Title: Establishment of a Bat Resource for Infectious Disease Research

Major Goals: The major goals of this proposal is to contribute significant insight into the viral determinants that confer henipaviral pathogenesis. The construction and generation of recombinant henipavirus chimeric viruses will be the primary means for determining how virus receptor usage and the expression of virulence factors act individually or in conjunction to cause limited or severe disease. The recombinant constructs generated from the proposed studies will also be used to determine host determinants of immunity in Jamaican fruit bats and animal models.

OVERLAP

In my role on this project, titled: Immune memory bait & capture to identify emerging henipavirus origins, I will be providing mentorship and my group will be providing recombinant antigenic material for multiplex serologies and our expertise in virology and assay development and interpretation to the PI and Co-PI. These research activities and mentorship overlap with my present role as a co-investigator within the EID-SEARCH center.

I, PD/PI or other senior/key personnel, certify that the statements herein are true, complete and accurate to the best of my knowledge, and accept the obligation to comply with Public Health Services terms and conditions if a grant is awarded as a result of this application. I am aware that any false, fictitious, or fraudulent statements or claims may subject me to criminal, civil, or administrative penalties.

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) are bat-borne zoonotic viruses and cause high mortality. The recent detection of closely related Mojiang and Langya viruses in rats and shrews, and isolation of Langya virus from individuals with acute febrile illness, challenges the dogma that fruit bats are the sole henipavirus reservoirs. The recently expanded <i>Henipavirus</i> genus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. As part of EID-SEARCH activities, we found serological evidence of infection by a Mojiang-related virus in a community of Thai bat guano collectors who have occupational exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to identify novel viruses and zoonotic reservoirs through serologic and cellular immune discovery. We will conduct follow-up human and wildlife (shrews and rodents) surveillance in the province where the seropositive humans were identified and apply an expanded serological test and genomic sequencing to detect this novel MojV-like henipavirus. Further, we</p>

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

plan to isolate anti-MojV monoclonal antibodies (mAb) from peripheral blood mononuclear cells collected from human study participants we have identified as immunoreactive with MojV antigens, and characterize the cross reactive and cross neutralizing potential of these mAbs to LayV.

Study Personnel

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as mentor for Dr. Srimuang and Mr. Sterling under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Laing is an assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses at Uniformed Services University, Bethesda, MD. Part of Dr. Laing's research focus in on the development of serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Dr. Laing has worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Through these collaborations, Dr. Laing's research group aims to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence.

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Specific Aims

The recent discovery of novel shrew and rodent-borne henipaviruses in East and Southeast Asia has highlighted gaps in our understanding of henipavirus transmission and underscores the importance of surveillance activities in the region. In particular the isolation of Langya virus from acutely ill humans and shrews demonstrated the need to further surveillance and therapeutic development against emergent henipaviruses. Therefore, this project aims to expand the study of known reservoirs of zoonotic pathogen origin by using genetic and serologic techniques, and to use cellular immune discovery in seropositive humans as a tool to determine henipaviral antigenic relatedness to assist with the functional assessment of current therapeutics as and their effect on these novel viruses.

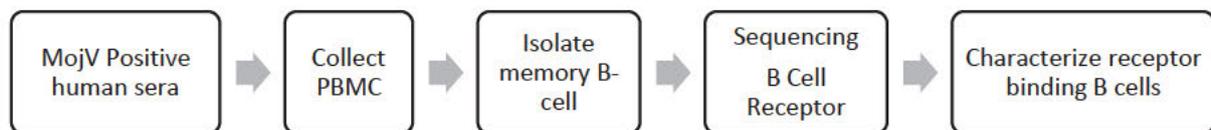

In our study, we detected that a high seroprevalence against MojV in human participants near the Khao Chong Phran Non-hunting Area in Ratchaburi province who we identified as representing a high risk population for zoonotic spillover. Yet, no virus sequences were detected. We hypothesize that (i) there is a novel henipavirus present in the local wildlife population that has spilled over into the human population at least once, and (ii) the antibodies from these seropositive people will react with the novel shrew-borne henipaviruses in a way that can inform us on therapeutic approaches for future outbreaks. We will follow-up with persons who had high anti-MojV IgG levels, sample new participants within this community who interact with the local wildlife, and sample shrews and rodents to identify the wildlife source of the MojV-like henipavirus. Additionally, in collaboration with NIH VRC PREMISE, MojV receptor binding protein (RBP) and fusion protein-reactive B cell will be isolated from previously-identified seropositive human participants. MojV-like virus-specific B-cell receptors will be sequenced and monoclonal antibodies specific to the infecting MojV-like virus RBP and F protein will be generated and tested for cross reactivity against presently described rodent associated henipavirus envelope glycoproteins, and cross neutralization against Langya virus.

The proposed project has two Aims:

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

The proposed project has two Objectives:

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Objective 2. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody discovery.

Study Rationale

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McLinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022) (Table 1). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genera of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, GAKV and DARV were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The henipaviral genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australia (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected 19% (54/284) seroprevalence for MojV in a high-risk cohort, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further

Identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

East and Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia and likely due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology (serologic and cellular) to identify a novel virus that can aid in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

Animal samples collection

200 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province (Figure 1) will be collected for surveillance targeting the Mojiang-like virus. We plan two sampling trips to collect target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect up to 200 samples and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored. Oral swab and rectal swab will also collect in 200 shrews or rodents. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

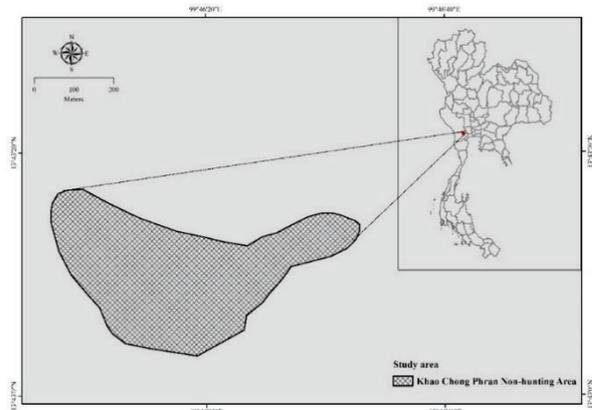

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Human surveillance

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, 100 human serum samples, nasopharyngeal swab and throat swab will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,150 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

We will target a total of 200 individuals of shrews and/or rodents across two trips for this project. This sample size is estimated based on a realistic detection rate and required sampling efforts from previous wildlife surveillance work, given the rodent/shrew population at the study site. Previous publications regarding Henipavirus discovery in small mammals had an average PCR detection prevalence between 20 and 33% (Wu et al., 2014, Lee et al., 2021, and Zhang et al., 2022). We acknowledge the challenge of identifying positive results, and very limited serology research has been done to provide guidance. However, we will make the best use of previous data and experience to conduct sampling at the selected site where human positives have been. We are confident that this targeted sampling and testing strategy offers the best chance to identify positive results and potentially novel henipaviruses.

Targeted viral sequencing and serologic testing

Targeted sequencing

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The nucleic acid from oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing.

Serological testing

Serum samples will be tested for RBP and envelope fusion protein (F) binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Data analysis

Sequencing will be analyzed assembling reads in MEGA11. The consensus sequences will compare to the references strains available in the GenBank data-base using the Basic Local Alignment Software Tool (BLAST) (National Center for Bio-technology Information). Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to LayV RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipas, and LayV, depending on how well these cross react.

Target human population

Human positive serum for MojV was found close to Khao Chong Phran Non-hunting Area in Ratchaburi Province (Figure 2).

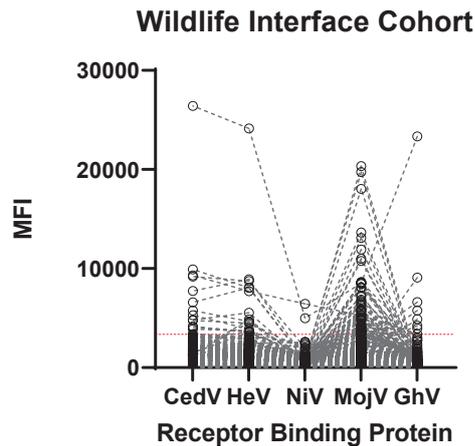

Figure 2: Seroprevalence of henipavirus proteins from a community with a large wildlife interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, a threshold for seropositivity.

PBMC sorting and B cell isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes). Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3⁺, CD14⁻, CD56⁻, IgM⁻, IgA⁻, CD19⁺, CD20⁺, CD27⁺). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will be synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor Amplicon Preparation and Recombinant Antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced. After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

We will first determine the extent to which isolated mAbs can bind binding to native-like MojV RBP and F proteins. We will also characterize the cross-reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. However, MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of MojV neutralizing potential is not possible. Though, we will test the cross-neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV utilizing a plaque reduction neutralization test with EID-SEARCH co-investigators at Duke-NUS. As LayV causes acute illness in human, cross neutralization functionality of these mAbs has therapeutic potential.

Research Performance Sites

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country. We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

CREID Research Center Collaboration

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. Further, Dr. Doeuk who is the director of the VRC PREMISE program is enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Ig) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Mentoring Plan

Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant writing and project management skills. My professional relationship Dr. Wacharapluesadee with began in 2018 when I participated in a DTRA BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group. Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally,

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Vertebrate Animals Section Requirements

Animal samples will be collected in Ratchaburi Province for this project under Aim 1 to understand the antigenic relationships among known and unknown henipaviruses. Protocol to perform animal sample collection has been reviewed and approved by the Institutional Animal Care and Use Committee at Tuft University under the EID-SEARCH project (No. G2020-42) and the Institutional Animal Care and Use Committee at Chulalongkorn University (No. 019/2563)

1. Description of Procedures

Rodents (order: *Rodentia*) and Shrew (order: *Scandentia* and *Eulipotyphla*)

- Species: Free-ranging rodents (family *Hystricidae*, *Muridae*, *Sciuridae*, *Spalacidae*) and shrew (tree shrews, shrews, moles) that present at the sites.
- Age & sex: Adults and juveniles, males and females. Neonates will not be sampled.
- Target Number: 200 individuals
- Capture and Restraint: Free-ranging wild mammal species will be captured with metal box traps (Sherman/Tomahawk traps). Traps will be prepared with food, water, padding and shelter, and be checked at least every 12 hours, in the morning and in the afternoon. If adverse weather (extreme heat, rain) is expected or researchers are working in areas where predation is common, traps will be checked more frequently and closed during adverse weather. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. Depending on the species, individual size, captive or free-ranging status of the individual, manual or chemical restraint and anesthesia (gas or injectable anesthesia) will be applied. Animals will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and animal. Based upon past field experience (>20 years of animal capture and release in Southeast Asia), we do not expect to trap sick, debilitated, or young animals that would be too young to cope with capture. Sick and debilitated animals tend not to roam widely, reducing their opportunity to enter traps. Additionally, should sick, debilitated, or young animals enter traps, we anticipate that they will not suffer adverse conditions because the traps contain food (the bait) and liquid (water or fruit as a source of water). These individuals would be examined by a veterinarian, rehydrated and if presenting clinical signs treated by a veterinarian, prior to release or sampling then release.
- Sample Collection: Once anesthetized or safely restrained, whole blood will be collected through the appropriate venipuncture site, no more than 1 ml of blood per 100 g (= 10 ml/kg or 1%) of body weight will be collected at any one time. Anesthetized animals will be monitored regularly during recovery until they can no longer be safely handled, at which point they will be confined in a trap or cage. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected.
- Release: Wild mammals are held for a maximum of thirteen hours depending on trap timing, but typically less than three hours. Captive animals are held for a maximum of two hours but typically less than one hour. At the completion of sampling, animals may be provided with rehydrating fluids (either subcutaneously if anesthetized or orally if manually handled and accepted). Wild mammals will be released at the site of capture in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided). Captive mammals will be released back into their captive setting as is appropriate for the species, either isolated or in social group if it is deemed safe from aggression from enclosure mates while the post-recovery period continues.

2. Justifications

The purpose of this study is to identify zoonotic pathogens through serologic and cellular immune discovery, including developing methods and standards for direct antibody-mediated virus capture in people and wildlife, focusing on rodent/shrew-borne Henipaviruses (HNVs). This will require hands-on fieldwork to collect whole blood and serum samples from rodents and shrews for lab analysis. One technique that avoids the direct capture and sampling of animals is to collect fresh feces or urine, but this will not be able to provide the appropriate samples for serologic analysis, and the research objectives cannot be achieved using an alternative methods (e.g., computational, human, invertebrate, in vitro). Therefore, we believe there are no viable alternatives than the use of live animals.

3. Minimization of Pain and Distress

In every situation, sampling of wildlife will be conducted in the most humane manner while minimizing the impacts on individual animals and their wild populations. In all instances, the fewest number of animals will be sampled that will provide valid information and statistical inference for the pathogen and disease of interest and every effort will be made to minimize stress and discomfort for the animal.

Small mammals may be held for up to 13 hours depending on trap capture timing. Field animal sampling team with zoologists and veterinarians have been well trained and have extensive experience in capture, anesthesia, and sampling of wildlife. In our team's experience, the target species tolerate the described procedure well. Mist nets will be attended continuously during capture periods. This will minimize stress and injury from entanglement.

For rodents and shrews, food, water, padding and shelter will be provided at traps, which will be checked at least every 12 hours. Traps will be checked more frequently or closed if adverse weather (extreme heat, rain) is expected, or researchers are working in areas where predation is common. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. All animal individuals will be monitored by a veterinarian or experienced field team member during all stages of capture, processing, anesthesia and release. Animals will be kept in a cool place, free from adverse weather conditions and access by non-field team members or other animals while in the pillowcases, trap, or cage for recovery. All recovering individuals will be observed until they are able to effectively ambulate and orient to their surroundings. Animals that are injured during the capture or sampling process will be assessed by an experienced team leader or attending veterinarian, and if the animal is determined to be unlikely to survive if released, it shall be euthanized humanely (see euthanasia section).

4. Method of Euthanasia

In the event that an animal has been injured or is moribund, a determination will be made as to whether it may be treated and released on site by veterinarians or transferred to facility that may treat and rehabilitate the animal, or if, as a last resort, the animal will require euthanasia. Euthanasia methods will vary depending on species; however methods to be used will not deviate from the AVMA "Guidelines for the Euthanasia of Animals" (2020 edition). Any animal that is euthanized using a chemical agent will be disposed of such that it will not be permitted to enter the food supply either through markets or hunting.

Human Subjects Research

1. Risks to the subjects

In this project, we will target populations in one community site who with frequent exposure to bats and other wildlife based on our previous behavioral survey. Subjects will be enrolled voluntarily, and informed consent will be obtained from all participants. Enrolled participants will provide biological samples. Survey data and biological samples will be collected from enrolled participants, and follow-up data collection will be performed among participants whose samples were tested positive.

Biological samples and questionnaire data will be collected from individuals who meet recruitment and inclusion criteria and complete the informed consent process. During data collection, a standardized questionnaire will be administered to all participants. This questionnaire will collect information of demographic background, wildlife contact, travel and daily movement, and unusual SARI/ILI symptoms, and biological specimens will be collected from participants. Both questionnaire and biological data will be analyzed to assess the exposure to coronaviruses and the spread risk among humans. From all participants, a one-time whole blood sample (Max. 15 mL) will be collected during the study period. This sample will allow us to test for historical exposure to bat or rodent-born henipaviruses and collect Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive.

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals who are proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions; however, the administration will be conducted privately and confidentially to protect individuals' health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

2. Adequacy of protection against these risks

2.1 Informed consent and assent

Only consented participants will be enrolled in the study. No research procedures will be undertaken before the participant fully understands the research, agrees to the study procedures, and completes the consent process will be enrolled in the study. Informed consent statements and forms, and project protocols will be translated into the local language of each study site. Research team members involved in this consent process will be required to be fluent in the local language to ensure that the subjects understand the study and all involved procedures.

If participants meet the criteria for enrollment, they will be invited to discuss the details of the study with the research staff. Study staff will review an information sheet and informed consent form with the participant when applicable. Each individual will be provided with a copy of the informed consent form that has been translated into the local language and written with a Flesch–Kincaid readability score equivalent to a 7th-grade reading level or below, to assure that potential participants understand the information being shared. The informed consent form will explain the details of the study, including how and why the individual was selected, the study process and procedures, risks and benefits, financial considerations and the gift of appreciation, confidentiality of data shared, alternatives to participating, and how to obtain more information now or at a later date. The informed consent form will be read in the local language of the site at a location ensuring participant privacy. After which individuals will have as much time as they would like to ask questions and discuss the

study with study staff. The study staff will endeavor to ensure that the participant understands the information provided. The study staff will then ask the participant to consider study participation. Participants will have as much time as required to consider the participation.

Those participants who consent to the study will sign and date two copies of the consent form. These form copies will be countersigned and dated by the study staff. A copy of the signed consent form must be provided to the subject and the other copy will be kept by study staff. Informed consent paperwork will be kept until the end of the project in a locked box at the local country project office.

2.2 Protection against risks

The potential risks to study participants as a result of study participation are minimal. Collection of venous blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. Potential complications associated with venipuncture include pain and/or hematoma at the site of collection. Trained medical professionals and/or clinic staff will monitor the blood collection site and treat any complications according to existing health facility protocols. A potential complication of nasal/ oropharyngeal sampling is minor irritation at the time of collection. Employing trained medical and/or clinic staff to collect blood and swab samples will minimize the potential for complications.

Another risk that this study may pose concerns the information to be gained on henipaviruses newly recognized in the community. We will provide participating communities, hospitals, and clinicians with information and background data on target zoonotic viruses to ensure up-to-date communication of risk. Because of the timeline for diagnostic testing and results interpretation, we are not likely to provide results to participating clinics within a time frame that would be clinically relevant to outbreaks of undiagnosed diseases. Therefore, the information provided by this project will not impact patient management or outlook.

If an individual decides to participate in this research, his/her participation and all information provided by the participant will be strictly confidential, and personal identifying information will not be shared with anyone outside of the study staff. Participants will not be identified or named in any reports or publications. Questionnaire information and all biological samples will be identified by an alphanumeric code, not by the participant's name. All records that contain names or other personal identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the study site in locked files cabinets or password-protected devices in areas with access limited to the research staff of this project. Research databases will be secured with password-protected access systems and controlled distribution web-based certificates and will not contain any identifying characteristics about study participants (e.g., name, address, or telephone number). Access to all data will be limited to the staff involved in this study. The health information disclosed by an individual will not be used by or disclosed (released) to another institution. Any surveillance report that is published or shared with partners will not contain any personally identifying information for individual participants.

3. Potential benefits of the research to the subjects and others

There are no measurable benefits to the individual study participants enrolled in this study. There are benefits to the community and regional healthcare providers to help them understand the risk of zoonotic infections among high-risk populations in the regions they work. At the conclusion of the study, we will deliver an educational workshop reporting aggregate study findings that will be open to both study and non-study participants, describing the health benefits of using personal protection equipment (PPE) and handwashing during animal handling activities throughout the day, as well as to share other prevention/interventions that emerge from the research data.

4. Importance of the knowledge to be gained

There are valuable potential benefits to the public from the knowledge to be gained from this study. One key benefit to the community is sharing information and knowledge to better understand the risk of zoonotic spillover events and related health risks, as well as information sharing with communities on practices that could reduce risks, such as the avoidance of particular animal contacts or the need for PPE and extra care when handling wildlife, that may substantially reduce the risk zoonotic pathogen transmission in the community. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to create or implement public health interventions to disrupt disease emergence and/or spread in an area that is beneficial to all. Additionally, there are valuable benefits to the general public from the knowledge to be gained from this study. Knowledge gained will increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

5. Country- / institution-specific ethics / IRB regulations addressed

Main research protocol and materials to conduct human subject research in this project have been reviewed and approved by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64). Amendment for PBMCs collection will be made and approved before the start of this project.

POSITION TITLE: Research Scientist

EDUCATION/TRAINING (Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Chulalongkorn University, Bangkok, Thailand	B.Sc.	03/2012	Medical Technology
Mahidol University, Bangkok, Thailand	Ph.D.	04/2017	Molecular Tropical Medicine and Genetics

A. Personal Statement

I am a medical technologist. My undergraduate training has provided me with a background in multiple biological disciplines including molecular biology, microbiology, and genetics. During my Ph.D., I conducted research with Dr. Mallika Imwong focused on Malaria. My thesis was entitled "Exploring the molecular mechanism of mefloquine resistance in *Plasmodium falciparum*". I conducted research on drug resistance to malaria in Southeast Asia. Specifically, my focus was on molecular techniques in identifying the genetic mutations involved with drug resistance. Moreover, I got experience in *Plasmodium falciparum* malaria culture. After my Ph.D., I worked at the genetics laboratory at Jetanin Institute of Assisted Conception. My responsibilities included Preimplantation Genetic Testing (PGT) is screen embryos for genetic abnormalities such as chromosome copy number gains or losses (PGT-A, aneuploidy screening), single gene disorders (PGT-M, monogenic or single-gene disease), or structural rearrangement (PGT-SR, structural rearrangement to identify embryos with chromosome imbalanced) by using Next Generation Sequencing. Additionally, I conducted genetic screening in couples for detecting carrier diseases such as glucose-6-phosphate dehydrogenase (G6PD), Alpha thalassemia, Beta thalassemia, and Spinal muscular atrophy (SMA) by using molecular genetics techniques. Currently, I am a Research Scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC EIDCC), King Chulalongkorn Memorial Hospital where I investigate emerging infectious diseases under the guidance of Dr. Supaporn Wacharapluesadee. The research focuses on detecting, identifying, and characterizing pathogens and human genome segments using molecular and serology techniques, including Next Generation Sequencing and Multiplex serology assays as a part of EID-SEARCH project. Additionally, I am the laboratory sequencing lead on the Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) project from patients in Thailand as part of a collaboration with the Department of Disease Control.

B. Positions, Scientific Appointments, and Honors

Positions and Scientific Appointments:

02/2022 – Present	Medical research scientist, Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital
05/2017 - 01/2022	Scientist, Genetics Laboratory, Jetanin Institute for Assisted Reproduction
10/2015 - 03/2016	Fellowship at Laboratory of Molecular and Cellular Parasitology, Department of Microbiology and Immunology, National University of Singapore, Singapore.
11/2011 – 02/2012	Training Medical Technology Programs at Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Honors:

2012 -2017	Scholarship for Ph.D. from the Royal Golden Jubilee, Ph.D. Grant (14th Batch).
------------	--------------------------------------------------------------------------------

C. Contributions to Science

Undergraduate Research: I participated in research activities under Dr. Attakorn Palasuwan to study in human genetic variants in proteins, such as G6PD, as they relate to the effect of exercise on the reduction of free radicals in the body. We conducted the multiplex PCR to identify the G6PD variants and found 8 variants including Vanua Lava, Mahidol, Mediterranean, Coimbra, Viangchan, Union, Canton, and Kaiping.

Graduate Research: I continued to studies under Dr. Mallika Imwong in the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University. My thesis, "Exploring the molecular mechanism of mefloquine resistance in *Plasmodium falciparum*", focused on the evolution of resistance to mefloquine, which is commonly used in Southeast Asia in Malaria treatment. The mechanism of mefloquine resistance remains unknown, but I focused on the *Pfmdr1* gene which is involved in the drug resistance mechanism in *Plasmodium falciparum*. I found mutations and polymorphisms in *Pfmdr1* gene.

Post-graduate Research: I was a scientist in genetics lab at Jetanin, a holistic center for infertility, offering counseling and treatment with Assisted Reproductive Technologies such as IVF, ICSI, and Preimplantation Genetic Testing (PGT). My work included the development of standard operating procedures for the lab, including Next Generation Sequencing, for detecting and identifying chromosomes in blastocyst growth to an embryo. Additionally, we assisted couples who had a family history of genetic diseases for screening before pregnancy. The carrier screening focused on highly prevalent diseases in Thailand such as alpha thalassemia, beta thalassemia, G6PD, and SMA. Currently, I am a Research Scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital. I am currently tasked with using molecular and serological techniques in the surveillance of novel, exotic, and known pathogens in wildlife and humans.

A. Personal Statement

As a current employee with Dr. Eric Laing under his emerging infectious diseases research program. My academic training and research experience have provided me with a background in molecular biology, virology, and epidemiological techniques for zoonosis investigations. As part of my original post-baccalaureate work, I worked in a small team lead by Dr. Chris Border tasked with developing a serological binding assay for Coronaviruses, Filoviruses, and Henipaviruses. During this process, I worked closely with Dr. Laing and scientists from multiple Asian countries in developing and applying the multiplex techniques for rapid, high-throughput serological assays. Throughout this time, I have led technical and data analysis trainings in Cambodia, Bangladesh, and Thailand, and have assisted collaborators in Singapore, Malaysia, Australia, India, South Africa, and the United Kingdom in implementing these novel techniques. Currently, I am a visiting scientist with Dr. Supaporn Wacharapluesadee in the Emerging Infectious Diseases Clinical Center at King Chulalongkorn Medical Hospital as part of the CREID-EID SEARCH program.

B. Positions, Scientific Appointments, and Honors

05/22-present Visiting Scientist, King Chulalongkorn Medical Hospital, Bangkok, Thailand. Advisors: Dr. Supaporn Wacharapluesadee, Dr. Opass Putchaeron, and Dr. Eric D. Laing.

02/22-present Scientific Project Coordinator, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisors: Dr. Christopher C. Broder and Dr. Eric D. Laing

- 08/20-02/22 Research Associate 2, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 08/19-08/20 Senior Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 06/15 – 08/19 Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 01/14-08/14 Laboratory research internship, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder

C. Contributions to Science

1. **Post-Baccalaureate:** My post-baccalaureate research works primarily targeted understanding the adaptive immune response to emerging zoonotic viruses as a tool for virus discovery. As part of the assay development team, I designed and expressed soluble, native-like filovirus and henipavirus attachment glycoproteins and developed the monoclonal antibodies and antisera used as standards in the assay. I have led technical training for international projects and assisted in data analysis
 - a. Laing ED, Mendenhall IH, Linster M, Low DHW, Chen Y, Yan L, **Sterling SL**, et al. “Serologic evidence of fruit bat exposure to filoviruses, Singapore, 2011–2016”. (2018). *Emerg Infect Dis.* 24(1):114-117. doi: 10.3201/eid2401.170401. PMID: 29260678.
 - b. Schulz JE, Seifert SN, Thompson JT, Avanzato V, **Sterling SL**, et al. “Serological evidence for henipavirus-like and filovirus-like viruses in Trinidad bats.” (2020) *J Infect Dis.* pii: jiz648. doi: 10.1093/infdis/jiz648. PMID: 32034942.

2. **Professional Studies:** While employed, I continued my studies by pursuing a Master’s in Public Health with a focus on Epidemiology. Immediately preceding my thesis work, COVID-19 was declared a pandemic, and I worked along side Dr. Eric Laing to develop and standardize a human coronavirus serological panel to track the serological response to SARS-CoV-2 infections and vaccinations among a military cohort. For my thesis, I evaluated the humoral immune response to SARS-CoV-2 patients as it related to the severity of the disease, where we observed significantly more robust antibody responses in people with more severe disease.

Uniformed Services University, Bethesda, MD	Postdoc	04/2019	Virology

A. Personal Statement

The spillover of zoonotic viruses into human populations remains an ever-prevalent threat to public and global health. Continual outbreaks of known and unknown zoonotic viruses highlights the paucity of our understanding of the viral diversity, geographic distribution, wildlife hosts, and human populations at-risk for spillover. I am a recently appointed assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses. I have completed virological training and spent my time as a post-doctoral fellow applying *in vitro* techniques to characterize the replication of, and mammalian ephrin receptors that mediate cellular entry of emergent henipaviruses. Since the start of the COVID-19 pandemic, I pivoted the focus of my research team to serological analysis of SARS-CoV-2 infection, and then to COVID-19 vaccine-induced antibody durability. In my ongoing research, I develop serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Since my position as a postdoctoral fellow I have worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Across all of these collaborations, we have aimed to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence. Throughout these research projects, we have detected unexpected serological profiles in communities of bats and humans that have not fit our prior understanding of the viral diversity established or detected by genetic techniques. This proposal aims to better understand these serological profiles of wildlife and humans with a targeted focus on henipaviruses and filoviruses. Ongoing projects that I would like to highlight include:

- HDTRA12110037. DTRA BRTP, E. Laing (Co-PI). 08/2021-07/2026, “Informing biosurveillance, contribution of pteropodid fruit bats to virus spillover in the Philippines.”

B. Positions, Scientific Appointments and Honors

Positions

- 2021-pres. Assistant Professor, Department of Microbiology and Immunology, School of Medicine, Uniformed Services University, Bethesda, MD.
- 2021-pres. Joint Appointment, Emerging Infectious Diseases Graduate Program, School of Medicine, Uniformed Services University, Bethesda, MD.
- 2019-21 Research Assistant Professor, Department of Microbiology and Immunology, Uniformed Services University, Bethesda, MD.
- 2016-19 Postdoctoral fellow, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD.
- 2010-16 Graduate research student, Department of Microbiology, Uniformed Services University, Bethesda, MD.

Other Experiences and Professional Memberships

- 2022-pres. Executive committee member, Emerging Infectious Diseases Graduate Program, USUHS
- 2021-pres. Research center representative, Laboratory Assays Oversight and Quality Working Group, Emerging Infectious Diseases: Southeast Asia Research Collaboration Hub (EID-SEARCH), Centers for Research in Emerging Infectious Diseases (CREID), NIAID, DMID, NIH
- 2021-pres. Review editor, *Frontiers in Virology - Emerging and Reemerging Viruses*
- 2021-pres. Ad hoc reviewer, *Frontiers in Immunology*, *Journal of Clinical Immunology*
- 2021-pres. Steering committee member, JPI/Military Infectious Diseases Research Program, Emerging Infectious Diseases
- 2019 Ad hoc reviewer, EcoHealthNet 2.0 Program, EcoHealth Alliance
- 2018 Ad hoc reviewer, Pakistan One-Health Fellowship Program, National Academy of Sciences & Pakistan Academy of Sciences
- 2014-2019 Member, American Society of Tropical Medicine and Hygiene
- 2014-2019 Member, American Society of Microbiology
- 2014-2019 Volunteer, AAAS STEM K-12 Volunteer Program

Mentoring

- Postdoctoral fellows* Si'Ana A. Coggins, PhD, 2020 - 2022
- Graduate students* Marana S. Tso, BS, 2021 -
McKenna Roe, BS, 2022 -
- Committee member* Celeste Huaman, BS, 2021 -
2LT Connor Perry, BS, 2021 -

Honors

- 2021-2022 Impact Award, USUHS School of Medicine
- 2021 Outstanding Research Accomplishment/Team/SARS-CoV-2, The EPICC COVID-19 Cohort Team, Military Health System Research Symposium
- 2020-2021 Impact Award, USUHS School of Medicine
- 2015-2016 Val G. Hemming Fellowship, Henry M. Jackson Foundation
- 2015 East Asia and Pacific Summer Institutes Fellowship, National Science Foundation

C. Contributions to Science ([†]mentee, *corresponding)

1. Lyssaviruses and the prototype, rabies virus, remain a public health concern. Beginning with my PhD thesis work, I've researched the virus host-interactions between a rabies-related lyssavirus, Australian bat lyssavirus (ABLV), and its bat host (*Pteropus alecto*). Research has focused on ABLV cellular entry mechanisms, the development of an animal model and ABLV reporters and exploration of novel monoclonal antibodies that neutralize ABLV and other phylogroup I lyssaviruses. Furthermore, comparative bat immunology research was conducted using black flying fox cell lines and ABLV as a model virus/host interaction. Physiological adaptations that accompanied the evolution of flight in bats have been proposed to contribute to the frequent role of bats as asymptomatic hosts of highly pathogenic zoonotic viruses.

Comparatively studying the autophagy pathway in bat cell lines revealed that bat cells had elevated levels of basal autophagy and experienced significantly less cell death when challenged with high virus doses.

- a. Weir D. L., **Laing E.D.**, Smith I.L., Wang L.F., and C. C. Broder. Host cell entry mediated by Australian bat lyssavirus G envelope glycoprotein occurs through a clathrin-mediated endocytic pathway that requires actin and Rab5. *Virology*. 2013. 11:40. doi: 10.1186/1743-422X-11-40. PMID: 24576301, PMCID: PMC3946599
- b. **Laing E.D.***, Sterling S.L., Weir D.L., Beauregard C.R., Smith I.L., Larsen S.E., Wang L-F., Snow A.L., Schaefer B.C., and Broder C.C. Enhanced autophagy contributes to reduced viral infection in black flying fox cells. *Viruses*. 2019. Mar 14;11(3). pii: E260. doi: 10.3390/v11030260. PMID: 30875748, PMCID: PMC6466025

PMID: 33804519; PMCID: PMC8001737.

2. My research experience as a postdoctoral fellow furthered my training in molecular virology techniques. I constructed a recombinant Cedar virus cDNA plasmid and optimized a reverse genetics approach to rescue a recombinant Cedar virus reporter virus, a non-pathogenic *Henipavirus* species. A molecular biology methods chapter detailing recombinant Cedar virus reverse genetics has been submitted and in press. Using this recombinant Cedar virus, we determined that Cedar virus can utilize several non-canonical henipavirus ephrin receptors for cellular entry and explored the structure of the receptor-binding pocket to understand the receptor promiscuity. The non-pathogenic phenotype of CedV creates a potential for CedV to act as a model henipavirus to explore host-pathogen interactions, cellular tropism and factors that determine henipaviral disease pathogenesis. Additionally, I have collaborated on projects detailing henipavirus infection and replication in bat hosts with colleagues at the Rocky Mountain Labs, studying whether specific species of bats are more competent hosts and whether virus-host restriction exists.

3. Bats are increasingly identified as animal reservoirs of emerging zoonotic viruses (e.g. Nipah virus, Ebola virus and SARS-coronavirus). I lead collaborative biosurveillance and research preparedness training including data analysis and interpretations at international partner institutes with lab technicians, field and lab scientists, and masters, doctoral and postdoctoral trainees. Collaborative biosurveillance is presently underway in Thailand (Chulalongkorn University, Bangkok) Malaysia (National Wildlife and Forensic Lab, Universti Purtra Malaysi, National Public Health Lab) via NIH Centers for Research in

Emerging Infectious Diseases, EID-Southeast Asia Research Collaborative Hub. As a collaborator within the DARPA PREEMPT network I supported surveillance for coronaviruses and other priority emerging zoonotic viruses, henipaviruses and filoviruses, in Ghana (Zoological Society of London), Australia (Black Mountain Labs) and Bangladesh (icddr,b). We aim to characterize the geographic distribution of zoonotic filoviruses/henipaviruses/coronaviruses, transmission dynamics in wildlife hosts and generate risk-models for Ebola virus, Nipah virus and SARS-related CoV outbreaks. Results discovered so far suggest a wider geographical footprint of Asiatic filoviruses and have identified several fruit bat species that act as natural reservoirs for these viruses.

4. Responding to the emergence of SARS-CoV-2, our lab developed multiplex serology strategies to identify SARS-CoV-2 antibodies and address research questions related to whether pre-existing antibody memory induced by prior infection with seasonal human coronaviruses affects COVID-19 severity. Our lab's serology efforts supported NIH and DHA collaboratively funded protocols including prospective, longitudinal serological analysis of hospital and community subjects, and health-care workers; and cross-sectional analyses of SARS-CoV-2 infection among deployed military health-care workers.

SARS-CoV-2 Infection Risk Among Active Duty Military Members Deployed to a Field Hospital - New York City, April 2020. *MMWR Morb Mortal Wkly Rep.* 2021 Mar 5;70(9):308-311. doi: 10.15585/mmwr.mm7009a3. PMID: 33661864; PMCID: PMC7948931.

5. In addition to providing serologic assessment of SARS-CoV-2 infection, my research team is actively engaged in examining the durability of COVID-19 vaccine induced humoral immunity. Antibody responses, particularly neutralizing antibodies, are frequently cited as a predictive correlate of protection. With the emergence of variants of concern and waning circulating antibodies, the timing of booster shots remains an important measure for controlling the pandemic. In my lab we evaluate the duration of neutralizing antibodies, durability and breadth of antibody responses against emerging variants of concern, hybrid immune responses, and post-vaccination infections.

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Wacharapluesadee, Supaporn

eRA COMMONS USER NAME (credential, e.g., agency login):

POSITION TITLE: Senior Researcher

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Chiang Mai University, Thailand	B.S.	02/1991	Medical Technology
Mahidol University, Thailand	M.S.	01/1994	Biochemistry
Chulalongkorn University, Thailand	Ph.D.	03/2006	Biomedical Sciences

A. Personal Statement

I have 29 years in public health research and 20+ years of experience in emerging viral zoonoses. I have managed many internationally funded research projects that involve working with and managing international and local interdisciplinary teams. Most of my research projects are diagnostics development, pathogen discovery, public health surveillance, field surveillance in wild mammals, human behavioral risk surveys, and clinical research. I conduct workshops on the development of novel diagnostic approaches, appropriate sample collection and handling for different pathogens, and viral characterization *in vitro* and *in vivo*. I am a senior researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, which conducts research on emerging zoonoses, clinical research, and public health surveillance research. My research background mainly focuses on understanding the process of zoonotic disease emergence, particularly viral zoonoses. This includes identifying the bat origin of Nipah virus, MERS-CoV, and SARS-CoV-2 and pathogenesis and diagnoses of Rabies. My studies on the emergence of novel betacoronaviruses found in Thai bats and Nipah virus have been published. My laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases, communicable diseases, and wastewater surveillance. I am the DDC instructor on the clinical sampling method and consultant for Ebola, MERS, and COVID-19 diagnosis. I am a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. I led the team to diagnose the first human MERS case in 2015 and the first human COVID-19 case outside China in January 2020. I have been the PI on six multidisciplinary research projects that use epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah, and Hendra viruses, Avian influenza, and novel viruses from bats. I am also the Thailand country coordinator for PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratorians.

B. Positions, Scientific Appointments, and Honors

Positions and Employment

- 1994 -97 Biochemical Technician, Department of Entomology, AFRIMS, Thailand
- 1997 Researcher, Department of Immunology, Chulabhorn Research Institute, Thailand
- 1997 -00 Medical Technologist, The HIV/AIDS Collaboration Thai-US, Thailand
- 2000 -16 Laboratory Chief, Neuroscience Centre for Research and Development & WHO Collaborating Centre for Research and Training on Viral Zoonoses, Faculty of Medicine, Chulalongkorn University Hospital, Thai Red Cross Society, Thailand
- 2016 -21 Deputy Chief of Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University Hospital
- 2021 - Senior Researcher, Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital
- Committee member, School of Global Health, Faculty of Medicine, Chulalongkorn University

Other Experience and Professional Membership

- 2010 -14 PREDICT Thailand Country Coordinator
- 2014 - Thai Ministry of Public Health (MOPH) Ebola Diagnostic Committee
- 2015 -19 PREDICT 2 Thailand Country Coordinator
- 2016 - Steering committee, Bat One Health Research Network, BTRP DTRA
- 2021 - WHO Scientific Advisory Group for the Origins on Novel Pathogens (SAGO)

C. Contributions to Science

1. **Research on One Health.** One Health is an integrated, unifying approach that aims to sustainably balance and optimize the health of people, animals, and ecosystems, as the definition by WHO. Our projects are multidisciplinary studies on human surveillance, wildlife surveillance, wastewater surveillance, and human behavior.
 - a. Tangwangvivat R, **Wacharapluesadee S**, Pinyopornpanish P, Petcharat S, Muangnoicharoen H. Behavioral-biological surveillance of emerging infectious diseases among a dynamic cohort in Thailand. **BMC Infect Dis**. 2022 May 16;22(1):472. doi: 10.1186/s12879-022-07439-7. PMID: 35578171; PMCID: PMC9109443.

2. Research on Public Health Surveillance in Thailand. Effective disease control programs rely on effective surveillance and response systems. Our laboratory collaborates with the Department of Diseases Control for active surveillance on syndromic surveillance and outbreak investigation. Both molecular and serology surveillance systems were conducted to identify the cause of the disease.

- a. Pliapat T, Buathong R, **Wacharapluesadee S**, Siriarayapon P, Pittayawonganon C, Sangsajja C, Kaewpom T, Petcharat S, Ponpinit T, Jumpasri J, Joyjinda Y, Rodpan A, Ghai S, Jittmittraphap A, Khongwichit S, Smith DR, Corman VM, Drosten C, Hemachudha T (2017). Detection of influenza virus in rectal swabs of patients admitted in hospital for febrile illnesses in Thailand. **SAGE Open Med**. 2021 Jan 22;9:2050312121989631. doi: 10.1177/2050312121989631. PMID: 33552519; PMCID: PMC7841862.

3. Research on diagnostic development. The molecular technique is a gold standard method for pathogen diagnosis and confirmation. The first COVID-19 case outside China in Thailand was primarily detected by family PCR and further confirmed by next-generation sequencing (NGS). The SARS-CoV-2 variants can be identified by the NGS technique or by identifying the mutation markers by MassARRAY technology.

Development and evaluation of a visible reverse transcription-loop-mediated isothermal amplification (RT-LAMP) for the detection of Asian lineage ZIKV in field-caught mosquitoes. **Acta Trop**. 2022 Dec;236:106691. doi: 10.1016/j.actatropica.2022.106691. Epub 2022 Sep 11. PMID: 36103950.
4. **Research on coronavirus prevalence in Thailand.** Numerous high-impact emerging viruses appear to have bat reservoirs. Our surveillance projects study the diversity of coronavirus (CoV) in bats in Thailand. We have isolated and characterized CoVs from many bat species and detected and sequenced CoV in bat guano collectors. Our surveillance studies continue to analyze the drivers of their emergence and risk factors for spillover.
- a. **Wacharapluesadee S**, Duengkae P, Chaiyes A, Kaewpom T, Rodpan A, Yingsakmongkon S, Petcharat S, Phengsakul P, Maneeorn P, Hemachudha T (2019). Longitudinal study of age-specific pattern of coronavirus infection in Lyle's flying fox (*Pteropus lylei*) in Thailand. **Virology** 20;15(1):38.

