of Science.  
 2001 Outstanding Instructor in Virology, USU, School of Medicine Class of 2003.  
 2008 The Henry Wu Award for Excellence in Basic Science Research.  
 2013 The 3<sup>rd</sup> Sidney Pestka Lecture; 22<sup>nd</sup> Annual Philadelphia Infection & Immunity Forum.

- 2013 The 2013 Federal Laboratory Consortium (FLC) Award for Excellence in Technology Transfer.
- 2013 The CSIRO Chairman's Medal. The Commonwealth Scientific and Industrial Research Organisation (CSIRO); Australia's national science agency.
- 2014 The Cinda Helke Award for Excellence in Graduate Student Advocacy.
- 2016 The James J. Leonard Award for Excellence in Translational/Clinical Research.
- 2017 USU, Impact Award for outstanding contributions to the School of Medicine.
- 2018 USU, Impact Award for outstanding contributions to the School of Medicine.
- 2019 The 2019 Federal Laboratory Consortium (FLC) Award for Excellence in Technology Transfer.
- 2019 USU Outstanding Biomedical Graduate Educator Award.
- 2019 Selection to the University of Florida, College of Medicine, "Wall of Fame".
- 2019 Dean's Award for Leadership, University of Florida, College of Medicine.
- 2020 Inaugural, 2020 Federal Laboratory Consortium (FLC) Impact Award.
- 2020 Military Health System Research Symposium (MHSRS) 2020 Outstanding Individual Research Accomplishment by an Individual Senior Researcher

### **PATENTS, INVENTIONS, LICENSES:**

- Bacterial Plasmin Receptors as Fibrinolytic Agents: **U.S. Patent No. 5,237,050.**
- Oligomeric HIV-1 Envelope Glycoproteins (gp140): **U.S. Patent Nos. 6,039,957 and 6,171,596.** Methods for Production, Purification, and Use as an Immunogen in Mammals.
- CC Chemokine Receptor 5 (CCR5) DNA, New Animal Models and Therapeutic Agents for HIV Infection. **U.S. Patent No. 7,151,087.**
- Cells Expressing Both Human CD4 and a Human Fusion Accessory Factor (CXCR4) Associated with HIV Infection: **U.S. Patent No. 6,197,578.**
- 4G10, a Monoclonal Antibody against the Chemokine Receptor CXCR4, Raised against the N-terminal Sequence of CXCR4. DHHS Reference No. E-340-2002/0. **Licensed to Santa Cruz Biotechnology 2002.**
- Compositions and Methods for the Inhibition of Membrane Fusion by Paramyxoviruses: **U.S. Patent Nos. 7,666,431 and 8,114,410.**
- Soluble Forms of Hendra and Nipah Virus G Glycoprotein. **Australian Patent No. 2005327194. U.S. Patent Nos. 8,865,171; 9,045,532; 9,056,902; 9,533,038, 10,053,495.**
- HIV-1 Envelope Glycoprotein Oligomer and Methods of Use. **U.S. Patent No. 8,597,658.**
- Soluble Forms of Hendra and Nipah Virus F Glycoprotein and Uses Thereof: **Australian Patent No. 2013276968. U.S. Patent Nos. 10,040,825; 10,590,172.**
- Human Monoclonal Antibodies against Hendra and Nipah viruses. **U.S. Patent Nos. 7,988,971; 8,313,746; 8,858,938**
- Antibodies against F glycoprotein of Hendra and Nipah viruses. **U.S. Patent Nos. 9,982,038 and 10,738,104.**
- Hendra sG: **Licensed to Zoetis, Inc. (formerly Pfizer Animal Health).** Equivac ® HeV; Nov, 2012, Australia.
- Human antibody m102.4 therapy against Hendra and Nipah virus infection; Phase I clinical trial completed in May 2016, Queensland Health, Queensland, Australia.
- Hendra sG: **Licensed to Auro Vaccines, Aurobindo Pharma USA.** Nipah/Hendra virus human vaccine.
- Cedar Virus and Methods of Use: **U.S. Patent No., 10,227,664.**

### **PROFESSIONAL SOCIETIES:**

American Society for Virology (ASV)

Association of Medical School Microbiology and Immunology Chairs (AMSMIC)

### **DEPARTMENTAL RESPONSIBILITIES (Teaching), Graduate and Medical Education:**

Annual: Lecturer; Medical School Integrated Curriculum; Viral Zoonoses; Antiviral Drugs; Gastrointestinal Viral Diseases; Viral Vaccines; Viral Infections of the central nervous system.

Biannual: Lecturer; virus entry, virus receptors, negative-stranded RNA viruses, emerging viruses.