5. **Research on Nipah virus prevalence in Thai bats.** Nipah virus outbreaks, previously in Thailand's neighboring country, Malaysia, and ongoing in Bangladesh, have high mortality rates. Our surveillance projects study the characterization of Nipah Virus (NiV) in bats in Thailand. In addition, our surveillance studies continue to analyze the drivers of their emergence, understanding their seasonal preferences and risk factors for spillover.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Co-PI Plan (only needed if applying as Co-PIs):

What each Co-PI will contribute to the proposed research study?

As stated in the Mentoring Plan, the co-PIs, Krongkan Srimuang and Spencer Sterling have different educational and training backgrounds. This Co-PI plan is proposed to fill the gaps in knowledge of each scientist and supports a collaborative working relationship for project success. Moreover, this plan was developed to maximize the strengths of each PI. Overall, the project is separated into two objectives, the proposal of this project will be equally managed by Dr. Srimuang and Mr. Sterling. Dr. Srimuang will be responsible for PBMC isolation, sorting, and characterization. Mr. Sterling will be responsible for the technical serological aspects of the project. Both will work closely with the Research Center Mentor, Dr. Eric Laing, to develop this project, protocol development, and network connections. Dr. Supaporn Wacharapluesade, the Co-mentor, will support the wildlife sampling, samples collection, and molecular aspects within Thailand.

How the Co-PIs will jointly work with the affiliated Research Center?

Dr. Srimuang is currently employed at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University and supports the molecular biology investigations in the EID-SEARCH project. Mr. Sterling is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Both Co-PIs will work closely with Dr. Laing, Dr. Wacharapluesadee, and the staff at EcoHealth Alliance to coordinate field sampling, research activities, data analysis, and manuscript production.

How the Co-PIs will jointly manage the proposed study?

This is a great opportunity for both PIs to undergo training in advanced techniques and develop skills in next-generation serology and molecular sequencing. Dr. Srimuang will learn and practice serologic techniques and data analysis from Mr. Sterling. Mr. Sterling will develop skills in cell isolation and molecular sequencing techniques from Dr. Srimuang. Moreover, Mr. Sterling will coordinate planning, sample processing, data analysis, and report preparation for this project with Dr. Srimuang.

WGS: Whole Genome Sequencing

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), cell sorting machine and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Computer:

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

PI Name: **Srimuang, Krongkan and Sterling, Spencer, Lee**
CREID CC Grant: 1U01AI151378

Foreign Site: **Thailand**

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Krongkan Srimuang
Project Title:	Immune memory bait & capture to identify emerging henipavirus origins
Institution:	King Chulalongkorn Memorial Hospital
Foreign Research Site:	Rama 4 Road, Pathumwan, Bangkok 10330 Thailand
Point of Contact for Research Site:	Krongkan Srimuang Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital Rama 4 Road, Pathumwan, Bangkok 10330 Thailand krongkan.sr@gmail.com

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goal of this project is to identify the origin of zoonotic pathogens by applying serologic and cellular immune tools in humans and animals for early detection and identification of novel pathogens to prevent the next pandemic.

To achieve this, the project will conduct serological surveillance among humans and rodents/shrews at this site, and perform lab analysis collaborating with NIH PREMISE for antibody-mediated bait & capture of Thai MojV-like virus.

\$149,937 of grant funds will be sent to the site for these research activities.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will 1) conduct all field work to collect human and animal samples from the study sites; 2) perform laboratory analysis using collected samples; and 3) conduct data analysis as proposed in the project.

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - IRB approval number for parent study: #894ECOH21b (US); #221/64 (Thailand)
 - IRB approval date: 12-05-2021 (US); 08-06-2021 (Thailand)
 - Human Subject Assurance Number: (FWA)#: #00001102 (external IRB); #00022431 (EcoHealth Alliance); #00000943 (Chulalongkorn University)
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - **Yes**
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - **No**
 - How many subjects provided the existing samples to be used? N/A
- **Will human subjects be recruited (Yes or No)**
 - **Yes**
 - Number of human subjects that will be recruited: 110
- **Population parameters:**
 - Gender: 55 males, 55 females
 - Age Group: Age >=18 years who provide informed consent.
 - Race/Ethnicity: 110 Asian
- **Sample collection will include:**
 - Blood: Yes
 - Urine: No
 - Tissues: No
 - Other samples (describe): Nasopharyngeal swab and throat swab
- **Sample collection will be completed in how many visits: 2 trips**
- **Will samples be de-identified (Yes or No)? If No, describe how they will be protected.**
 - **Yes**
- **Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.**
 - **Yes**
- **Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.**
 - **Yes**
- **Will samples be brought back to the US (Yes or No)?**
 - **No**
- **Will data be brought back to the US (Yes or No)?**
 - **Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.**

Animal Subjects (1 word or 1 sentence per bullet):

- **Parent study IACUC approval**
 - IACUC approval number for parent study: #G2020-42 (US); #019/2563 (Thailand)
 - IACUC approval date: 05-05-2020 (US); 03-12-2020 (Thailand)
 - Animal Welfare Assurance Number: D16-00572 (A4059-01)

- **Does this study require a modification to the IACUC approval of a parent study (Yes or No)?**
 - **No**
- **Will existing samples from animal subjects will be used: (Yes or No)?**
 - **No**
 - How many animal subjects provided the existing samples to be used? **N/A**
- **Will vertebrate animals be collected (Yes or No)?**
 - **Yes**
- **Species of animals (e.g. rats, mice, rabbits, monkeys):** **Rodents and shrews**
- **Animal parameters:**
 - **Total number of animals:** **200 (200 rodents and shrews)**
 - **Gender:** **100 males, 100 females**
 - **Age range:** **4 - 12 months and elder depending upon species**
 - **Lab strain (e.g. Sprague-Dawley rats, Balb/C mice):** **None**
 - **Wild animals procured in country (e.g. Rhesus monkeys from a reserve):** **No**
- **What will be done to them or with them and how often?**
 - **Free-ranging rodents and shrews will be captured through pit traps and box traps.**
 - **Anesthesia will be conducted for captive rodents and shrews.**
 - **Once anesthetized blood will be collected.**
 - **All actions will only be performed one time for each animal individual.**
 - **All animals will be released after sampling.**
- **What are the follow-ups?**
 - **No follow-up relevant as per protocol, since all animals will be released after sampling ups**
- **What will be their fate at the end of the experiments – will they be euthanized?**
 - **All animals will not be held longer than 6 hours (typically less than 3 hours) during the sampling process and released after sampling.**
- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - **Yes**
- **Will samples be brought back to the US (Yes or No)?**
 - **No**
- **Will data be brought back to the US (Yes or No)?**
 - **Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.**

27th January 2022

Krongkan Srimuang Ph.D.
Research Scientist
Thai Red Cross Emerging Infectious Diseases Clinical Center
King Chulalongkorn Memorial Hospital
Rama 4 Road
Pathumwan, Bangkok 10330
Thailand

Subject: Letter of Support for CREID Network Pilot Research Program

Dear Dr. Srimuang,

I am writing to express my support for your CREID Network Pilot Research Program proposal titled, “Immune memory bait and capture to identify emerging henipavirus origins.” Your preliminary data demonstrating immunoreactivity against Mojiang henipavirus in individuals sampled as part of the Emerging Infectious Diseases Southeast Asia Research Collaborative Hub (EID-SEARCH) center, provides compelling serologic evidence that novel henipaviruses spill over into human populations. Point-of-care diagnostics and nucleic acid-amplification tests rely on our present understanding of medically relevant pathogens. Thus, emergence of novel zoonotic viruses may go undetected. Serological profiling provides us an ability to measure the human infectome through broad-scale peptide arrays or targeted antigen-based detection.

The research activities conducted at the Thai Red Cross Emerging Infectious Diseases Clinical Center are complementary to the focus of the Vaccine Research Center’s PREMISE (Pandemic REsponse REpository through Microbial and Immunological Surveillance and Epidemiology) program. PREMISE works closely with intramural and extramural NIH programs and in partnership with a global network of investigators and collaborators to achieve its objectives through 3 core activities: (1) genetic analysis of zoonotic reservoirs and symptomatic humans for pathogen discovery; (2) development of high throughput, multiplexed serologic and cellular assays; and (3) global blood sampling to identify antigen-specific and cross-reactive immune responses to known and previously unknown viruses of pandemic potential. Biological samples including serum and PBMC are obtained from broad-based population cohorts as well as targeted populations at risk from emerging infections. At the same time, sequence data from known and unknown (through virus discovery) pathogens are analyzed to design and express candidate antigenic proteins of interest. These proteins are then used in high throughput multiplexed assays to screen sera for antibody reactivity. Serum reactivity to candidate antigens is followed by further interrogation of the adaptive immune response at the cellular level using corresponding PBMC samples. Proteins used in the serological arrays are conjugated to fluorophores and used as probes to sort antigen-specific B cells by flow cytometry. In addition, the sequence of such candidate antigens provides the template for the design of overlapping peptide pools to assess T cell responses. Further analysis allows for the identification of

neutralizing antibodies specific for the target antigens as well as specific T cell epitopes which may be tested in animal models. Epitope identification informs and guides immunogen design. At the conclusion of this pipeline of assays and analysis, PREMISE delivers the following:

1. reagent and data resources for early detection and diagnosis
2. monoclonal antibodies with therapeutic potential
3. candidate immunogens for further vaccine development

Thus, PREMISE serves as a translational vehicle to integrate serologic and cellular immune discovery, targeting a broad array of pathogens, into product development, and constitutes an anticipatory reagent repository to accelerate the global response to pandemic threats.

As investigators in the Vaccine Research Center at the National Institute of Allergy and Infectious Diseases (NIAID), we are not eligible to be listed as a “co-investigator” on the application but look forward to participating as collaborators. All materials from us will be provided under an approved material transfer or other collaborative agreement. This collaboration is part of our official duties as employees at the NIAID, and no funds from the grant will be used in intramural research, neither will we accept any form of remuneration, whether in the form of salary, honoraria, or travel expenses. We will provide scientific input and mentoring but will not have any duties associated with programmatic stewardship, which will be performed by NIAID extramural program officials. Further, in keeping with the mission of NIAID to promote and facilitate biomedical research and the dissemination of new knowledge, we would supply requested research materials and technical expertise not only to you, but also to other interested and qualified parties for research purposes.

My group has met with Dr. Eric Laing (USU) one of the two mentors for this pilot research program to discuss ways we can collaborate and support your research application. We are enthusiastic about providing the technological and subject-expertise in immunology and translational therapeutic discovery afforded by the PREMISE program that would enhance your knowledge base and broaden your own scientific training.

Sincerely,

Daniel C. Douek

30 January 2023

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC),

King Chulalongkorn Memorial Hospital

Object: Thai Red Cross Emerging Infectious Diseases Clinical Center support for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

Dear Dr. Srimuang & Mr. Sterling,

Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC) is pleased to support your application to the **CREID Pilot Research Program**, entitled “Immune memory bait & capture to identify emerging henipavirus origins.” We are fully committed to executing the statement of work to study zoonotic reservoirs for pathogen origins by using serologic and cellular immune discovery in humans and wildlife and their application as a tool for early detection and identification of novel pathogens in pandemic prevention.

The work proposed in this project is a great opportunity for collaboration with our team, it serves to enhance the use of serology and immunology for the detection of novel virus pathogens in Thailand using new technology and techniques. Moreover, the building of capacity and capability in our laboratory and Faculty will enhance the regional capacity, and the Chulalongkorn network will be used to ensure the success and completion of this project.

This letter expresses my strong interest in you pursuing this application and I fully support the project. I look forward to collaborating with you on this project and I wish you success in the CREID Pilot Research Program application.

Sincerely,

(b) (6)

Assistant Professor Opass Pucharoen, MD, Msc

Head of Thai Red Cross Emerging Infectious Diseases Clinical Center

King Chulalongkorn Memorial Hospital

Dr. Krongkan Srimuang, Mr. Spencer Sterling
Thai Red Cross Emerging Infectious Diseases Clinical Center
King Chulalongkorn Memorial Hospital
1873, Rama 4 Road, Pathumwan
Bangkok, Thailand 10330

Dear Krongkan and Spencer,

This letter conveys a strong interest from the Emerging Infectious Disease-Southeast Asia Research Collaboration Hub (EID-SEARCH) at EcoHealth Alliance to collaborate with you at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital on the proposed project titled "*Immune memory bait & capture to identify emerging henipavirus origins*" in Thailand.

The question of the origin of emerging Henipaviruses (HPVs) was identified from the EID-SEARCH human surveillance when a Mojiang-related virus was identified in a local population highly exposed to bats in Thailand. Faced with the challenges of PCR detection and viral isolation, this project will establish and validate a new serological approach to develop MojV-like virus-specific MAbs and define the antigenic spatial relationships between all known rodent- and bat-borne HPVs, revealing the serologic signature of all related undiscovered HPVs. This will significantly contribute to the objectives of EID-SEARCH to conduct targeted and strategic surveillance to identify emerging pathogens with zoonotic potential at the high-risk human-animal interfaces. The research population and site for this project – bat guano collection – represents one of the key scenarios where zoonotic spillover is mostly concerned that requires further in-depth investigation to identify the reservoir hosts. In addition to the gained knowledge, established methods from this project will be shared and used as standards in zoonotic HPVs surveillance and prevention strategies in Thailand and regionally through collaborative and coordinative cooperation among multiple stakeholders.

I am very excited to work with you both on this project, given your critical roles in the previous surveillance work to identify the question and develop the research idea. This project will bring valuable insights to advance disease surveillance and early warning systems for endemic and emerging infectious diseases in Thailand. Members of EID-SEARCH are committed to working closely with you to develop the research project and support the efforts necessary for the success of this project. You will be invited to join all training conducted by EID-SEARCH and EcoHealth Alliance regarding emerging infectious disease surveillance, relevant statistical analysis, and grant writing to expand your skill set. You'll also be supported to present the findings from this research at international conferences, the CREID Network meetings, and external partners and produce high-quality publications from this research.

Developing and implementing this project will advance your skills in project management for future research as an independent researcher. Co-Investigators of EID-SEARCH, Dr. Eric Laing from the Uniformed Services University of the Health Sciences and Dr. Supaporn Wacharapluesadee from the Thai Red Cross Emerging Infectious Diseases Clinical Center, have enthusiastically joined the project as your Mentors. Dr. Laing will advise on the study design and provide training on data analysis, and Dr. Wacharapluesadee from your institute will work closely with you to advise on the day-to-day project implementation. Both Mentors will work with you for manuscript writing and provide pertinent and timely career advice to assist in your professional development. They will bring a well-established

EID-SEARCH

Emerging Infectious Diseases
South East Asia Research Collaboration Hub

network of leaders and experts in emerging infectious disease research in Thailand, Southeast Asia, and North America for your network building.

I am confident that this proposed project will bring genuine opportunities for your professional development. And the combined experience in the field and lab and interdisciplinary expertise in serology and public health from the co-PIs will make this a successful and purposeful project to bring public health impacts in a broad region. I look forward to collaborating with you and your team on all phases of this proposed project. I wish you success in the CREID Pilot Research Program application.

Sincerely,

Peter T. Asza

Subject: Letter of Support for CREID Network Pilot Research Program

Dear Dr. Srimuang,

I am writing to express my enthusiastic support for your CREID Network Pilot Research Program proposal titled, "Immune memory bait & capture to identify emerging henipavirus origins." In 2018, I led a training and multiplex serology technology transfer to your mentor Dr. Wacharapluesadee's research group via DTRA-funded project Chulalongkorn Luminex Training and Research Preparedness (HDTRA1-17-C-0019), and was excited to leverage those activities into ongoing research within the EID-SEARCH. Since 2015 I have been developing serological-approaches for biosurveillance of zoonotic viruses in wildlife and human populations, and I am excited to serve as a co-mentor for this pilot program application.

I hope to provide you with the research and career developmental support for the activities outlined in the proposal. The serological data on henipavirus exposure in Thai guano farmers provides compelling evidence that Mojiang-like henipaviruses can cross the species barrier and may be widely distributed in Southeast Asia. The research aims detailed in the proposal will facilitate critical follow-up sampling of this human cohort to identify whether acute infection causes clinical disease, estimate the sero-attack rate of this novel henipavirus, and will apply a cutting-edge serologic and immunologic approach for monoclonal antibody development and novel emergent virus immunogenic characterization. If awarded, a collaboration with VRC PREMISE program scientists will facilitate an important opportunity to broaden your knowledge base of cellular immunology and B cell biology. You have an extensive background in next-generation sequencing application, and through this proposal would gain a considerable understanding of how next-generation sequencing is used for BCR-sequencing, IgG characterization and monoclonal antibody discovery.

Your proposal is an excellent extension of the EID-SEARCH activities and significant training opportunity.

Sincerely,

(b) (6)

Eric D. Laing

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious
Diseases Clinical Centre (TRC-EIDCC),
King Chulalongkorn Memorial Hospital

Dear Dr. Srimuang & Mr. Sterling,

I am writing in support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

With my 20 years of experience in conducting surveillance for novel viruses in wildlife, humans, and bats using molecular technology, I will support the growth of the scientists in the CREID Pilot Research Program. The research aims have the potential to significantly enhance our approach to pathogen surveillance at high-risk human-animal interfaces. Given the understanding of pathogen origins by using serologic and cellular immune discovery in humans, and applying these techniques as a tool for early detection and identification of novel pathogens.

As the head laboratory chief at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, I believe that this is a great opportunity for our Thailand team to train in the characterization of memory B cells from peripheral blood mononuclear cells (PBMC) and enhanced serological surveillance in novel virus pathogens. Moreover, our laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases and communicable diseases such as Ebola, MERS, and COVID-19. I am also a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. With my experience in diagnosing the first human MERS case in Thailand in 2015 and the first human COVID-19 case outside China in January 2020, I will support multidisciplinary projects involving epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah and Hendra viruses, Avian influenza, and novel viruses from bats. I was also the Thailand country coordinator for the PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratory staff. I will enthusiastically support the development of a strong knowledge base to build capacity and capability in this project and our team in Thailand.

The CREID Network and the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH) will support scientists in regions around the world where emerging and reemerging infectious disease outbreaks. Many Southeast Asian partnerships in EID-SEARCH have strong potential to enhance innovations in this area.

I believe that Dr. Laing, and I will provide scientific skills, expertise, and networks for this project.

Towards that aim, I am committed to supporting your professional development in the following ways:

1. I will maintain regular bi-weekly meetings for the project progresses.
2. I will support the resources in our country and research team in this project.
3. I will create opportunities for scientists network to ensure the success of research project.
4. I will provide and share advice and technical expertise in specific knowledge for this project.

I'm very much looking forward to working closely with you on this 1-year research project and beyond as you continue to develop your surveillance zoonotic disease research program.

Best regards,

(b) (6)

Supaporn Wacharapluesadee, Ph.D.

Head Laboratory,

Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC),

Direct Costs	\$138,831
Indirect Costs	\$11,106
Proposed Start Date	1 May 2023
Proposed End Date	30 April 2024

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) are bat-borne zoonotic viruses and cause high mortality. The recent detection of closely related Mojiang and Langya viruses in rats and shrews, and isolation of Langya virus from individuals with acute febrile illness, challenges the dogma that fruit bats are the sole henipavirus reservoirs. The recently expanded <i>Henipavirus</i> genus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. As part of EID-SEARCH activities, we found serological evidence of infection by a Mojiang-related virus in a community of Thai bat guano collectors who have occupational exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to identify novel viruses and zoonotic reservoirs through serologic and cellular immune discovery. We will conduct follow-up human and wildlife shrews and rodents) surveillance in the province where the seropositive humans were identified and apply an expanded serological test and genomic sequencing to detect this novel MojV-like henipavirus. Further, we</p>

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

plan to isolate anti-MojV monoclonal antibodies (mAb) from peripheral blood mononuclear cells collected from human study participants we have identified as immunoreactive with MojV antigens, and characterize the cross reactive and cross neutralizing potential of these mAbs to LayV.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Study Personnel

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as mentor for Dr. Srimuang and Mr. Sterling under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Laing is an assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses at Uniformed Services University, Bethesda, MD. Part of Dr. Laing's research focus in on the development of serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Dr. Laing has worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Through these collaborations, Dr. Laing's research group aims to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence.

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

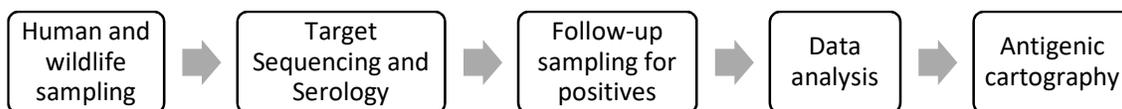

Specific Aims

The recent discovery of novel shrew and rodent-borne henipaviruses in East and Southeast Asia has highlighted gaps in our understanding of henipavirus transmission and underscores the importance of surveillance activities in the region. In particular the isolation of Langya virus from acutely ill humans and shrews demonstrated the need to further surveillance and therapeutic development against emergent henipaviruses. Therefore, **this project aims to expand the study of known reservoirs of zoonotic pathogen origin by using genetic and serologic techniques, and to use cellular immune discovery in seropositive humans as a tool to determine henipaviral antigenic relatedness to assist with the functional assessment of current therapeutics as and their effect on these novel viruses.**

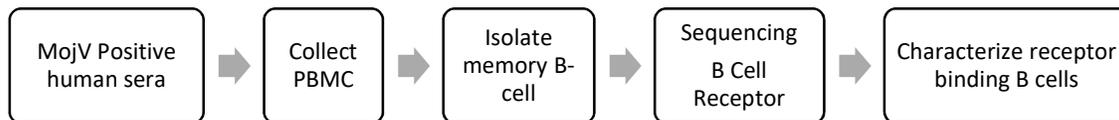

In our study, we detected that a high seroprevalence against MojV in human participants near the Khao Chong Phran Non-hunting Area in Ratchaburi province who we identified as representing a high risk population for zoonotic spillover. Yet, no virus sequences were detected. We hypothesize that (i) there is a novel henipavirus present in the local wildlife population that has spilled over into the human population at least once, and (ii) the antibodies from these seropositive people will react with the novel shrew-borne henipaviruses in a way that can inform us on therapeutic approaches for future outbreaks. We will follow-up with persons who had high anti-MojV IgG levels, sample new participants within this community who interact with the local wildlife, and sample shrews and rodents to identify the wildlife source of the MojV-like henipavirus. Additionally, in collaboration with NIH VRC PREMISE, MojV receptor binding protein (RBP) and fusion protein-reactive B cell will be isolated from previously-identified seropositive human participants. MojV-like virus-specific B-cell receptors will be sequenced and monoclonal antibodies specific to the infecting MojV-like virus RBP and F protein will be generated and tested for cross reactivity against presently described rodent associated henipavirus envelope glycoproteins, and cross neutralization against Langya virus.

The proposed project has two aims:

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

The proposed project has two objectives:

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Objective 2. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody discovery.

Study Rationale

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McLinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genera of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, GAKV and DARV were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The henipaviral genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australia (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected 19% (54/284) seroprevalence for MojV in a high-risk cohort, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dogan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia and likely due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology (serologic and cellular) to identify a novel virus that can aide in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus

isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

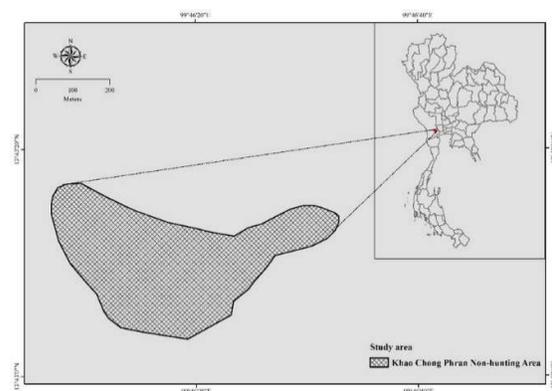

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Site wildlife samples collection

200 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. We plan two sampling trip to collect target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect up to 200 samples and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored. Oral swab and rectal swab will also collect in 200 shrews or rodents. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

Human surveillance

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, 100 human serum samples, nasopharyngeal swab and throat swab will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,150 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

We will target a total of 200 individuals of shrews and/or rodents across two trips for this project. This sample size is estimated based on a realistic detection rate and required sampling efforts from previous wildlife surveillance work, given the rodent/shrew population at the study site. Previous publications regarding Henipavirus discovery in small mammals had an average PCR detection prevalence between 20 and 33% (Wu et al., 2014, Lee et al., 2021, and Zhang et al., 2022). We acknowledge the challenge of identifying positive results, and very limited serology research has been done to provide guidance. However, we will make the best use of previous data and experience to conduct sampling at the selected site where human positives have been. We are confident that this targeted sampling and testing strategy offers the best chance to identify positive results and potentially novel henipaviruses.

Targeted Viral Sequencing and Serologic testing

Targeted sequencing

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The nucleic acid from oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing.

Serological testing

Serum samples will be tested for RBP and envelope fusion protein (F) binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Data analysis

Sequencing will be analyzed assembling reads in MEGA11. The consensus sequences will compare to the references strains available in the GenBank data-base using the Basic Local Alignment Software Tool (BLAST) (National Center for Bio-technology Information). Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to LayV RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipass, and LayV, depending on how well these cross react.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran Non-hunting Area in Ratchaburi Province (Figure 2).

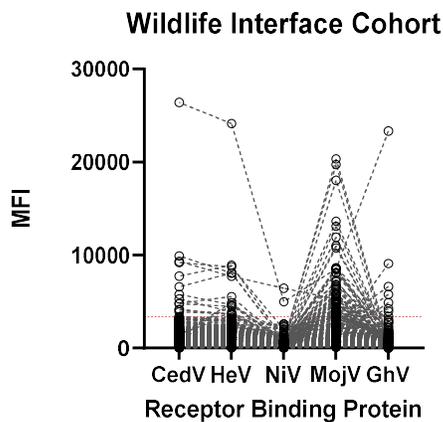

Figure 2: Seroprevalence of henipavirus proteins from a community with a large wildlife interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, a threshold for seropositivity.

PBMC Sorting and B Cell isolation

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes). Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3⁻, CD14⁻, CD56⁻, IgM⁻, IgA⁻, CD19⁺, CD20⁺, CD27⁺). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor Amplicon Preparation and Recombinant Antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced. After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

We will first determine the extent to which isolated mAbs can bind binding to native-like MojV RBP and F proteins. We will also characterize the cross-reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. However, MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of MojV neutralizing potential is not possible. Though, we will test the cross-neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV utilizing a plaque reduction neutralization test with EID-SEARCH co-investigators at Duke-NUS. As LayV causes acute illness in human, cross neutralization functionality of these mAbs has therapeutic potential.

Research Performance Sites

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country. We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

CREID Research Center Collaboration

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. Further, Dr. Doeuk who is the director of the VRC PREMISE program is enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Ig) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Mentoring Plan

Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant writing and project management skills. My professional relationship with Dr. Wacharapluesadee began in 2018 when I participated in a DTRA BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group. Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Vertebrate Animals Section Requirements

Animal samples will be collected in Ratchaburi Province for this project under Aim 1 to understand the antigenic relationships among known and unknown henipaviruses. Protocol to perform animal sample collection has been reviewed and approved by the Institutional Animal Care and Use Committee at Tuft University under the EID-SEARCH project (No. G2020-42) and the Institutional Animal Care and Use Committee at Chulalongkorn University (No. 019/2563)

1. Description of Procedures

Rodents (order: *Rodentia*) and Shrew (order: *Scandentia* and *Eulipotyphla*)

- Species: Free-ranging rodents (family *Hystricidae*, *Muridae*, *Sciuridae*, *Spalacidae*) and shrew (tree shrews, shrews, moles) that present at the sites.
- Age & sex: Adults and juveniles, males and females. Neonates will not be sampled.
- Target Number: 200 individuals
- Capture and Restraint: Free-ranging wild mammal species will be captured with metal box traps (Sherman/Tomahawk traps). Traps will be prepared with food, water, padding and shelter, and be checked at least every 12 hours, in the morning and in the afternoon. If adverse weather (extreme heat, rain) is expected or researchers are working in areas where predation is common, traps will be checked more frequently and closed during adverse weather. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. Depending on the species, individual size, captive or free-ranging status of the individual, manual or chemical restraint and anesthesia (gas or injectable anesthesia) will be applied. Animals will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and animal. Based upon past field experience (>20 years of animal capture and release in Southeast Asia), we do not expect to trap sick, debilitated, or young animals that would be too young to cope with capture. Sick and debilitated animals tend not to roam widely, reducing their opportunity to enter traps. Additionally, should sick, debilitated, or young animals enter traps, we anticipate that they will not suffer adverse conditions because the traps contain food (the bait) and liquid (water or fruit as a source of water). These individuals would be examined by a veterinarian, rehydrated and if presenting clinical signs treated by a veterinarian, prior to release or sampling then release.
- Sample Collection: Once anesthetized or safely restrained, whole blood will be collected through the appropriate venipuncture site, no more than 1 ml of blood per 100 g (= 10 ml/kg or 1%) of body weight will be collected at any one time. Anesthetized animals will be monitored regularly during recovery until they can no longer be safely handled, at which point they will be confined in a trap or cage. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected.
- Release: Wild mammals are held for a maximum of thirteen hours depending on trap timing, but typically less than three hours. Captive animals are held for a maximum of two hours but typically less than one hour. At the completion of sampling, animals may be provided with rehydrating

fluids (either subcutaneously if anesthetized or orally if manually handled and accepted). Wild mammals will be released at the site of capture in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided). Captive mammals will be released back into their captive setting as is appropriate for the species, either isolated or in social group if it is deemed safe from aggression from enclosure mates while the post-recovery period continues.

2. Justifications

The purpose of this study is to identify zoonotic pathogens through serologic and cellular immune discovery, including developing methods and standards for direct antibody-mediated virus capture in people and wildlife, focusing on rodent/shrew-borne Henipaviruses (HNVs). This will require hands-on fieldwork to collect whole blood and serum samples from rodents and shrews for lab analysis. One technique that avoids the direct capture and sampling of animals is to collect fresh feces or urine, but this will not be able to provide the appropriate samples for serologic analysis, and the research objectives cannot be achieved using an alternative methods (e.g., computational, human, invertebrate, in vitro). Therefore, we believe there are no viable alternatives than the use of live animals.

3. Minimization of Pain and Distress

In every situation, sampling of wildlife will be conducted in the most humane manner while minimizing the impacts on individual animals and their wild populations. In all instances, the fewest number of animals will be sampled that will provide valid information and statistical inference for the pathogen and disease of interest and every effort will be made to minimize stress and discomfort for the animal.

Small mammals may be held for up to 13 hours depending on trap capture timing. Field animal sampling team with zoologists and veterinarians have been well trained and have extensive experience in capture, anesthesia, and sampling of wildlife. In our team's experience, the target species tolerate the described procedure well. Mist nets will be attended continuously during capture periods. This will minimize stress and injury from entanglement.

For rodents and shrews, food, water, padding and shelter will be provided at traps, which will be checked at least every 12 hours. Traps will be checked more frequently or closed if adverse weather (extreme heat, rain) is expected, or researchers are working in areas where predation is common. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. All animal individuals will be monitored by a veterinarian or experienced field team member during all stages of capture, processing, anesthesia and release. Animals will be kept in a cool place, free from adverse weather conditions and access by non-field team members or other animals while in the pillowcases, trap, or cage for recovery. All recovering individuals will be observed until they are able to effectively ambulate and orient to their surroundings. Animals that are injured during the capture or sampling process will be assessed by an experienced team leader or attending veterinarian, and if the animal is determined to be unlikely to survive if released, it shall be euthanized humanely (see euthanasia section).

4. Method of Euthanasia

In the event that an animal has been injured or is moribund, a determination will be made as to whether it may be treated and released on site by veterinarians or transferred to facility that may treat and rehabilitate the animal, or if, as a last resort, the animal will require euthanasia. Euthanasia methods will vary depending on species; however methods to be used will not deviate from the AVMA "Guidelines for the Euthanasia of Animals" (2020 edition). Any animal that is euthanized using a chemical agent will be disposed of such that it will not be permitted to enter the food supply either through markets or hunting.

Human Subjects Research

1. Risks to the subjects

In this project, we will target populations in one community site who with frequent exposure to bats and other wildlife based on our previous behavioral survey. Subjects will be enrolled voluntarily, and informed consent will be obtained from all participants. Enrolled participants will provide biological samples. Survey data and biological samples will be collected from enrolled participants, and follow-up data collection will be performed among participants whose samples were tested positive. Biological samples and questionnaire data will be collected from individuals who meet recruitment and inclusion criteria and complete the informed consent process. During data collection, a standardized questionnaire will be administered to all participants. This questionnaire will collect information of demographic background, wildlife contact, travel and daily movement, and unusual SARI/ILI symptoms, and biological specimens will be collected from participants. Both questionnaire and biological data will be analyzed to assess the exposure to coronaviruses and the spread risk among humans. From all participants, a one-time whole blood sample (Max. 15 mL) will be collected during the study period. This sample will allow us to test for historical exposure to bat or rodent-borne henipaviruses and collect Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive.

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals who are proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions; however, the administration will be conducted privately and confidentially to protect individuals' health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

2. Adequacy of protection against these risks

2.1 Informed consent and assent

Only consented participants will be enrolled in the study. No research procedures will be undertaken before the participant fully understands the research, agrees to the study procedures, and completes the consent process will be enrolled in the study. Informed consent statements and forms, and project protocols will be translated into the local language of each study site. Research team members involved in this consent process will be required to be fluent in the local language to ensure that the subjects understand the study and all involved procedures.

If participants meet the criteria for enrollment, they will be invited to discuss the details of the study with the research staff. Study staff will review an information sheet and informed consent form with the participant when applicable. Each individual will be provided with a copy of the informed consent form that has been translated into the local language and written with a Flesch–Kincaid readability score equivalent to a 7th-grade reading level or below, to assure that potential participants understand the information being shared. The informed consent form will explain the details of the study, including how and why the individual was selected, the study process and procedures, risks and benefits, financial considerations and the gift of appreciation, confidentiality of data shared, alternatives to participating, and how to obtain more information now or at a later date. The informed consent form will be read in the local language of the site at a location ensuring participant privacy. After which individuals will have as much time as they would like to ask questions and discuss the study with study staff. The study staff will endeavor to ensure that the participant understands the information provided. The study staff will then ask the participant to consider study participation. Participants will have as much time as required to consider the participation.

Those participants who consent to the study will sign and date two copies of the consent form. These form copies will be countersigned and dated by the study staff. A copy of the signed consent form must be provided to the subject and the other copy will be kept by study staff. Informed consent paperwork will be kept until the end of the project in a locked box at the local country project office.

2.2 Protection against risks

The potential risks to study participants as a result of study participation are minimal. Collection of venous blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. Potential complications associated with venipuncture include pain and/or hematoma at the site of collection. Trained medical professionals and/or clinic staff will monitor the blood collection site and treat any complications according to existing health facility protocols. A potential complication of nasal/ oropharyngeal sampling is minor irritation at the time of collection. Employing trained medical and/or clinic staff to collect blood and swab samples will minimize the potential for complications.

Another risk that this study may pose concerns the information to be gained on henipaviruses newly recognized in the community. We will provide participating communities, hospitals, and clinicians with information and background data on target zoonotic viruses to ensure up-to-date communication of risk. Because of the timeline for diagnostic testing and results interpretation, we are not likely to provide results to participating clinics within a time frame that would be clinically relevant to outbreaks of undiagnosed diseases. Therefore, the information provided by this project will not impact patient management or outlook.

If an individual decides to participate in this research, his/her participation and all information provided by the participant will be strictly confidential, and personal identifying information will not be shared with anyone outside of the study staff. Participants will not be identified or named in any reports or publications. Questionnaire information and all biological samples will be identified by an alphanumeric code, not by the participant's name. All records that contain names or other personal

identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the study site in locked files cabinets or password-protected devices in areas with access limited to the research staff of this project. Research databases will be secured with password-protected access systems and controlled distribution web-based certificates and will not contain any identifying characteristics about study participants (e.g., name, address, or telephone number). Access to all data will be limited to the staff involved in this study. The health information disclosed by an individual will not be used by or disclosed (released) to another institution. Any surveillance report that is published or shared with partners will not contain any personally identifying information for individual participants.

3. Potential benefits of the research to the subjects and others

There are no measurable benefits to the individual study participants enrolled in this study. There are benefits to the community and regional healthcare providers to help them understand the risk of zoonotic infections among high-risk populations in the regions they work. At the conclusion of the study, we will deliver an educational workshop reporting aggregate study findings that will be open to both study and non-study participants, describing the health benefits of using personal protection equipment (PPE) and handwashing during animal handling activities throughout the day, as well as to share other prevention/interventions that emerge from the research data.

4. Importance of the knowledge to be gained

There are valuable potential benefits to the public from the knowledge to be gained from this study. One key benefit to the community is sharing information and knowledge to better understand the risk of zoonotic spillover events and related health risks, as well as information sharing with communities on practices that could reduce risks, such as the avoidance of particular animal contacts or the need for PPE and extra care when handling wildlife, that may substantially reduce the risk zoonotic pathogen transmission in the community. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to create or implement public health interventions to disrupt disease emergence and/or spread in an area that is beneficial to all. Additionally, there are valuable benefits to the general public from the knowledge to be gained from this study. Knowledge gained will increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

5. Country- / institution-specific ethics / IRB regulations addressed

Main research protocol and materials to conduct human subject research in this project have been reviewed and approved by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b)

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64). Amendment for PBMCs collection will be made and approved before the start of this project.

6. Does this project involve activities outside of the United States or partnership with international collaborators?	Yes	X	No	
6.a. If yes, identify countries	Thailand			
6.b. Optional explanation				

Budget Justification

A. Key Personnel (Total \$24,000)

Dr. Krongkan Srimuang, PI (12 months) is a medical research scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital (TRC-EIDCC) who have been leading the laboratory analysis for the EID-SEARCH work in Thailand in the past three years to perform molecular, serological, and next-generation sequencing to identify novel viruses from human and animal samples. Dr. Srimuang will commit 12 months to this project to design, manage, and perform all project activities in the lab and field by supervising a lab technician and working with the field coordinator. Dr. Srimuang will also work closely with the co-PI and Mentors to conduct data analysis and develop manuscript and join EID-SEARCH and CREID meetings to prevent the project findings.

Spencer Sterling, Co-PI (6 months) is the research coordinator of Laing Lab at the Uniformed Services University for Indo-Pacific region and a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC). Sterling will commit 6 months to this project as the co-PI, who will work closely with the PI in the study design, SOP development, sampling process, data analysis of for serological investigations. No salary is required for Sterling.

B. Other Personnel (Total \$20,000)

One (1) Laboratory Technician (12 months) will committee 12 months to this project to conduct PCR and serological testing of animal and human samples at TRC-EIDCC, under the supervision of Dr. Srimuang and Sterling. Salaries for 12 months at \$1,250 per month is requested (\$15,000).

One (1) Field Coordinator (4 months) will committee 4 months to this project, working closely with Dr. Srimuang and Sterling to organize and conduct field sample collection among humans and animals at the study sites, and support relevant financial management. Salaries for 4 months at \$1,250 per month is requested (\$5,000).

C. Fringe Benefits

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

No Fringe is requested.

D. Equipment

No equipment is requested.

E. Travel (Total \$48,375, Years 1-5)

Domestic Travel (\$11,005)

Support for domestic travel for field sampling is requested in the amount of \$11,005 per to conduct four (4) trips of sample collection from humans and rodents/shrews.

- The first trip is a one-day trip to collect samples from human participants who were tested positive ($n < 10$), the cost is estimated at van rental for local transportation between Bangkok and the study site (\$260) and meals for five (5) field team members at \$49 per person (\$245), in total of \$505 for the first trip.
- The other three (3) field trips will be conducted to collect samples from 100 humans and 200 rodents/shrews, respectively. Each trip is a duration of 6 days and 5 nights. For each person, 5-night stay in hotels at \$75.5/night ($5 \times \$75.5 = \378); 3 meals per day and incidental expenses at \$49 per day prorated to 75% (\$36.75) for first and last day of travel ($\$36.75 \times 2 + \$49 \times 4 = \$270$), the total meals and accommodations for each person per trip is \$648 ($\$378 + \270), cost for five (5) field team members is \$3,240. A van will be rented for local transportation between Bangkok and the study site that is estimated at \$260 per trip. Total cost for each 6-day trip is \$3,500, three trips will be \$10,500.

International Travel (\$5,023)

Support for international travel for Dr. Srimuang from Bangkok to Washington DC to attend the CREID Annual Meeting and receive lab training at the National Institute of Allergy and Infectious Diseases (NIAID) is requested in the amount of \$5,023. Trips are for a duration of 10 days and 9 nights. Travel costs for one trip are estimated using federal per diem rates for hotels, meals, and incidental expenses as follows: nine-night stay in DC area hotel at \$286/night ($9 \times \$258 = \$2,322$); Ten days' meals and incidental expenses at \$79 per day prorated to 75% (\$59.25) for first and last day of travel ($\$59.25 \times 2 + \$79 \times 8 = \$750.5$); Round trip flight between Bangkok to Dulles International Airport is estimated at \$1,650; local transportation/taxi between hotel and airport per round trip between Chulalongkorn Hospital to airport is estimated at \$40, between hotel and the airport in the US is estimated at \$200, and \$60 for transportation within the region (\$300).

F. Participant Support Costs

No participant support is requested.

G. Other Direct Costs (Total \$78,803)

Materials and Supplies (\$72,830)

PBMCs isolation (\$47,000). We request funds to conduct PBMC isolation from collected sample, costs including the reagents and lab consumable and supplies are estimated at \$47 per cell for 1,000 cells.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Multiplex microsphere immunoassay detection (\$2,275). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at \$6.5 per sample for 350 samples.