### **Current and Former Postdoctoral Trainees:**

Krishnamurthy Govindaraj, PhD, Institute of Medical Sciences, Lucknow, India. 1999-2004. (Research Associate, Henry M. Jackson Foundation for the Advancement of Military Medicine)

Hong Chen, MD, Hunan Med. Uni. Hunan, China. 1997-00. (Scientist, AscentGene, Inc., College Park, MD)

Sanjay Phogat, PhD, University of Delhi South Campus, New Delhi, India. 2000-2001. (Principal Scientist, Immunogen

Design, International AIDS Vaccine Initiative (IAVI), New York)

Tzanko S. Stantchev, MD, Varna Institute of Medicine, Rousse, Bulgaria. 1998-2008. (Research Scientist, Division of Monoclonal Antibodies, CDER, FDA, Silver Spring, MD)

Anil Choudhary, PhD, University, Rohtak, India. 2001-2006. (Scientist, Profectus, Inc. Baltimore, MD).

Antony S. Dimitrov, PhD, The University of Tokyo, Japan. 2004-2006. (Senior Staff Scientist, Profectus BioSciences, Inc. Baltimore, MD; Department of Microbiology and Immunology, Uniformed Services University)

Matthew I. Bonaparte, PhD, SUNY Upstate Medical University, NY, 2005-2007. (Scientist, Global Clinical Immunology Sanofi Pasteur, Swiftwater, PA)

Dimple Khetawat (Harit), PhD, University of Calcutta, India. 2003-2011. (Research Associate, UNC Eshelman School of Pharmacy, Division of Molecular Pharmaceutics, University of North Carolina at Chapel Hill)

Yee-Peng Chan, PhD, The University of Malaya, Kuala Lumpur, Malaysia, 2005-2014

Vidita Choudhry, PhD, Jawaharlal Nehru University, New Delhi, India 2006-2014 (NMRC, Silver Spring, MD)

Bang Vu, PhD, Free University of Brussels, Belgium, 2010-2017

Moushimi Amaya, PhD, George Mason University, VA, 2016-

### **Current and Former Graduate Students:**

Donald J. Chabot, PhD (Microbiology and Immunology-97'; 2000), (Microbiologist, Clinical Research Management, Inc./ Team Akimeka, USAMRIID, Bacteriology Division, Fort Detrick, MD)

Agnes Jones-Trower, PhD (Molecular and Cellular Biology-97', 2001), (Staff Fellow, Division of Viral Products, CBER, FDA, Bethesda, MD (Ret.))

Katharine N. Bossart, PhD (Microbiology and Immunology-98'; 2003), (President & Owner; Integrated Research Associates, LLC. San Rafael, CA)

Jared Patch, PhD (Emerging Infectious Diseases-01'; 2007), (Research Scientist, Food Animal Vaccine Development, Elanco, Inc., Greenfield, IN)

Julie A. Pavlin, MD, PhD, MPH, COL, USA, Ret. (Emerging Infectious Diseases-00'; 2007), (Director, Board on Global Health, Health and Medicine Division, The National Academies of Sciences, Engineering, and Medicine, Washington, DC)

Kimberly Bishop, PhD (Emerging Infectious Diseases-02': 2007), (Deputy Head, Genomics Dept., Biological Defense Research Directorate (BDRD) Naval Medical Research Center (NMRC), Fort Detrick, MD)

Andrew Hickey, PhD, MPH, LCDR, USPHS (Emerging Infectious Diseases-03': 2009) (LT, United States Public Health Service, Chief, HIV/STD Laboratory Research Section, CDC-Thailand).

Stephanie Petzing, PhD (Emerging Infectious Diseases-05': 2012), (AAAS Science & Technology Policy Fellow, U.S. Department of Defense, Threat Reduction Program Oversight Office)

Dawn L. Weir, PhD, LCDR, USN (Emerging Infectious Diseases-07': 2013), (LCDR, United States Navy, Medical Services Corps), Presently; Naval Research Laboratories, Washington, DC)

Deborah L. Steffen, PhD (Emerging Infectious Diseases-07': 2013) (Faculty, Stone Ridge HS, Bethesda, MD; Ret.)