PCR testing and sequencing (\$20,475). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at average \$58.5 per sample 350 samples, given a 10%~15% positive rate.

Field supplies for PBMC collection and processing (\$1,225). Funds are requested to perform PBMCs collection and processing in the field. Costs including the reagents and lab consumable and supplies are estimated at average \$3.5 per sample 350 samples.

Field supplies for animal sampling (\$1,160). Funds are requested to purchase supplies for animal capture, anesthesia, and sample collection. A total cost of \$1,160 is estimated

Field work disposable (\$668). Funds are requested to purchase disposable materials (tips, tubes, gloves, masks, googles etc.) for field work.

Consultants Service (\$3,000)

One (1) zoologist and one (1) veterinarian will provide consultancy service to this project to help 1) select sites for animal sampling and join the sampling trip to 2) identify species; and 3) provide veterinary care in the sample collection of rodents and shrews. The consultancy fee is estimated at \$1,500 per person for the project, in total of \$3,000.

Publication Fee (\$3,000)

We request \$3,000 of publication costs for one peer-review paper generated from the project. The cost is estimated at the reimbursed Open Access fees of \$2,900 - \$5,000 per manuscript in the past two years for six peer-review papers.

H. Total Direct Costs (Total \$138,831)

I. Indirect Costs (Total \$11,106)

An indirect cost at 8% is requested.

J. Total Direct and Indirect Costs (Total \$149,937)

A total amount of \$149,937 is requested.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Co-PI Plan (only needed if applying as Co-PIs):

What each Co-PI will contribute to the proposed research study

As stated in the Mentoring Plan, the co-PIs, Krongkan Srimuang and Spencer Sterling have different educational and training backgrounds. This Co-PI plan is proposed to fill the gaps in knowledge of each scientist and supports a collaborative working relationship for project success. Moreover, this plan was developed to maximize the strengths of each PI. Overall, the project is separated into two objectives, the proposal of this project will be equally managed by Dr. Srimuang and Mr. Sterling. Dr. Srimuang will be responsible for PBMC isolation, sorting, and characterization. Mr. Sterling will be responsible for the technical serological aspects of the project. Both will work closely with the Research Center Mentor, Dr. Eric Laing, to develop this project, protocol development, and network connections. Dr. Supaporn Wacharapluesade, the Co-mentor, will support the wildlife sampling, samples collection, and molecular aspects within Thailand.

How the Co-PIs will jointly work with the affiliated Research Center

Dr. Srimuang is currently employed at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University and supports the molecular biology investigations in the EID-SEARCH project. Mr. Sterling is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Both Co-PIs will work closely with Dr. Laing, Dr. Wacharapluesadee, and the staff at EcoHealth Alliance to coordinate field sampling, research activities, data analysis, and manuscript production.

How the Co-PIs will jointly manage the proposed study

This is a great opportunity for both PIs to undergo training in advanced techniques and develop skills in next-generation serology and molecular sequencing. Dr. Srimuang will learn and practice serologic

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

techniques and data analysis from Mr. Sterling. Mr. Sterling will develop skills in cell isolation and molecular sequencing techniques from Dr. Srimuang. Moreover, Mr. Sterling will coordinate planning, sample processing, data analysis, and report preparation for this project with Dr. Srimuang.

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), cell sorting machine and a BSL3 laboratory. Moreover, the facility provides general equipment, such

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country.

Computer:

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

PI Name: **Srimuang, Krongkan and Sterling, Spencer**
CREID CC Grant: 1U01AI151378

Foreign Site: **Thailand**

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Krongkan Srimuang
Project Title:	Immune memory bait & capture to identify emerging henipavirus origins
Institution:	King Chulalongkorn Memorial Hospital
Foreign Research Site:	Rama 4 Road, Pathumwan, Bangkok 10330 Thailand
Point of Contact for Research Site:	Krongkan Srimuang Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital Rama 4 Road, Pathumwan, Bangkok 10330 Thailand krongkan.sr@gmail.com

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goals of this project are to know zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

To achieve these goals, the investigator will collaborate with NIH PREMISE for Antibody-mediated bait & capture of Thai MojV-like virus.

\$149,937 of grant funds will be sent to the site for these studies.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will 1) conduct all filed work to collect human and animal samples from the study sites; 2) perform laboratory analysis using collected samples; and 3) conduct data analysis as proposed in the project.

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - **IRB approval number for parent study:** #894ECOH21b (US); #221/64 (Thailand)
 - **IRB approval date:** 12-05-2021 (US); 08-06-2021 (Thailand)
 - **Human Subject Assurance Number: (FWA)#:** #00001102 (external IRB); #00022431 (EcoHealth Alliance); #00000943 (Chulalongkorn University)
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - **Yes**
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - **No**
 - **How many subjects provided the existing samples to be used?** N/A
- **Will human subjects be recruited (Yes or No)**
 - **Yes**
 - **Number of human subjects that will be recruited:** 110
- **Population parameters:**
 - **Gender:** 55 males, 55 females
 - **Age Group:** Age >=18 years who provide informed consent.
 -
 - **Race/Ethnicity:** 110 Asian
- **Sample collection will include:**
 - **Blood:** Yes
 - **Urine:** No
 - **Tissues:** No
 - **Other samples (describe):** Nasopharyngeal swab and throat swab

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

- **Sample collection will be completed in how many visits:** 2 trips
- **Will samples be de-identified (Yes or No)? If No, describe how they will be protected.**
 - Yes
- **Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.**
 - Yes
- **Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Animal Subjects (1 word or 1 sentence per bullet):

- **Parent study IACUC approval**
 - IACUC approval number for parent study: #G2020-42 (US); #019/2563 (Thailand)
 - IACUC approval date: 05-05-2020 (US); 03-12-2020 (Thailand)
 - Animal Welfare Assurance Number: D16-00572 (A4059-01)
- **Does this study require a modification to the IACUC approval of a parent study (Yes or No)?**
 - No
- **Will existing samples from animal subjects will be used: (Yes or No)?**
 - No
 - How many animal subjects provided the existing samples to be used? N/A
- **Will vertebrate animals be collected (Yes or No)?**
 - Yes
- **Species of animals (e.g. rats, mice, rabbits, monkeys):** Rodents and shrews
- **Animal parameters:**
 - Total number of animals: 200 (200 rodents and shrews)
 - Gender: 100 males, 100 females
 - Age range: 4 - 12 months and elder depending upon species
 - Lab strain (e.g. Sprague-Dawley rats, Balb/C mice): None
 - Wild animals procured in country (e.g. Rhesus monkeys from a reserve): No
- **What will be done to them or with them and how often?**
 - Free-ranging rodents and shrews will be captured through pit traps and box traps.
 - Anesthesia will be conducted for captive rodents and shrews.
 - Once anesthetized blood will be collected.
 - All action will only be performed one time for each animal individual.
 - All animals will be released after sampling.
- **What are the follow-ups?**
 - No follow-up relevant as per protocol, since all animals will be released after sampling ups

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

- **What will be their fate at the end of the experiments – will they be euthanized?**
 - All animals will not be held longer than 6 hours (typically less than 3 hours) during the sampling process and released after sampling.

- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Total Budget	<i>Repeat this table if there are two Co-PIs</i>
Direct Costs	\$138,831
Indirect Costs	\$11,106
Proposed Start Date	1 May 2023
Proposed End Date	30 April 2024

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) are bat-borne zoonotic viruses and cause high mortality. The recent detection of closely related Mojiang and Langya viruses in rats and shrews, and isolation of Langya virus from individuals with acute febrile illness, challenges the dogma that fruit bats are the sole henipavirus reservoirs. The recently expanded <i>Henipavirus</i> genus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. As part of EID-SEARCH activities, we found serological evidence of infection by a Mojiang-related virus in a community of Thai bat guano collectors who have occupational exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to identify novel viruses and zoonotic reservoirs through serologic and cellular immune discovery. We will conduct follow-up human and wildlife (bats and rodents) surveillance in the province where the seropositive humans were identified and apply an expanded serological test and genomic sequencing to detect this novel MojV-like henipavirus. Further, we</p>

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

plan to isolate anti-MojV monoclonal antibodies (mAb) from peripheral blood mononuclear cells collected from human study participants we have identified as immunoreactive with MojV antigens, and characterize the cross reactive and cross neutralizing potential of these mAbs to LayV.

Study Personnel

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as mentor for Dr. Srimuang and Mr. Sterling under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Laing is an assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses at Uniformed Services University, Bethesda, MD. Part of Dr. Laing's research focus is on the development of serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Dr. Laing has worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Through these collaborations, Dr. Laing's research group aims to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence.

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Formatted: Font: Bold

Objective 2. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody production and discovery.

Formatted: Font: Bold

~~Objective 3. To determine epitope binding and antigenic relationships from henipavirus reactive serum to the known henipaviruses.~~

Formatted: Font: Bold

Commented [EL4]: Where is this described?

Study Rationale

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McClinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genera of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, [GAKV and DARV](#) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding

Commented [EL5]: Abbreviations already used above

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The henipaviral genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australia (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected 19% (54/284) seroprevalence for MojV [in](#) a high-risk cohort, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia and likely due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology (serologic and cellular) to identify a novel virus that can aid in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. ~~In addition to the translational application of mAbs as therapeutics, we intend to utilize these mAb as non-clinical diagnostics surveillance tools for virus/virus antigen capture.~~ Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

Commented [EL6]: You may want to put this in the 2nd aim after you discuss the development of a mAb that could be also used for antigen detection as a diagnostic tool

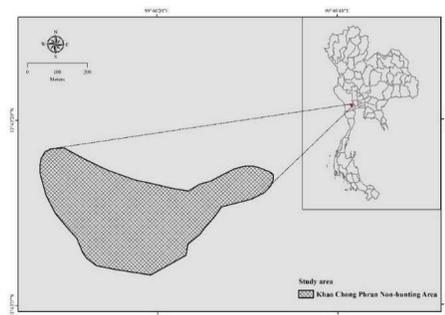

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Site wildlife samples collection

100 bats and 100 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. We plan one sampling trip to collect

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

bats, and a second trip to target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect 100 samples, and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored. Oral swab and rectal swab will also collect in 100 bats and 100 shrews or rodents. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

Human surveillance

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, 100 human serum samples, nasopharyngeal swab and throat swab will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,150 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

The sample size of 100 of each species follows the guidelines established during the PREDICT project.

Targeted Viral Sequencing and Serologic testing

Targeted sequencing

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The nucleic acid from oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing.

Serological testing

Serum samples will be tested for RBP and envelope fusion protein (F) binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Data analysis

Sequencing will be analyzed assembling reads in MEGA11. The consensus sequences will compare to the references strains available in the GenBank data-base using the Basic Local Alignment Software Tool (BLAST) (National Center for Bio-technology Information). Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to LayV RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipas, and LayV, depending on how well these cross react.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 2).

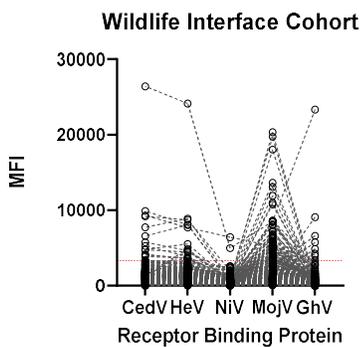

Figure 2: Seroprevalence of henipavirus proteins from a community with a large bat interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, a threshold for seropositivity.

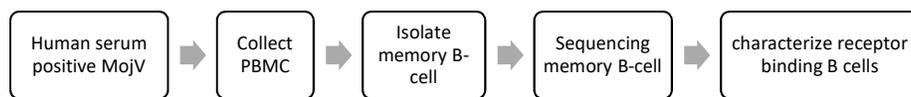

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

PBMC Sorting and B Cell isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes). Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3-,CD14-,CD56-, IgM-, IgA-, CD19+,CD20+,CD27+). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor Amplicon Preparation and Recombinant Antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced. After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

We will first determine the extent to which isolated mAbs can bind binding to native-like MojV RBP and F proteins. We will also characterize the [cross-reaction](#) potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. However, MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of MojV neutralizing potential is not possible. Though, we will test the [cross-neutralization](#) potential of these anti-MojV RBP and F mAbs to neutralize LayV utilizing a plaque reduction neutralization test with EID-SEARCH co-investigators at Duke-NUS. As LayV causes acute illness in human, cross neutralization functionality of these mAbs has therapeutic potential.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Research Performance Sites

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country. We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

CREID Research Center Collaboration

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. Further, Dr. Doeuk who is the director of the VRC PREMISE program is enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Ig) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Mentoring Plan

Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant writing and project management skills. My professional relationship with Dr. Wacharapluesadee began in 2018 when I participated in a DTRA BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group. Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Vertebrate Animals Section Requirements

Animal samples will be collected in Ratchaburi Province for this project under Aim 2 to understand the antigenic relationships among known and unknown henipaviruses. Protocol to perform animal sample collection has been reviewed and approved by the Institutional Animal Care and Use Committee at Tuft University under the EID-SEARCH project (No. G2020-42) and the Institutional Animal Care and Use Committee at Chulalongkorn University (No. 019/2563)

1. Description of Procedures

Bats (order *Chiroptera*)

- Species: Free-ranging mega and micro-*Chiroptera* that present at the site (family *Pteropodidae*, *Rhinopomatidae*, *Emballonuridae*, *Craseonycteridae*, *Megadermatidae*, *Rhinolophidae*, *Hipposideridae*, *Vespertilionidae*, *Mollossidae*, etc.)
- Age & Sex: Fully flighted adults and juveniles, males and females; neonates dependent on the dam will not be used.
- Target Number: 100 individuals
- Capture and Restraint: Bats will be captured using either a mist net or harp trap. The net system is manned by at least two people during the entire capture period, and bats are removed from the net as soon as they become entangled to minimize stress and prevent injury. In our previous field research experience, a maximum of 20-30 bats can be safely held and processed by a team of three people per trapping period. Duration of trapping will depend on the capture rate. Bats are individually placed into a pillowcase or small cloth bag and hung from a branch or post in a location that is free from access by both predators and people, and is protected from the elements (e.g., rain), until the animal is restrained for sample collection. Bats will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and bat. The study protocol covers over 69 bat species that are most likely to be captured given their natural occurrence and previous surveillance experience in Southeast Asia. The potential for non-target species to be captured is very low because mist nets are opened at the cave entrance at night, after other species (e.g., birds) have ceased flying and returned to roost. Any non-target species will be rapidly identified, removed from the mist net and released immediately.
- Sample Collection: Depending on the species and size of bat, blood will be collected from smaller insectivorous bats (<50g) using a 27g needle to puncture the brachial artery and a 70ul hematocrit tube to collect the blood. For larger bats (>50g) we will collect blood from either the cephalic vein or from the radial artery or vein using a 25- or 23-gauge needle and 3cc syringe. Blood will be collected in quantities not exceeding 6 μ L/g of body mass from each individual. Wing punch biopsies will be collected to confirm host identification using DNA barcoding. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected and whole body submitted to museums as voucher specimens.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- **Release:** Bats are held for a maximum of six hours (typically less than three hours), and at the completion of sampling are provided with rehydrating fluids (either subcutaneously or orally as needed) and released in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided).

Rodents (order: *Rodentia*) and Shrew (order: *Scandentia* and *Eulipotyphla*)

- **Species:** Free-ranging rodents (family *Hystricidae*, *Muridae*, *Sciuridae*, *Spalacidae*) and shrew (tree shrews, shrews, moles) that present at the sites.
- **Age & sex:** Adults and juveniles, males and females. Neonates will not be sampled.
- **Target Number:** 100 individuals
- **Capture and Restraint:** Free-ranging wild mammal species will be captured with metal box traps (Sherman/Tomahawk traps). Traps will be prepared with food, water, padding and shelter, and be checked at least every 12 hours, in the morning and in the afternoon. If adverse weather (extreme heat, rain) is expected or researchers are working in areas where predation is common, traps will be checked more frequently and closed during adverse weather. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. Depending on the species, individual size, captive or free-ranging status of the individual, manual or chemical restraint and anesthesia (gas or injectable anesthesia) will be applied. Animals will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and animal. Based upon past field experience (>20 years of animal capture and release in Southeast Asia), we do not expect to trap sick, debilitated, or young animals that would be too young to cope with capture. Sick and debilitated animals tend not to roam widely, reducing their opportunity to enter traps. Additionally, should sick, debilitated, or young animals enter traps, we anticipate that they will not suffer adverse conditions because the traps contain food (the bait) and liquid (water or fruit as a source of water). These individuals would be examined by a veterinarian, rehydrated and if presenting clinical signs treated by a veterinarian, prior to release or sampling then release.
- **Sample Collection:** Once anesthetized or safely restrained, whole blood will be collected through the appropriate venipuncture site, no more than 1 ml of blood per 100 g (= 10 ml/kg or 1%) of body weight will be collected at any one time. Anesthetized animals will be monitored regularly during recovery until they can no longer be safely handled, at which point they will be confined in a trap or cage. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected.
- **Release:** Wild mammals are held for a maximum of thirteen hours depending on trap timing, but typically less than three hours. Captive animals are held for a maximum of two hours but typically less than one hour. At the completion of sampling, animals may be provided with rehydrating fluids (either subcutaneously if anesthetized or orally if manually handled and accepted). Wild mammals will be released at the site of capture in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided). Captive mammals will be released back into their captive setting as is appropriate for the species, either isolated or in social group if it is deemed safe from aggression from enclosure mates while the post-recovery period continues.

2. Justifications

The purpose of this study is to identify zoonotic pathogens through serologic and cellular immune discovery, including developing methods and standards for direct antibody-mediated virus capture in people and wildlife, focusing on rodent/shrew- and bat-borne HPVs. This will require hands-on fieldwork to collect whole blood and serum samples from bats, rodents, and shrews for lab analysis. One technique that avoids the direct capture and sampling of animals is to collect fresh feces or urine,

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

but this will not be able to provide the appropriate samples for serologic analysis, and the research objectives cannot be achieved using an alternative methods (e.g., computational, human, invertebrate, in vitro). Therefore, we believe there are no viable alternatives than the use of live animals.

3. Minimization of Pain and Distress

In every situation, sampling of wildlife will be conducted in the most humane manner while minimizing the impacts on individual animals and their wild populations. In all instances, the fewest number of animals will be sampled that will provide valid information and statistical inference for the pathogen and disease of interest and every effort will be made to minimize stress and discomfort for the animal.

Bats will not be held longer than six hours during the sampling process whereas small mammals may be held for up to 13 hours depending on trap capture timing. Field animal sampling team with zoologists and veterinarians have been well trained and have extensive experience in capture, anesthesia, and sampling of wildlife. In our team's experience, the target species tolerate the described procedure well. Mist nets will be attended continuously during capture periods, and bats will be extracted from the net as soon as they become entangled. This will minimize stress and injury from entanglement. Bats will be placed individually in cloth bags and hung from tree branches while awaiting processing and during recovery. The bags are sufficiently porous as to allow for ventilation and are designed for bat capture. The enclosed environment seems to calm the bats, as they do not struggle once inside, but they hang quietly – this is a standard and accepted practice in bat research and the best way to minimize stress to the animal.

For rodents and shrews, food, water, padding and shelter will be provided at traps, which will be checked at least every 12 hours. Traps will be checked more frequently or closed if adverse weather (extreme heat, rain) is expected, or researchers are working in areas where predation is common. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. All animal individuals will be monitored by a veterinarian or experienced field team member during all stages of capture, processing, anesthesia and release. Animals will be kept in a cool place, free from adverse weather conditions and access by non-field team members or other animals while in the pillowcases, trap, or cage for recovery. All recovering individuals will be observed until they are able to effectively ambulate and orient to their surroundings. Animals that are injured during the capture or sampling process will be assessed by an experienced team leader or attending veterinarian, and if the animal is determined to be unlikely to survive if released, it shall be euthanized humanely (see euthanasia section).

4. Method of Euthanasia

In the event that an animal has been injured or is moribund, a determination will be made as to whether it may be treated and released on site by veterinarians or transferred to facility that may treat and rehabilitate the animal, or if, as a last resort, the animal will require euthanasia. Euthanasia methods will vary depending on species; however methods to be used will not deviate from the AVMA "Guidelines for the Euthanasia of Animals" (2020 edition). Any animal that is euthanized using a chemical agent will be disposed of such that it will not be permitted to enter the food supply either through markets or hunting.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Human Subjects Research

1. Risks to the subjects

In this project, we will target populations in one community site who with frequent exposure to bats and other wildlife based on our previous behavioral survey. Subjects will be enrolled voluntarily, and informed consent will be obtained from all participants, along with assent from all participants aged 12-17. Enrolled participants will provide biological samples. Survey data and biological samples will be collected from enrolled participants, and follow-up data collection will be performed among participants whose samples were tested positive.

Biological samples and questionnaire data will be collected from individuals who meet recruitment and inclusion criteria and complete the informed consent process. During data collection, a standardized questionnaire will be administered to all participants. This questionnaire will collect information of demographic background, wildlife contact, travel and daily movement, and unusual SARI/ILI symptoms, and biological specimens will be collected from participants. Both questionnaire and biological data will be analyzed to assess the exposure to coronaviruses and the spread risk among humans. From all participants, a one-time whole blood sample (Max. 15 mL) will be collected during the study period. This sample will allow us to test for historical exposure to bat or rodent-borne henipaviruses and collect Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive.

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals who are proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions; however, the administration will be conducted privately and confidentially to protect individuals' health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

2. Adequacy of protection against these risks

2.1 Informed consent and assent

Only consented participants will be enrolled in the study. No research procedures will be undertaken before the participant fully understands the research, agrees to the study procedures, and completes the consent process will be enrolled in the study. Informed consent statements and forms, and project protocols will be translated into the local language of each study site. Research team members involved in this consent process will be required to be fluent in the local language to ensure that the subjects understand the study and all involved procedures.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

If participants meet the criteria for enrollment, they will be invited to discuss the details of the study with the research staff. Study staff will review an information sheet and informed consent form with the participant and the parent or legal guardian when applicable. Each individual will be provided with a copy of the informed consent form that has been translated into the local language and written with a Flesch–Kincaid readability score equivalent to a 7th-grade reading level or below, to assure that potential participants understand the information being shared. The informed consent form will explain the details of the study, including how and why the individual was selected, the study process and procedures, risks and benefits, financial considerations and the gift of appreciation, confidentiality of data shared, alternatives to participating, and how to obtain more information now or at a later date. The informed consent form will be read in the local language of the site at a location ensuring participant privacy. After which individuals will have as much time as they would like to ask questions and discuss the study with study staff. The study staff will endeavor to ensure that the participant understands the information provided. The study staff will then ask the participant/parent or legal guardian to consider study participation. Participants will have as much time as required to consider the participation.

Those participants who consent to the study will sign and date two copies of the consent form. These form copies will be countersigned and dated by the study staff. A copy of the signed consent form must be provided to the subject and the other copy will be kept by study staff. Informed consent paperwork will be kept until the end of the project in a locked box at the local country project office.

2.2 Protection against risks

The potential risks to study participants as a result of study participation are minimal. Collection of venous blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. Potential complications associated with venipuncture include pain and/or hematoma at the site of collection. Trained medical professionals and/or clinic staff will monitor the blood collection site and treat any complications according to existing health facility protocols. A potential complication of nasal/ oropharyngeal sampling is minor irritation at the time of collection. Employing trained medical and/or clinic staff to collect blood and swab samples will minimize the potential for complications.

Another risk that this study may pose concerns the information to be gained on henipaviruses newly recognized in the community. We will provide participating communities, hospitals, and clinicians with information and background data on target zoonotic viruses to ensure up-to-date communication of risk. Because of the timeline for diagnostic testing and results interpretation, we are not likely to provide results to participating clinics within a time frame that would be clinically relevant to outbreaks of undiagnosed diseases. Therefore, the information provided by this project will not impact patient management or outlook.

If an individual decides to participate in this research, his/her participation and all information provided by the participant will be strictly confidential, and personal identifying information will not be shared with anyone outside of the study staff. Participants will not be identified or named in any reports or publications. Questionnaire information and all biological samples will be identified by an alphanumeric code, not by the participant's name. All records that contain names or other personal identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the study site in locked files cabinets or password-protected devices in areas with access limited to the research staff of this project. Research databases will be secured with password-protected access systems and controlled distribution web-based certificates and will not contain any identifying characteristics about study participants (e.g., name, address, or telephone number). Access to all data will be limited to the staff involved in this study. The health information disclosed by an individual will not be used

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

by or disclosed (released) to another institution. Any surveillance report that is published or shared with partners will not contain any personally identifying information for individual participants.

3. Potential benefits of the research to the subjects and others

There are no measurable benefits to the individual study participants enrolled in this study. There are benefits to the community and regional healthcare providers to help them understand the risk of zoonotic infections among high-risk populations in the regions they work. At the conclusion of the study, we will deliver an educational workshop reporting aggregate study findings that will be open to both study and non-study participants, describing the health benefits of using personal protection equipment (PPE) and handwashing during animal handling activities throughout the day, as well as to share other prevention/interventions that emerge from the research data.

4. Importance of the knowledge to be gained

There are valuable potential benefits to the public from the knowledge to be gained from this study. One key benefit to the community is sharing information and knowledge to better understand the risk of zoonotic spillover events and related health risks, as well as information sharing with communities on practices that could reduce risks, such as the avoidance of particular animal contacts or the need for PPE and extra care when handling wildlife, that may substantially reduce the risk zoonotic pathogen transmission in the community. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to create or implement public health interventions to disrupt disease emergence and/or spread in an area that is beneficial to all. Additionally, there are valuable benefits to the general public from the knowledge to be gained from this study. Knowledge gained will increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

5. Country- / institution-specific ethics / IRB regulations addressed

Main research protocol and materials to conduct human subject research in this project have been reviewed and approved by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64). Amendment for PBMCs collection will be made and approved before the start of this project.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Budget Justification

A. Key Personnel (Total \$24,000)

Dr. Krongkan Srimuang, PI (12 months) is a medical research scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital (TRC-EIDCC) who have been leading the laboratory analysis for the EID-SEARCH work in Thailand in the past three years to perform molecular, serological, and next-generation sequencing to identify novel viruses from human and animal samples. Dr. Srimuang will commit 12 months to this project to design, manage, and perform all project activities in the lab and field by supervising a lab technician and working with the field coordinator. Dr. Srimuang will also work closely with the co-PI and Mentors to conduct data analysis and develop manuscript and join EID-SEARCH and CREID meetings to present the project findings.

Spencer Sterling, Co-PI (6 months) is the research coordinator of Laing Lab at the Uniformed Services University for Indo-Pacific region and a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC). Sterling will commit 6 months to this project as the co-PI, who will work closely with the PI in the study design, SOP development, sampling process, data analysis of for serological investigations. No salary is required for Sterling.

B. Other Personnel (Total \$20,000)

One (1) Laboratory Technician (12 months) will commit 12 months to this project to conduct PCR and serological testing of animal and human samples at TRC-EIDCC, under the supervision of Dr. Srimuang and Sterling. Salaries for 12 months at \$1,250 per month is requested (\$15,000).

One (1) Field Coordinator (4 months) will commit 4 months to this project, working closely with Dr. Srimuang and Sterling to organize and conduct field sample collection among humans and animals at the study sites, and support relevant financial management. Salaries for 4 months at \$1,250 per month is requested (\$5,000).

C. Fringe Benefits

No Fringe is requested.

D. Equipment

No equipment is requested.

E. Travel (Total \$48,375, Years 1-5)

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Domestic Travel (\$11,005)

Support for domestic travel for field sampling is requested in the amount of \$11,005 per to conduct four (4) trips of sample collection from humans, bats, and rodents/shrews.

- The first trip is a one-day trip to collect samples from human participants who were tested positive ($n < 10$), the cost is estimated at van rental for local transportation between Bangkok and the study site (\$260) and meals for five (5) field team members at \$49 per person (\$245), in total of \$505 for the first trip.
- The other three (3) field trips will be conducted to collect samples from 100 bats, 100 humans, and 100 rodents/shrews, respectively. Each trip is a duration of 6 days and 5 nights. For each person, 5-night stay in hotels at \$75.5/night ($5 \times \$75.5 = \378); 3 meals per day and incidental expenses at \$49 per day prorated to 75% (\$36.75) for first and last day of travel ($\$36.75 \times 2 + \$49 \times 4 = \$270$), the total meals and accommodations for each person per trip is \$648 ($\$378 + 270$), cost for five (5) field team members is \$3,240. A van will be rented for local transportation between Bangkok and the study site that is estimated at \$260 per trip. Total cost for each 6-day trip is \$3,500, three trips will be \$10,500.

International Travel (\$5,023)

Support for international travel for Dr. Srimuang from Bangkok to Washington DC to attend the CREID Annual Meeting and receive lab training at the National Institute of Allergy and Infectious Diseases (NIAID) is requested in the amount of \$5,023. Trips are for a duration of 10 days and 9 nights. Travel costs for one trip are estimated using federal per diem rates for hotels, meals, and incidental expenses as follows: nine-night stay in DC area hotel at \$286/night ($9 \times \$258 = \$2,322$); Ten days' meals and incidental expenses at \$79 per day prorated to 75% (\$59.25) for first and last day of travel ($\$59.25 \times 2 + \$79 \times 8 = \$750.5$); Round trip flight between Bangkok to Dulles International Airport is estimated at \$1,650; local transportation/taxi between hotel and airport per round trip between Chulalongkorn Hospital to airport is estimated at \$40, between hotel and the airport in the US is estimated at \$200, and \$60 for transportation within the region (\$300).

F. Participant Support Costs

No participant support is requested.

G. Other Direct Costs (Total \$78,803)

Materials and Supplies (\$72,830)

PBMCs isolation (\$47,000). We request funds to conduct PBMC isolation from collected sample, costs including the reagents and lab consumable and supplies are estimated at \$47 per cell for 1,000 cells.

Multiplex microsphere immunoassay detection (\$2,275). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at \$6.5 per sample for 350 samples.

PCR testing and sequencing (\$20,475). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at average \$58.5 per sample 350 samples, given a 10%~15% positive rate.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Field supplies for PBMC collection and processing (\$1,225). Funds are requested to perform PBMCs collection and processing in the field. Costs including the reagents and lab consumable and supplies are estimated at average \$3.5 per sample 350 samples.

Field supplies for animal sampling (\$1,160). Funds are requested to purchase supplies for animal capture, anesthesia, and sample collection. A total cost of \$1,160 is estimated

Field work disposable (\$668). Funds are requested to purchase disposable materials (tips, tubes, gloves, masks, googles etc.) for field work.

Consultants Service (\$3,000)

One (1) zoologist and one (1) veterinarian will provide consultancy service to this project to help 1) select sites for animal sampling and join the sampling trip to 2) identify species; and 3) provide veterinary care in the sample collection of bats, rodents, and shrews. The consultancy fee is estimated at \$1,500 per person for the project, in total of \$3,000.

Publication Fee (\$3,000)

We request \$3,000 of publication costs for one peer-review paper generated from the project. The cost is estimated at the reimbursed Open Access fees of \$2,900 - \$5,000 per manuscript in the past two years for six peer-review papers.

H. Total Direct Costs (Total \$138,831)

I. Indirect Costs (Total \$11,106)

An indirect cost at 8% is requested.

J. Total Direct and Indirect Costs (Total \$149,937)

A total amount of \$149,937 is requested.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Co-PI Plan (only needed if applying as Co-PIs):

What each Co-PI will contribute to the proposed research study

As stated in the Mentoring Plan, the co-PIs, Krongkan Srimuang and Spencer Sterling have different educational and training backgrounds. This Co-PI plan is proposed to fill the gaps in knowledge of each scientist and supports a collaborative working relationship for project success. Moreover, this plan was developed to maximize the strengths of each PI. Overall, the project is separated into two objectives, the proposal of this project will be equally managed by Dr. Srimuang and Mr. Sterling. Dr. Srimuang will be responsible for PBMC isolation, sorting, and characterization. Mr. Sterling will be responsible for the technical serological aspects of the project. Both will work closely with the Research Center Mentor, Dr. Eric Laing, to develop this project, protocol development, and network connections. Dr. Supaporn Wacharapluesade, the Co-mentor, will support the wildlife sampling, samples collection, and molecular aspects within Thailand.

How the Co-PIs will jointly work with the affiliated Research Center

Mr. Sterling is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region.

Commented [EL7]: Need something for KIO

How the Co-PIs will jointly manage the proposed study

This is a great opportunity for both PIs to undergo training in advanced techniques and develop skills in next-generation serology and molecular sequencing. Dr. Srimuang will learn and practice serologic techniques and data analysis from Mr. Sterling. Mr. Sterling will develop skills in cell isolation and molecular sequencing techniques from Dr. Srimuang. Moreover, Mr. Sterling will coordinate planning, sample processing, data analysis, and report preparation for this project with Dr. Srimuang.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), cell sorting machine and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country. Bats are considered protected wildlife in Thailand by Wildlife Conservation, Department of National Parks, Wildlife and Plant Conservation.

Computer:

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

PI Name: **Srimuang, Krongkan and Sterling, Spencer**
CREID CC Grant: 1U01AI151378

Foreign Site: **Thailand**

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Krongkan Srimuang
Project Title:	Immune memory bait & capture to identify emerging henipavirus origins
Institution:	King Chulalongkorn Memorial Hospital
Foreign Research Site:	Rama 4 Road, Pathumwan, Bangkok 10330 Thailand
Point of Contact for Research Site:	Krongkan Srimuang Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital Rama 4 Road, Pathumwan, Bangkok 10330 Thailand krongkan.sr@gmail.com

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goals of this project are to know zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

To achieve these goals, the investigator will collaborate with NIH PREMISE for Antibody-mediated bait & capture of Thai MojV-like virus.

\$149,937 of grant funds will be sent to the site for these studies.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

The site will 1) conduct all field work to collect human and animal samples from the study sites; 2) perform laboratory analysis using collected samples; and 3) conduct data analysis as proposed in the project.

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - IRB approval number for parent study: #894ECOH21b (US); #221/64 (Thailand)
 - IRB approval date: 12-05-2021 (US); 08-06-2021 (Thailand)
 - Human Subject Assurance Number: (FWA)#: #00001102 (external IRB); #00022431 (EcoHealth Alliance); #00000943 (Chulalongkorn University)
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - Yes
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - No
 - How many subjects provided the existing samples to be used? N/A
- **Will human subjects be recruited (Yes or No)**
 - Yes
 - Number of human subjects that will be recruited: 110
- **Population parameters:**
 - Gender: 55 males, 55 females
 - Age Group: Age >=18 years who provide informed consent.
 -
 - Race/Ethnicity: 110 Asian
- **Sample collection will include:**
 - Blood: Yes
 - Urine: No
 - Tissues: No
 - Other samples (describe): Nasopharyngeal swab and throat swab
- **Sample collection will be completed in how many visits: 2 trips**
- **Will samples be de-identified (Yes or No)? If No, describe how they will be protected.**
 - Yes
- **Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.**
 - Yes
- **Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**

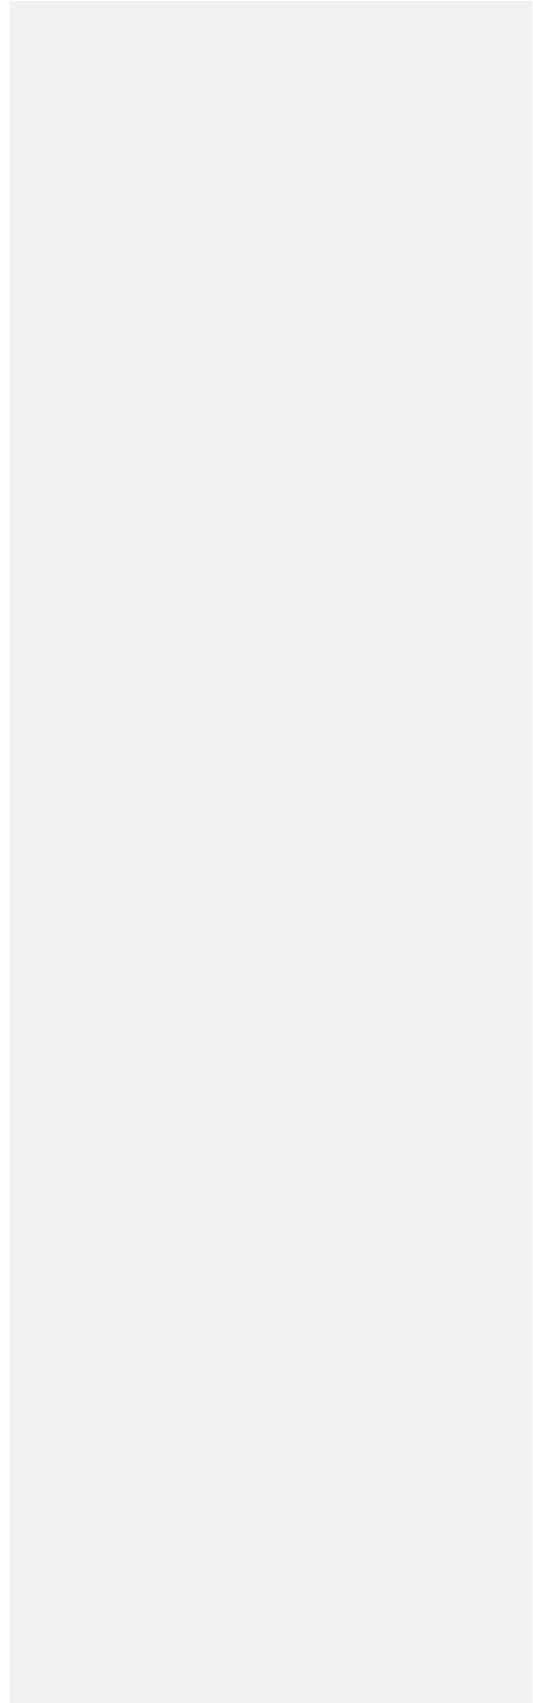

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Animal Subjects (1 word or 1 sentence per bullet):

- **Parent study IACUC approval**
 - IACUC approval number for parent study: #G2020-42 (US); #019/2563 (Thailand)
 - IACUC approval date: 05-05-2020 (US); 03-12-2020 (Thailand)
 - Animal Welfare Assurance Number: D16-00572 (A4059-01)
- **Does this study require a modification to the IACUC approval of a parent study (Yes or No)?**
 - No
- **Will existing samples from animal subjects will be used: (Yes or No)?**
 - No
 - How many animal subjects provided the existing samples to be used? N/A
- **Will vertebrate animals be collected (Yes or No)?**
 - Yes
- **Species of animals (e.g. rats, mice, rabbits, monkeys):** Bats, rodents, and shrews
- **Animal parameters:**
 - Total number of animals: 200 (100 bats, 100 rodents and shrews)
 - Gender: 100 males, 100 females
 - Age range: 4 - 12 months and elder depending upon species
 - Lab strain (e.g. Sprague-Dawley rats, Balb/C mice): None
 - Wild animals procured in country (e.g. Rhesus monkeys from a reserve): No
- **What will be done to them or with them and how often?**
 - Free-ranging bats will be captured using either a mist net or harp trap, and manually restrained during sampling; free-ranging rodents and shrews will be captured through pit traps and box traps.
 - Anesthesia will be conducted for captive rodents and shrews.
 - Once anesthetized blood will be collected.
 - All action will only be performed one time for each animal individual.
 - All animals will be released after sampling.
- **What are the follow-ups?**
 - No follow-up relevant as per protocol, since all animals will be released after sampling ups
- **What will be their fate at the end of the experiments – will they be euthanized?**
 - All animals will not be held longer than 6 hours (typically less than 3 hours) during the sampling process and released after sampling.
- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Proposed End Date	30 April 2024

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) are bat-borne zoonotic viruses and cause high mortality. The recent detection of closely related Mojiang and Langya viruses in rats and shrews, and isolation of Langya virus from individuals with acute febrile illness, challenges the dogma that fruit bats are the sole henipavirus reservoirs. The recently expanded <i>Henipavirus</i> genus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. As part of EID-SEARCH activities, we found serological evidence of infection by a Mojiang-related virus in a community of Thai bat guano collectors who have occupational exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to identify novel viruses and zoonotic reservoirs through serologic and cellular immune discovery. We will conduct follow-up human and wildlife (bats and rodents) surveillance in the province where the seropositive humans were identified and apply an expanded serological test and genomic sequencing to detect this novel MojV-like henipavirus. Further, we</p>

Study Personnel

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as mentor for Dr. Srimuang and Mr. Sterling under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Laing is an assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses at Uniformed Services University, Bethesda, MD. Part of Dr. Laing's research focus is on the development of serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Dr. Laing has worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Through these collaborations, Dr. Laing's research group aims to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence.

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

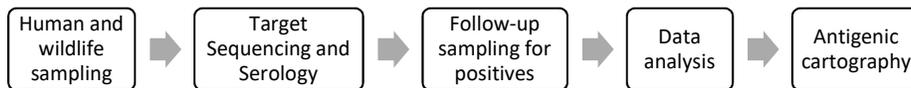

Specific Aims

The recent discovery of novel shrew and rodent-borne henipaviruses in East and Southeast Asia has highlighted gaps in our understanding of henipavirus transmission and underscores the importance of surveillance activities in the region. Therefore, this project aims to expand the study of known reservoirs of zoonotic pathogen origin by using genetic and serologic techniques, and to use cellular immune discovery in seropositive humans to be used as a tool to determine henipaviral antigenic relatedness to assist with the functional assessment of current therapeutics as and their effect on these novel viruses.

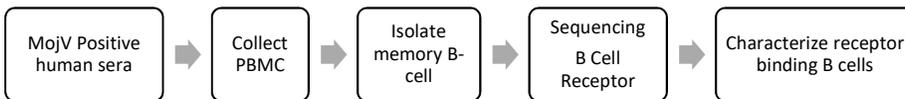

Human populations near the Khao Chong Phran Non-hunting Area in Ratchaburi province have shown a high seroprevalence to the MojV RBP without confirmed sequencing results. We hypothesize that (i) there is a novel henipavirus present in the local wildlife population that has spilled over into the human population at least once, and (ii) the antibodies from these seropositive people will react with the novel shrew-borne henipaviruses in a way that can inform us on therapeutic approaches for future outbreaks. We will follow-up on persons with high MojV RBP IgG titers, sample new people within the population that interact with the local wildlife, and sample bats, shrews, and rodents to find the source of the MojV-reactive antibodies. Additionally, in collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

The proposed project has two aims:

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

The proposed project has three objectives:

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Objective 2. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody production.

Objective 3. To determine epitope binding and antigenic relationships from henipavirus-reactive serum to the known henipaviruses.

Study Rationale

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McClinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genera of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, [GAKV and DARV](#) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The henipaviral genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Commented [EL2]: Abbreviations already used above

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australia (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected 19% (54/284) seroprevalence for MojV [in](#) a high-risk cohort, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia and likely due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology (serologic and cellular) to identify a novel virus that can aide in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. ~~In addition to the translational application of mAbs as therapeutics, we intend to utilize these mAb as non-clinical diagnostics surveillance tools for virus/virus antigen capture.~~ Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

Commented [EL3]: You may want to put this in the 2nd aim after you discuss the development of a mAb that could be also used for antigen detection as a diagnostic tool

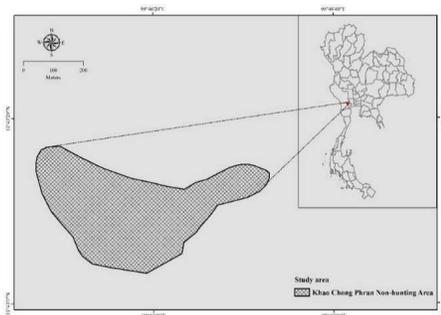

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Site wildlife samples collection

100 bats and 100 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. We plan one sampling trip to collect bats, and a second trip to target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect 100 samples, and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored. Oral swab and rectal swab will also collect in 100 bats and 100 shrews or rodents. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Human surveillance

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, 100 human serum samples, nasopharyngeal swab and throat swab will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,150 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

The sample size of 100 of each species follows the guidelines established during the PREDICT project.

Targeted Viral Sequencing and Serologic testing

Targeted sequencing

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The nucleic acid from oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing.

Serological testing

Serum samples will be tested for RBP and envelope fusion protein (F) binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Data analysis

Sequencing will be analyzed assembling reads in MEGA11. The consensus sequences will compare to the references strains available in the GenBank data-base using the Basic Local Alignment Software Tool (BLAST) (National Center for Bio-technology Information). Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to LayV RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipavas, and LayV, depending on how well these cross react.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 2).

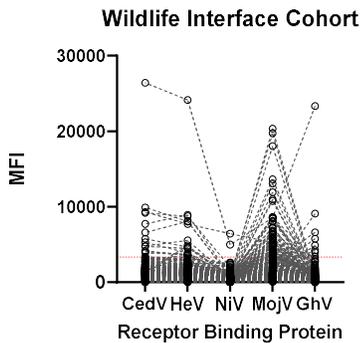

Figure 2: Seroprevalence of henipavirus proteins from a community with a large bat interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, a threshold for seropositivity.

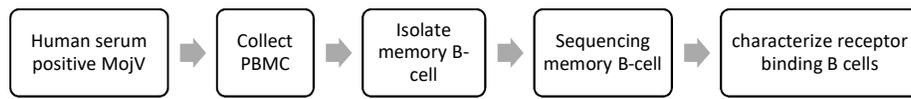

PBMC Sorting and B Cell isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes). Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3-, CD14-, CD56-, IgM-, IgA-, CD19+, CD20+, CD27+). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

B cell receptor Amplicon Preparation and Recombinant Antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced. After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

We will first determine the extent to which isolated mAbs can bind binding to native-like MojV RBP and F proteins. We will also characterize the [cross-reaction](#) potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. However, MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of MojV neutralizing potential is not possible. Though, we will test the [cross-neutralization](#) potential of these anti-MojV RBP and F mAbs to neutralize LayV utilizing a plaque reduction neutralization test with EID-SEARCH co-investigators at Duke-NUS. As LayV causes acute illness in human, cross neutralization functionality of these mAbs has therapeutic potential.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Research Performance Sites

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country. We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

CREID Research Center Collaboration

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. Further, Dr. Doeuk who is the director of the VRC PREMISE program is enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Ig) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Mentoring Plan

Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant writing and project management skills. My professional relationship Dr. Wacharapluesadee with began in 2018 when I participated in a DTRA

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group. Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Vertebrate Animals Section Requirements

Animal samples will be collected in Ratchaburi Province for this project under Aim 2 to understand the antigenic relationships among known and unknown henipaviruses. Protocol to perform animal sample collection has been reviewed and approved by the Institutional Animal Care and Use Committee at Tuft University under the EID-SEARCH project (No. G2020-42) and the Institutional Animal Care and Use Committee at Chulalongkorn University (No. 019/2563)

1. Description of Procedures

Bats (order *Chiroptera*)

- **Species:** Free-ranging mega and micro-*Chiroptera* that present at the site (family *Pteropodidae*, *Rhinopomatidae*, *Emballonuridae*, *Craseonycteridae*, *Megadermatidae*, *Rhinolophidae*, *Hipposideridae*, *Vespertilionidae*, *Mollossidae*, etc.)
- **Age & Sex:** Fully flighted adults and juveniles, males and females; neonates dependent on the dam will not be used.
- **Target Number:** 100 individuals
- **Capture and Restraint:** Bats will be captured using either a mist net or harp trap. The net system is manned by at least two people during the entire capture period, and bats are removed from the net as soon as they become entangled to minimize stress and prevent injury. In our previous field research experience, a maximum of 20-30 bats can be safely held and processed by a team of three people per trapping period. Duration of trapping will depend on the capture rate. Bats are individually placed into a pillowcase or small cloth bag and hung from a branch or post in a location that is free from access by both predators and people, and is protected from the elements (e.g., rain), until the animal is restrained for sample collection. Bats will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and bat. The study protocol covers over 69 bat species that are most likely to be captured given their natural occurrence and previous surveillance experience in Southeast Asia. The potential for non-target species to be captured is very low because mist nets are opened at the cave entrance at night, after other species (e.g., birds) have ceased flying and returned to roost. Any non-target species will be rapidly identified, removed from the mist net and released immediately.
- **Sample Collection:** Depending on the species and size of bat, blood will be collected from smaller insectivorous bats (<50g) using a 27g needle to puncture the brachial artery and a 70ul hematocrit tube to collect the blood. For larger bats (>50g) we will collect blood from either the cephalic vein or from the radial artery or vein using a 25- or 23-gauge needle and 3cc syringe. Blood will be collected in quantities not exceeding 6 μ L/g of body mass from each individual. Wing punch biopsies will be collected to confirm host identification using DNA barcoding. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected and whole body submitted to museums as voucher specimens.
- **Release:** Bats are held for a maximum of six hours (typically less than three hours), and at the completion of sampling are provided with rehydrating fluids (either subcutaneously or orally as needed) and released in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided).

Rodents (order: *Rodentia*) and Shrew (order: *Scandentia* and *Eulipotyphla*)

- **Species:** Free-ranging rodents (family *Hystricidae*, *Muridae*, *Sciuridae*, *Spalacidae*) and shrew (tree shrews, shrews, moles) that present at the sites.
- **Age & sex:** Adults and juveniles, males and females. Neonates will not be sampled.
- **Target Number:** 100 individuals

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- **Capture and Restraint:** Free-ranging wild mammal species will be captured with metal box traps (Sherman/Tomahawk traps). Traps will be prepared with food, water, padding and shelter, and be checked at least every 12 hours, in the morning and in the afternoon. If adverse weather (extreme heat, rain) is expected or researchers are working in areas where predation is common, traps will be checked more frequently and closed during adverse weather. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. Depending on the species, individual size, captive or free-ranging status of the individual, manual or chemical restraint and anesthesia (gas or injectable anesthesia) will be applied. Animals will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and animal. Based upon past field experience (>20 years of animal capture and release in Southeast Asia), we do not expect to trap sick, debilitated, or young animals that would be too young to cope with capture. Sick and debilitated animals tend not to roam widely, reducing their opportunity to enter traps. Additionally, should sick, debilitated, or young animals enter traps, we anticipate that they will not suffer adverse conditions because the traps contain food (the bait) and liquid (water or fruit as a source of water). These individuals would be examined by a veterinarian, rehydrated and if presenting clinical signs treated by a veterinarian, prior to release or sampling then release.
- **Sample Collection:** Once anesthetized or safely restrained, whole blood will be collected through the appropriate venipuncture site, no more than 1 ml of blood per 100 g (= 10 ml/kg or 1%) of body weight will be collected at any one time. Anesthetized animals will be monitored regularly during recovery until they can no longer be safely handled, at which point they will be confined in a trap or cage. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected.
- **Release:** Wild mammals are held for a maximum of thirteen hours depending on trap timing, but typically less than three hours. Captive animals are held for a maximum of two hours but typically less than one hour. At the completion of sampling, animals may be provided with rehydrating fluids (either subcutaneously if anesthetized or orally if manually handled and accepted). Wild mammals will be released at the site of capture in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided). Captive mammals will be released back into their captive setting as is appropriate for the species, either isolated or in social group if it is deemed safe from aggression from enclosure mates while the post-recovery period continues.

2. Justifications

The purpose of this study is to identify zoonotic pathogens through serologic and cellular immune discovery, including developing methods and standards for direct antibody-mediated virus capture in people and wildlife, focusing on rodent/shrew- and bat-borne HPVs. This will require hands-on fieldwork to collect whole blood and serum samples from bats, rodents, and shrews for lab analysis. One technique that avoids the direct capture and sampling of animals is to collect fresh feces or urine, but this will not be able to provide the appropriate samples for serologic analysis, and the research objectives cannot be achieved using an alternative methods (e.g., computational, human, invertebrate, in vitro). Therefore, we believe there are no viable alternatives than the use of live animals.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

3. Minimization of Pain and Distress

In every situation, sampling of wildlife will be conducted in the most humane manner while minimizing the impacts on individual animals and their wild populations. In all instances, the fewest number of animals will be sampled that will provide valid information and statistical inference for the pathogen and disease of interest and every effort will be made to minimize stress and discomfort for the animal.

Bats will not be held longer than six hours during the sampling process whereas small mammals may be held for up to 13 hours depending on trap capture timing. Field animal sampling team with zoologists and veterinarians have been well trained and have extensive experience in capture, anesthesia, and sampling of wildlife. In our team's experience, the target species tolerate the described procedure well. Mist nets will be attended continuously during capture periods, and bats will be extracted from the net as soon as they become entangled. This will minimize stress and injury from entanglement. Bats will be placed individually in cloth bags and hung from tree branches while awaiting processing and during recovery. The bags are sufficiently porous as to allow for ventilation and are designed for bat capture. The enclosed environment seems to calm the bats, as they do not struggle once inside, but they hang quietly – this is a standard and accepted practice in bat research and the best way to minimize stress to the animal.

For rodents and shrews, food, water, padding and shelter will be provided at traps, which will be checked at least every 12 hours. Traps will be checked more frequently or closed if adverse weather (extreme heat, rain) is expected, or researchers are working in areas where predation is common. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. All animal individuals will be monitored by a veterinarian or experienced field team member during all stages of capture, processing, anesthesia and release. Animals will be kept in a cool place, free from adverse weather conditions and access by non-field team members or other animals while in the pillowcases, trap, or cage for recovery. All recovering individuals will be observed until they are able to effectively ambulate and orient to their surroundings. Animals that are injured during the capture or sampling process will be assessed by an experienced team leader or attending veterinarian, and if the animal is determined to be unlikely to survive if released, it shall be euthanized humanely (see euthanasia section).

4. Method of Euthanasia

In the event that an animal has been injured or is moribund, a determination will be made as to whether it may be treated and released on site by veterinarians or transferred to facility that may treat and rehabilitate the animal, or if, as a last resort, the animal will require euthanasia. Euthanasia methods will vary depending on species; however methods to be used will not deviate from the AVMA "Guidelines for the Euthanasia of Animals" (2020 edition). Any animal that is euthanized using a chemical agent will be disposed of such that it will not be permitted to enter the food supply either through markets or hunting.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Human Subjects Research

1. Risks to the subjects

In this project, we will target populations in one community site who with frequent exposure to bats and other wildlife based on our previous behavioral survey. Subjects will be enrolled voluntarily, and informed consent will be obtained from all participants, along with assent from all participants aged 12-17. Enrolled participants will provide biological samples. Survey data and biological samples will be collected from enrolled participants, and follow-up data collection will be performed among participants whose samples were tested positive.

Biological samples and questionnaire data will be collected from individuals who meet recruitment and inclusion criteria and complete the informed consent process. During data collection, a standardized questionnaire will be administered to all participants. This questionnaire will collect information of demographic background, wildlife contact, travel and daily movement, and unusual SARI/ILI symptoms, and biological specimens will be collected from participants. Both questionnaire and biological data will be analyzed to assess the exposure to coronaviruses and the spread risk among humans. From all participants, a one-time whole blood sample (Max. 15 mL) will be collected during the study period. This sample will allow us to test for historical exposure to bat or rodent-borne henipaviruses and collect Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive.

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals who are proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions; however, the administration will be conducted privately and confidentially to protect individuals' health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

2. Adequacy of protection against these risks

2.1 Informed consent and assent

Only consented participants will be enrolled in the study. No research procedures will be undertaken before the participant fully understands the research, agrees to the study procedures, and completes the consent process will be enrolled in the study. Informed consent statements and forms, and project protocols will be translated into the local language of each study site. Research team members involved in this consent process will be required to be fluent in the local language to ensure that the subjects understand the study and all involved procedures.

If participants meet the criteria for enrollment, they will be invited to discuss the details of the study with the research staff. Study staff will review an information sheet and informed consent form with the participant and the parent or legal guardian when applicable. Each individual will be provided with a copy of the informed consent form that has been translated into the local language and written with a Flesch-Kincaid readability score equivalent to a 7th-grade reading level or below, to assure that potential participants understand the information being shared. The informed consent form will explain the details of the study, including how and why the individual was selected, the study process and procedures, risks and benefits, financial considerations and the gift of appreciation, confidentiality of data shared, alternatives to participating, and how to obtain more information now or at a later

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

date. The informed consent form will be read in the local language of the site at a location ensuring participant privacy. After which individuals will have as much time as they would like to ask questions and discuss the study with study staff. The study staff will endeavor to ensure that the participant understands the information provided. The study staff will then ask the participant/parent or legal guardian to consider study participation. Participants will have as much time as required to consider the participation.

Those participants who consent to the study will sign and date two copies of the consent form. These form copies will be countersigned and dated by the study staff. A copy of the signed consent form must be provided to the subject and the other copy will be kept by study staff. Informed consent paperwork will be kept until the end of the project in a locked box at the local country project office.

2.2 Protection against risks

The potential risks to study participants as a result of study participation are minimal. Collection of venous blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. Potential complications associated with venipuncture include pain and/or hematoma at the site of collection. Trained medical professionals and/or clinic staff will monitor the blood collection site and treat any complications according to existing health facility protocols. A potential complication of nasal/ oropharyngeal sampling is minor irritation at the time of collection. Employing trained medical and/or clinic staff to collect blood and swab samples will minimize the potential for complications.

Another risk that this study may pose concerns the information to be gained on henipaviruses newly recognized in the community. We will provide participating communities, hospitals, and clinicians with information and background data on target zoonotic viruses to ensure up-to-date communication of risk. Because of the timeline for diagnostic testing and results interpretation, we are not likely to provide results to participating clinics within a time frame that would be clinically relevant to outbreaks of undiagnosed diseases. Therefore, the information provided by this project will not impact patient management or outlook.

If an individual decides to participate in this research, his/her participation and all information provided by the participant will be strictly confidential, and personal identifying information will not be shared with anyone outside of the study staff. Participants will not be identified or named in any reports or publications. Questionnaire information and all biological samples will be identified by an alphanumeric code, not by the participant's name. All records that contain names or other personal identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the study site in locked files cabinets or password-protected devices in areas with access limited to the research staff of this project. Research databases will be secured with password-protected access systems and controlled distribution web-based certificates and will not contain any identifying characteristics about study participants (e.g., name, address, or telephone number). Access to all data will be limited to the staff involved in this study. The health information disclosed by an individual will not be used by or disclosed (released) to another institution. Any surveillance report that is published or shared with partners will not contain any personally identifying information for individual participants.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

3. Potential benefits of the research to the subjects and others

There are no measurable benefits to the individual study participants enrolled in this study. There are benefits to the community and regional healthcare providers to help them understand the risk of zoonotic infections among high-risk populations in the regions they work. At the conclusion of the study, we will deliver an educational workshop reporting aggregate study findings that will be open to both study and non-study participants, describing the health benefits of using personal protection equipment (PPE) and handwashing during animal handling activities throughout the day, as well as to share other prevention/interventions that emerge from the research data.

4. Importance of the knowledge to be gained

There are valuable potential benefits to the public from the knowledge to be gained from this study. One key benefit to the community is sharing information and knowledge to better understand the risk of zoonotic spillover events and related health risks, as well as information sharing with communities on practices that could reduce risks, such as the avoidance of particular animal contacts or the need for PPE and extra care when handling wildlife, that may substantially reduce the risk zoonotic pathogen transmission in the community. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to create or implement public health interventions to disrupt disease emergence and/or spread in an area that is beneficial to all. Additionally, there are valuable benefits to the general public from the knowledge to be gained from this study. Knowledge gained will increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

5. Country- / institution-specific ethics / IRB regulations addressed

Main research protocol and materials to conduct human subject research in this project have been reviewed and approved by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64). Amendment for PBMCs collection will be made and approved before the start of this project.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Budget Justification

A. Key Personnel (Total \$24,000)

Dr. Krongkan Srimuang, PI (12 months) is a medical research scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital (TRC-EIDCC) who have been leading the laboratory analysis for the EID-SEARCH work in Thailand in the past three years to perform molecular, serological, and next-generation sequencing to identify novel viruses from human and animal samples. Dr. Srimuang will commit 12 months to this project to design, manage, and perform all project activities in the lab and field by supervising a lab technician and working with the field coordinator. Dr. Srimuang will also work closely with the co-PI and Mentors to conduct data analysis and develop manuscript and join EID-SEARCH and CREID meetings to prevent the project findings.

Spencer Sterling, Co-PI (6 months) is the research coordinator of Laing Lab at the Uniformed Services University for Indo-Pacific region and a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC). Sterling will commit 6 months to this project as the co-PI, who will work closely with the PI in the study design, SOP development, sampling process, data analysis of for serological investigations. No salary is required for Sterling.

B. Other Personnel (Total \$20,000)

One (1) Laboratory Technician (12 months) will committee 12 months to this project to conduct PCR and serological testing of animal and human samples at TRC-EIDCC, under the supervision of Dr. Srimuang and Sterling. Salaries for 12 months at \$1,250 per month is requested (\$15,000).

One (1) Field Coordinator (4 months) will committee 4 months to this project, working closely with Dr. Srimuang and Sterling to organize and conduct field sample collection among humans and animals at the study sites, and support relevant financial management. Salaries for 4 months at \$1,250 per month is requested (\$5,000).

C. Fringe Benefits

No Fringe is requested.

D. Equipment

No equipment is requested.

E. Travel (Total \$48,375, Years 1-5)

Domestic Travel (\$11,005)

Support for domestic travel for field sampling is requested in the amount of \$11,005 per to conduct four (4) trips of sample collection from humans, bats, and rodents/shrews.

- The first trip is a one-day trip to collect samples from human participants who were tested positive (n<10), the cost is estimated at van rental for local transportation between Bangkok and the study site (\$260) and meals for five (5) field team members at \$49 per person (\$245), in total of \$505 for the first trip.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- The other three (3) field trips will be conducted to collect samples from 100 bats, 100 humans, and 100 rodents/shrews, respectively. Each trip is a duration of 6 days and 5 nights. For each person, 5-night stay in hotels at \$75.5/night (5 x \$75.5 = \$378); 3 meals per day and incidental expenses at \$49 per day prorated to 75% (\$36.75) for first and last day of travel (\$36.75 x 2 + \$49 x 4 = \$270), the total meals and accommodations for each person per trip is \$648 (\$378+270), cost for five (5) field team members is \$3,240. A van will be rented for local transportation between Bangkok and the study site that is estimated at \$260 per trip. Total cost for each 6-day trip is \$3,500, three trips will be \$10,500.

International Travel (\$5,023)

Support for international travel for Dr. Srimuang from Bangkok to Washington DC to attend the CREID Annual Meeting and receive lab training at the National Institute of Allergy and Infectious Diseases (NIAID) is requested in the amount of \$5,023. Trips are for a duration of 10 days and 9 nights. Travel costs for one trip are estimated using federal per diem rates for hotels, meals, and incidental expenses as follows: nine-night stay in DC area hotel at \$286/night (9 x \$258 = \$2,322); Ten days' meals and incidental expenses at \$79 per day prorated to 75% (\$59.25) for first and last day of travel (\$59.25 x 2 + \$79 x 8 = \$750.5); Round trip flight between Bangkok to Dulles International Airport is estimated at \$1,650; local transportation/taxi between hotel and airport per round trip between Chulalongkorn Hospital to airport is estimated at \$40, between hotel and the airport in the US is estimated at \$200, and \$60 for transportation within the region (\$300).

F. Participant Support Costs

No participant support is requested.

G. Other Direct Costs (Total \$78,803)

Materials and Supplies (\$72,830)

PBMCs isolation (\$47,000). We request funds to conduct PBMC isolation from collected sample, costs including the reagents and lab consumable and supplies are estimated at \$47 per cell for 1,000 cells.

Multiplex microsphere immunoassay detection (\$2,275). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at \$6.5 per sample for 350 samples.

PCR testing and sequencing (\$20,475). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at average \$58.5 per sample 350 samples, given a 10%~15% positive rate.

Field supplies for PBMC collection and processing (\$1,225). Funds are requested to perform PBMCs collection and processing in the field. Costs including the reagents and lab consumable and supplies are estimated at average \$3.5 per sample 350 samples.

Field supplies for animal sampling (\$1,160). Funds are requested to purchase supplies for animal capture, anesthesia, and sample collection. A total cost of \$1,160 is estimated

Field work disposable (\$668). Funds are requested to purchase disposable materials (tips, tubes, gloves, masks, googles etc.) for field work.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Consultants Service (\$3,000)

One (1) zoologist and one (1) veterinarian will provide consultancy service to this project to help 1) select sites for animal sampling and join the sampling trip to 2) identify species; and 3) provide veterinary care in the sample collection of bats, rodents, and shrews. The consultancy fee is estimated at \$1,500 per person for the project, in total of \$3,000.

Publication Fee (\$3,000)

We request \$3,000 of publication costs for one peer-review paper generated from the project. The cost is estimated at the reimbursed Open Access fees of \$2,900 - \$5,000 per manuscript in the past two years for six peer-review papers.

H. Total Direct Costs (Total \$138,831)

I. Indirect Costs (Total \$11,106)

An indirect cost at 8% is requested.

J. Total Direct and Indirect Costs (Total \$149,937)

A total amount of \$149,937 is requested.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Co-PI Plan (only needed if applying as Co-PIs):

What each Co-PI will contribute to the proposed research study

As stated in the Mentoring Plan, the co-PIs, Krongkan Srimuang and Spencer Sterling have different educational and training backgrounds. This Co-PI plan is proposed to fill the gaps in knowledge of each scientist and supports a collaborative working relationship for project success. Moreover, this plan was developed to maximize the strengths of each PI. Overall, the project is separated into two objectives, the proposal of this project will be equally managed by Dr. Srimuang and Mr. Sterling. Dr. Srimuang will be responsible for PBMC isolation, sorting, and characterization. Mr. Sterling will be responsible for the technical serological aspects of the project. Both will work closely with the Research Center Mentor, Dr. Eric Laing, to develop this project, protocol development, and network connections. Dr. Supaporn Wacharapluesade, the Co-mentor, will support the wildlife sampling, samples collection, and molecular aspects within Thailand.

How the Co-PIs will jointly work with the affiliated Research Center

Mr. Sterling is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region.

Commented [EL4]: Need something for KIO

How the Co-PIs will jointly manage the proposed study

This is a great opportunity for both PIs to undergo training in advanced techniques and develop skills in next-generation serology and molecular sequencing. Dr. Srimuang will learn and practice serologic techniques and data analysis from Mr. Sterling. Mr. Sterling will develop skills in cell isolation and molecular sequencing techniques from Dr. Srimuang. Moreover, Mr. Sterling will coordinate planning, sample processing, data analysis, and report preparation for this project with Dr. Srimuang.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), cell sorting machine and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country. Bats are considered protected wildlife in Thailand by Wildlife Conservation, Department of National Parks, Wildlife and Plant Conservation.

Computer:

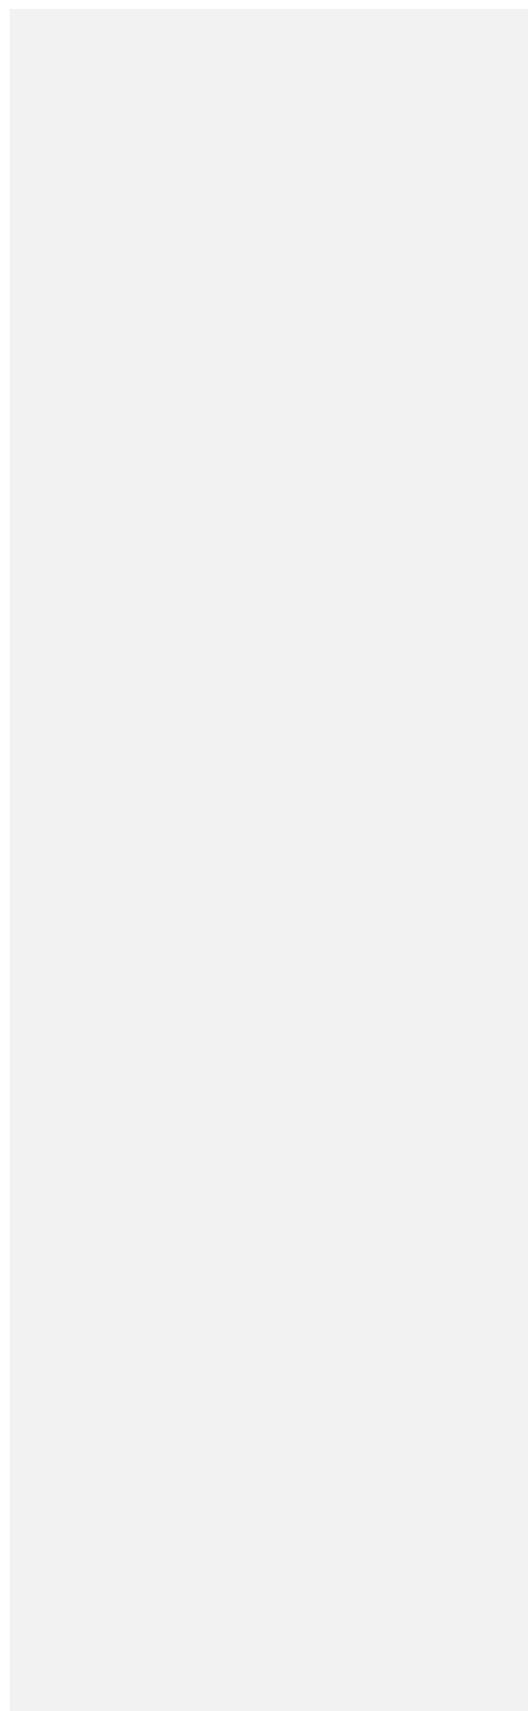

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

PI Name: **Srimuang, Krongkan and Sterling, Spencer**
CREID CC Grant: 1U01AI151378

Foreign Site: **Thailand**

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Krongkan Srimuang
Project Title:	Immune memory bait & capture to identify emerging henipavirus origins
Institution:	King Chulalongkorn Memorial Hospital
Foreign Research Site:	Rama 4 Road, Pathumwan, Bangkok 10330 Thailand
Point of Contact for Research Site:	Krongkan Srimuang Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital Rama 4 Road, Pathumwan, Bangkok 10330 Thailand krongkan.sr@gmail.com

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goals of this project are to know zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

To achieve these goals, the investigator will collaborate with NIH PREMISE for Antibody-mediated bait & capture of Thai MojV-like virus.

\$149,937 of grant funds will be sent to the site for these studies.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will 1) conduct all filed work to collect human and animal samples from the study sites; 2) perform laboratory analysis using collected samples; and 3) conduct data analysis as proposed in the project.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - IRB approval number for parent study: #894ECOH21b (US); #221/64 (Thailand)
 - IRB approval date: 12-05-2021 (US); 08-06-2021 (Thailand)
 - Human Subject Assurance Number: (FWA)#: #00001102 (external IRB); #00022431 (EcoHealth Alliance); #00000943 (Chulalongkorn University)
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - Yes
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - No
 - How many subjects provided the existing samples to be used? N/A
- **Will human subjects be recruited (Yes or No)**
 - Yes
 - Number of human subjects that will be recruited: 110
- **Population parameters:**
 - Gender: 55 males, 55 females
 - Age Group: Age >=18 years who provide informed consent.
 -
 - Race/Ethnicity: 110 Asian
- **Sample collection will include:**
 - Blood: Yes
 - Urine: No
 - Tissues: No
 - Other samples (describe): Nasopharyngeal swab and throat swab
- **Sample collection will be completed in how many visits: 2 trips**
- **Will samples be de-identified (Yes or No)? If No, describe how they will be protected.**
 - Yes
- **Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.**
 - Yes
- **Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Animal Subjects (1 word or 1 sentence per bullet):

- **Parent study IACUC approval**
 - IACUC approval number for parent study: #G2020-42 (US); #019/2563 (Thailand)
 - IACUC approval date: 05-05-2020 (US); 03-12-2020 (Thailand)
 - Animal Welfare Assurance Number: D16-00572 (A4059-01)

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- **Does this study require a modification to the IACUC approval of a parent study (Yes or No)?**
 - **No**
- **Will existing samples from animal subjects will be used: (Yes or No)?**
 - **No**
 - **How many animal subjects provided the existing samples to be used? N/A**
- **Will vertebrate animals be collected (Yes or No)?**
 - **Yes**
- **Species of animals (e.g. rats, mice, rabbits, monkeys): Bats, rodents, and shrews**
- **Animal parameters:**
 - **Total number of animals: 200 (100 bats, 100 rodents and shrews)**
 - **Gender: 100 males, 100 females**
 - **Age range: 4 - 12 months and elder depending upon species**
 - **Lab strain (e.g. Sprague-Dawley rats, Balb/C mice): None**
 - **Wild animals procured in country (e.g. Rhesus monkeys from a reserve): No**
- **What will be done to them or with them and how often?**
 - **Free-ranging bats will be captured using either a mist net or harp trap, and manually restrained during sampling; free-ranging rodents and shrews will be captured through pit traps and box traps.**
 - **Anesthesia will be conducted for captive rodents and shrews.**
 - **Once anesthetized blood will be collected.**
 - **All action will only be performed one time for each animal individual.**
 - **All animals will be released after sampling.**
- **What are the follow-ups?**
 - **No follow-up relevant as per protocol, since all animals will be released after sampling ups**
- **What will be their fate at the end of the experiments – will they be euthanized?**
 - **All animals will not be held longer than 6 hours (typically less than 3 hours) during the sampling process and released after sampling.**
- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - **Yes**
- **Will samples be brought back to the US (Yes or No)?**
 - **No**
- **Will data be brought back to the US (Yes or No)?**
 - **Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.**

Proposed End Date	30 April 2024

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) are bat-borne zoonotic viruses <u>and</u>, cause high mortality. The recent detection of closely-related Mojiang and Langya viruses in rats and shrews, and isolation of Langya virus from individuals with acute febrile illness, challenges the dogma that fruit bats are the <u>key-sole</u> henipavirus reservoirs. The recently expanded <i>Henipavirus</i> genus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. As part of EID-SEARCH activities, we found serological evidence of infection by a Mojiang-related virus in a community of Thai bat guano collectors who have occupational exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to identify novel viruses and zoonotic reservoirs through serologic and cellular immune discovery. We will conduct follow-up human and wildlife (bats and rodents) surveillance in the province where the seropositive humans were identified, <u>and apply an expanded serological test and genomic sequencing to detect this novel MojV-like henipavirus.</u>- Further, we</p>

Study Personnel

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as ~~m~~Mentor for Dr. Srimuang and Mr. Sterling under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Laing is an assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses at Uniformed Services University, Bethesda, MD. ~~Part of Dr. Laing's research focus in on the development study to develop of~~ serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Dr. Laing has ~~ve~~ worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. ~~Through Across all of~~ these collaborations, ~~Dr. Laing's research group aims the aimed~~ to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence.

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Specific Aims

This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The hypothesis

1. Can the memory B-cell immune response be used as a tool for the discovery of novel henipaviruses?
2. Can the spatial relationships between henipaviruses receptor binding proteins be generated that would allow for an understanding of antigenic evolution and functional characterization?

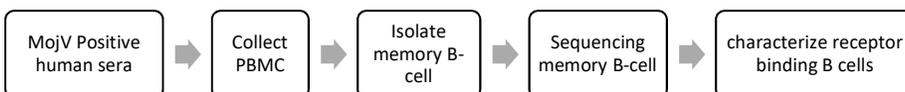

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population.

Human populations near the Khao Chong Phran Non-hunting Area in Ratchaburi province have shown a high seroprevalence to the MojV RBP without confirmed sequencing results. We will follow-up on persons with high MojV RBP IgG titers, sample new people within the population that interact with the local wildlife, and sample shrews and rodents to find the source of the MojV-reactive antibodies.

Aim 2. Antibody-mediated bait & capture of the Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Objective 2. To isolate and sequence memory B-cells from humans positive for MojV virus in Ratchaburi province, Thailand for antibody production.

Objective 3. To determine epitope binding and antigenic relationships from henipavirus-reactive serum to the known henipaviruses.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Study Rationale

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McClinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genera of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, Gamak virus (GAKV), and Daeryong virus (DARV) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The hHenipavirales genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and

Commented [EL2]: Abbreviations already used above

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australian (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected 19% (54/284) seroprevalence for members of a high-risk cohort with MojV-reactive serum a high-risk cohort, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia and likely is due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

This study uses immunology (serologic and cellular) to identify a novel virus that can aid in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. In addition to the translational application of mAbs as therapeutics, we intend to utilize these mAb as non-clinical diagnostics surveillance tools for virus/virus antigen capture. Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

Commented [EL3]: You may want to put this in the 2nd aim after you discuss the development of a mAb that could be also used for antigen detection as a diagnostic tool

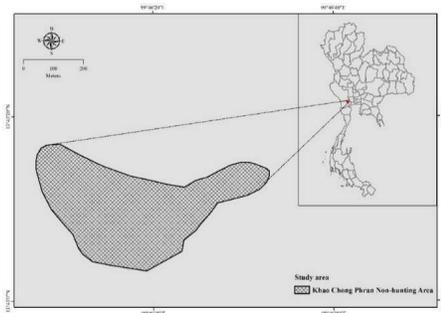

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Site wildlife samples collection

100 bats and 100 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. We plan one sampling trip to collect bats, and a second trip to target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect 100 samples, and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

stored. Oral swab and rectal swab will also collect in 100 bats and 100 shrews or rodents. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

Human surveillance

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, 100 human serum samples, nasopharyngeal swab and throat swab will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,510 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

The sample size of 100 of each species follows the guidelines established during the PREDICT project.

Targeted Viral Sequencing and Serologic testing

Targeted sequencing

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The nucleic acid from oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing.

Serological testing

Serum samples will be tested for RBP **and envelope fusion protein (F)** binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Data analysis

Sequencing will be analyzed assembling reads in MEGA11. The consensus sequences will compare to the references strains available in the GenBank data-base using the Basic Local Alignment Software Tool (BLAST) (National Center for Bio-technology Information). Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to LayV RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipas, and LayV, depending on how well these cross react.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 2).

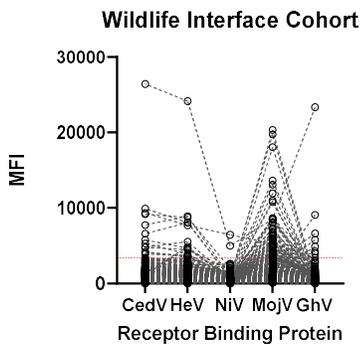

Figure 2: Seroprevalence of henipavirus proteins from a community with a large bat interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, a threshold for seropositivity, the assay cutoff.

PBMC Sorting and B Cell isolation

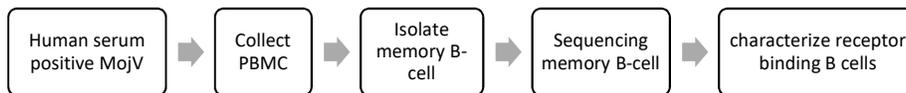

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes). Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3-, CD14-, CD56-, IgM-, IgA-, CD19+, CD20+, CD27+). Avi-tag for biotinylation and 6xHIS tag for

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will be synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor Amplicon Preparation and Recombinant Antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced. After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

~~We will first determine the extent to which isolated mAbs can bind will be assessed for binding to native-like MojV RBP and F proteins. We will also characterize through multiplex binding serology. Further, the cross reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. However, MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of MojV cross-neutralizing potential is not possible. Next~~ ~~Though~~, we will test the cross neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV utilizing a plaque reduction neutralization test with EID-SEARCH co-investigators at Duke-NUS. ~~(Duke NUS/LinFa should be able to do this, if they have LayV and are propagating it, they can use cell-cell fusion/CPE in a straight PRNT).~~ As LayV causes acute illness in human, cross neutralization functionality of these mAbs has therapeutic potential.

Determination of envelope glycoprotein epitope binding

~~Isolated mAbs will be assessed for binding to MojV RBP and F proteins through multiplex binding serology. Further, the cross reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of cross neutralizing potential is not possible. However, through cyro-electron microscopy we can investigate binding epitopes between these mAbs and MojV and LayV envelope glycoproteins. Epitope identification can then be used to make predictions about neutralizing potential through deductions about the location of henipavirus RBP receptor binding pockets.~~

Research Performance Sites

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

-We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country. We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

CREID Research Center Collaboration

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. Further, Dr. Doeuk who is the ~~director~~director of the VRC PREMISE program is ~~enthusiatic~~enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Ig) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see

Formatted: Font color: Auto

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Mentoring Plan

Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as ~~grant writing~~grant writing and project management skills. My professional relationship Dr. Wacharapluesadee with began in 2018 when I participated in a DTRA BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group. Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors ~~will provide~~will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Vertebrate Animals Section Requirements

Animal samples will be collected in Ratchaburi Province for this project under Aim 2 to understand the antigenic relationships among known and unknown henipaviruses. Protocol to perform animal sample collection has been reviewed and approved by the Institutional Animal Care and Use Committee at Tuft University under the EID-SEARCH project (No. G2020-42) and the Institutional Animal Care and Use Committee at Chulalongkorn University (No. 019/2563)

1. Description of Procedures

Bats (order *Chiroptera*)

- **Species:** Free-ranging mega and micro-*Chiroptera* that present at the site (family *Pteropodidae*, *Rhinopomatidae*, *Emballonuridae*, *Craseonycteridae*, *Megadermatidae*, *Rhinolophidae*, *Hipposideridae*, *Vespertilionidae*, *Mollossidae*, etc.)
- **Age & Sex:** Fully flighted adults and juveniles, males and females; neonates dependent on the dam will not be used.
- **Target Number:** 100 individuals
- **Capture and Restraint:** Bats will be captured using either a mist net or harp trap. The net system is manned by at least two people during the entire capture period, and bats are removed from the net as soon as they become entangled to minimize stress and prevent injury. In our previous field research experience, a maximum of 20-30 bats can be safely held and processed by a team of three people per trapping period. Duration of trapping will depend on the capture rate. Bats are individually placed into a pillowcase or small cloth bag and hung from a branch or post in a location that is free from access by both predators and people, and is protected from the elements (e.g., rain), until the animal is restrained for sample collection. Bats will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and bat. The study protocol covers over 69 bat species that are most likely to be captured given their natural occurrence and previous surveillance experience in Southeast Asia. The potential for non-target species to be captured is very low because mist nets are opened at the cave entrance at night, after other species (e.g., birds) have ceased flying and returned to roost. Any non-target species will be rapidly identified, removed from the mist net and released immediately.
- **Sample Collection:** Depending on the species and size of bat, blood will be collected from smaller insectivorous bats (<50g) using a 27g needle to puncture the brachial artery and a 70ul hematocrit

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

tube to collect the blood. For larger bats (>50g) we will collect blood from either the cephalic vein or from the radial artery or vein using a 25- or 23-gauge needle and 3cc syringe. Blood will be collected in quantities not exceeding 6 μ L/g of body mass from each individual. Wing punch biopsies will be collected to confirm host identification using DNA barcoding. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected and whole body submitted to museums as voucher specimens.

- **Release:** Bats are held for a maximum of six hours (typically less than three hours), and at the completion of sampling are provided with rehydrating fluids (either subcutaneously or orally as needed) and released in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided).