Eric Laing, PhD (Emerging Infectious Diseases-10:' 2016) (Research Assistant Professor, Department of Microbiology and Immunology, USU, 2019)

Chelsi Beauregard, PhD (Emerging Infectious Diseases-13': 2020), (Assistant Professor of Biology, Southern New Hampshire University, Manchester, NH)

Sofia Da Silva, PhD (Emerging Infectious Diseases-13': 2020), (ORISE fellowship; Division of Research, Innovation, and Ventures (DRIVE). Biomedical Advanced Research and Development Authority (BARDA))

Grant Title: Structural and Functional Analysis of HIV-1 Entry Cofactors  
Grant Number: R0 73FG-01  
Grant Period: 10/01/96-09/30/99  
Total Direct: \$81,000 Agency: USUHS/DOD, Role: Principal Investigator

Grant Title: HIV-1 Fusion Cofactors  
Grant Number: R01 AI043885  
Grant Period: 07/15/98-01/31/11  
Total Direct: \$2,167,550 Agency: NIH/NIAID, Role: Principal Investigator

Grant Title: Analysis of Oligomeric HIV-1 Envelope Glycoproteins  
Grant Number: R21 AI42599-01

Grant Period: 11/01/97-10/31/00-expiring  
 Total Direct: \$300,000 Agency: NIH/NIAID, Role: Principal Investigator

Grant Title: HIV-1 Envelope-CD4-Coreceptor Complexes as Vaccines  
 Grant Number: R21 AI47697-01  
 Grant Period: 7/01/00-6/30/02  
 Total Direct: \$300,000 Agency: NIH/NIAID, Role: Principal Investigator

Grant Title: Program title: Broadly Effective Neutralization and CTL against HIV-1  
 Project 2 title: HIV-1 gp140 Oligomers as Vaccine immunogens  
 Grant Number: PO1 AI48380  
 Grant Period: 09/01/01-06/31/06  
 Total Direct: \$1,261,561 Agency: NIH/NIAID, Role: Principal Investigator, Project 2

Grant Title: Nipah Virus and Hendra Virus Subunit Vaccines  
 Grant Number: R21 AI065597  
 Grant Period: 07/01/05-06/30/07  
 Total Direct: \$275,000 Agency: NIH/NIAID, Role: Principal Investigator

Grant Title: Nipah Virus and Hendra Virus Peptide Therapeutics  
 Grant Number: U01 AI056423  
 Grant Period: 09/15/03 – 08/01/08  
 Total Direct: \$2,025,326 Agency: NIH/NIAID, Role: Principal Investigator

Grant Title: Biodefense and Emerging Infectious Diseases Research: (MARCE)  
 Program II: Emerging Virus Entry into Host Cells: Strategies for Inhibition  
 Project II-3: Hemorrhagic Fever Viruses / Australian Bat Lyssavirus Tropism Entry and Host Factor Dependence  
 Grant Number: 2U54 AI057168  
 Grant Period: 08/01/03 – 02/28/14  
 Total Direct: \$1,661,546 Agency: NIH/NIAID, Role: Principal Investigator, Project II-3

Grant Title: Characterization of the Envelope Glycoproteins of Beilong and J-virus  
 Grant Number: R073NN  
 Grant Period: 10/01/06-09/30/09  
 Total Direct: \$60,000 Agency: USUHS/DOD, Role: Principal Investigator

Grant Title: Emerging Viruses and Host Cell Interactions in Bats  
 Grant Number: R073SA  
 Grant Period: 10/01/09-09/30/12  
 Total Direct: \$60,000 Agency: USUHS/DOD, Role: Principal Investigator

Grant Title: High Potency HIV-1 Broadly Cross-Reactive Neutralization  
 Grant Number: U01AI078412  
 Grant Period: 04/01/2008 – 03/31/2013  
 Total Direct: \$3,000,000 Agency: NIH/NIAID, Role: Co-Principal Investigator

Grant Title: Vaccines and Therapeutics for Nipah and Hendra virus  
 Grant Number: U01AI077995  
 Grant Period: 06/01/2008 – 8/31/2014  
 Total Direct: \$5,617,562; Agency: NIH/NIAID, Role: Principal Investigator

Grant title: Development of sG as a human vaccine against Nipah/Hendra  
 Principal Investigator: T. Fouts, A. Dimitrov / Co-PI: Christopher C. Broder, Ph.D., Subaward.  
 Period: May 1, 2012 to April 30, 2017  
 Total Direct: \$225,000; Agency: NIH/NIAID, Type: 1R01AI098760-02.

Grant title: Preclinical Development of m102.4, a Human Anti-Hendra and Nipah Antibody  
 Principal Investigator: T. Fouts, A. Dimitrov / Co-PI: Christopher C. Broder, Ph.D., Subaward.  
 Period: May 1, 2011 to April 30, 2016  
 Total Direct: \$225,000; Agency: NIH/NIAID, Type: 1R01AI093346-03.

Grant Title: Nipah & Hendra virus Nonhuman Primate Model & Therapeutics Development  
 Grant Number: U01 AI182121  
 Grant Period: 03/15/2009 – 02/28/2015  
 Total Direct: \$6,940,076. Agency: NIH/NIAID, Role: Co-Principal Investigator (with T. Geisbert, UTMB).