Rodents (order: *Rodentia*) and Shrew (order: *Scandentia* and *Eulipotyphla*)

- **Species:** Free-ranging rodents (family *Hystricidae*, *Muridae*, *Sciuridae*, *Spalacidae*) and shrew (tree shrews, shrews, moles) that present at the sites.
- **Age & sex:** Adults and juveniles, males and females. Neonates will not be sampled.
- **Target Number:** 100 individuals
- **Capture and Restraint:** Free-ranging wild mammal species will be captured with metal box traps (Sherman/Tomahawk traps). Traps will be prepared with food, water, padding and shelter, and be checked at least every 12 hours, in the morning and in the afternoon. If adverse weather (extreme heat, rain) is expected or researchers are working in areas where predation is common, traps will be checked more frequently and closed during adverse weather. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. Depending on the species, individual size, captive or free-ranging status of the individual, manual or chemical restraint and anesthesia (gas or injectable anesthesia) will be applied. Animals will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and animal. Based upon past field experience (>20 years of animal capture and release in Southeast Asia), we do not expect to trap sick, debilitated, or young animals that would be too young to cope with capture. Sick and debilitated animals tend not to roam widely, reducing their opportunity to enter traps. Additionally, should sick, debilitated, or young animals enter traps, we anticipate that they will not suffer adverse conditions because the traps contain food (the bait) and liquid (water or fruit as a source of water). These individuals would be examined by a veterinarian, rehydrated and if presenting clinical signs treated by a veterinarian, prior to release or sampling then release.
- **Sample Collection:** Once anesthetized or safely restrained, whole blood will be collected through the appropriate venipuncture site, no more than 1 ml of blood per 100 g (= 10 ml/kg or 1%) of body weight will be collected at any one time. Anesthetized animals will be monitored regularly during recovery until they can no longer be safely handled, at which point they will be confined in a trap or cage. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected.
- **Release:** Wild mammals are held for a maximum of thirteen hours depending on trap timing, but typically less than three hours. Captive animals are held for a maximum of two hours but typically less than one hour. At the completion of sampling, animals may be provided with rehydrating fluids (either subcutaneously if anesthetized or orally if manually handled and accepted). Wild mammals will be released at the site of capture in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided). Captive mammals will be released back into their captive setting as is appropriate for the species, either isolated or in social group if it is deemed safe from aggression from enclosure mates while the post-recovery period continues.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

2. Justifications

The purpose of this study is to identify zoonotic pathogens through serologic and cellular immune discovery, including developing methods and standards for direct antibody-mediated virus capture in people and wildlife, focusing on rodent/shrew- and bat-borne HPVs. This will require hands-on fieldwork to collect whole blood and serum samples from bats, rodents, and shrews for lab analysis. One technique that avoids the direct capture and sampling of animals is to collect fresh feces or urine, but this will not be able to provide the appropriate samples for serologic analysis, and the research objectives cannot be achieved using an alternative methods (e.g., computational, human, invertebrate, in vitro). Therefore, we believe there are no viable alternatives than the use of live animals.

3. Minimization of Pain and Distress

In every situation, sampling of wildlife will be conducted in the most humane manner while minimizing the impacts on individual animals and their wild populations. In all instances, the fewest number of animals will be sampled that will provide valid information and statistical inference for the pathogen and disease of interest and every effort will be made to minimize stress and discomfort for the animal.

Bats will not be held longer than six hours during the sampling process whereas small mammals may be held for up to 13 hours depending on trap capture timing. Field animal sampling team with zoologists and veterinarians have been well trained and have extensive experience in capture, anesthesia, and sampling of wildlife. In our team's experience, the target species tolerate the described procedure well. Mist nets will be attended continuously during capture periods, and bats will be extracted from the net as soon as they become entangled. This will minimize stress and injury from entanglement. Bats will be placed individually in cloth bags and hung from tree branches while awaiting processing and during recovery. The bags are sufficiently porous as to allow for ventilation and are designed for bat capture. The enclosed environment seems to calm the bats, as they do not struggle once inside, but they hang quietly – this is a standard and accepted practice in bat research and the best way to minimize stress to the animal.

For rodents and shrews, food, water, padding and shelter will be provided at traps, which will be checked at least every 12 hours. Traps will be checked more frequently or closed if adverse weather (extreme heat, rain) is expected, or researchers are working in areas where predation is common. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. All animal individuals will be monitored by a veterinarian or experienced field team member during all stages of capture, processing, anesthesia and release. Animals will be kept in a cool place, free from adverse weather conditions and access by non-field team members or other animals while in the pillowcases, trap, or cage for recovery. All recovering individuals will be observed until they are able to effectively ambulate and orient to their surroundings. Animals that are injured during the capture or sampling process will be assessed by an experienced team leader or attending veterinarian, and if the animal is determined to be unlikely to survive if released, it shall be euthanized humanely (see euthanasia section).

4. Method of Euthanasia

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

In the event that an animal has been injured or is moribund, a determination will be made as to whether it may be treated and released on site by veterinarians or transferred to facility that may treat and rehabilitate the animal, or if, as a last resort, the animal will require euthanasia. Euthanasia methods will vary depending on species; however methods to be used will not deviate from the AVMA "Guidelines for the Euthanasia of Animals" (2020 edition). Any animal that is euthanized using a chemical agent will be disposed of such that it will not be permitted to enter the food supply either through markets or hunting.

Human Subjects Research

1. Risks to the subjects

In this project, we will target populations in one community site who with frequent exposure to bats and other wildlife based on our previous behavioral survey. Subjects will be enrolled voluntarily, and informed consent will be obtained from all participants, along with assent from all participants aged 12-17. Enrolled participants will provide biological samples. Survey data and biological samples will be collected from enrolled participants, and follow-up data collection will be performed among participants whose samples were tested positive.

Biological samples and questionnaire data will be collected from individuals who meet recruitment and inclusion criteria and complete the informed consent process. During data collection, a standardized questionnaire will be administered to all participants. This questionnaire will collect information of demographic background, wildlife contact, travel and daily movement, and unusual SARI/ILI symptoms, and biological specimens will be collected from participants. Both questionnaire and biological data will be analyzed to assess the exposure to coronaviruses and the spread risk among humans. From all participants, a one-time whole blood sample (Max. 15 mL) will be collected during the study period. This sample will allow us to test for historical exposure to bat or rodent-borne henipaviruses and collect Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive.

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals who are proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions; however, the administration will be conducted privately and confidentially to protect individuals' health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

2. Adequacy of protection against these risks

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

2.1 Informed consent and assent

Only consented participants will be enrolled in the study. No research procedures will be undertaken before the participant fully understands the research, agrees to the study procedures, and completes the consent process will be enrolled in the study. Informed consent statements and forms, and project protocols will be translated into the local language of each study site. Research team members involved in this consent process will be required to be fluent in the local language to ensure that the subjects understand the study and all involved procedures.

If participants meet the criteria for enrollment, they will be invited to discuss the details of the study with the research staff. Study staff will review an information sheet and informed consent form with the participant and the parent or legal guardian when applicable. Each individual will be provided with a copy of the informed consent form that has been translated into the local language and written with a Flesch–Kincaid readability score equivalent to a 7th-grade reading level or below, to assure that potential participants understand the information being shared. The informed consent form will explain the details of the study, including how and why the individual was selected, the study process and procedures, risks and benefits, financial considerations and the gift of appreciation, confidentiality of data shared, alternatives to participating, and how to obtain more information now or at a later date. The informed consent form will be read in the local language of the site at a location ensuring participant privacy. After which individuals will have as much time as they would like to ask questions and discuss the study with study staff. The study staff will endeavor to ensure that the participant understands the information provided. The study staff will then ask the participant/parent or legal guardian to consider study participation. Participants will have as much time as required to consider the participation.

Those participants who consent to the study will sign and date two copies of the consent form. These form copies will be countersigned and dated by the study staff. A copy of the signed consent form must be provided to the subject and the other copy will be kept by study staff. Informed consent paperwork will be kept until the end of the project in a locked box at the local country project office.

2.2 Protection against risks

The potential risks to study participants as a result of study participation are minimal. Collection of venous blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. Potential complications associated with venipuncture include pain and/or hematoma at the site of collection. Trained medical professionals and/or clinic staff will monitor the blood collection site and treat any complications according to existing health facility protocols. A potential complication of nasal/ oropharyngeal sampling is minor irritation at the time of collection. Employing trained medical and/or clinic staff to collect blood and swab samples will minimize the potential for complications.

Another risk that this study may pose concerns the information to be gained on henipaviruses newly recognized in the community. We will provide participating communities, hospitals, and clinicians with information and background data on target zoonotic viruses to ensure up-to-date communication of risk. Because of the timeline for diagnostic testing and results interpretation, we are not likely to provide results to participating clinics within a time frame that would be clinically relevant to outbreaks of undiagnosed diseases. Therefore, the information provided by this project will not impact patient management or outlook.

If an individual decides to participate in this research, his/her participation and all information provided by the participant will be strictly confidential, and personal identifying information will not be shared with anyone outside of the study staff. Participants will not be identified or named in any reports or publications. Questionnaire information and all biological samples will be identified by an

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

alphanumeric code, not by the participant's name. All records that contain names or other personal identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the study site in locked files cabinets or password-protected devices in areas with access limited to the research staff of this project. Research databases will be secured with password-protected access systems and controlled distribution web-based certificates and will not contain any identifying characteristics about study participants (e.g., name, address, or telephone number). Access to all data will be limited to the staff involved in this study. The health information disclosed by an individual will not be used by or disclosed (released) to another institution. Any surveillance report that is published or shared with partners will not contain any personally identifying information for individual participants.

3. Potential benefits of the research to the subjects and others

There are no measurable benefits to the individual study participants enrolled in this study. There are benefits to the community and regional healthcare providers to help them understand the risk of zoonotic infections among high-risk populations in the regions they work. At the conclusion of the study, we will deliver an educational workshop reporting aggregate study findings that will be open to both study and non-study participants, describing the health benefits of using personal protection equipment (PPE) and handwashing during animal handling activities throughout the day, as well as to share other prevention/interventions that emerge from the research data.

4. Importance of the knowledge to be gained

There are valuable potential benefits to the public from the knowledge to be gained from this study. One key benefit to the community is sharing information and knowledge to better understand the risk of zoonotic spillover events and related health risks, as well as information sharing with communities on practices that could reduce risks, such as the avoidance of particular animal contacts or the need for PPE and extra care when handling wildlife, that may substantially reduce the risk zoonotic pathogen transmission in the community. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to create or implement public health interventions to disrupt disease emergence and/or spread in an area that is beneficial to all. Additionally, there are valuable benefits to the general public from the knowledge to be gained from this study. Knowledge gained will increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

5. Country- / institution-specific ethics / IRB regulations addressed

Main research protocol and materials to conduct human subject research in this project have been reviewed and approved by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b)

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

impact -- positive or negative -- on the environment?

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Budget Justification

A. Key Personnel (Total \$24,000)

Dr. Krongkan Srimuang, PI (12 months) is a medical research scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital (TRC-EIDCC) who have been leading the laboratory analysis for the EID-SEARCH work in Thailand in the past three years to perform molecular, serological, and next-generation sequencing to identify novel viruses from human and animal samples. Dr. Srimuang will commit 12 months to this project to design, manage, and perform all project activities in the lab and field by supervising a lab technician and working with the field coordinator. Dr. Srimuang will also work closely with the co-PI and Mentors to conduct data analysis and develop manuscript and join EID-SEARCH and CREID meetings to present the project findings.

Spencer Sterling, Co-PI (6 months) is the research coordinator of Laing Lab at the Uniformed Services University for Indo-Pacific region and a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC). Sterling will commit 6 months to this project as the co-PI, who will work closely with the PI in the study design, SOP development, sampling process, data analysis of for serological investigations. No salary is required for Sterling.

B. Other Personnel (Total \$20,000)

One (1) Laboratory Technician (12 months) will commit 12 months to this project to conduct PCR and serological testing of animal and human samples at TRC-EIDCC, under the supervision of Dr. Srimuang and Sterling. Salaries for 12 months at \$1,250 per month is requested (\$15,000).

One (1) Field Coordinator (4 months) will commit 4 months to this project, working closely with Dr. Srimuang and Sterling to organize and conduct field sample collection among humans and animals at the study sites, and support relevant financial management. Salaries for 4 months at \$1,250 per month is requested (\$5,000).

C. Fringe Benefits

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

No Fringe is requested.

D. Equipment

No equipment is requested.

E. Travel (Total \$48,375, Years 1-5)

Domestic Travel (\$11,005)

Support for domestic travel for field sampling is requested in the amount of \$11,005 per to conduct four (4) trips of sample collection from humans, bats, and rodents/shrews.

- The first trip is a one-day trip to collect samples from human participants who were tested positive ($n < 10$), the cost is estimated at van rental for local transportation between Bangkok and the study site (\$260) and meals for five (5) field team members at \$49 per person (\$245), in total of \$505 for the first trip.
- The other three (3) field trips will be conducted to collect samples from 100 bats, 100 humans, and 100 rodents/shrews, respectively. Each trip is a duration of 6 days and 5 nights. For each person, 5-night stay in hotels at \$75.5/night ($5 \times \$75.5 = \378); 3 meals per day and incidental expenses at \$49 per day prorated to 75% (\$36.75) for first and last day of travel ($\$36.75 \times 2 + \$49 \times 4 = \$270$), the total meals and accommodations for each person per trip is \$648 ($\$378 + \270), cost for five (5) field team members is \$3,240. A van will be rented for local transportation between Bangkok and the study site that is estimated at \$260 per trip. Total cost for each 6-day trip is \$3,500, three trips will be \$10,500.

International Travel (\$5,023)

Support for international travel for Dr. Srimuang from Bangkok to Washington DC to attend the CREID Annual Meeting and receive lab training at the National Institute of Allergy and Infectious Diseases (NIAID) is requested in the amount of \$5,023. Trips are for a duration of 10 days and 9 nights. Travel costs for one trip are estimated using federal per diem rates for hotels, meals, and incidental expenses as follows: nine-night stay in DC area hotel at \$286/night ($9 \times \$258 = \$2,322$); Ten days' meals and incidental expenses at \$79 per day prorated to 75% (\$59.25) for first and last day of travel ($\$59.25 \times 2 + \$79 \times 8 = \$750.5$); Round trip flight between Bangkok to Dulles International Airport is estimated at \$1,650; local transportation/taxi between hotel and airport per round trip between Chulalongkorn Hospital to airport is estimated at \$40, between hotel and the airport in the US is estimated at \$200, and \$60 for transportation within the region (\$300).

F. Participant Support Costs

No participant support is requested.

G. Other Direct Costs (Total \$78,803)

Materials and Supplies (\$72,830)

PBMCs isolation (\$47,000). We request funds to conduct PBMC isolation from collected sample, costs including the reagents and lab consumable and supplies are estimated at \$47 per cell for 1,000 cells.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Multiplex microsphere immunoassay detection (\$2,275). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at \$6.5 per sample for 350 samples.

PCR testing and sequencing (\$20,475). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at average \$58.5 per sample 350 samples, given a 10%~15% positive rate.

Field supplies for PBMC collection and processing (\$1,225). Funds are requested to perform PBMCs collection and processing in the field. Costs including the reagents and lab consumable and supplies are estimated at average \$3.5 per sample 350 samples.

Field supplies for animal sampling (\$1,160). Funds are requested to purchase supplies for animal capture, anesthesia, and sample collection. A total cost of \$1,160 is estimated

Field work disposable (\$668). Funds are requested to purchase disposable materials (tips, tubes, gloves, masks, googles etc.) for field work.

Consultants Service (\$3,000)

One (1) zoologist and one (1) veterinarian will provide consultancy service to this project to help 1) select sites for animal sampling and join the sampling trip to 2) identify species; and 3) provide veterinary care in the sample collection of bats, rodents, and shrews. The consultancy fee is estimated at \$1,500 per person for the project, in total of \$3,000.

Publication Fee (\$3,000)

We request \$3,000 of publication costs for one peer-review paper generated from the project. The cost is estimated at the reimbursed Open Access fees of \$2,900 - \$5,000 per manuscript in the past two years for six peer-review papers.

H. Total Direct Costs (Total \$138,831)

I. Indirect Costs (Total \$11,106)

An indirect cost at 8% is requested.

J. Total Direct and Indirect Costs (Total \$149,937)

A total amount of \$149,937 is requested.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Co-PI Plan (only needed if applying as Co-PIs):

What each Co-PI will contribute to the proposed research study

As stated in the Mentoring Plan, the co-PIs, Krongkan Srimuang and Spencer Sterling have different educational and training backgrounds. This Co-PI plan is proposed to fill the gaps in knowledge of each scientist and supports a collaborative working relationship for project success. Moreover, this plan was developed to maximize the strengths of each PI. Overall, the project is separated into two objectives, the proposal of this project will be equally managed by Dr. Srimuang and Mr. Sterling. Dr. Srimuang will be responsible for PBMC isolation, sorting, and characterization. Mr. Sterling will be responsible for the technical serological aspects of the project. Both will work closely with the Research Center Mentor, Dr. Eric Laing, to develop this project, protocol development, and network connections. Dr. Supaporn Wacharapluesade, the Co-mentor, will support the wildlife sampling, samples collection, and molecular aspects within Thailand.

How the Co-PIs will jointly work with the affiliated Research Center

Mr. Sterling is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region.

Commented [EL4]: Need something for KIO

How the Co-PIs will jointly manage the proposed study

This is a great opportunity for both PIs to undergo training in advanced techniques and develop skills in next-generation serology and molecular sequencing. Dr. Srimuang will learn and practice serologic techniques and data analysis from Mr. Sterling. Mr. Sterling will develop skills in cell isolation and molecular sequencing techniques from Dr. Srimuang. Moreover, Mr. Sterling will coordinate planning, sample processing, data analysis, and report preparation for this project with Dr. Srimuang.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), cell sorting machine and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country. Bats are considered protected wildlife in Thailand by Wildlife Conservation, Department of National Parks, Wildlife and Plant Conservation.

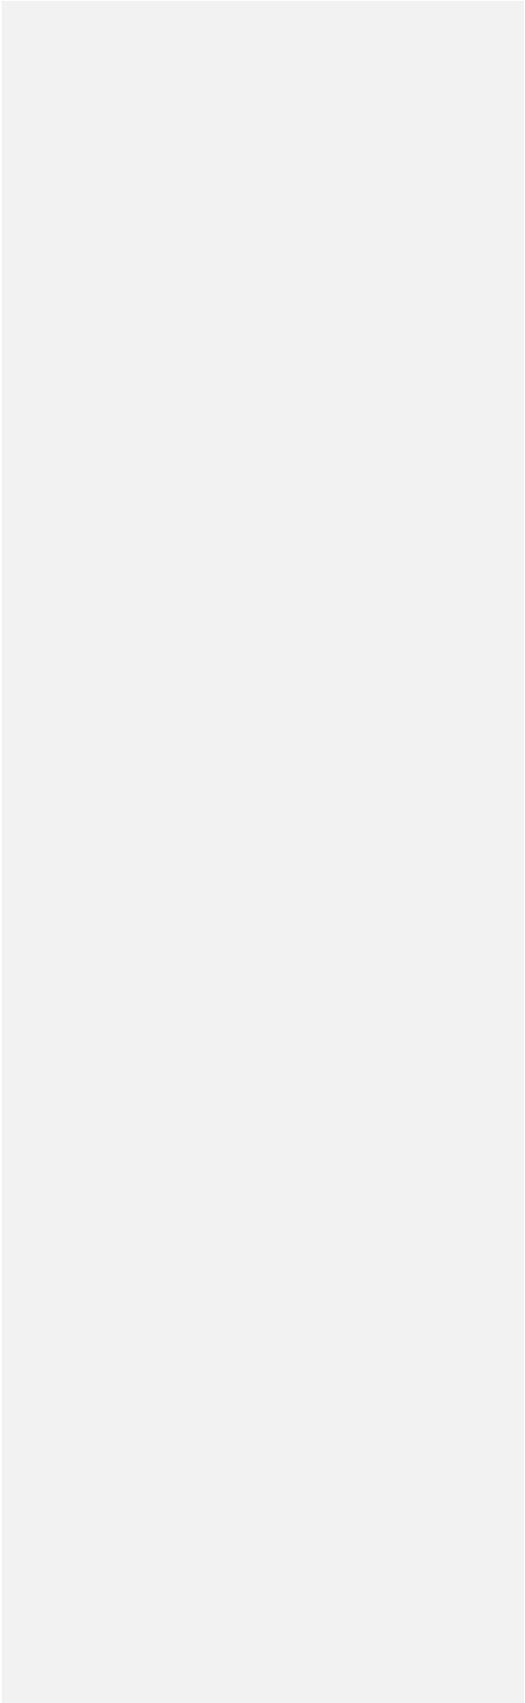

Computer:

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

PI Name: **Srimuang, Krongkan and Sterling, Spencer**
CREID CC Grant: 1U01AI151378

Foreign Site: **Thailand**

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Krongkan Srimuang
Project Title:	Immune memory bait & capture to identify emerging henipavirus origins
Institution:	King Chulalongkorn Memorial Hospital
Foreign Research Site:	Rama 4 Road, Pathumwan, Bangkok 10330 Thailand
Point of Contact for Research Site:	Krongkan Srimuang Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital Rama 4 Road, Pathumwan, Bangkok 10330 Thailand krongkan.sr@gmail.com

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goals of this project are to know zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

To achieve these goals, the investigator will collaborate with NIH PREMISE for Antibody-mediated bait & capture of Thai MoJV-like virus.

\$149,937 of grant funds will be sent to the site for these studies.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will 1) conduct all filed work to collect human and animal samples from the study sites; 2) perform laboratory analysis using collected samples; and 3) conduct data analysis as proposed in the project.

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - IRB approval number for parent study: #894ECOH21b (US); #221/64 (Thailand)
 - IRB approval date: 12-05-2021 (US); 08-06-2021 (Thailand)
 - Human Subject Assurance Number: (FWA)#: #00001102 (external IRB); #00022431 (EcoHealth Alliance); #00000943 (Chulalongkorn University)
- Does this study require a modification to the IRB approval of a parent study (Yes or No)?
 - Yes
- Will existing samples from human subjects will be used: (Yes or No)?
 - No
 - How many subjects provided the existing samples to be used? N/A
- Will human subjects be recruited (Yes or No)
 - Yes
 - Number of human subjects that will be recruited: 110
- **Population parameters:**
 - Gender: 55 males, 55 females
 - Age Group: Age >=18 years who provide informed consent.
 -
 - Race/Ethnicity: 110 Asian
- **Sample collection will include:**
 - Blood: Yes
 - Urine: No
 - Tissues: No
 - Other samples (describe): Nasopharyngeal swab and throat swab
- **Sample collection will be completed in how many visits: 2 trips**
- Will samples be de-identified (Yes or No)? If No, describe how they will be protected.
 - Yes
- Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.
 - Yes

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

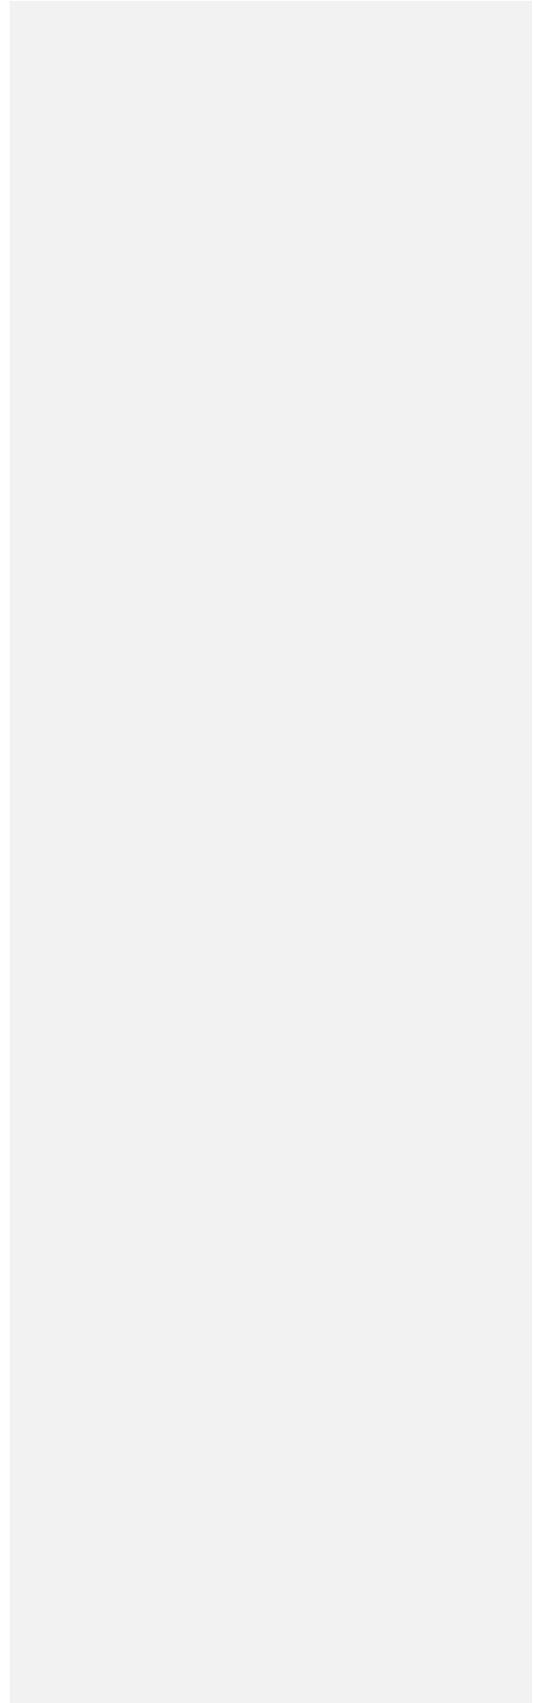

- **Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Animal Subjects (1 word or 1 sentence per bullet):

- **Parent study IACUC approval**
 - IACUC approval number for parent study: #G2020-42 (US); #019/2563 (Thailand)
 - IACUC approval date: 05-05-2020 (US); 03-12-2020 (Thailand)
Animal Welfare Assurance Number: D16-00572 (A4059-01)
- **Does this study require a modification to the IACUC approval of a parent study (Yes or No)?**
 - No
- **Will existing samples from animal subjects will be used: (Yes or No)?**
 - No
 - How many animal subjects provided the existing samples to be used? N/A
- **Will vertebrate animals be collected (Yes or No)?**
 - Yes
- **Species of animals (e.g. rats, mice, rabbits, monkeys): Bats, rodents, and shrews**
- **Animal parameters:**
 - Total number of animals: 200 (100 bats, 100 rodents and shrews)
 - Gender: 100 males, 100 females
 - Age range: 4 - 12 months and elder depending upon species
 - Lab strain (e.g. Sprague-Dawley rats, Balb/C mice): None
 - Wild animals procured in country (e.g. Rhesus monkeys from a reserve): No
- **What will be done to them or with them and how often?**
 - Free-ranging bats will be captured using either a mist net or harp trap, and manually restrained during sampling; free-ranging rodents and shrews will be captured through pit traps and box traps.
 - Anesthesia will be conducted for captive rodents and shrews.
 - Once anesthetized blood will be collected.
 - All action will only be performed one time for each animal individual.
 - All animals will be released after sampling.
- **What are the follow-ups?**
 - No follow-up relevant as per protocol, since all animals will be released after sampling ups
- **What will be their fate at the end of the experiments – will they be euthanized?**
 - All animals will not be held longer than 6 hours (typically less than 3 hours) during the sampling process and released after sampling.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Proposal Cover Sheet

Project Title	Immune memory bait & capture to identify emerging henipavirus origins
Principal Investigator Name	Krongkan Srimuang, Ph.D.
Position/Title	Research Scientist
Department	Thai Red Cross Emerging Infectious Diseases Clinical Center
Institution Name	King Chulalongkorn Memorial Hospital
Street	Rama 4 Road
City, State, Zip Code	Pathumwan, Bangkok 10330
Country	Thailand
Email	Krongkan.sr@gmail.com
Phone	+66 (0) 92-453-0808
Country(ies) where work will be conducted	Thailand
Pathogen(s) focus	Mojiang Virus, Henipavirus, Paramyxovirus
Co-Principal Investigator Name (If applicable)	Spencer Sterling, MPH
Position/Title	Scientific Project Coordinator
Department	Microbiology and Immunology

Proposed End Date	30 April 2024

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) are bat-borne zoonotic viruses, cause high mortality. The recent detection of closely-related Mojiang and Langya viruses in rats and shrews, and isolation of Langya virus from individuals with acute febrile illness, challenges the dogma that fruit bats are the key henipavirus reservoirs. The recently expanded <i>Henipavirus</i> genus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. As part of EID-SEARCH activities, we found serological evidence of infection by a Mojiang-related virus in a community of Thai bat guano collectors who have occupational exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to identify novel viruses and zoonotic reservoirs through serologic and cellular immune discovery. We will conduct follow-up human and wildlife (bats and rodents) surveillance in the province where the seropositive humans were identified. Further, we plan to isolate anti-MojV monoclonal antibodies (mAb) from peripheral blood mononuclear cells collected</p>

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

from human study participants we have identified as immunoreactive with MojV antigens, and characterize the cross neutralizing potential of these mAbs to MojV and LayV envelope glycoproteins. In addition to our antigen-based approach, we will utilize the mAbs for direct antibody-mediated virus capture of this novel henipavirus from human and wildlife samples, and downstream genomic sequencing.

Study Personnel

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as Mentor for Dr. Srimuang and Mr. Sterling under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Laing is an assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses at Uniformed Services University, Bethesda, MD. Dr. Laing study to develop serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Dr. Laing have worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Across all of these collaborations, the aimed to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence.

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Specific Aims

This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The hypothesis

1. Can the memory B-cell immune response be used as a tool for the discovery of novel henipaviruses?
2. Can the spatial relationships between henipaviruses receptor binding proteins be generated that would allow for an understanding of antigenic evolution and functional characterization?

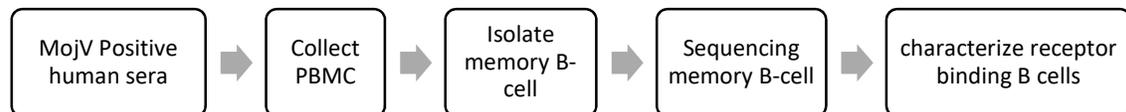

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population.

Human populations near the Khao Chong Phran Non-hunting Area in Ratchaburi province have shown a high seroprevalence to the MojV RBP without confirmed sequencing results. We will follow-up on persons with high MojV RBP IgG titers, sample new people within the population that interact with the local wildlife, and sample shrews and rodents to find the source of the MojV-reactive antibodies.

Aim 2. Antibody-mediated bait & capture of the Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Objective 2. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody production.

Objective 3. To determine epitope binding and antigenic relationships from henipavirus-reactive serum to the known henipaviruses.

Study Rationale

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McLinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genus of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, Gamak virus (GAKV), and Daeryong virus (DARV) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The Henipavirus genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australian (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected four members of a high-risk cohort with MojV-reactive serum, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia is due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology to identify a novel virus that can aide in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in

wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. In addition to the translational application of mAbs as therapeutics, we intend to utilize these mAb as non-clinical diagnostics surveillance tools for virus/virus antigen capture. Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

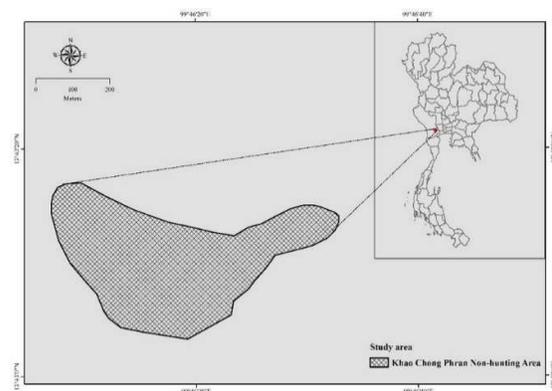

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Site wildlife samples collection

100 bats and 100 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. We plan one sampling trip to collect bats, and a second trip to target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect 100 samples, and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored. Oral swab and rectal swab will also collect in 100 bats and 100 shrews or rodents. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Human surveillance

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, 100 human serum samples, nasopharyngeal swab and throat swab will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,150 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

The sample size of 100 of each species follows the guidelines established during the PREDICT project.

Targeted Viral Sequencing and Serologic testing

Targeted sequencing

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The nucleic acid from oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing.

Serological testing

Serum samples will be tested for RBP binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Data analysis

Sequencing will be analyzed assembling reads in MEGA11. The consensus sequences will compare to the references strains available in the GenBank data-base using the Basic Local Alignment Software Tool (BLAST) (National Center for Bio-technology Information). Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to LayV RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipaviruses, and LayV, depending on how well these cross react.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 2).

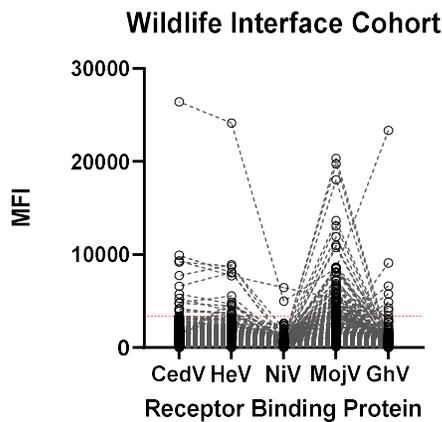

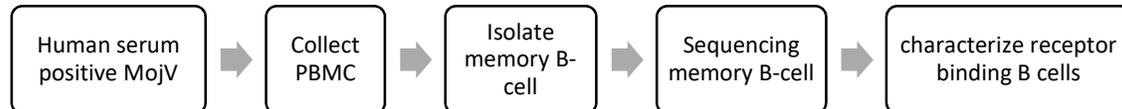

Figure 2: Seroprevalence of henipavirus proteins from a community with a large bat interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, the assay cutoff.

PBMC Sorting and B Cell isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes). Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3⁻, CD14⁻, CD56⁻, IgM⁻, IgA⁻, CD19⁺, CD20⁺, CD27⁺). Avi-tag for biotinylation and 6xHis tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor Amplicon Preparation and Recombinant Antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced. After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. Next, we will test the cross neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV (Duke NUS/LinFa should be able to do this, if they have LayV and are propagating it, they can use cell-cell fusion/CPE in a straight PRNT).

Determination of envelope glycoprotein epitope binding

Isolated mAbs will be assessed for binding to MojV RBP and F proteins through multiplex binding serology. Further, the cross reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of cross neutralizing potential is not possible. However, through cyro-electron microscopy we can investigate binding epitopes between these mAbs and MojV and LayV envelope glycoproteins. Epitope identification can then be used to make predictions about neutralizing potential through deductions about the location of henipavirus RBP receptor-binding pockets.

Research Performance Sites

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country. We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

CREID Research Center Collaboration

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. Further, Dr. Doeuk who is the director of the VRC PREMISE program is enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Ig) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Mentoring Plan

Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant writing and project management skills. My professional relationship Dr. Wacharapluesadee with began in 2018 when I participated in a DTRA

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group. Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Vertebrate Animals Section Requirements

Animal samples will be collected in Ratchaburi Province for this project under Aim 2 to understand the antigenic relationships among known and unknown henipaviruses. Protocol to perform animal sample collection has been reviewed and approved by the Institutional Animal Care and Use Committee at Tuft University under the EID-SEARCH project (No. G2020-42) and the Institutional Animal Care and Use Committee at Chulalongkorn University (No. 019/2563)

1. Description of Procedures

Bats (order *Chiroptera*)

- Species: Free-ranging mega and micro-*Chiroptera* that present at the site (family *Pteropodidae*, *Rhinopomatidae*, *Emballonuridae*, *Craseonycteridae*, *Megadermatidae*, *Rhinolophidae*, *Hipposideridae*, *Vespertilionidae*, *Mollossidae*, etc.)
- Age & Sex: Fully flighted adults and juveniles, males and females; neonates dependent on the dam will not be used.
- Target Number: 100 individuals
- Capture and Restraint: Bats will be captured using either a mist net or harp trap. The net system is manned by at least two people during the entire capture period, and bats are removed from the net as soon as they become entangled to minimize stress and prevent injury. In our previous field research experience, a maximum of 20-30 bats can be safely held and processed by a team of three people per trapping period. Duration of trapping will depend on the capture rate. Bats are individually placed into a pillowcase or small cloth bag and hung from a branch or post in a location that is free from access by both predators and people, and is protected from the elements (e.g., rain), until the animal is restrained for sample collection. Bats will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and bat. The study protocol covers over 69 bat species that are most likely to be captured given their natural occurrence and previous surveillance experience in Southeast Asia. The potential for non-target species to be captured is very low because mist nets are opened at the cave entrance at night, after other species (e.g., birds) have ceased flying and returned to roost. Any non-target species will be rapidly identified, removed from the mist net and released immediately.
- Sample Collection: Depending on the species and size of bat, blood will be collected from smaller insectivorous bats (<50g) using a 27g needle to puncture the brachial artery and a 70ul hematocrit tube to collect the blood. For larger bats (>50g) we will collect blood from either the cephalic vein or from the radial artery or vein using a 25- or 23-gauge needle and 3cc syringe. Blood will be collected in quantities not exceeding 6 μ L/g of body mass from each individual. Wing punch biopsies will be collected to confirm host identification using DNA barcoding. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected and whole body submitted to museums as voucher specimens.
- Release: Bats are held for a maximum of six hours (typically less than three hours), and at the completion of sampling are provided with rehydrating fluids (either subcutaneously or orally as needed) and released in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided).

Rodents (order: *Rodentia*) and Shrew (order: *Scandentia* and *Eulipotyphla*)

- Species: Free-ranging rodents (family *Hystriidae*, *Muridae*, *Sciuridae*, *Spalacidae*) and shrew (tree shrews, shrews, moles) that present at the sites.
- Age & sex: Adults and juveniles, males and females. Neonates will not be sampled.
- Target Number: 100 individuals

- **Capture and Restraint:** Free-ranging wild mammal species will be captured with metal box traps (Sherman/Tomahawk traps). Traps will be prepared with food, water, padding and shelter, and be checked at least every 12 hours, in the morning and in the afternoon. If adverse weather (extreme heat, rain) is expected or researchers are working in areas where predation is common, traps will be checked more frequently and closed during adverse weather. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. Depending on the species, individual size, captive or free-ranging status of the individual, manual or chemical restraint and anesthesia (gas or injectable anesthesia) will be applied. Animals will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and animal. Based upon past field experience (>20 years of animal capture and release in Southeast Asia), we do not expect to trap sick, debilitated, or young animals that would be too young to cope with capture. Sick and debilitated animals tend not to roam widely, reducing their opportunity to enter traps. Additionally, should sick, debilitated, or young animals enter traps, we anticipate that they will not suffer adverse conditions because the traps contain food (the bait) and liquid (water or fruit as a source of water). These individuals would be examined by a veterinarian, rehydrated and if presenting clinical signs treated by a veterinarian, prior to release or sampling then release.
- **Sample Collection:** Once anesthetized or safely restrained, whole blood will be collected through the appropriate venipuncture site, no more than 1 ml of blood per 100 g (= 10 ml/kg or 1%) of body weight will be collected at any one time. Anesthetized animals will be monitored regularly during recovery until they can no longer be safely handled, at which point they will be confined in a trap or cage. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected.
- **Release:** Wild mammals are held for a maximum of thirteen hours depending on trap timing, but typically less than three hours. Captive animals are held for a maximum of two hours but typically less than one hour. At the completion of sampling, animals may be provided with rehydrating fluids (either subcutaneously if anesthetized or orally if manually handled and accepted). Wild mammals will be released at the site of capture in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided). Captive mammals will be released back into their captive setting as is appropriate for the species, either isolated or in social group if it is deemed safe from aggression from enclosure mates while the post-recovery period continues.

2. Justifications

The purpose of this study is to identify zoonotic pathogens through serologic and cellular immune discovery, including developing methods and standards for direct antibody-mediated virus capture in people and wildlife, focusing on rodent/shrew- and bat-borne HPVs. This will require hands-on fieldwork to collect whole blood and serum samples from bats, rodents, and shrews for lab analysis. One technique that avoids the direct capture and sampling of animals is to collect fresh feces or urine, but this will not be able to provide the appropriate samples for serologic analysis, and the research objectives cannot be achieved using an alternative methods (e.g., computational, human, invertebrate, in vitro). Therefore, we believe there are no viable alternatives than the use of live animals.

3. Minimization of Pain and Distress

In every situation, sampling of wildlife will be conducted in the most humane manner while minimizing the impacts on individual animals and their wild populations. In all instances, the fewest number of animals will be sampled that will provide valid information and statistical inference for the pathogen and disease of interest and every effort will be made to minimize stress and discomfort for the animal.

Bats will not be held longer than six hours during the sampling process whereas small mammals may be held for up to 13 hours depending on trap capture timing. Field animal sampling team with zoologists and veterinarians have been well trained and have extensive experience in capture, anesthesia, and sampling of wildlife. In our team's experience, the target species tolerate the described procedure well. Mist nets will be attended continuously during capture periods, and bats will be extracted from the net as soon as they become entangled. This will minimize stress and injury from entanglement. Bats will be placed individually in cloth bags and hung from tree branches while awaiting processing and during recovery. The bags are sufficiently porous as to allow for ventilation and are designed for bat capture. The enclosed environment seems to calm the bats, as they do not struggle once inside, but they hang quietly – this is a standard and accepted practice in bat research and the best way to minimize stress to the animal.

For rodents and shrews, food, water, padding and shelter will be provided at traps, which will be checked at least every 12 hours. Traps will be checked more frequently or closed if adverse weather (extreme heat, rain) is expected, or researchers are working in areas where predation is common. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. All animal individuals will be monitored by a veterinarian or experienced field team member during all stages of capture, processing, anesthesia and release. Animals will be kept in a cool place, free from adverse weather conditions and access by non-field team members or other animals while in the pillowcases, trap, or cage for recovery. All recovering individuals will be observed until they are able to effectively ambulate and orient to their surroundings. Animals that are injured during the capture or sampling process will be assessed by an experienced team leader or attending veterinarian, and if the animal is determined to be unlikely to survive if released, it shall be euthanized humanely (see euthanasia section).

4. Method of Euthanasia

In the event that an animal has been injured or is moribund, a determination will be made as to whether it may be treated and released on site by veterinarians or transferred to facility that may treat and rehabilitate the animal, or if, as a last resort, the animal will require euthanasia. Euthanasia methods will vary depending on species; however methods to be used will not deviate from the AVMA "Guidelines for the Euthanasia of Animals" (2020 edition). Any animal that is euthanized using a chemical agent will be disposed of such that it will not be permitted to enter the food supply either through markets or hunting.

Human Subjects Research

1. Risks to the subjects

In this project, we will target populations in one community site who with frequent exposure to bats and other wildlife based on our previous behavioral survey. Subjects will be enrolled voluntarily, and informed consent will be obtained from all participants, along with assent from all participants aged 12-17. Enrolled participants will provide biological samples. Survey data and biological samples will be collected from enrolled participants, and follow-up data collection will be performed among participants whose samples were tested positive.

Biological samples and questionnaire data will be collected from individuals who meet recruitment and inclusion criteria and complete the informed consent process. During data collection, a standardized questionnaire will be administered to all participants. This questionnaire will collect information of demographic background, wildlife contact, travel and daily movement, and unusual SARI/ILI symptoms, and biological specimens will be collected from participants. Both questionnaire and biological data will be analyzed to assess the exposure to coronaviruses and the spread risk among humans. From all participants, a one-time whole blood sample (Max. 15 mL) will be collected during the study period. This sample will allow us to test for historical exposure to bat or rodent-borne henipaviruses and collect Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive.

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals who are proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions; however, the administration will be conducted privately and confidentially to protect individuals' health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

2. Adequacy of protection against these risks

2.1 Informed consent and assent

Only consented participants will be enrolled in the study. No research procedures will be undertaken before the participant fully understands the research, agrees to the study procedures, and completes the consent process will be enrolled in the study. Informed consent statements and forms, and project protocols will be translated into the local language of each study site. Research team members involved in this consent process will be required to be fluent in the local language to ensure that the subjects understand the study and all involved procedures.

If participants meet the criteria for enrollment, they will be invited to discuss the details of the study with the research staff. Study staff will review an information sheet and informed consent form with the participant and the parent or legal guardian when applicable. Each individual will be provided with a copy of the informed consent form that has been translated into the local language and written with a Flesch-Kincaid readability score equivalent to a 7th-grade reading level or below, to assure that potential participants understand the information being shared. The informed consent form will explain the details of the study, including how and why the individual was selected, the study process and procedures, risks and benefits, financial considerations and the gift of appreciation, confidentiality of data shared, alternatives to participating, and how to obtain more information now or at a later

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

date. The informed consent form will be read in the local language of the site at a location ensuring participant privacy. After which individuals will have as much time as they would like to ask questions and discuss the study with study staff. The study staff will endeavor to ensure that the participant understands the information provided. The study staff will then ask the participant/parent or legal guardian to consider study participation. Participants will have as much time as required to consider the participation.

Those participants who consent to the study will sign and date two copies of the consent form. These form copies will be countersigned and dated by the study staff. A copy of the signed consent form must be provided to the subject and the other copy will be kept by study staff. Informed consent paperwork will be kept until the end of the project in a locked box at the local country project office.

2.2 Protection against risks

The potential risks to study participants as a result of study participation are minimal. Collection of venous blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. Potential complications associated with venipuncture include pain and/or hematoma at the site of collection. Trained medical professionals and/or clinic staff will monitor the blood collection site and treat any complications according to existing health facility protocols. A potential complication of nasal/ oropharyngeal sampling is minor irritation at the time of collection. Employing trained medical and/or clinic staff to collect blood and swab samples will minimize the potential for complications.

Another risk that this study may pose concerns the information to be gained on henipaviruses newly recognized in the community. We will provide participating communities, hospitals, and clinicians with information and background data on target zoonotic viruses to ensure up-to-date communication of risk. Because of the timeline for diagnostic testing and results interpretation, we are not likely to provide results to participating clinics within a time frame that would be clinically relevant to outbreaks of undiagnosed diseases. Therefore, the information provided by this project will not impact patient management or outlook.

If an individual decides to participate in this research, his/her participation and all information provided by the participant will be strictly confidential, and personal identifying information will not be shared with anyone outside of the study staff. Participants will not be identified or named in any reports or publications. Questionnaire information and all biological samples will be identified by an alphanumeric code, not by the participant's name. All records that contain names or other personal identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the study site in locked files cabinets or password-protected devices in areas with access limited to the research staff of this project. Research databases will be secured with password-protected access systems and controlled distribution web-based certificates and will not contain any identifying characteristics about study participants (e.g., name, address, or telephone number). Access to all data will be limited to the staff involved in this study. The health information disclosed by an individual will not be used by or disclosed (released) to another institution. Any surveillance report that is published or shared with partners will not contain any personally identifying information for individual participants.

3. Potential benefits of the research to the subjects and others

There are no measurable benefits to the individual study participants enrolled in this study. There are benefits to the community and regional healthcare providers to help them understand the risk of zoonotic infections among high-risk populations in the regions they work. At the conclusion of the study, we will deliver an educational workshop reporting aggregate study findings that will be open to both study and non-study participants, describing the health benefits of using personal protection equipment (PPE) and handwashing during animal handling activities throughout the day, as well as to share other prevention/interventions that emerge from the research data.

4. Importance of the knowledge to be gained

There are valuable potential benefits to the public from the knowledge to be gained from this study. One key benefit to the community is sharing information and knowledge to better understand the risk of zoonotic spillover events and related health risks, as well as information sharing with communities on practices that could reduce risks, such as the avoidance of particular animal contacts or the need for PPE and extra care when handling wildlife, that may substantially reduce the risk zoonotic pathogen transmission in the community. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to create or implement public health interventions to disrupt disease emergence and/or spread in an area that is beneficial to all. Additionally, there are valuable benefits to the general public from the knowledge to be gained from this study. Knowledge gained will increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

5. Country- / institution-specific ethics / IRB regulations addressed

Main research protocol and materials to conduct human subject research in this project have been reviewed and approved by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64). Amendment for PBMCs collection will be made and approved before the start of this project.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Budget Justification

A. Key Personnel (Total \$24,000)

Dr. Krongkan Srimuang, PI (12 months) is a medical research scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital (TRC-EIDCC) who have been leading the laboratory analysis for the EID-SEARCH work in Thailand in the past three years to perform molecular, serological, and next-generation sequencing to identify novel viruses from human and animal samples. Dr. Srimuang will commit 12 months to this project to design, manage, and perform all project activities in the lab and field by supervising a lab technician and working with the field coordinator. Dr. Srimuang will also work closely with the co-PI and Mentors to conduct data analysis and develop manuscript and join EID-SEARCH and CREID meetings to prevent the project findings.

Spencer Sterling, Co-PI (6 months) is the research coordinator of Laing Lab at the Uniformed Services University for Indo-Pacific region and a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC). Sterling will commit 6 months to this project as the co-PI, who will work closely with the PI in the study design, SOP development, sampling process, data analysis of for serological investigations. No salary is required for Sterling.

B. Other Personnel (Total \$20,000)

One (1) Laboratory Technician (12 months) will committee 12 months to this project to conduct PCR and serological testing of animal and human samples at TRC-EIDCC, under the supervision of Dr. Srimuang and Sterling. Salaries for 12 months at \$1,250 per month is requested (\$15,000).

One (1) Field Coordinator (4 months) will committee 4 months to this project, working closely with Dr. Srimuang and Sterling to organize and conduct field sample collection among humans and animals at the study sites, and support relevant financial management. Salaries for 4 months at \$1,250 per month is requested (\$5,000).

C. Fringe Benefits

No Fringe is requested.

D. Equipment

No equipment is requested.

E. Travel (Total \$48,375, Years 1-5)

Domestic Travel (\$11,005)

Support for domestic travel for field sampling is requested in the amount of \$11,005 per to conduct four (4) trips of sample collection from humans, bats, and rodents/shrews.

- The first trip is a one-day trip to collect samples from human participants who were tested positive ($n < 10$), the cost is estimated at van rental for local transportation between Bangkok and the study site (\$260) and meals for five (5) field team members at \$49 per person (\$245), in total of \$505 for the first trip.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- The other three (3) field trips will be conducted to collect samples from 100 bats, 100 humans, and 100 rodents/shrews, respectively. Each trip is a duration of 6 days and 5 nights. For each person, 5-night stay in hotels at \$75.5/night ($5 \times \$75.5 = \378); 3 meals per day and incidental expenses at \$49 per day prorated to 75% (\$36.75) for first and last day of travel ($\$36.75 \times 2 + \$49 \times 4 = \$270$), the total meals and accommodations for each person per trip is \$648 ($\$378 + \270), cost for five (5) field team members is \$3,240. A van will be rented for local transportation between Bangkok and the study site that is estimated at \$260 per trip. Total cost for each 6-day trip is \$3,500, three trips will be \$10,500.

International Travel (\$5,023)

Support for international travel for Dr. Srimuang from Bangkok to Washington DC to attend the CREID Annual Meeting and receive lab training at the National Institute of Allergy and Infectious Diseases (NIAID) is requested in the amount of \$5,023. Trips are for a duration of 10 days and 9 nights. Travel costs for one trip are estimated using federal per diem rates for hotels, meals, and incidental expenses as follows: nine-night stay in DC area hotel at \$286/night ($9 \times \$258 = \$2,322$); Ten days' meals and incidental expenses at \$79 per day prorated to 75% (\$59.25) for first and last day of travel ($\$59.25 \times 2 + \$79 \times 8 = \$750.5$); Round trip flight between Bangkok to Dulles International Airport is estimated at \$1,650; local transportation/taxi between hotel and airport per round trip between Chulalongkorn Hospital to airport is estimated at \$40, between hotel and the airport in the US is estimated at \$200, and \$60 for transportation within the region (\$300).

F. Participant Support Costs

No participant support is requested.

G. Other Direct Costs (Total \$78,803)

Materials and Supplies (\$72,830)

PBMCs isolation (\$47,000). We request funds to conduct PBMC isolation from collected sample, costs including the reagents and lab consumable and supplies are estimated at \$47 per cell for 1,000 cells.

Multiplex microsphere immunoassay detection (\$2,275). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at \$6.5 per sample for 350 samples.

PCR testing and sequencing (\$20,475). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at average \$58.5 per sample 350 samples, given a 10%~15% positive rate.

Field supplies for PBMC collection and processing (\$1,225). Funds are requested to perform PBMCs collection and processing in the field. Costs including the reagents and lab consumable and supplies are estimated at average \$3.5 per sample 350 samples.

Field supplies for animal sampling (\$1,160). Funds are requested to purchase supplies for animal capture, anesthesia, and sample collection. A total cost of \$1,160 is estimated

Field work disposable (\$668). Funds are requested to purchase disposable materials (tips, tubes, gloves, masks, goggles etc.) for field work.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Consultants Service (\$3,000)

One (1) zoologist and one (1) veterinarian will provide consultancy service to this project to help 1) select sites for animal sampling and join the sampling trip to 2) identify species; and 3) provide veterinary care in the sample collection of bats, rodents, and shrews. The consultancy fee is estimated at \$1,500 per person for the project, in total of \$3,000.

Publication Fee (\$3,000)

We request \$3,000 of publication costs for one peer-review paper generated from the project. The cost is estimated at the reimbursed Open Access fees of \$2,900 - \$5,000 per manuscript in the past two years for six peer-review papers.

H. Total Direct Costs (Total \$138,831)

I. Indirect Costs (Total \$11,106)

An indirect cost at 8% is requested.

J. Total Direct and Indirect Costs (Total \$149,937)

A total amount of \$149,937 is requested.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Co-PI Plan (only needed if applying as Co-PIs):

What each Co-PI will contribute to the proposed research study

As stated in the Mentoring Plan, the co-PIs, Krongkan Srimuang and Spencer Sterling have different educational and training backgrounds. This Co-PI plan is proposed to fill the gaps in knowledge of each scientist and supports a collaborative working relationship for project success. Moreover, this plan was developed to maximize the strengths of each PI. Overall, the project is separated into two objectives, the proposal of this project will be equally managed by Dr. Srimuang and Mr. Sterling. Dr. Srimuang will be responsible for PBMC isolation, sorting, and characterization. Mr. Sterling will be responsible for the technical serological aspects of the project. Both will work closely with the Research Center Mentor, Dr. Eric Laing, to develop this project, protocol development, and network connections. Dr. Supaporn Wacharapluesade, the Co-mentor, will support the wildlife sampling, samples collection, and molecular aspects within Thailand.

How the Co-PIs will jointly work with the affiliated Research Center

Mr. Sterling is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region.

How the Co-PIs will jointly manage the proposed study

This is a great opportunity for both PIs to undergo training in advanced techniques and develop skills in next-generation serology and molecular sequencing. Dr. Srimuang will learn and practice serologic techniques and data analysis from Mr. Sterling. Mr. Sterling will develop skills in cell isolation and molecular sequencing techniques from Dr. Srimuang. Moreover, Mr. Sterling will coordinate planning, sample processing, data analysis, and report preparation for this project with Dr. Srimuang.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

TRC-EIDCC: Thai Red Cross. Emerging Infectious Diseases. Clinical Center

USA: United States

WGS: Whole Genome Sequencing

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), cell sorting machine and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country. Bats are considered protected wildlife in Thailand by Wildlife Conservation, Department of National Parks, Wildlife and Plant Conservation.

Computer:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

PI Name: **Srimuang, Krongkan and Sterling, Spencer**
CREID CC Grant: 1U01AI151378

Foreign Site: **Thailand**

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Krongkan Srimuang
Project Title:	Immune memory bait & capture to identify emerging henipavirus origins
Institution:	King Chulalongkorn Memorial Hospital
Foreign Research Site:	Rama 4 Road, Pathumwan, Bangkok 10330 Thailand
Point of Contact for Research Site:	Krongkan Srimuang Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital Rama 4 Road, Pathumwan, Bangkok 10330 Thailand krongkan.sr@gmail.com

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goals of this project are to know zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

To achieve these goals, the investigator will collaborate with NIH PREMISE for Antibody-mediated bait & capture of Thai MojV-like virus.

\$149,937 of grant funds will be sent to the site for these studies.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will 1) conduct all filed work to collect human and animal samples from the study sites; 2) perform laboratory analysis using collected samples; and 3) conduct data analysis as proposed in the project.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - IRB approval number for parent study: #894ECOH21b (US); #221/64 (Thailand)
 - IRB approval date: 12-05-2021 (US); 08-06-2021 (Thailand)
 - Human Subject Assurance Number: (FWA)#: #00001102 (external IRB); #00022431 (EcoHealth Alliance); #00000943 (Chulalongkorn University)
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - **Yes**
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - **No**
 - How many subjects provided the existing samples to be used? N/A
- **Will human subjects be recruited (Yes or No)**
 - **Yes**
 - Number of human subjects that will be recruited: 110
- **Population parameters:**
 - Gender: 55 males, 55 females
 - Age Group: Age >=18 years who provide informed consent.
 -
 - Race/Ethnicity: 110 Asian
- **Sample collection will include:**
 - Blood: Yes
 - Urine: No
 - Tissues: No
 - Other samples (describe): Nasopharyngeal swab and throat swab
- **Sample collection will be completed in how many visits: 2 trips**
- **Will samples be de-identified (Yes or No)? If No, describe how they will be protected.**
 - **Yes**
- **Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.**
 - **Yes**
- **Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.**
 - **Yes**
- **Will samples be brought back to the US (Yes or No)?**
 - **No**
- **Will data be brought back to the US (Yes or No)?**
 - **Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.**

Animal Subjects (1 word or 1 sentence per bullet):

- **Parent study IACUC approval**
 - IACUC approval number for parent study: #G2020-42 (US); #019/2563 (Thailand)
 - IACUC approval date: 05-05-2020 (US); 03-12-2020 (Thailand)
 - Animal Welfare Assurance Number: D16-00572 (A4059-01)

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- **Does this study require a modification to the IACUC approval of a parent study (Yes or No)?**
 - **No**
- **Will existing samples from animal subjects will be used: (Yes or No)?**
 - **No**
 - How many animal subjects provided the existing samples to be used? **N/A**
- **Will vertebrate animals be collected (Yes or No)?**
 - **Yes**
- **Species of animals (e.g. rats, mice, rabbits, monkeys):** **Bats, rodents, and shrews**
- **Animal parameters:**
 - **Total number of animals:** **200 (100 bats, 100 rodents and shrews)**
 - **Gender:** **100 males, 100 females**
 - **Age range:** **4 - 12 months and elder depending upon species**
 - **Lab strain (e.g. Sprague-Dawley rats, Balb/C mice):** **None**
 - **Wild animals procured in country (e.g. Rhesus monkeys from a reserve):** **No**
- **What will be done to them or with them and how often?**
 - **Free-ranging bats will be captured using either a mist net or harp trap, and manually restrained during sampling; free-ranging rodents and shrews will be captured through pit traps and box traps.**
 - **Anesthesia will be conducted for captive rodents and shrews.**
 - **Once anesthetized blood will be collected.**
 - **All action will only be performed one time for each animal individual.**
 - **All animals will be released after sampling.**
- **What are the follow-ups?**
 - **No follow-up relevant as per protocol, since all animals will be released after sampling ups**
- **What will be their fate at the end of the experiments – will they be euthanized?**
 - **All animals will not be held longer than 6 hours (typically less than 3 hours) during the sampling process and released after sampling.**
- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - **Yes**
- **Will samples be brought back to the US (Yes or No)?**
 - **No**
- **Will data be brought back to the US (Yes or No)?**
 - **Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.**

Mentor phone	+66 (0) 89-920-6292
Research Center Affiliation	The Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH)

Total Budget	<i>Repeat this table if there are two Co-PIs</i>
Direct Costs	\$138,831
Indirect Costs	\$11,106
Proposed Start Date	1 May 2023
Proposed End Date	30 April 2024

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) are bat-borne zoonotic viruses, cause high mortality. The recent detection of closely-related Mojiang and Langya viruses in rats and shrews, and isolation of Langya virus from individuals with acute febrile illness, challenges the dogma that fruit bats are the key henipavirus reservoirs. The recently expanded <i>Henipavirus</i> genus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. As part of EID-SEARCH activities, we found serological evidence of infection by a Mojiang-related virus in a community of Thai bat guano collectors who have occupational exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to identify novel viruses and zoonotic reservoirs through serologic and cellular immune discovery. We will conduct</p>

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

follow-up human and wildlife (bats and rodents) surveillance in the province where the seropositive humans were identified. Further, we plan to isolate anti-MojV monoclonal antibodies (mAb) from peripheral blood mononuclear cells collected from human study participants we have identified as immunoreactive with MojV antigens, and characterize the cross neutralizing potential of these mAbs to MojV and LayV envelope glycoproteins. In addition to our antigen-based approach, we will utilize the mAbs for direct antibody-mediated virus capture of this novel henipavirus from human and wildlife samples, and downstream genomic sequencing.

Study Personnel

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as Mentor for Dr. Srimuang and Mr. Sterling under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Laing is an assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses at Uniformed Services University, Bethesda, MD. Dr. Laing study to develop serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Dr. Laing have worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Across all of these collaborations, the aimed to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence.

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Specific Aims

This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The hypothesis

1. Can the memory B-cell immune response be used as a tool for the discovery of novel henipaviruses?
2. Can the spatial relationships between henipaviruses receptor binding proteins be generated that would allow for an understanding of antigenic evolution and functional characterization?

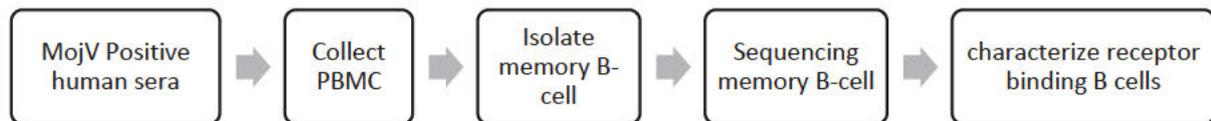

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population.

Human populations near the Khao Chong Phran Non-hunting Area in Ratchaburi province have shown a high seroprevalence to the MojV RBP without confirmed sequencing results. We will follow-up on persons with high MojV RBP IgG titers, sample new people within the population that interact with the local wildlife, and sample shrews and rodents to find the source of the MojV-reactive antibodies.

Aim 2. Antibody-mediated bait & capture of the Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Objective 2. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody production.

Objective 3. To determine epitope binding and antigenic relationships from henipavirus-reactive serum to the known henipaviruses.

Study Rationale

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McLinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genus of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, Gamak virus (GAKV), and Daeryong virus (DARV) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The Henipavirus genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australian (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected four members of a high-risk cohort with MojV-reactive serum, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia is due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology to identify a novel virus that can aide in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in

wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. In addition to the translational application of mAbs as therapeutics, we intend to utilize these mAb as non-clinical diagnostics surveillance tools for virus/virus antigen capture. Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

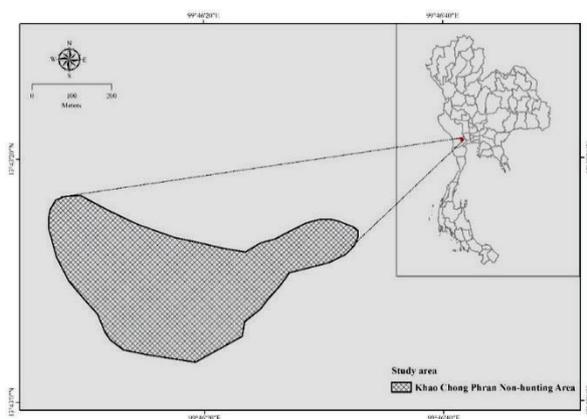

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Site wildlife samples collection

100 bats and 100 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. We plan one sampling trip to collect bats, and a second trip to target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect 100 samples, and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored. Oral swab and rectal swab will also collect in 100 bats and 100 shrews or rodents. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

Human surveillance

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, 100 human serum samples, nasopharyngeal swab and throat swab will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

-
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,510 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

The sample size of 100 of each species follows the guidelines established during the PREDICT project.

Targeted Viral Sequencing and Serologic testing

Targeted sequencing

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The nucleic acid from oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing.

Serological testing

Serum samples will be tested for RBP binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Data analysis

Sequencing will be analyzed assembling reads in MEGA11. The consensus sequences will compare to the references strains available in the GenBank data-base using the Basic Local Alignment Software Tool (BLAST) (National Center for Bio-technology Information). Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to LayV RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipias, and LayV, depending on how well these cross react.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 2).

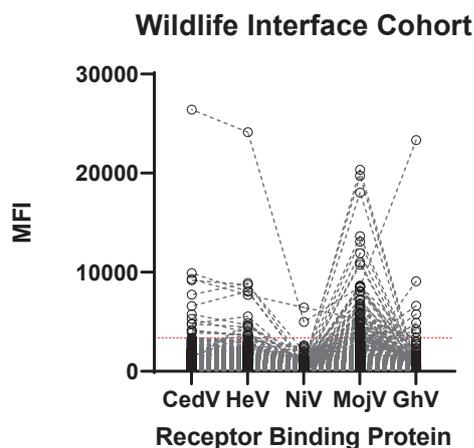

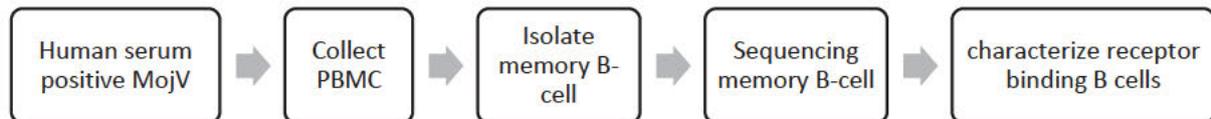

Figure 2: Seroprevalence of henipavirus proteins from a community with a large bat interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, the assay cutoff.

PBMC Sorting and B Cell isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes). Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, 4 5 7 -tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor Amplicon Preparation and Recombinant Antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced. After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. Next, we will test the cross neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV (Duke NUS/LinFa should be able to do this, if they have LayV and are propagating it, they can use cell-cell fusion/CPE in a straight PRNT).

Determination of envelope glycoprotein epitope binding

Isolated mAbs will be assessed for binding to MojV RBP and F proteins through multiplex binding serology. Further, the cross reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of cross neutralizing potential is not possible. However, through cyro-electron microscopy we can investigate binding epitopes between these mAbs and MojV and LayV envelope glycoproteins. Epitope identification can then be used to make predictions about neutralizing potential through deductions about the location of henipavirus RBP receptor-binding pockets.

Research Performance Sites

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country. We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

CREID Research Center Collaboration

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. Further, Dr. Doeuk who is the director of the VRC PREMISE program is enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Ig) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Mentoring Plan

Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

writing and project management skills. My professional relationship with Dr. Wacharapluesadee began in 2018 when I participated in a DTRA BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group. Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Vertebrate Animals Section Requirements

Animal samples will be collected in Ratchaburi Province for this project under Aim 2 to understand the antigenic relationships among known and unknown henipaviruses. Protocol to perform animal sample collection has been reviewed and approved by the Institutional Animal Care and Use Committee at Tuft University under the EID-SEARCH project (No. G2020-42) and the Institutional Animal Care and Use Committee at Chulalongkorn University (No. 019/2563)

1. Description of Procedures

Bats (order *Chiroptera*)

- Species: Free-ranging mega and micro-*Chiroptera* that present at the site (family *Pteropodidae*, *Rhinopomatidae*, *Emballonuridae*, *Craseonycteridae*, *Megadermatidae*, *Rhinolophidae*, *Hipposideridae*, *Vespertilionidae*, *Mollossidae*, etc.)
- Age & Sex: Fully flighted adults and juveniles, males and females; neonates dependent on the dam will not be used.
- Target Number: 100 individuals
- Capture and Restraint: Bats will be captured using either a mist net or harp trap. The net system is manned by at least two people during the entire capture period, and bats are removed from the net as soon as they become entangled to minimize stress and prevent injury. In our previous field research experience, a maximum of 20-30 bats can be safely held and processed by a team of three people per trapping period. Duration of trapping will depend on the capture rate. Bats are individually placed into a pillowcase or small cloth bag and hung from a branch or post in a location that is free from access by both predators and people, and is protected from the elements (e.g., rain), until the animal is restrained for sample collection. Bats will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and bat. The study protocol covers over 69 bat species that are most likely to be captured given their natural occurrence and previous surveillance experience in Southeast Asia. The potential for non-target species to be captured is very low because mist nets are opened at the cave entrance at night, after other species (e.g., birds) have ceased flying and returned to roost. Any non-target species will be rapidly identified, removed from the mist net and released immediately.
- Sample Collection: Depending on the species and size of bat, blood will be collected from smaller insectivorous bats (<50g) using a 27g needle to puncture the brachial artery and a 70ul hematocrit tube to collect the blood. For larger bats (>50g) we will collect blood from either the cephalic vein or from the radial artery or vein using a 25- or 23-gauge needle and 3cc syringe. Blood will be collected collected to confirm host identification using DNA barcoding. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected and whole body submitted to museums as voucher specimens.
- Release: Bats are held for a maximum of six hours (typically less than three hours), and at the completion of sampling are provided with rehydrating fluids (either subcutaneously or orally as needed) and released in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided).

Rodents (order: *Rodentia*) and Shrew (order: *Scandentia* and *Eulipotyphla*)

- Species: Free-ranging rodents (family *Hystricidae*, *Muridae*, *Sciuridae*, *Spalacidae*) and shrew (tree shrews, shrews, moles) that present at the sites.
- Age & sex: Adults and juveniles, males and females. Neonates will not be sampled.
- Target Number: 100 individuals
- Capture and Restraint: Free-ranging wild mammal species will be captured with metal box traps (Sherman/Tomahawk traps). Traps will be prepared with food, water, padding and shelter, and be checked at least every 12 hours, in the morning and in the afternoon. If adverse weather (extreme heat, rain) is expected or researchers are working in areas where predation is common, traps will be checked more frequently and closed during adverse weather. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. Depending on the species, individual size, captive or free-ranging status of the individual, manual or chemical restraint and anesthesia (gas or injectable anesthesia) will be applied. Animals will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and animal. Based upon past field experience (>20 years of animal capture and release in Southeast Asia), we do not expect to trap sick, debilitated, or young animals that would be too young to cope with capture. Sick and debilitated animals tend not to roam widely, reducing their opportunity to enter traps. Additionally, should sick, debilitated, or young animals enter traps, we anticipate that they will not suffer adverse conditions because the traps contain food (the bait) and liquid (water or fruit as a source of water). These individuals would be examined by a veterinarian, rehydrated and if presenting clinical signs treated by a veterinarian, prior to release or sampling then release.
- Sample Collection: Once anesthetized or safely restrained, whole blood will be collected through the appropriate venipuncture site, no more than 1 ml of blood per 100 g (= 10 ml/kg or 1%) of body weight will be collected at any one time. Anesthetized animals will be monitored regularly during recovery until they can no longer be safely handled, at which point they will be confined in a trap or cage. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected.
- Release: Wild mammals are held for a maximum of thirteen hours depending on trap timing, but typically less than three hours. Captive animals are held for a maximum of two hours but typically less than one hour. At the completion of sampling, animals may be provided with rehydrating fluids (either subcutaneously if anesthetized or orally if manually handled and accepted). Wild mammals will be released at the site of capture in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided). Captive mammals will be released back into their captive setting as is appropriate for the species, either isolated or in social group if it is deemed safe from aggression from enclosure mates while the post-recovery period continues.

2. Justifications

The purpose of this study is to identify zoonotic pathogens through serologic and cellular immune discovery, including developing methods and standards for direct antibody-mediated virus capture in people and wildlife, focusing on rodent/shrew- and bat-borne HPVs. This will require hands-on fieldwork to collect whole blood and serum samples from bats, rodents, and shrews for lab analysis. One technique that avoids the direct capture and sampling of animals is to collect fresh feces or urine, but this will not be able to provide the appropriate samples for serologic analysis, and the research objectives cannot be

achieved using an alternative methods (e.g., computational, human, invertebrate, in vitro). Therefore, we believe there are no viable alternatives than the use of live animals.

3. Minimization of Pain and Distress

In every situation, sampling of wildlife will be conducted in the most humane manner while minimizing the impacts on individual animals and their wild populations. In all instances, the fewest number of animals will be sampled that will provide valid information and statistical inference for the pathogen and disease of interest and every effort will be made to minimize stress and discomfort for the animal.

Bats will not be held longer than six hours during the sampling process whereas small mammals may be held for up to 13 hours depending on trap capture timing. Field animal sampling team with zoologists and veterinarians have been well trained and have extensive experience in capture, anesthesia, and sampling of wildlife. In our team's experience, the target species tolerate the described procedure well. Mist nets will be attended continuously during capture periods, and bats will be extracted from the net as soon as they become entangled. This will minimize stress and injury from entanglement. Bats will be placed individually in cloth bags and hung from tree branches while awaiting processing and during recovery. The bags are sufficiently porous as to allow for ventilation and are designed for bat capture. The enclosed environment seems to calm the bats, as they do not struggle once inside, but they hang quietly – this is a standard and accepted practice in bat research and the best way to minimize stress to the animal.

For rodents and shrews, food, water, padding and shelter will be provided at traps, which will be checked at least every 12 hours. Traps will be checked more frequently or closed if adverse weather (extreme heat, rain) is expected, or researchers are working in areas where predation is common. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. All animal individuals will be monitored by a veterinarian or experienced field team member during all stages of capture, processing, anesthesia and release. Animals will be kept in a cool place, free from adverse weather conditions and access by non-field team members or other animals while in the pillowcases, trap, or cage for recovery. All recovering individuals will be observed until they are able to effectively ambulate and orient to their surroundings. Animals that are injured during the capture or sampling process will be assessed by an experienced team leader or attending veterinarian, and if the animal is determined to be unlikely to survive if released, it shall be euthanized humanely (see euthanasia section).

4. Method of Euthanasia

In the event that an animal has been injured or is moribund, a determination will be made as to whether it may be treated and released on site by veterinarians or transferred to facility that may treat and rehabilitate the animal, or if, as a last resort, the animal will require euthanasia. Euthanasia methods will not deviate from the AVMA “Guidelines for the Euthanasia of Animals” (2020 edition). Any animal that is euthanized using a chemical agent will be disposed of such that it will not be permitted to enter the food supply either through markets or hunting.

Human Subjects Research

1. Risks to the subjects

In this project, we will target populations in one community site who with frequent exposure to bats and other wildlife based on our previous behavioral survey. Subjects will be enrolled voluntarily, and informed consent will be obtained from all participants, along with assent from all participants aged 12-17. Enrolled participants will provide biological samples. Survey data and biological samples will be collected from enrolled participants, and follow-up data collection will be performed among participants whose samples were tested positive.

Biological samples and questionnaire data will be collected from individuals who meet recruitment and inclusion criteria and complete the informed consent process. During data collection, a standardized questionnaire will be administered to all participants. This questionnaire will collect information of demographic background, wildlife contact, travel and daily movement, and unusual SARI/ILI symptoms, and biological specimens will be collected from participants. Both questionnaire and biological data will be analyzed to assess the exposure to coronaviruses and the spread risk among humans. From all participants, a one-time whole blood sample (Max. 15 mL) will be collected during the study period. This sample will allow us to test for historical exposure to bat or rodent-born henipaviruses and collect Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive.

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals who are proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions; however, the administration will be conducted privately and confidentially to protect individuals' health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

2. Adequacy of protection against these risks

2.1 Informed consent and assent

Only consented participants will be enrolled in the study. No research procedures will be undertaken before the participant fully understands the research, agrees to the study procedures, and completes the consent process will be enrolled in the study. Informed consent statements and forms, and project protocols will be translated into the local language of each study site. Research team members involved in this consent process will be required to be fluent in the local language to ensure that the subjects understand the study and all involved procedures.

If participants meet the criteria for enrollment, they will be invited to discuss the details of the study with the research staff. Study staff will review an information sheet and informed consent form with the participant and the parent or legal guardian when applicable. Each individual will be provided with a copy of the informed consent form that has been translated into the local language and written with a Flesch–Kincaid readability score equivalent to a 7th-grade reading level or below, to assure that potential participants understand the information being shared. The informed consent form will explain the details

of the study, including how and why the individual was selected, the study process and procedures, risks and benefits, financial considerations and the gift of appreciation, confidentiality of data shared, alternatives to participating, and how to obtain more information now or at a later date. The informed consent form will be read in the local language of the site at a location ensuring participant privacy. After which individuals will have as much time as they would like to ask questions and discuss the study with study staff. The study staff will endeavor to ensure that the participant understands the information provided. The study staff will then ask the participant/parent or legal guardian to consider study participation. Participants will have as much time as required to consider the participation.

Those participants who consent to the study will sign and date two copies of the consent form. These form copies will be countersigned and dated by the study staff. A copy of the signed consent form must be provided to the subject and the other copy will be kept by study staff. Informed consent paperwork will be kept until the end of the project in a locked box at the local country project office.

2.2 Protection against risks

The potential risks to study participants as a result of study participation are minimal. Collection of venous blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. Potential complications associated with venipuncture include pain and/or hematoma at the site of collection. Trained medical professionals and/or clinic staff will monitor the blood collection site and treat any complications according to existing health facility protocols. A potential complication of nasal/oropharyngeal sampling is minor irritation at the time of collection. Employing trained medical and/or clinic staff to collect blood and swab samples will minimize the potential for complications.

Another risk that this study may pose concerns the information to be gained on henipaviruses newly recognized in the community. We will provide participating communities, hospitals, and clinicians with information and background data on target zoonotic viruses to ensure up-to-date communication of risk. Because of the timeline for diagnostic testing and results interpretation, we are not likely to provide results to participating clinics within a time frame that would be clinically relevant to outbreaks of undiagnosed diseases. Therefore, the information provided by this project will not impact patient management or outlook.

If an individual decides to participate in this research, his/her participation and all information provided by the participant will be strictly confidential, and personal identifying information will not be shared with anyone outside of the study staff. Participants will not be identified or named in any reports or publications. Questionnaire information and all biological samples will be identified by an alphanumeric code, not by the participant's name. All records that contain names or other personal identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the study site in locked files cabinets or password-protected devices in areas with access limited to the research staff of this project. Research databases will be secured with password-protected access systems and controlled distribution web-based certificates and will not contain any identifying characteristics about study participants (e.g., name, address, or telephone number). Access to all data will be limited to the staff involved in this study. The health information disclosed by an individual will not be used by or disclosed (released) to another institution. Any surveillance report that is published or shared with partners will not contain any personally identifying information for individual participants.

3. Potential benefits of the research to the subjects and others

There are no measurable benefits to the individual study participants enrolled in this study. There are benefits to the community and regional healthcare providers to help them understand the risk of zoonotic infections among high-risk populations in the regions they work. At the conclusion of the study, we will deliver an educational workshop reporting aggregate study findings that will be open to both study and non-study participants, describing the health benefits of using personal protection equipment (PPE) and handwashing during animal handling activities throughout the day, as well as to share other prevention/interventions that emerge from the research data.

4. Importance of the knowledge to be gained

There are valuable potential benefits to the public from the knowledge to be gained from this study. One key benefit to the community is sharing information and knowledge to better understand the risk of zoonotic spillover events and related health risks, as well as information sharing with communities on practices that could reduce risks, such as the avoidance of particular animal contacts or the need for PPE and extra care when handling wildlife, that may substantially reduce the risk zoonotic pathogen transmission in the community. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to create or implement public health interventions to disrupt disease emergence and/or spread in an area that is beneficial to all. Additionally, there are valuable benefits to the general public from the knowledge to be gained from this study. Knowledge gained will increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

5. Country- / institution-specific ethics / IRB regulations addressed

Main research protocol and materials to conduct human subject research in this project have been reviewed and approved by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64). Amendment for PBMCs collection will be made and approved before the start of this project.

Budget Justification

A. Key Personnel (Total \$24,000)

Dr. Krongkan Srimuang, PI (12 months) is a medical research scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital (TRC-EIDCC) who have been leading the laboratory analysis for the EID-SEARCH work in Thailand in the past three years to perform molecular, serological, and next-generation sequencing to identify novel viruses from human and animal samples. Dr. Srimuang will commit 12 months to this project to design, manage, and perform all project activities in the lab and field by supervising a lab technician and working with the field coordinator. Dr. Srimuang will also work closely with the co-PI and Mentors to conduct data analysis and develop manuscript and join EID-SEARCH and CREID meetings to prevent the project findings.

Spencer Sterling, Co-PI (6 months) is the research coordinator of Laing Lab at the Uniformed Services University for Indo-Pacific region and a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC). Sterling will commit 6 months to this project as the co-PI, who will work closely with the PI in the study design, SOP development, sampling process, data analysis of for serological investigations. No salary is required for Sterling.

B. Other Personnel (Total \$20,000)

One (1) Laboratory Technician (12 months) will committee 12 months to this project to conduct PCR and serological testing of animal and human samples at TRC-EIDCC, under the supervision of Dr. Srimuang and Sterling. Salaries for 12 months at \$1,250 per month is requested (\$15,000).

One (1) Field Coordinator (4 months) will committee 4 months to this project, working closely with Dr. Srimuang and Sterling to organize and conduct field sample collection among humans and animals at the study sites, and support relevant financial management. Salaries for 4 months at \$1,250 per month is requested (\$5,000).

C. Fringe Benefits

No Fringe is requested.

D. Equipment

No equipment is requested.

E. Travel (Total \$48,375, Years 1-5)

Domestic Travel (\$11,005)

Support for domestic travel for field sampling is requested in the amount of \$11,005 per to conduct four (4) trips of sample collection from humans, bats, and rodents/shrews.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

- The first trip is a one-day trip to collect samples from human participants who were tested positive ($n < 10$), the cost is estimated at van rental for local transportation between Bangkok and the study site (\$260) and meals for five (5) field team members at \$49 per person (\$245), in total of \$505 for the first trip.
- The other three (3) field trips will be conducted to collect samples from 100 bats, 100 humans, and 100 rodents/shrews, respectively. Each trip is a duration of 6 days and 5 nights. For each person, 5-night stay in hotels at \$75.5/night ($5 \times \$75.5 = \378); 3 meals per day and incidental expenses at \$49 per day prorated to 75% (\$36.75) for first and last day of travel ($\$36.75 \times 2 + \$49 \times 4 = \$270$), the total meals and accommodations for each person per trip is \$648 (\$378+\$270), cost for five (5) field team members is \$3,240. A van will be rented for local transportation between Bangkok and the study site that is estimated at \$260 per trip. Total cost for each 6-day trip is \$3,500, three trips will be \$10,500.

International Travel (\$5,023)

Support for international travel for Dr. Srimuang from Bangkok to Washington DC to attend the CREID Annual Meeting and receive lab training at the National Institute of Allergy and Infectious Diseases (NIAID) is requested in the amount of \$5,023. Trips are for a duration of 10 days and 9 nights. Travel costs for one trip are estimated using federal per diem rates for hotels, meals, and incidental expenses as follows: nine-night stay in DC area hotel at \$286/night ($9 \times \$258 = \$2,322$); Ten days' meals and incidental expenses at \$79 per day prorated to 75% (\$59.25) for first and last day of travel ($\$59.25 \times 2 + \$79 \times 8 = \$750.5$); Round trip flight between Bangkok to Dulles International Airport is estimated at \$1,650; local transportation/taxi between hotel and airport per round trip between Chulalongkorn Hospital to airport is estimated at \$40, between hotel and the airport in the US is estimated at \$200, and \$60 for transportation within the region (\$300).

F. Participant Support Costs

No participant support is requested.

G. Other Direct Costs (Total \$78,803)

Materials and Supplies (\$72,830)

PBMCs isolation (\$47,000). We request funds to conduct PBMC isolation from collected sample, costs including the reagents and lab consumable and supplies are estimated at \$47 per cell for 1,000 cells.

Multiplex microsphere immunoassay detection (\$2,275). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at \$6.5 per sample for 350 samples.

PCR testing and sequencing (\$20,475). Funds are requested to perform serological testing of collected human and animal samples. Costs including the reagents and lab consumable and supplies are estimated at average \$58.5 per sample 350 samples, given a 10%~15% positive rate.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Field supplies for PBMC collection and processing (\$1,225). Funds are requested to perform PBMCs collection and processing in the field. Costs including the reagents and lab consumable and supplies are estimated at average \$3.5 per sample 350 samples.