Grant Title: Analysis of the entry and egress of Cedar virus a new species of Henipavirus  
 Grant Number: R0732012  
 Grant Period: 10/01/12-09/30/15  
 Total Direct: \$60,000 Agency: USUHS/DOD, Role: Principal Investigator

Grant Title: Identification, Countermeasures, and New Therapies Toward Biological Threat Agents;  
 Component Project: Soluble Trimeric Filovirus Envelope Glycoproteins  
 Grant Number: #HT9404-13-1-0021  
 Grant Period: 10/01/14-03/31/17

Total Direct: \$78,085. Agency: BDRD/NMRC (DoD), Role: Component Project PI (with J. Czarnecki, NMRC)

Grant Title: Therapies for Neurotropic Viral Biothreat Pathogens

Grant Number: PPG. HT9404-13-1-0008

Grant Period: 10/01/13 – 9/30/17

Total Direct: \$1,950,882.

Agency: USUHS, Role: Component Project PI (with B. Schaefer, USU)

Grant Title: Nipah Virus and Hendra Virus Entry and Virion Assembly

Grant Number: R01 AI054715

Grant Period: 04/01/06-09/30/18

Total Direct: \$2,225,000 Agency: NIH/NIAID, Role: Principal Investigator

Grant Title: A Recombinant Cedar Virus-based Henipavirus Replication Platform for High-throughput Inhibitor Screening

Grant Number: R21 AI137813

Grant Period: 04/01/18-03/31/20

Total Direct: \$275,000 Agency: NIH/NIAID, Role: PI

Grant Title: Chulalongkorn Luminex Training and Research Preparedness

Grant Number: DTRA STEP HDTRA1-17-C-0019

Grant Period: 01/05/19 – 06/01/19

Total Direct: \$195,178; Agency: DTRA, DoD, Role: PI

### INVITED LECTURES (>100):

**1994.** Department of Pathology and Lab Med., University of Pennsylvania, Jan 13. ***"HIV-1 Envelope Glycoprotein Mediated Cell Fusion: Structural Features of CD4 and Involvement of Accessory Components"***.

**1994.** GSF-Forschungszentrum für Umwelt und Gesundheit, GmbH, Neuherberg. Institut für Molekulare Virologie, Oberschleißheim, Germany. Current Advances In Molecular Biology Seminar Series. Aug 10. ***"Factors Associated with the Selective Fusogenic Activities of HIV-1 Envelope Glycoproteins for Specific CD4+ Cell Types"***.

**1995.** Department of Microbiology, campus-wide series. University of Pennsylvania Feb 22. ***"Molecular Characterization of Viral Glycoprotein Mediated Membrane Fusion"***.

**1996.** 3rd International Workshop on HIV and Cells of Macrophage Lineage. Villa Monastero, Piazza Venini, Varenna, Italy. Oct 17. ***"HIV Tropism: Distinct Accessory Fusion Factors for Different CD4+ Cell Types"***.

**1998.** Molecular Basis of Disease / Molecular and Cellular Biology Program, Medical College of Ohio, Health Education Building, Toledo, Ohio. February 17. ***"HIV: Envelope Glycoprotein and Membrane Receptors"***.

**1999.** Division of Retrovirology, WRAIR, Dec 10. ***"HIV Envelope and Virus Entry"***.

**2000.** Division of Viral Products, seminar series-CME credit approved, CBER, FDA, NIH, Bethesda, MD. February 24. ***"HIV-1 Envelope Glycoprotein: Receptor Interactions and Refined Subunit Immunogens"***.

**2000.** Center for Immunology & Microbial Disease, CME approved. Albany Medical College, Albany New York. March 27. ***"HIV-1 Envelope Glycoprotein-Receptor Interactions and new Subunit Immunogens"***.

**2000.** 2nd Frederick Workshop on the Cell Biology of Viral Entry. May 7-10, NCI-FCRDC, Frederick, MD, Invited Chair, Session I: ***"Virus-Receptor Interactions and Entry"***.

**2001.** Indiana University School of Medicine, Department of Microbiology, Indianapolis, IN, Mar 15. ***"Virus-Receptor Interactions: Tropism, Entry, and Refined Subunit Immunogens"***.

**2001.** Department of Microbiology, campus-wide seminar series-CME credit approved. University of Pennsylvania School of Medicine, Philadelphia, PA. October 3. ***"Functional and Structural Studies on Hendra and Nipah viruses - Newly Emerging and Highly Lethal Zoonotic Paramyxoviruses"***.

**2002.** 2nd Collaborative Research Seminar on HIV and other Viral Entry Inhibitors. New York, NY. May 5. ***"Hendra and Nipah Viruses – Newly Emerging and Highly Lethal, Zoonotic Paramyxovirus Threats"***.