Field supplies for animal sampling (\$1,160). Funds are requested to purchase supplies for animal capture, anesthesia, and sample collection. A total cost of \$1,160 is estimated

Field work disposable (\$668). Funds are requested to purchase disposable materials (tips, tubes, gloves, masks, googles etc.) for field work.

Consultants Service (\$3,000)

One (1) zoologist and one (1) veterinarian will provide consultancy service to this project to help 1) select sites for animal sampling and join the sampling trip to 2) identify species; and 3) provide veterinary care in the sample collection of bats, rodents, and shrews. The consultancy fee is estimated at \$1,500 per person for the project, in total of \$3,000.

Publication Fee (\$3,000)

We request \$3,000 of publication costs for one peer-review paper generated from the project. The cost is estimated at the reimbursed Open Access fees of \$2,900 - \$5,000 per manuscript in the past two years for six peer-review papers.

H. Total Direct Costs (Total \$138,831)

I. Indirect Costs (Total \$11,106)

An indirect cost at 8% is requested.

J. Total Direct and Indirect Costs (Total \$149,937)

A total amount of \$149,937 is requested.

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Srimuang, Krongkan

eRA COMMONS USER NAME (credential, e.g., agency login):

POSITION TITLE: Research Scientist

EDUCATION/TRAINING (Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Chulalongkorn University, Bangkok, Thailand	B.Sc.	03/2012	Medical Technology
Mahidol University, Bangkok, Thailand	Ph.D.	04/2017	Molecular Tropical Medicine and Genetics

A. Personal Statement

I am a medical technologist. My undergraduate training has provided me with a background in multiple biological disciplines including molecular biology, microbiology, and genetics. During my Ph.D., I conducted research with Dr. Mallika Imwong focused on Malaria. My thesis was entitled "Exploring the molecular mechanism of mefloquine resistance in *Plasmodium falciparum*". I conducted research on drug resistance to malaria in Southeast Asia. Specifically, my focus was on molecular techniques in identifying the genetic mutations involved with drug resistance. Moreover, I got experience in *Plasmodium falciparum* malaria culture. After my Ph.D., I worked at the genetics laboratory at Jetanin Institute of Assisted Conception. My responsibilities included Preimplantation Genetic Testing (PGT) is screen embryos for genetic abnormalities such as chromosome copy number gains or losses (PGT-A, aneuploidy screening), single gene disorders (PGT-M, monogenic or single-gene disease), or structural rearrangement (PGT-SR, structural rearrangement to identify embryos with chromosome imbalanced) by using Next Generation Sequencing. Additionally, I conducted genetic screening in couples for detecting carrier diseases such as glucose-6-phosphate dehydrogenase (G6PD), Alpha thalassemia, Beta thalassemia, and Spinal muscular atrophy (SMA) by using molecular genetics techniques. Currently, I am a Research Scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC EIDCC), King Chulalongkorn Memorial Hospital where I investigate emerging infectious diseases under the guidance of Dr. Supaporn Wacharapluesadee. The research focuses on detecting, identifying, and characterizing pathogens and human genome segments using molecular and serology techniques, including Next Generation Sequencing and Multiplex serology assays as a part of EID-SEARCH project. Additionally, I am the laboratory sequencing lead on the Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) project from patients in Thailand as part of a collaboration with the Department of Disease Control.

B. Positions, Scientific Appointments, and Honors

Positions and Scientific Appointments:

02/2022 – Present	Medical research scientist, Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital
05/2017 - 01/2022	Scientist, Genetics Laboratory, Jetanin Institute for Assisted Reproduction
10/2015 - 03/2016	Fellowship at Laboratory of Molecular and Cellular Parasitology, Department of Microbiology and Immunology, National University of Singapore, Singapore.
11/2011 – 02/2012	Training Medical Technology Programs at Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Honors:

2012 -2017	Scholarship for Ph.D. from the Royal Golden Jubilee, Ph.D. Grant (14th Batch).
------------	--------------------------------------------------------------------------------

C. Contributions to Science

Undergraduate Research: I participated in research activities under Dr. Attakorn Palasuwan to study in human genetic variants in proteins, such as G6PD, as they relate to the effect of exercise on the reduction of free radicals in the body. We conducted the multiplex PCR to identify the G6PD variants and found 8 variants including Vanua Lava, Mahidol, Mediterranean, Coimbra, Viangchan, Union, Canton, and Kaiping.

Graduate Research: I continued to studies under Dr. Mallika Imwong in the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University. My thesis, “Exploring the molecular mechanism of mefloquine resistance in *Plasmodium falciparum*”, focused on the evolution of resistance to mefloquine, which is commonly used in Southeast Asia in Malaria treatment. The mechanism of mefloquine resistance remains unknown, but I focused on the *Pfmdr1* gene which is involved in the drug resistance mechanism in *Plasmodium falciparum*. I found mutations and polymorphisms in *Pfmdr1* gene.

1. **Srimuang K**, Miotto O, Lim P, Fairhurst RM, Kwiatkowski DP, Woodrow CJ, Imwong M; Tracking Resistance to Artemisinin Collaboration. “Analysis of anti-malarial resistance markers in *pfmdr1* and *pfcr1* across Southeast Asia in the Tracking Resistance to Artemisinin Collaboration” *Malar J.* 2016 Nov 8;15(1):541.
2. Reamtong O, **Srimuang K**, Saralamba N, Sangvanich P, Day NP, White NJ, Imwong M. “Protein profiling of mefloquine resistant *Plasmodium falciparum* using mass spectrometry- based proteomics” *Int J Mass Spectrom.* 2015 Nov 30;391:82-92

Post-graduate Research: I was a scientist in genetics lab at Jetanin, a holistic center for infertility, offering counseling and treatment with Assisted Reproductive Technologies such as IVF, ICSI, and Preimplantation Genetic Testing (PGT). My work included the development of standard operating procedures for the lab, including Next Generation Sequencing, for detecting and identifying chromosomes in blastocyst growth to an embryo. Additionally, we assisted couples who had a family history of genetic diseases for screening before pregnancy. The carrier screening focused on highly prevalent diseases in Thailand such as alpha thalassemia, beta thalassemia, G6PD, and SMA. Currently, I am a Research Scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital. I am currently tasked with using molecular and serological techniques in the surveillance of novel, exotic, and known pathogens in wildlife and humans.

1. **Srimuang K**, Udompat P, Thippamom N, Petchrat S, Doung-Ngern P, Kripattanapong S, Supataragul S, Sterling SL, Wacharapluesadee S, Puthachoen O. “Genetic characterization of Norovirus strains from an unusual diarrheal outbreak in the community in Eastern Thailand” (Submitted, January 2023)

BIOGRAPHICAL SKETCH

A. Personal Statement

As a current employee with Dr. Eric Laing under his emerging infectious diseases research program. My academic training and research experience have provided me with a background in molecular biology, virology, and epidemiological techniques for zoonosis investigations. As part of my original post-baccalaureate work, I worked in a small team lead by Dr. Chris Border tasked with developing a serological binding assay for Coronaviruses, Filoviruses, and Henipaviruses. During this process, I worked closely with Dr. Laing and scientists from multiple Asian countries in developing and applying the multiplex techniques for rapid, high-throughput serological assays. Throughout this time, I have led technical and data analysis trainings in Cambodia, Bangladesh, and Thailand, and have assisted collaborators in Singapore, Malaysia, Australia, India, South Africa, and the United Kingdom in implementing these novel techniques. Currently, I am a visiting scientist with Dr. Supaporn Wacharapluesadee in the Emerging Infectious Diseases Clinical Center at King Chulalongkorn Medical Hospital as part of the CREID-EID SEARCH program.

B. Positions, Scientific Appointments, and Honors

05/22-present Visiting Scientist, King Chulalongkorn Medical Hospital, Bangkok, Thailand. Advisors: Dr. Supaporn Wacharapluesadee, Dr. Opass Putchaeron, and Dr. Eric D. Laing.

02/22-present Scientific Project Coordinator, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisors: Dr. Christopher C. Broder and Dr. Eric D. Laing

- 08/20-02/22 Research Associate 2, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 08/19-08/20 Senior Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 06/15 – 08/19 Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 01/14-08/14 Laboratory research internship, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder

C. Contributions to Science

1. **Post-Baccalaureate:** My post-baccalaureate research works primarily targeted understanding the adaptive immune response to emerging zoonotic viruses as a tool for virus discovery. As part of the assay development team, I designed and expressed soluble, native-like filovirus and henipavirus attachment glycoproteins and developed the monoclonal antibodies and antisera used as standards in the assay. I have led technical training for international projects and assisted in data analysis
 - a. Laing ED, Mendenhall IH, Linster M, Low DHW, Chen Y, Yan L, **Sterling SL**, et al. “Serologic evidence of fruit bat exposure to filoviruses, Singapore, 2011–2016”. (2018). *Emerg Infect Dis.* 24(1):114-117. doi: 10.3201/eid2401.170401. PMID: 29260678.

2. **Professional Studies:** While employed, I continued my studies by pursuing a Master’s in Public Health with a focus on Epidemiology. Immediately preceding my thesis work, COVID-19 was declared a pandemic, and I worked along side Dr. Eric Laing to develop and standardize a human coronavirus serological panel to track the serological response to SARS-CoV-2 infections and vaccinations among a military cohort. For my thesis, I evaluated the humoral immune response to SARS-CoV-2 patients as it related to the severity of the disease, where we observed significantly more robust antibody responses in people with more severe disease.

Uniformed Services University, Bethesda, MD	Postdoc	04/2019	Virology

A. Personal Statement

The spillover of zoonotic viruses into human populations remains an ever-prevalent threat to public and global health. Continual outbreaks of known and unknown zoonotic viruses highlights the paucity of our understanding of the viral diversity, geographic distribution, wildlife hosts, and human populations at-risk for spillover. I am a recently appointed assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses. I have completed virological training and spent my time as a post-doctoral fellow applying *in vitro* techniques to characterize the replication of, and mammalian ephrin receptors that mediate cellular entry of emergent henipaviruses. Since the start of the COVID-19 pandemic, I pivoted the focus of my research team to serological analysis of SARS-CoV-2 infection, and then to COVID-19 vaccine-induced antibody durability. In my ongoing research, I develop serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Since my position as a postdoctoral fellow I have worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Across all of these collaborations, we have aimed to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence. Throughout these research projects, we have detected unexpected serological profiles in communities of bats and humans that have not fit our prior understanding of the viral diversity established or detected by genetic techniques. This proposal aims to better understand these serological profiles of wildlife and humans with a targeted focus on henipaviruses and filoviruses. Ongoing projects that I would like to highlight include:

HDTRA12110037. DTRA BRTP, E. Laing (Co-PI). 08/2021-07/2026, "Informing biosurveillance, contribution of pteropodid fruit bats to virus spillover in the Philippines."

HU00012020067, HU00011920111. Defense Health Program, NIAID, E. Laing (Associate Investigator). 03/2020 – 09/2023, "Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EpiCC-EID)."

B. Positions, Scientific Appointments and Honors

Positions

2021-pres.	Assistant Professor, Department of Microbiology and Immunology, School of Medicine, Uniformed Services University, Bethesda, MD.
2021-pres.	Joint Appointment, Emerging Infectious Diseases Graduate Program, School of Medicine, Uniformed Services University, Bethesda, MD.
2019-21	Research Assistant Professor, Department of Microbiology and Immunology, Uniformed Services University, Bethesda, MD.
2016-19	Postdoctoral fellow, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD.
2010-16	Graduate research student, Department of Microbiology, Uniformed Services University, Bethesda, MD.

Other Experiences and Professional Memberships

2022-pres.	Executive committee member, Emerging Infectious Diseases Graduate Program, USUHS
2021-pres.	Research center representative, Laboratory Assays Oversight and Quality Working Group, Emerging Infectious Diseases: Southeast Asia Research Collaboration Hub (EID-SEARCH), Centers for Research in Emerging Infectious Diseases (CREID), NIAID, DMID, NIH
2021-pres.	Review editor, Frontiers in Virology - Emerging and Reemerging Viruses
2021-pres.	Ad hoc reviewer, Frontiers in Immunology, Journal of Clinical Immunology
2021-pres.	Steering committee member, JPI/Military Infectious Diseases Research Program, Emerging Infectious Diseases
2019	Ad hoc reviewer, EcoHealthNet 2.0 Program, EcoHealth Alliance
2018	Ad hoc reviewer, Pakistan One-Health Fellowship Program, National Academy of Sciences & Pakistan Academy of Sciences
2014-2019	Member, American Society of Tropical Medicine and Hygiene
2014-2019	Member, American Society of Microbiology
2014-2019	Volunteer, AAAS STEM K-12 Volunteer Program

Mentoring

<i>Postdoctoral fellows</i>	Si'Ana A. Coggins, PhD, 2020 - 2022
<i>Graduate students</i>	Marana S. Tso, BS, 2021 - McKenna Roe, BS, 2022 -
<i>Committee member</i>	Celeste Huaman, BS, 2021 - 2LT Connor Perry, BS, 2021 -

Honors

2021-2022	Impact Award, USUHS School of Medicine
2021	Outstanding Research Accomplishment/Team/SARS-CoV-2, The EPICC COVID-19 Cohort Team, Military Health System Research Symposium
2020-2021	Impact Award, USUHS School of Medicine
2015-2016	Val G. Hemming Fellowship, Henry M. Jackson Foundation
2015	East Asia and Pacific Summer Institutes Fellowship, National Science Foundation

C. Contributions to Science ([†]mentee, *corresponding)

1. Lyssaviruses and the prototype, rabies virus, remain a public health concern. Beginning with my PhD thesis work, I've researched the virus host-interactions between a rabies-related lyssavirus, Australian bat lyssavirus (ABLV), and its bat host (*Pteropus alecto*). Research has focused on ABLV cellular entry mechanisms, the development of an animal model and ABLV reporters and exploration of novel monoclonal antibodies that neutralize ABLV and other phylogroup I lyssaviruses. Furthermore, comparative bat immunology research was conducted using black flying fox cell lines and ABLV as a model virus/host interaction. Physiological adaptations that accompanied the evolution of flight in bats have been proposed to contribute to the frequent role of bats as asymptomatic hosts of highly pathogenic zoonotic viruses.

Comparatively studying the autophagy pathway in bat cell lines revealed that bat cells had elevated levels of basal autophagy and experienced significantly less cell death when challenged with high virus doses.

PMID: 33804519; PMCID: PMC8001737.

2. My research experience as a postdoctoral fellow furthered my training in molecular virology techniques. I constructed a recombinant Cedar virus cDNA plasmid and optimized a reverse genetics approach to rescue a recombinant Cedar virus reporter virus, a non-pathogenic *Henipavirus* species. A molecular biology methods chapter detailing recombinant Cedar virus reverse genetics has been submitted and in press. Using this recombinant Cedar virus, we determined that Cedar virus can utilize several non-canonical henipavirus ephrin receptors for cellular entry and explored the structure of the receptor-binding pocket to understand the receptor promiscuity. The non-pathogenic phenotype of CedV creates a potential for CedV to act as a model henipavirus to explore host-pathogen interactions, cellular tropism and factors that determine henipaviral disease pathogenesis. Additionally, I have collaborated on projects detailing henipavirus infection and replication in bat hosts with colleagues at the Rocky Mountain Labs, studying whether specific species of bats are more competent hosts and whether virus-host restriction exists.

3. Bats are increasingly identified as animal reservoirs of emerging zoonotic viruses (e.g. Nipah virus, Ebola virus and SARS-coronavirus). I lead collaborative biosurveillance and research preparedness training including data analysis and interpretations at international partner institutes with lab technicians, field and lab scientists, and masters, doctoral and postdoctoral trainees. Collaborative biosurveillance is presently underway in Thailand (Chulalongkorn University, Bangkok) Malaysia (National Wildlife and Forensic Lab, Universti Purtra Malaysi, National Public Health Lab) via NIH Centers for Research in

Emerging Infectious Diseases, EID-Southeast Asia Research Collaborative Hub. As a collaborator within the DARPA PREEMPT network I supported surveillance for coronaviruses and other priority emerging zoonotic viruses, henipaviruses and filoviruses, in Ghana (Zoological Society of London), Australia (Black Mountain Labs) and Bangladesh (icddr,b). We aim to characterize the geographic distribution of zoonotic filoviruses/henipaviruses/coronaviruses, transmission dynamics in wildlife hosts and generate risk-models for Ebola virus, Nipah virus and SARS-related CoV outbreaks. Results discovered so far suggest a wider geographical footprint of Asiatic filoviruses and have identified several fruit bat species that act as natural reservoirs for these viruses.

PMID: 33661864; PMCID: PMC7948931.
5. In addition to providing serologic assessment of SARS-CoV-2 infection, my research team is actively engaged in examining the durability of COVID-19 vaccine induced humoral immunity. Antibody responses, particularly neutralizing antibodies, are frequently cited as a predictive correlate of protection. With the emergence of variants of concern and waning circulating antibodies, the timing of booster shots remains an important measure for controlling the pandemic. In my lab we evaluate the duration of neutralizing antibodies, durability and breadth of antibody responses against emerging variants of concern, hybrid immune responses, and post-vaccination infections.

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Wacharapluesadee, Supaporn

eRA COMMONS USER NAME (credential, e.g., agency login):

POSITION TITLE: Senior Researcher

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Chiang Mai University, Thailand	B.S.	02/1991	Medical Technology
Mahidol University, Thailand	M.S.	01/1994	Biochemistry
Chulalongkorn University, Thailand	Ph.D.	03/2006	Biomedical Sciences

A. Personal Statement

I have 29 years in public health research and 20+ years of experience in emerging viral zoonoses. I have managed many internationally funded research projects that involve working with and managing international and local interdisciplinary teams. Most of my research projects are diagnostics development, pathogen discovery, public health surveillance, field surveillance in wild mammals, human behavioral risk surveys, and clinical research. I conduct workshops on the development of novel diagnostic approaches, appropriate sample collection and handling for different pathogens, and viral characterization *in vitro* and *in vivo*. I am a senior researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, which conducts research on emerging zoonoses, clinical research, and public health surveillance research. My research background mainly focuses on understanding the process of zoonotic disease emergence, particularly viral zoonoses. This includes identifying the bat origin of Nipah virus, MERS-CoV, and SARS-CoV-2 and pathogenesis and diagnoses of Rabies. My studies on the emergence of novel betacoronaviruses found in Thai bats and Nipah virus have been published. My laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases, communicable diseases, and wastewater surveillance. I am the DDC instructor on the clinical sampling method and consultant for Ebola, MERS, and COVID-19 diagnosis. I am a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. I led the team to diagnose the first human MERS case in 2015 and the first human COVID-19 case outside China in January 2020. I have been the PI on six multidisciplinary research projects that use epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah, and Hendra viruses, Avian influenza, and novel viruses from bats. I am also the Thailand country coordinator for PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratorians.

B. Positions, Scientific Appointments, and Honors

Positions and Employment

- 1994 -97 Biochemical Technician, Department of Entomology, AFRIMS, Thailand
- 1997 Researcher, Department of Immunology, Chulabhorn Research Institute, Thailand
- 1997 -00 Medical Technologist, The HIV/AIDS Collaboration Thai-US, Thailand
- 2000 -16 Laboratory Chief, Neuroscience Centre for Research and Development & WHO Collaborating Centre for Research and Training on Viral Zoonoses, Faculty of Medicine, Chulalongkorn University Hospital, Thai Red Cross Society, Thailand
- 2016 -21 Deputy Chief of Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University Hospital
- 2021 - Senior Researcher, Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital
- Committee member, School of Global Health, Faculty of Medicine, Chulalongkorn University

Other Experience and Professional Membership

- 2010 -14 PREDICT Thailand Country Coordinator
- 2014 - Thai Ministry of Public Health (MOPH) Ebola Diagnostic Committee
- 2015 -19 PREDICT 2 Thailand Country Coordinator
- 2016 - Steering committee, Bat One Health Research Network, BTRP DTRA
- 2021 - WHO Scientific Advisory Group for the Origins on Novel Pathogens (SAGO)

C. Contributions to Science

1. **Research on One Health.** One Health is an integrated, unifying approach that aims to sustainably balance and optimize the health of people, animals, and ecosystems, as the definition by WHO. Our projects are multidisciplinary studies on human surveillance, wildlife surveillance, wastewater surveillance, and human behavior.
 - a. Tangwangvivat R, **Wacharapluesadee S**, Pinyopornpanish P, Petcharat S, Muangnoicharoen H. Behavioral-biological surveillance of emerging infectious diseases among a dynamic cohort in Thailand. **BMC Infect Dis**. 2022 May 16;22(1):472. doi: 10.1186/s12879-022-07439-7. PMID: 35578171; PMCID: PMC9109443.

2. Research on Public Health Surveillance in Thailand. Effective disease control programs rely on effective surveillance and response systems. Our laboratory collaborates with the Department of Diseases Control for active surveillance on syndromic surveillance and outbreak investigation. Both molecular and serology surveillance systems were conducted to identify the cause of the disease.

PMID: 33552519; PMCID: PMC7841862.

3. Research on diagnostic development. The molecular technique is a gold standard method for pathogen diagnosis and confirmation. The first COVID-19 case outside China in Thailand was primarily detected by family PCR and further confirmed by next-generation sequencing (NGS). The SARS-CoV-2 variants can be identified by the NGS technique or by identifying the mutation markers by MassARRAY technology.

Epub 2022 Sep 11. PMID: 36103950.
4. **Research on coronavirus prevalence in Thailand.** Numerous high-impact emerging viruses appear to have bat reservoirs. Our surveillance projects study the diversity of coronavirus (CoV) in bats in Thailand. We have isolated and characterized CoVs from many bat species and detected and sequenced CoV in bat guano collectors. Our surveillance studies continue to analyze the drivers of their emergence and risk factors for spillover.
- a. **Wacharapluesadee S**, Duengkae P, Chaiyes A, Kaewpom T, Rodpan A, Yingsakmongkon S, Petcharat S, Phengsakul P, Maneeorn P, Hemachudha T (2019). Longitudinal study of age-specific pattern of coronavirus infection in Lyle's flying fox (*Pteropus lylei*) in Thailand. **Virology** 20;15(1):38.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

Co-PI Plan (only needed if applying as Co-PIs):

What each Co-PI will contribute to the proposed research study

As stated in the Mentoring Plan, the co-PIs, Krongkan Srimuang and Spencer Sterling have different educational and training backgrounds. This Co-PI plan is proposed to fill the gaps in knowledge of each scientist and supports a collaborative working relationship for project success. Moreover, this plan was developed to maximize the strengths of each PI. Overall, the project is separated into two objectives, the proposal of this project will be equally managed by Dr. Srimuang and Mr. Sterling. Dr. Srimuang will be responsible for PBMC isolation, sorting, and characterization. Mr. Sterling will be responsible for the technical serological aspects of the project. Both will work closely with the Research Center Mentor, Dr. Eric Laing, to develop this project, protocol development, and network connections. Dr. Supaporn Wacharapluesade, the Co-mentor, will support the wildlife sampling, samples collection, and molecular aspects within Thailand.

How the Co-PIs will jointly work with the affiliated Research Center

Mr. Sterling is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region.

How the Co-PIs will jointly manage the proposed study

This is a great opportunity for both PIs to undergo training in advanced techniques and develop skills in next-generation serology and molecular sequencing. Dr. Srimuang will learn and practice serologic techniques and data analysis from Mr. Sterling. Mr. Sterling will develop skills in cell isolation and molecular sequencing techniques from Dr. Srimuang. Moreover, Mr. Sterling will coordinate planning, sample processing, data analysis, and report preparation for this project with Dr. Srimuang.

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), cell sorting machine and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country. Bats are considered protected wildlife in Thailand by Wildlife Conservation, Department of National Parks, Wildlife and Plant Conservation.

Computer:

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Krongkan Srimuang
Project Title:	Immune memory bait & capture to identify emerging henipavirus origins
Institution:	King Chulalongkorn Memorial Hospital
Foreign Research Site:	Rama 4 Road, Pathumwan, Bangkok 10330 Thailand
Point of Contact for Research Site:	Krongkan Srimuang Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital Rama 4 Road, Pathumwan, Bangkok 10330 Thailand krongkan.sr@gmail.com

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goals of this project are to know zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

To achieve these goals, the investigator will collaborate with NIH PREMISE for Antibody-mediated bait & capture of Thai MojV-like virus.

\$149,937 of grant funds will be sent to the site for these studies.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will 1) conduct all filed work to collect human and animal samples from the study sites; 2) perform laboratory analysis using collected samples; and 3) conduct data analysis as proposed in the project.

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - IRB approval number for parent study: #894ECOH21b (US); #221/64 (Thailand)
 - IRB approval date: 12-05-2021 (US); 08-06-2021 (Thailand)
 - Human Subject Assurance Number: (FWA)#: #00001102 (external IRB); #00022431 (EcoHealth Alliance); #00000943 (Chulalongkorn University)
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - **Yes**
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - **No**
 - How many subjects provided the existing samples to be used? *N/A*
- **Will human subjects be recruited (Yes or No)**
 - **Yes**
 - Number of human subjects that will be recruited: **110**

- **Population parameters:**
 - **Gender:** 55 males, 55 females
 - **Age Group:** Age \geq 18 years who provide informed consent.
 -
 - **Race/Ethnicity:** 110 Asian
- **Sample collection will include:**
 - **Blood:** Yes
 - **Urine:** No
 - **Tissues:** No
 - **Other samples (describe):** Nasopharyngeal swab and throat swab
- **Sample collection will be completed in how many visits:** 2 trips
- **Will samples be de-identified (Yes or No)? If No, describe how they will be protected.**
 - Yes
- **Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.**
 - Yes
- **Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Animal Subjects (1 word or 1 sentence per bullet):

- **Parent study IACUC approval**
 - IACUC approval number for parent study: #G2020-42 (US); #019/2563 (Thailand)
 - IACUC approval date: 05-05-2020 (US); 03-12-2020 (Thailand)
Animal Welfare Assurance Number: D16-00572 (A4059-01)
- **Does this study require a modification to the IACUC approval of a parent study (Yes or No)?**
 - No
- **Will existing samples from animal subjects will be used: (Yes or No)?**
 - No
 - How many animal subjects provided the existing samples to be used? N/A
- **Will vertebrate animals be collected (Yes or No)?**
 - Yes
- **Species of animals (e.g. rats, mice, rabbits, monkeys):** Bats, rodents, and shrews
- **Animal parameters:**
 - **Total number of animals:** 200 (100 bats, 100 rodents and shrews)
 - **Gender:** 100 males, 100 females
 - **Age range:** 4 - 12 months and elder depending upon species

- **Lab strain (e.g. Sprague-Dawley rats, Balb/C mice):** None
- **Wild animals procured in country (e.g. Rhesus monkeys from a reserve):** No
- **What will be done to them or with them and how often?**
 - Free-ranging bats will be captured using either a mist net or harp trap, and manually restrained during sampling; free-ranging rodents and shrews will be captured through pit traps and box traps.
 - Anesthesia will be conducted for captive rodents and shrews.
 - Once anesthetized blood will be collected.
 - All action will only be performed one time for each animal individual.
 - All animals will be released after sampling.
- **What are the follow-ups?**
 - No follow-up relevant as per protocol, since all animals will be released after sampling ups
- **What will be their fate at the end of the experiments – will they be euthanized?**
 - All animals will not be held longer than 6 hours (typically less than 3 hours) during the sampling process and released after sampling.
- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

27th January 2022

Krongkan Srimuang Ph.D.
Research Scientist
Thai Red Cross Emerging Infectious Diseases Clinical Center
King Chulalongkorn Memorial Hospital
Rama 4 Road
Pathumwan, Bangkok 10330
Thailand

Subject: Letter of Support for CREID Network Pilot Research Program

Dear Dr. Srimuang,

I am writing to express my support for your CREID Network Pilot Research Program proposal titled, “Immune memory bait and capture to identify emerging henipavirus origins.” Your preliminary data demonstrating immunoreactivity against Mojiang henipavirus in individuals sampled as part of the Emerging Infectious Diseases Southeast Asia Research Collaborative Hub (EID-SEARCH) center, provides compelling serologic evidence that novel henipaviruses spill over into human populations. Point-of-care diagnostics and nucleic acid-amplification tests rely on our present understanding of medically relevant pathogens. Thus, emergence of novel zoonotic viruses may go undetected. Serological profiling provides us an ability to measure the human infectome through broad-scale peptide arrays or targeted antigen-based detection.

The research activities conducted at the Thai Red Cross Emerging Infectious Diseases Clinical Center are complementary to the focus of the Vaccine Research Center’s PREMISE (Pandemic REsponse REpository through Microbial and Immunological Surveillance and Epidemiology) program. PREMISE works closely with intramural and extramural NIH programs and in partnership with a global network of investigators and collaborators to achieve its objectives through 3 core activities: (1) genetic analysis of zoonotic reservoirs and symptomatic humans for pathogen discovery; (2) development of high throughput, multiplexed serologic and cellular assays; and (3) global blood sampling to identify antigen-specific and cross-reactive immune responses to known and previously unknown viruses of pandemic potential. Biological samples including serum and PBMC are obtained from broad-based population cohorts as well as targeted populations at risk from emerging infections. At the same time, sequence data from known and unknown (through virus discovery) pathogens are analyzed to design and express candidate antigenic proteins of interest. These proteins are then used in high throughput multiplexed assays to screen sera for antibody reactivity. Serum reactivity to candidate antigens is followed by further interrogation of the adaptive immune response at the cellular level using corresponding PBMC samples. Proteins used in the serological arrays are conjugated to fluorophores and used as probes to sort antigen-specific B cells by flow cytometry. In addition, the sequence of such candidate antigens provides the template for the design of overlapping peptide pools to assess T cell responses. Further analysis allows for the identification of

neutralizing antibodies specific for the target antigens as well as specific T cell epitopes which may be tested in animal models. Epitope identification informs and guides immunogen design. At the conclusion of this pipeline of assays and analysis, PREMISE delivers the following:

1. reagent and data resources for early detection and diagnosis
2. monoclonal antibodies with therapeutic potential
3. candidate immunogens for further vaccine development

Thus, PREMISE serves as a translational vehicle to integrate serologic and cellular immune discovery, targeting a broad array of pathogens, into product development, and constitutes an anticipatory reagent repository to accelerate the global response to pandemic threats.

As investigators in the Vaccine Research Center at the National Institute of Allergy and Infectious Diseases (NIAID), we are not eligible to be listed as a “co-investigator” on the application but look forward to participating as collaborators. All materials from us will be provided under an approved material transfer or other collaborative agreement. This collaboration is part of our official duties as employees at the NIAID, and no funds from the grant will be used in intramural research, neither will we accept any form of remuneration, whether in the form of salary, honoraria, or travel expenses. We will provide scientific input and mentoring but will not have any duties associated with programmatic stewardship, which will be performed by NIAID extramural program officials. Further, in keeping with the mission of NIAID to promote and facilitate biomedical research and the dissemination of new knowledge, we would supply requested research materials and technical expertise not only to you, but also to other interested and qualified parties for research purposes.

My group has met with Dr. Eric Laing (USU) one of the two mentors for this pilot research program to discuss ways we can collaborate and support your research application. We are enthusiastic about providing the technological and subject-expertise in immunology and translational therapeutic discovery afforded by the PREMISE program that would enhance your knowledge base and broaden your own scientific training.

Sincerely,

Daniel C. Douek

Dr. Krongkan Srimuang, Mr. Spencer Sterling
Thai Red Cross Emerging Infectious Diseases Clinical Center
King Chulalongkorn Memorial Hospital
1873, Rama 4 Road, Pathumwan
Bangkok, Thailand 10330

Dear Krongkan and Spencer,

This letter conveys a strong interest from the Emerging Infectious Disease-Southeast Asia Research Collaboration Hub (EID-SEARCH) at EcoHealth Alliance to collaborate with you at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital on the proposed project titled *“Immune memory bait & capture to identify emerging henipavirus origins”* in Thailand.

The question of the origin of emerging Henipaviruses (HPVs) was identified from the EID-SEARCH human surveillance when a Mojiang-related virus was identified in a local population highly exposed to bats in Thailand. Faced with the challenges of PCR detection and viral isolation, this project will establish and validate a new serological approach to develop MojV-like virus-specific MAbs and define the antigenic spatial relationships between all known rodent- and bat-borne HPVs, revealing the serologic signature of all related undiscovered HPVs. This will significantly contribute to the objectives of EID-SEARCH to conduct targeted and strategic surveillance to identify emerging pathogens with zoonotic potential at the high-risk human-animal interfaces. The research population and site for this project – bat guano collection – represents one of the key scenarios where zoonotic spillover is mostly concerned that requires further in-depth investigation to identify the reservoir hosts. In addition to the gained knowledge, established methods from this project will be shared and used as standards in zoonotic HPVs surveillance and prevention strategies in Thailand and regionally through collaborative and coordinative cooperation among multiple stakeholders.

I am very excited to work with you both on this project, given your critical roles in the previous surveillance work to identify the question and develop the research idea. This project will bring valuable insights to advance disease surveillance and early warning systems for endemic and emerging infectious diseases in Thailand. Members of EID-SEARCH are committed to working closely with you to develop the research project and support the efforts necessary for the success of this project. You will be invited to join all training conducted by EID-SEARCH and EcoHealth Alliance regarding emerging infectious disease surveillance, relevant statistical analysis, and grant writing to expand your skill set. You'll also be supported to present the findings from this research at international conferences, the CREID Network meetings, and external partners and produce high-quality publications from this research.

Developing and implementing this project will advance your skills in project management for future research as an independent researcher. Co-Investigators of EID-SEARCH, Dr. Eric Laing from the Uniformed Services University of the Health Sciences and Dr. Supaporn Wacharapluesadee from the Thai Red Cross Emerging Infectious Diseases Clinical Center, have enthusiastically joined the project as your Mentors. Dr. Laing will advise on the study design and provide training on data analysis, and Dr. Wacharapluesadee from your institute will work closely with you to advise on the day-to-day project implementation. Both Mentors will work with you for manuscript writing and provide pertinent and timely career advice to assist in your professional development. They will bring a well-established

EID-SEARCH

Emerging Infectious Diseases
South East Asia Research Collaboration Hub

network of leaders and experts in emerging infectious disease research in Thailand, Southeast Asia, and North America for your network building.

I am confident that this proposed project will bring genuine opportunities for your professional development. And the combined experience in the field and lab and interdisciplinary expertise in serology and public health from the co-PIs will make this a successful and purposeful project to bring public health impacts in a broad region. I look forward to collaborating with you and your team on all phases of this proposed project. I wish you success in the CREID Pilot Research Program application.

Sincerely,

Peter T. Asza
Principal Investigator, EID-SEARCH
President, EcoHealth Alliance

30 January 2023

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC),

King Chulalongkorn Memorial Hospital

Object: Thai Red Cross Emerging Infectious Diseases Clinical Center support for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

Dear Dr. Srimuang & Mr. Sterling,

Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC) is pleased to support your application to the **CREID Pilot Research Program**, entitled “Immune memory bait & capture to identify emerging henipavirus origins.” We are fully committed to executing the statement of work to study zoonotic reservoirs for pathogen origins by using serologic and cellular immune discovery in humans and wildlife and their application as a tool for early detection and identification of novel pathogens in pandemic prevention.

The work proposed in this project is a great opportunity for collaboration with our team, it serves to enhance the use of serology and immunology for the detection of novel virus pathogens in Thailand using new technology and techniques. Moreover, the building of capacity and capability in our laboratory and Faculty will enhance the regional capacity, and the Chulalongkorn network will be used to ensure the success and completion of this project.

This letter expresses my strong interest in you pursuing this application and I fully support the project. I look forward to collaborating with you on this project and I wish you success in the CREID Pilot Research Program application.

Sincerely,

A black rectangular redaction box covering the signature of the sender. The text "(b) (6)" is written in red inside the box, indicating that the signature is redacted under FOIA exemption (b)(6).

Subject: Letter of Support for CREID Network Pilot Research Program

Dear Dr. Srimuang,

I am writing to express my enthusiastic support for your CREID Network Pilot Research Program proposal titled, "Immune memory bait & capture to identify emerging henipavirus origins." In 2018, I led a training and multiplex serology technology transfer to your mentor Dr. Wacharapluesadee's research group via DTRA-funded project Chulalongkorn Luminex Training and Research Preparedness (HDTRA1-17-C-0019), and was excited to leverage those activities into ongoing research within the EID-SEARCH. Since 2015 I have been developing serological-approaches for biosurveillance of zoonotic viruses in wildlife and human populations, and I am excited to serve as a co-mentor for this pilot program application.

I hope to provide you with the research and career developmental support for the activities outlined in the proposal. The serological data on henipavirus exposure in Thai guano farmers provides compelling evidence that Mojiang-like henipaviruses can cross the species barrier and may be widely distributed in Southeast Asia. The research aims detailed in the proposal will facilitate critical follow-up sampling of this human cohort to identify whether acute infection causes clinical disease, estimate the sero-attack rate of this novel henipavirus, and will apply a cutting-edge serologic and immunologic approach for monoclonal antibody development and novel emergent virus immunogenic characterization. If awarded, a collaboration with VRC PREMISE program scientists will facilitate an important opportunity to broaden your knowledge base of cellular immunology and B cell biology. You have an extensive background in next-generation sequencing application, and through this proposal would gain a considerable understanding of how next-generation sequencing is used for BCR-sequencing, IgG characterization and monoclonal antibody discovery.

Your proposal is an excellent extension of the EID-SEARCH activities and significant training opportunity.

Sincerely,

(b) (6)

Eric D. Laing
Assistant Professor
Department of Microbiology and Immunology
Uniformed Services University

Thai Red Cross Emerging Infectious
Diseases Clinical Centre (TRC-EIDCC),
King Chulalongkorn Memorial Hospital

Dear Dr. Srimuang & Mr. Sterling,

I am writing in support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

With my 20 years of experience in conducting surveillance for novel viruses in wildlife, humans, and bats using molecular technology, I will support the growth of the scientists in the CREID Pilot Research Program. The research aims have the potential to significantly enhance our approach to pathogen surveillance at high-risk human-animal interfaces. Given the understanding of pathogen origins by using serologic and cellular immune discovery in humans, and applying these techniques as a tool for early detection and identification of novel pathogens.

As the head laboratory chief at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, I believe that this is a great opportunity for our Thailand team to train in the characterization of memory B cells from peripheral blood mononuclear cells (PBMC) and enhanced serological surveillance in novel virus pathogens. Moreover, our laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases and communicable diseases such as Ebola, MERS, and COVID-19. I am also a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. With my experience in diagnosing the first human MERS case in Thailand in 2015 and the first human COVID-19 case outside China in January 2020, I will support multidisciplinary projects involving epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah and Hendra viruses, Avian influenza, and novel viruses from bats. I was also the Thailand country coordinator for the PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratory staff. I will enthusiastically support the development of a strong knowledge base to build capacity and capability in this project and our team in Thailand.

The CREID Network and the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH) will support scientists in regions around the world where emerging and reemerging infectious disease outbreaks. Many Southeast Asian partnerships in EID-SEARCH have strong potential to enhance innovations in this area.

I believe that Dr. Laing, and I will provide scientific skills, expertise, and networks for this project.

Towards that aim, I am committed to supporting your professional development in the following ways:

1. I will maintain regular bi-weekly meetings for the project progresses.
2. I will support the resources in our country and research team in this project.
3. I will create opportunities for scientists network to ensure the success of research project.
4. I will provide and share advice and technical expertise in specific knowledge for this project.

I'm very much looking forward to working closely with you on this 1-year research project and beyond as you continue to develop your surveillance zoonotic disease research program.

Best regards,

(b) (6)

Supaporn Wacharapluesadee, Ph.D.

Languages for animal sample size justification, feel free to edit, Eric and Spencer. (I think we are dropping the 100 bats and doing 200 rodents/shrews now?)

We will target a total of 200 individuals of rodent/shrew for this project, this sample size is estimated based on a realistic detection rate and required sampling efforts from our previous wildlife surveillance work, given the rodent/shrew population at the study site. Previous work of PMVs in wildlife had an average PCR detection prevalence of ~1.5%, sampling 200 individuals will yield 3 positives. We assume the serology prevalence will be higher, so expect about **5 positives for serology surveillance???** We acknowledge the challenge of identifying positive results, and very limited serology research has been done to provide guidance. However, we will make the best use of previous data and experience to conduct sampling at the selected site where human positives have been identified and based on the potential seasonality at different time points throughout the project period (Ref. **S. Wacharapluesadee *et al.*, A longitudinal study of the prevalence of Nipah virus in Pteropus lylei bats in Thailand: evidence for seasonal preference in disease transmission. *Vector borne and zoonotic diseases (Larchmont, N.Y.)* 10, 183-190 (2010)**). We are confident that this targeted sampling and testing strategy offers the best chance to identify positive results and potentially additional strains henipaviruses.

Hi All,

1. Would it be possible to strengthen the sample size justification. I know there might not be any sample size calculation because this focuses on developing the method, but there is a statistical review panel, maybe you can briefly talk about this? E.g. given the estimated positive rate of X%, or total population of the community or animals etc.

2. Are you doing questionnaires when collect samples for humans? If so please describe it in the Method part; if not, please remove these languages from the human subject section.

3. It seems you don't plan to enroll children, then please remove these languages about parents/legal guardians in the human subject protection section.

Hongying Li

Specific Aims (1-page limit)

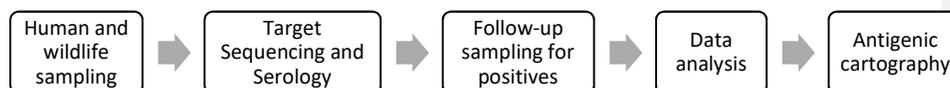

This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The hypothesis

1. Can the memory B-cell immune response be used as a tool for the discovery of novel henipaviruses?
2. Can the spatial relationships between henipaviruses receptor binding proteins be generated that would allow for an understanding of antigenic evolution and functional characterization?

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population.

Human populations near the Khao Chong Phran Non-hunting Area in Ratchaburi province have shown a high seroprevalence to the MojV RBP without confirmed sequencing results. We will follow-up on persons with high MojV RBP IgG titers, sample new people within the population that interact with the local wildlife, and sample shrews and rodents to find the source of the MojV-reactive antibodies.

Aim 2. Antibody-mediated bait & capture of the Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Objective 2. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody production.

Objective 3. To determine epitope binding and antigenic relationships from henipavirus-reactive serum to the known henipaviruses.

Study Rationale (7-page limit)

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McLinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genus of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, Gamak virus (GAKV), and Daeryong virus (DARV) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The Henipavirus genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australian (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected four members of a high-risk cohort with MojV-reactive serum, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia is due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology to identify a novel virus that can aide in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus

isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. In addition to the translational application of mAbs as therapeutics, we intend to utilize these mAb as non-clinical diagnostics surveillance tools for virus/virus antigen capture. Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

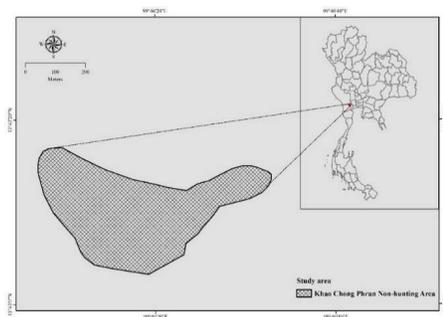

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Site wildlife samples collection

100 bats and 100 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. We plan one sampling trip to collect bats, and a second trip to target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect 100 samples, and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex.

Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored. **Oral swab and rectal swab will also collect in 100 bats and 100 shrews or rodents.** Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

Human surveillance

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, **100 human serum samples, nasopharyngeal swab and throat swab** will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,150 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

The sample size of 100 of each species follows the guidelines established during the PREDICT project.

Targeted Viral Sequencing and Serologic testing

Targeted sequencing

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing. Then we use Next Generation Sequencing (NGS) technology to perform Whole Genome Sequencing (WGS) on the nucleic acid specimens with relatively strong PCR positive signals. WGS libraries will use an enrichment

library preparation (Respiratory Viral Oligos Panel, RVOP) or Viral Surveillance Panel with Illumina RNA Prep with Enrichment kit. Libraries will sequence on the Illumina MiSeq 3000 sequencer (Illumina).

Serological testing

Serum samples will be tested for RBP binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Data analysis

Sequencing will be analyzed using the SPAdes software (version 3.13.0, <http://cab.spbu.ru/software/spades/>) in Metagenome mode. Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with Mojv infection.

In collaboration with NIH VRC PREMISE, Mojv RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. Mojv-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to Layv RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for Mojv, Mojv-like henipavas, and Layv, depending on how well these cross react.

Human samples collection site

Human positive serum for Mojv was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 2).

Commented [EL1]: Also propose to pull these out with Mojv F.

And that you will test binding of these against Layv G and Layv F. To see cross reaction.

One antibody Broder has against Mojv already has demonstrated cross reaction with a Layv protein.

David Veessler can do all the Cyro-EM to look at where these mAbs bind on the proteins.

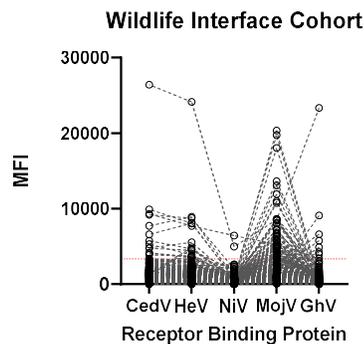

Figure 2: Seroprevalence of henipavirus proteins from a community with a large bat interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, the assay cutoff.

Commented [MOU2]: Add in the longitudinal data

PBMC Sorting and B Cell isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes).

Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3-, CD14-, CD56-, IgM-, IgA-, CD19+, CD20+, CD27+). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

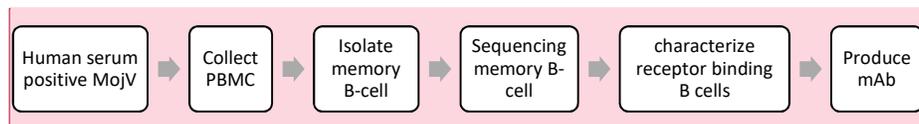

B cell receptor Amplicon Preparation and Recombinant Antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced.

After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. Next, we will test the cross neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV (Duke NUS/LinFa should be able to do this, if they have LayV and are propagating it, they can use cell-cell fusion/CPE in a straight PRNT). Decide if you want to incorporate this.

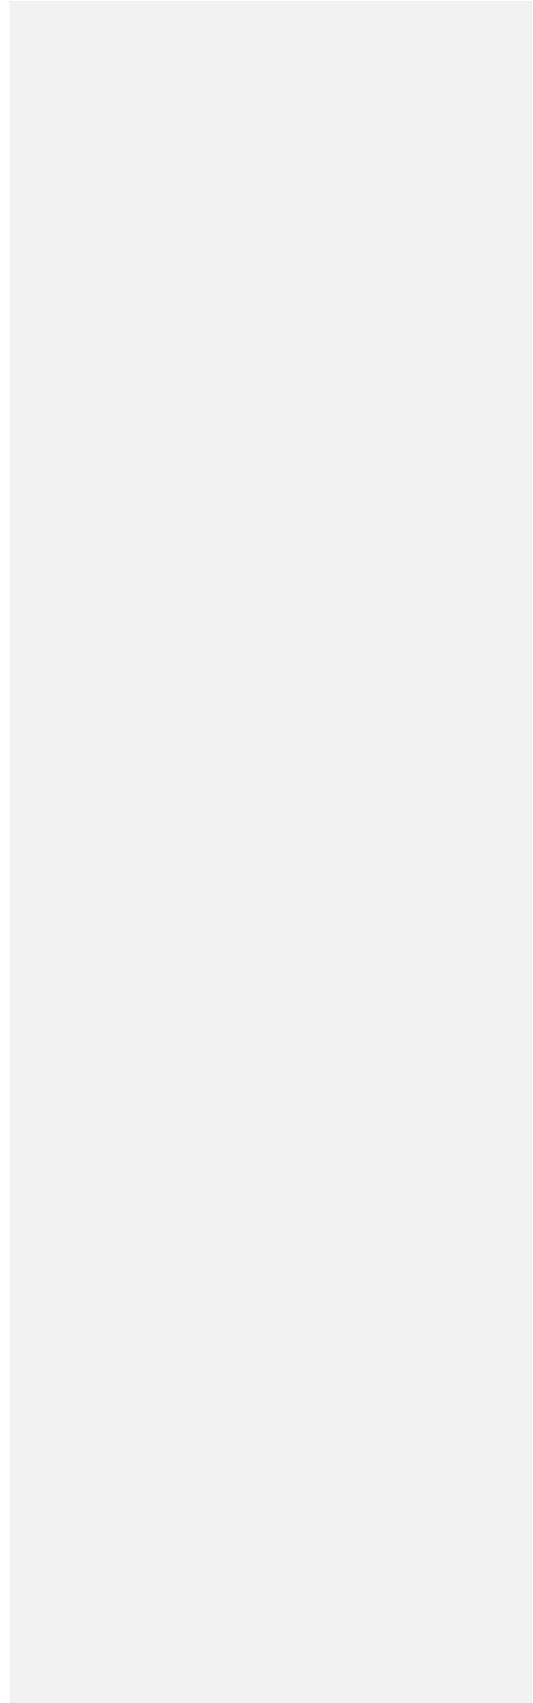

Commented [EL3]: Put this under innovation

Determination of envelope glycoprotein epitope binding

Isolated mAbs will be assessed for binding to MojV RBP and F proteins through multiplex binding serology. Further, the cross reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered [2 citations]. Thus, a functional assessment of cross neutralizing potential is not possible. However, through cyro-electron microscopy we can investigate binding epitopes between

these mAbs and MojV and LayV envelope glycoproteins. Epitope identification can then be used to make predictions about neutralizing potential through deductions about the location of henipavirus RBP receptor-binding pockets.

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Laing, Eric D.

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Assistant Professor

EDUCATION/TRAINING (Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
University of Maryland, College Park, MD	B.S. (hons)	05/2008	Biology
Uniformed Services University, Bethesda, MD	Ph.D.	10/2016	Emerging Infectious Diseases
Uniformed Services University, Bethesda, MD	Postdoc	04/2019	Virology

A. Personal Statement

The spillover of zoonotic viruses into human populations remains an ever-prevalent threat to public and global health. Continual outbreaks of known and unknown zoonotic viruses highlights the paucity of our understanding of the viral diversity, geographic distribution, wildlife hosts, and human populations at-risk for spillover. I am a recently appointed assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses. I have completed virological training and spent my time as a post-doctoral fellow applying *in vitro* techniques to characterize the replication of, and mammalian ephrin receptors that mediate cellular entry of emergent henipaviruses. Since the start of the COVID-19 pandemic, I pivoted the focus of my research team to serological analysis of SARS-CoV-2 infection, and then to COVID-19 vaccine-induced antibody durability. In my ongoing research, I develop serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Since my position as a postdoctoral fellow I have worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Across all of these collaborations, we have aimed to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence. Throughout these research projects, we have detected unexpected serological profiles in communities of bats and humans that have not fit our prior understanding of the viral diversity established or detected by genetic techniques. This proposal aims to better understand these serological profiles of wildlife and humans with a targeted focus on henipaviruses and filoviruses. Ongoing projects that I would like to highlight include:

- HDTRA12110037. DTRA BRTP, E. Laing (Co-PI). 08/2021-07/2026, “Informing biosurveillance, contribution of pteropodid fruit bats to virus spillover in the Philippines.”
- HU00012020067, HU00012120104, HU00012120094. Defense Health Program/CARES Act, NIAID, E. Laing (Associate Investigator). 9/2020-9/2025, “Prospective Assessment of SARS-CoV-2 Seroconversion.”
- HDTRA12010025. DTRA BTRP, E. Laing (Co-I). 7/2020 – 6/2025, “Biosurveillance for Viral Zoonoses around Bat-Livestock-Human interfaces in Southern Africa.”
- U01AI151797. NIH, Centers for Research in Emerging Infectious Diseases, E. Laing (Co-I). 02/2020 – 03/2025, “EID-Southeast Asia Research Collaborative Hub.”
- HU00012020067, HU00011920111. Defense Health Program, NIAID, E. Laing (Associate Investigator). 03/2020 – 09/2023, “Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EpiCC-EID).”

B. Positions, Scientific Appointments and Honors
Positions

- 2021-pres. Assistant Professor, Department of Microbiology and Immunology, School of Medicine, Uniformed Services University, Bethesda, MD.
- 2021-pres. Joint Appointment, Emerging Infectious Diseases Graduate Program, School of Medicine, Uniformed Services University, Bethesda, MD.
- 2019-21 Research Assistant Professor, Department of Microbiology and Immunology, Uniformed Services University, Bethesda, MD.
- 2016-19 Postdoctoral fellow, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD.
- 2010-16 Graduate research student, Department of Microbiology, Uniformed Services University, Bethesda, MD.

Other Experiences and Professional Memberships

- 2022-pres. Executive committee member, Emerging Infectious Diseases Graduate Program, USUHS
- 2021-pres. Research center representative, Laboratory Assays Oversight and Quality Working Group, Emerging Infectious Diseases: Southeast Asia Research Collaboration Hub (EID-SEARCH), Centers for Research in Emerging Infectious Diseases (CREID), NIAID, DMID, NIH
- 2021-pres. Review editor, *Frontiers in Virology - Emerging and Reemerging Viruses*
- 2021-pres. Ad hoc reviewer, *Frontiers in Immunology*, *Journal of Clinical Immunology*
- 2021-pres. Steering committee member, JPI/Military Infectious Diseases Research Program, Emerging Infectious Diseases
- 2019 Ad hoc reviewer, EcoHealthNet 2.0 Program, EcoHealth Alliance
- 2018 Ad hoc reviewer, Pakistan One-Health Fellowship Program, National Academy of Sciences & Pakistan Academy of Sciences
- 2014-2019 Member, American Society of Tropical Medicine and Hygiene
- 2014-2019 Member, American Society of Microbiology
- 2014-2019 Volunteer, AAAS STEM K-12 Volunteer Program

Mentoring

- Postdoctoral fellows* Si'Ana A. Coggins, PhD, 2020 - 2022
- Graduate students* Marana S. Tso, BS, 2021 - McKenna Roe, BS, 2022 -
- Committee member* Celeste Huaman, BS, 2021 - 2LT Connor Perry, BS, 2021 -

Honors

- 2021-2022 Impact Award, USUHS School of Medicine
- 2021 Outstanding Research Accomplishment/Team/SARS-CoV-2, The EPICC COVID-19 Cohort Team, Military Health System Research Symposium
- 2020-2021 Impact Award, USUHS School of Medicine
- 2015-2016 Val G. Hemming Fellowship, Henry M. Jackson Foundation
- 2015 East Asia and Pacific Summer Institutes Fellowship, National Science Foundation

C. Contributions to Science ([†]mentee, *corresponding)

1. Lyssaviruses and the prototype, rabies virus, remain a public health concern. Beginning with my PhD thesis work, I've researched the virus host-interactions between a rabies-related lyssavirus, Australian bat lyssavirus (ABLV), and its bat host (*Pteropus alecto*). Research has focused on ABLV cellular entry mechanisms, the development of an animal model and ABLV reporters and exploration of novel monoclonal antibodies that neutralize ABLV and other phylogroup I lyssaviruses. Furthermore, comparative bat immunology research was conducted using black flying fox cell lines and ABLV as a model virus/host interaction. Physiological adaptations that accompanied the evolution of flight in bats have been proposed to contribute to the frequent role of bats as asymptomatic hosts of highly pathogenic zoonotic viruses. Comparatively studying the autophagy pathway in bat cell lines revealed that bat cells had elevated levels of basal autophagy and experienced significantly less cell death when challenged with high virus doses.

PMID: 33804519; PMCID: PMC8001737.

2. My research experience as a postdoctoral fellow furthered my training in molecular virology techniques. I constructed a recombinant Cedar virus cDNA plasmid and optimized a reverse genetics approach to rescue a recombinant Cedar virus reporter virus, a non-pathogenic *Henipavirus* species. A molecular biology methods chapter detailing recombinant Cedar virus reverse genetics has been submitted and in press. Using this recombinant Cedar virus, we determined that Cedar virus can utilize several non-canonical henipavirus ephrin receptors for cellular entry and explored the structure of the receptor-binding pocket to understand the receptor promiscuity. The non-pathogenic phenotype of CedV creates a potential for CedV to act as a model henipavirus to explore host-pathogen interactions, cellular tropism and factors that determine henipaviral disease pathogenesis. Additionally, I have collaborated on projects detailing henipavirus infection and replication in bat hosts with colleagues at the Rocky Mountain Labs, studying whether specific species of bats are more competent hosts and whether virus-host restriction exists.

3. Bats are increasingly identified as animal reservoirs of emerging zoonotic viruses (e.g. Nipah virus, Ebola virus and SARS-coronavirus). I lead collaborative biosurveillance and research preparedness training including data analysis and interpretations at international partner institutes with lab technicians, field and lab scientists, and masters, doctoral and postdoctoral trainees. Collaborative biosurveillance is presently underway in Thailand (Chulalongkorn University, Bangkok) Malaysia (National Wildlife and Forensic Lab, Universti Purtra Malaysi, National Public Health Lab) via NIH Centers for Research in Emerging Infectious Diseases, EID-Southeast Asia Research Collaborative Hub. As a collaborator within the DARPA PREEMPT network I supported surveillance for coronaviruses and other priority emerging zoonotic viruses, henipaviruses and filoviruses, in Ghana (Zoological Society of London), Australia (Black

Mountain Labs) and Bangladesh (icddr,b). We aim to characterize the geographic distribution of zoonotic filoviruses/henipaviruses/coronaviruses, transmission dynamics in wildlife hosts and generate risk-models for Ebola virus, Nipah virus and SARS-related CoV outbreaks. Results discovered so far suggest a wider geographical footprint of Asiatic filoviruses and have identified several fruit bat species that act as natural reservoirs for these viruses.

4. Responding to the emergence of SARS-CoV-2, our lab developed multiplex serology strategies to identify SARS-CoV-2 antibodies and address research questions related to whether pre-existing antibody memory induced by prior infection with seasonal human coronaviruses affects COVID-19 severity. Our lab's serology efforts supported NIH and DHA collaboratively funded protocols including prospective, longitudinal serological analysis of hospital and community subjects, and health-care workers; and cross-sectional analyses of SARS-CoV-2 infection among deployed military health-care workers.

5. In addition to providing serologic assessment of SARS-CoV-2 infection, my research team is actively engaged in examining the durability of COVID-19 vaccine induced humoral immunity. Antibody responses, particularly neutralizing antibodies, are frequently cited as a predictive correlate of protection. With the emergence of variants of concern and waning circulating antibodies, the timing of booster shots remains an important measure for controlling the pandemic. In my lab we evaluate the duration of neutralizing antibodies, durability and breadth of antibody responses against emerging variants of concern, hybrid immune responses, and post-vaccination infections.

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as Mentor for Dr. Krongkan and Spencer under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program.

Commented [e11]: For Eric

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Specific Aims (1-page limit)

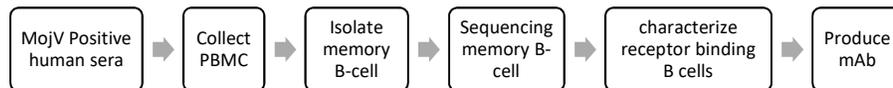

This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The hypothesis

1. Can the memory B-cell immune response be used as a tool for the discovery of novel henipaviruses?
2. Can the spatial relationships between henipaviruses receptor binding proteins be generated that would allow for an understanding of antigenic evolution and functional characterization.

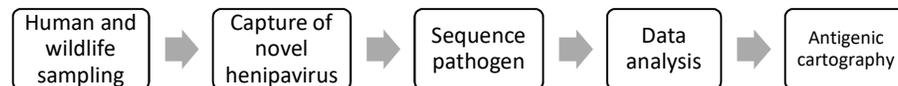

Aim 1. Antibody-mediated bait & capture of Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Aim 2. Modeling antigenic relationships among known and unknown henipaviruses.

Defining antigenic relationships among these will allow the serologic signature of related undiscovered henipaviruses to be identified. We will develop anti-RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus.

Objective 1. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody production.

Objective 2. To capture unknown MojV-like viruses during syndromic surveillance in humans and routine surveillance in wildlife in Ratchaburi province, Thailand.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Objective 3: To generate antigenic maps using anti-henipavirus RBP standards.

Study Rationale (7-page limit)

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McLinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022).

HeV was first identified in Australia in 1994 as ~~the~~ cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no approved vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

~~During follow-up investigations into lethal pneumonia from three miners in 2012 in China, multiple genera of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested~~

Commented [e13]: cite

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

in an animal model. Additionally, the novel shrew-borne henipaviruses, Gamak virus (GAKV), and Daeryong virus (DARV) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The Henipavirus genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australian (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV),	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	(Madera et al., 2022)

Viruses in the genus *Henipavirus* have a ~~broad~~ diverse natural reservoirs and ~~several are known to cause disease may cause high case fatality rate in s following human infection humans.~~ The surveillance for known, and the discovery and characterization novel henipaviruses of the novel Henipavirus is a remains a high public health priority for public and global health.

Research Gap

Commented [MOU4]: clean up the format so the cell size is consistent

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

~~The tropical rain forests of South East Asia host The greatest global diversity of bat diversity species around the world especially appears to be found in the tropical rain forests of South East Asia.~~ In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genera *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating ~~vivorous~~ bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which ~~represent high-risk interfaces for~~ zoonotic spillover. Bats are widely considered the animal hosts of ~~several zoonotic viral families, including pathogens such as~~ rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, ~~and many~~ Many of these bat reservoir species can be regionally found ~~of the host species can be found~~ in Thailand.

Formatted: Font: Italic

Formatted: Font: Italic

~~The MojV genome was detected in rodents sampled in a mineshaft in Yunnan, China frequented by miners who died from an undiagnoses was associated with a lethal severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China.~~ Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in Rhinolophid bats (Rahalkar and Bahulikar, 2020). ~~This was the first time the full genome of a henipavirus had been detected in a non-bat wildlife host. Studies of the MojV virus receptor have yet to identify a cellular receptor, and whether this virus can mediate entry and fusion in human [cite]. It is clear that human ephrinB2 and ephrinB3, canonical receptors for HeV, NiV, CedV, and GhV, do not interact with the MojV receptor-binding glycoprotein (RBP). Thus, the zoonotic potential remains elusive. Subsequently, genomes of GamV and DarV were detected in shrews sampled in South Korea, however, it is not yet clear whether these viruses are zoonotic or pathogenic to humans. The isolation of LayV from humans with febrile illness and isolation from shrews in eastern China was the first evidence that rodent-associated henipavirus are capable of zoonotic transmission and can cause disease in humans. Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.~~

Commented [MOU5]: 3 or 6?

Commented [MOU6]: You need to introduce the shrew-associated henipaviruses here, and focus on LayV.

Commented [MOU7]: I'd cut this sentence out since it's dealing with CoV

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a ~~antigen-based~~ multiplex microsphere-based immunoassay (MMIA) have detected four ~~members individuals~~ of a high-risk ~~human~~ cohort with MojV-reactive serum, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. ~~These results are suprising as Despite this,~~ genomic surveillance has not detected MojV or any novel MojV-like viruses ~~to date in Thailand.~~ These results indicate that the MojV-like henipaviruses may have a regional footprint in Thailand yet remain undetectable by current PCR and sequencing approached. ~~For this result Here, we aim to apply serological and immunological techniques to virus discovery that would permis us to ,we would to further identify and characterize the origin of the the MojViang-like virus and to explore the novel MojV like virus in Thailand.~~

Research Impact

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Commented [MOU8]: Spencer, can you assist with a revision here?

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia is due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology to identify a novel virus that can aide in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Aim 1. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

As part of our ongoing virus surveillance conducted through EID-SEARCH, we have detected XX% (XX/XX) MojV seroprevalence in a cohort of guano farmers. In our pan-henipavirus that tested sera against the RBP of presently described henipaviruses, sera IgG bound specifically to MojV RBP (Figure 1), demonstrating little cross reaction with the bat-borne ephrinB2 utilizing henipaviruses.

~~In collaboration with NIH VRC PREMISE, MojV RBP reactive B cells will be captured, and the B cell receptor will be sequenced from previously identified seropositive human participants. MojV-like virus-specific mAbs.~~

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipas, and LayV, depending on how well these cross react.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 1).

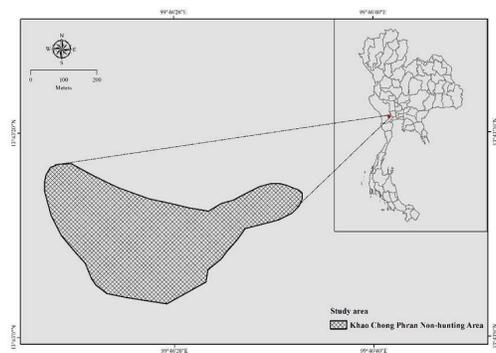

Figure 1: Map of Khao Chong Phran Non hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Commented [EL9]: Also propose to pull these out with MojV F.

And that you will test binding of these against LayV G and LayV F. To see cross reaction.

One antibody Broder has against MojV already has demonstrated cross reaction with a LayV protein.

David Veessler can do all the Cyro-EM to look at where these mAbs bind on the proteins.

Commented [EL10]: Show serological profile Figure

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

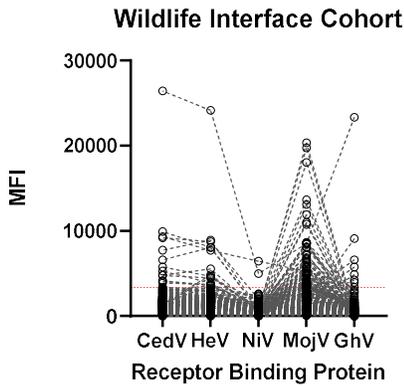

Figure 2: Seroprevalence of henipavirus proteins from a community with a large bat interface. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, the assay cutoff.

In collaboration with NIH VRC PREMISE, MojV RBP-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants to generate MojV-like virus-specific mAbs.

PBMC collection and Single Memory B Cell Isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes).

Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3-, CD14-, CD56-, IgM-, IgA-, CD19+, CD20+, CD27+). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single mMemory B Cells specific to MojV RBP and F will be probed with these recombinant proteins and will be sorted, cells will proliferate, cDNA will synthesized, then hHeavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B-cell receptor Amplicon Preparation

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced.

B-cell receptor Data Analysis

After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline.

Commented [MOU11]: Add in the longitudinal data

Commented [EL12]: Also propose to pull these out with MojV F.

And that you will test binding of these against LayV G and LayV F. To see cross reaction.

One antibody Broder has against MojV already has demonstrated cross reaction with a LayV protein.

David Veessler can do all the Cyro-EM to look at where these mAbs bind on the proteins.

Commented [EL13]: Condense these subheadings

Commented [MOU14]: Read the Lima paper I sent about the methods and revise this section

Formatted: Indent: First line: 0"

Formatted: Indent: First line: 0"

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Recombinant Antibody Cloning, Production, and Purification

Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression.

Formatted: Indent: First line: 0"

Functional assessment

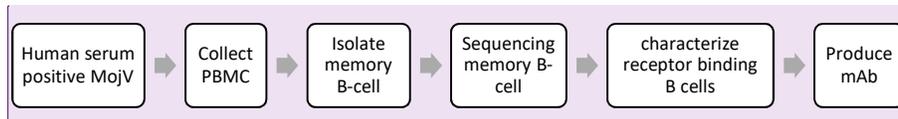

Isolated mAbs will be assessed for binding to MojV RBP and F proteins through multiplex binding serology. Further, the cross reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered [2 citations]. Thus, a functional assessment of cross neutralizing potential is not possible.

Formatted: Indent: First line: 0"

~~Neutralization of viruses remains a critical correlate of protection for most vaccine strategies.~~

Formatted: Indent: First line: 0"

Next, ~~However~~, we will test the cross neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV in collaboration with our EID-SEARCH co-investigators, Dr. Lin-Fa Wang (Duke NUS). ~~/LinFa should be able to do this, if they have LayV and are propagating it, they can use cell-cell fusion/CPE in a straight PRNT). Decide if you want to incorporate this.~~

Commented [EL15]: Put this under innovation

Commented [EL16]:

Commented [EL17R16]:

Antigenic cartography

Antisera and monoclonal antibodies to henipavirus RBP, including the novel MojV like henipavirus, will be generated and tested against all the known RBP. The resulting binding data will be compiled, and antigenic relatedness will be determined using RStudio.

Commented [EL18]: You could propose to look at mAb cartography of the mAbs that have unique IgG seq across the 4 donors and between the probes (RBP/F) and GamV/DarV/LayV/MojV. This would work

Determination of envelope glycoprotein epitope binding

Isolated mAbs will be assessed for binding to MojV RBP and F proteins through multiplex binding serology. Further, the cross reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered [2 citations]. Thus, a functional assessment of cross neutralizing potential is not possible. However, through cryo-electron microscopy we can investigate binding epitopes between these mAbs and MojV and LayV envelope glycoproteins. Epitope identification can then be used to make predictions about neutralizing potential through deductions about the location of henipavirus RBP receptor binding pockets.

Formatted: Font: Not Bold

Aim 2. Utility of Thai MojV-like mAbs for surveillance.

Serological profiling provides an indirect measurement of the infecting virus. Despite XX% (XX/XXX), seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. In addition to the translational application of mAbs as therapeutics, we intend to utilize these mAb as non-clinical diagnostics surveillance tools for virus/virus antigen capture.

Commented [MOU19]: Do you have more to add to this Aim?

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Site wildlife samples collection

Human positive serum for MoV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 2). Here, we propose to undertake additional field collections, incorporating collections of samples from shrews in the area, which are linked to LayV, GamV, and DarV henipaviruses.

Commented [EL20]: Show serological profile Figure

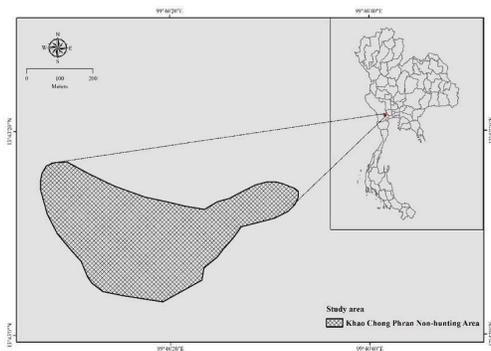

Figure 2: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

100 Rodents 100 bats, and 100 shrews in Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. In this study, we can collect only one time for a limited grant and time.

Enrollment criteria: Random age, random weight, random sex.

Blood from animals will collect by using a needle in vein blood using serum to detect the undiscovered henipaviruses.

Human syndromic surveillance

100 human samples will collect serum to detect henipa-like virus near Khao Chong Phran cave in Ratchaburi Province for 1 year.

Enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who have sick without any reason such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats

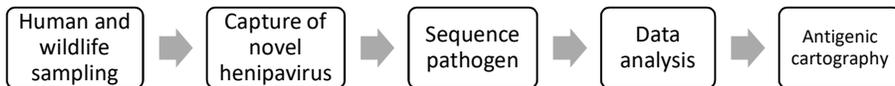

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

- Who is involved with livestock or wildlife farming
- Who hunts wildlife or works with wildlife

Data analysis

Virus sequencing....after mAb pulldown.

Research Performance Sites (1-page limit)

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country.

We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

CREID Research Center Collaboration (1-page limit)

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team.

Further, Dr. Doeuk who is the director of the VRC PREMISE program is enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Jg) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Mentoring Plan (2-page limit)

1. Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand from for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

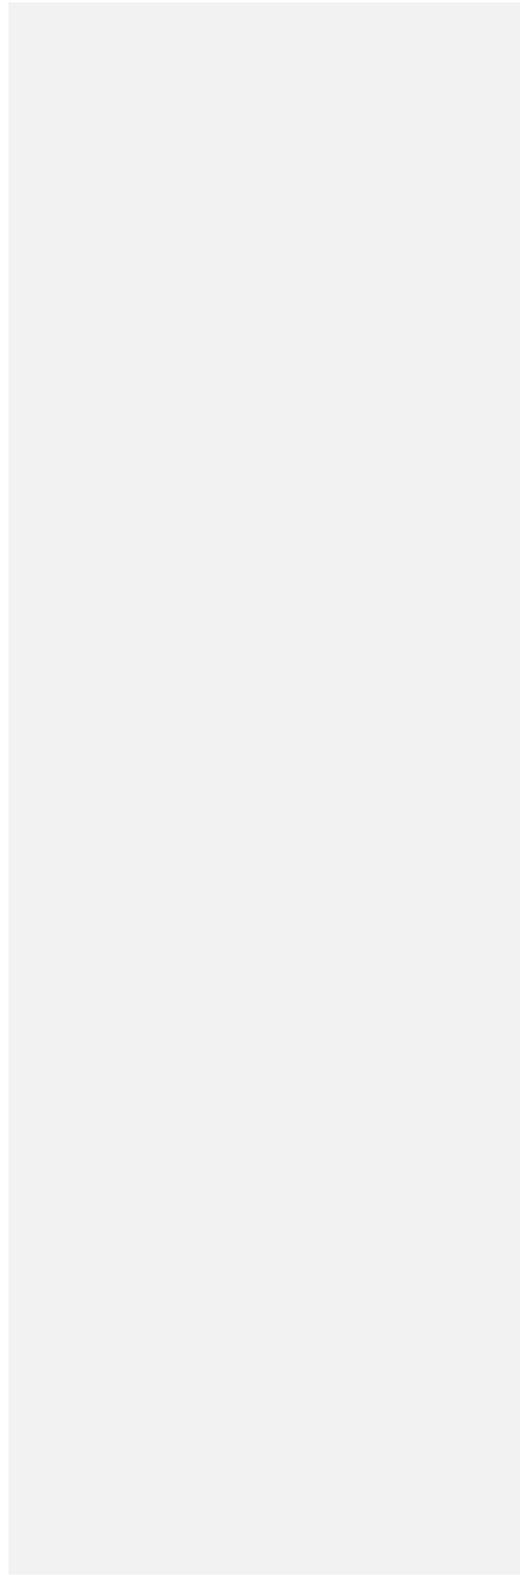

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant writing and project management skills. [My professional relationship Dr. Wacharapluesadee with began in 2018 when I participated in a DTRA BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group](#) Additionally, ~~Dr. Wacharapluesadee.~~ [Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.](#)

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Vertebrate Animals Section Requirements

1. Description of Procedures (Vertebrate Animals Section)

Animal samples will be collect in the Khao Chong Phran cave in Ratchaburi Province, including bats, rodents, and shrews as were approved by the IACUC for the project "Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia" (Animal Protocol #G2020-42). Moreover, the project

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

has been approved by the Thai Department of National Park, Wildlife and Plant Conservation on 0907.4/28372.

1.1 Bats (order Chiroptera): Family Pteropodidae; Family Rhinopomatidae; Family Emballonuridae; Family Craseonycteridae; Family Megadermatidae; Family Rhinolophidae; Family Hipposideridae; Family Vespertilionidae; Family Mollossidae; etc.

Random age, random weight, random sex, and total number 100.

1.2 Rodents (order Rodentia) Maxomys whiteheadi; Rattus exulans; Rattus annandalei; Leopoldamys sabanus; Sundamys muelleri; Chiropodomys gliroides; Niviventer cremoriventer; Maxomys rajah; Hylomys suillus; Niviventer; Maxomys; Maxomys surifer; Rhizomys sumatrensis; Rhinosciurus laticaudatus; Callosciurus notatus; Rattus tiomanicus; Tupaia glis; Petaurillus hosei; Rattus tanezumi; Rattus norvegicus; Rattus rattus; Sundasciurus lowii; Tupaia longipes; Tupaia tana; Callosciurus prevostii; Sundasciurus hippurus; Tupaia minor; Hystrix crassispinis; Maxomys alticola; Rattus argentiventer; Trichys fasciculata; Dremomys everetti; Callosciurus adamsi; Rattus baluensis; Rattus losea; Bandicota indica; Mus cookie; Berylmys bowersi; Rattus nitidus; Mus caroli; Leopoldamys neilli; Leopoldamys edwardsi; Mus cervicolor; Mus fragilicauda; Niviventer confucianus; Niviventer fulvescens; Bandicota Savile; etc.

Random age, random weight, random sex, and total number 100.

1.3 Shrews (order Soricomorpha) Sorex isodon; Crocidura attenuate; Crocidura fuliginosa; Crocidura horsfieldii; Crocidura vorax; etc.

Random age, random weight, random sex, and total number 100.

2. Justifications (Vertebrate Animals Section)

For our Aim 2. Modeling antigenic relationships among known and unknown henipaviruses.

We will develop anti-Henipavirus RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus. We would like to survey all animals that could be reservoir hosts or intermediate hosts of novel henipaviruses that can be spillover to humans to increase the likelihood of detecting a novel virus. Therefore, the research goals be accomplished using an alternative model (e.g., computational, human, invertebrate, in vitro).

3. Minimization of Pain and Distress (Vertebrate Animals Section)

For animals requiring anesthesia- Blockage of visual stimulus, handling in cloth bags and other methods will be employed to keep handling procedures gentle and to minimize stress.

4. Method of Euthanasia

This study will not use methods of euthanasia in all animals.

Human Subjects Research

This project will enroll human subjects under the approved protocols by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64).

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

All applicants proposing human subjects research should address the following elements on the Protection of Human Subjects:

1. Risks to the subjects

Human blood will be collected by a needle from a vein in the arm (approximately 15 ml) into a heparin tube.

Having blood drawn may produce discomfort or minor bleeding and the possibility of bruising at the site of the needle puncture. There is also a slight risk of infection at the site of the

needle puncture. Although rare, some people have experienced nausea, light headedness, and fainting in association with a blood draw.

2. Adequacy of protection against these risks

Vital signs will be taken at each visit. Vital signs include measurements of your pulse (heart rate), respirations (breaths per minute), blood pressure, height, weight, and body temperature.

3. Potential benefits of the research to the subjects and others

There are no direct benefits to the research subjects. Indirect benefits to the research to subjects is the possible identification of undiscovered henipaviruses infections in this population. Detection can lead to correct diagnostics and proper treatment of the disease

4. Importance of the knowledge gained or to be gained

This study will bring opportunity, experience, and knowledge in immunology and serology to research staff in Thailand. Moreover, the new methods and techniques to identify novel pathogens by using memory B-cell can be used in the study of zoonotic reservoirs and pathogen origins. By using serologic and cellular immune discovery in humans and wildlife, we seek the ability for early detection and identification of novel pathogens to prevent the next pandemic.

5. Country- / institution-specific ethics / IRB regulations addressed

This project will enroll human subjects under the approved protocols by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64).

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), **cell sorting machine** and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country. Bats are considered protected wildlife in Thailand by Wildlife Conservation, Department of National Parks, Wildlife and Plant Conservation.

Computer:

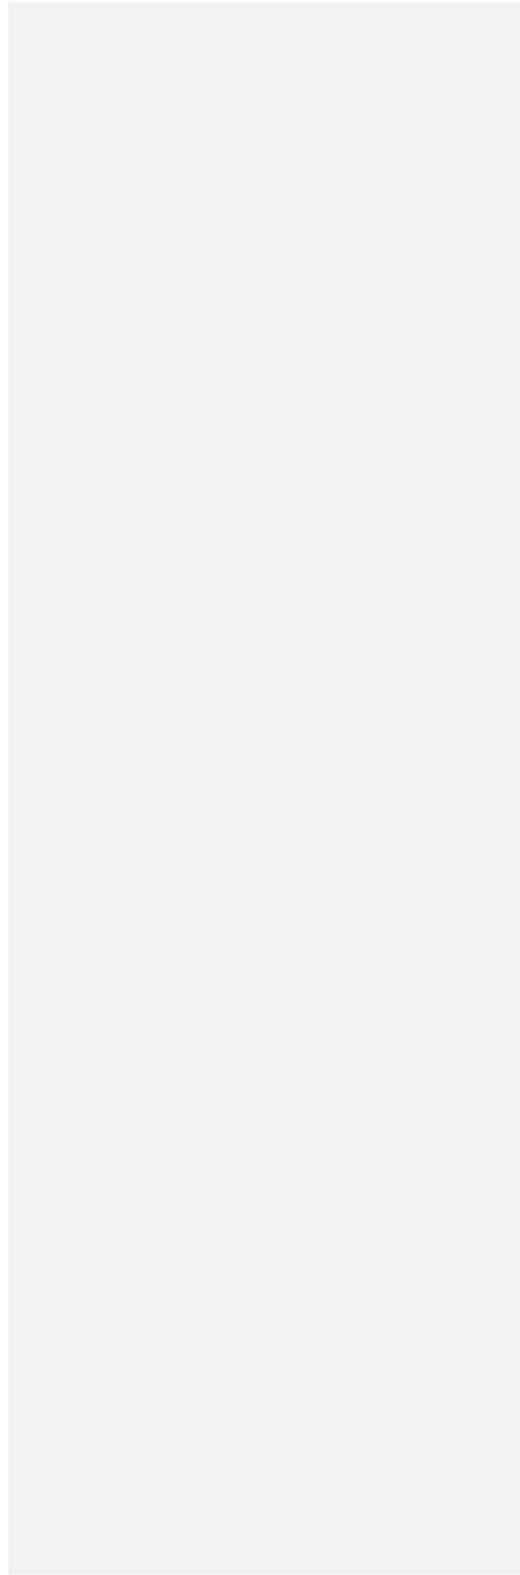

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

30 January 2023

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC),
King Chulalongkorn Memorial Hospital

Object: Thai Red Cross Emerging Infectious Diseases Clinical Center support for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

Dear Dr. Srimuang & Mr. Sterling,

Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC) is pleased to support your application to the **CREID Pilot Research Program**, entitled “Immune memory bait & capture to identify emerging henipavirus origins.” We are fully committed to executing the statement of work to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The work proposed in this project will be given a great opportunity and collaboration to our team, it serves very strong knowledge in serology and immunology for the detection of novel virus pathogens in Thailand using new technology and techniques. Moreover, the building capacity and capability of our laboratory and Faculty will access and support to make the success and completion of this project.

This letter expresses my strong interest and drives forward to making this application a success. I look forward to collaborating with you of this project. I wish you success in the CREID Pilot Research Program application.

Sincerely,

Assistant Professor Opass Putcharoen, MD, Msc

Head of Thai Red Cross Emerging Infectious Diseases Clinical Center

King Chulalongkorn Memorial Hospital

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

30th January, 2022

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious

Diseases Clinical Centre (TRC-EIDCC),

King Chulalongkorn Memorial Hospital

Dear Dr. Srimuang & Mr. Sterling,

I am writing this letter to express my support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled "Immune memory bait & capture to identify emerging henipavirus origins."

My experience in immunology and serology will support them in the CREID Pilot Research Program. The research aim has the potential to have a strong impact on our approach to pathogen surveillance at high-risk human-animal interfaces. Given the understanding of the pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

I believe that this is a great opportunity to use scientific knowledge and expertise to train the characterization of memory B cells from peripheral blood mononuclear cells (PBMC) and serology background to the team at Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital, Thailand. Our stronger partnerships have the potential to really drive forward innovations in this serology and immunology which include the implementation of novel techniques for pathogen surveillance as proposed in your pilot project application.

The CREID Network and the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH) will support scientists in regions around the world where emerging and reemerging infectious disease outbreaks. Many Southeast Asian partnerships in EID-SEARCH have strong the potential to really drive forward innovations in this area.

I believe that Dr. Wacharapluesadee, Co-PI, and I will provide scientific skills, expertise, and networks for this project.

Towards that aim, I am committed to supporting your professional development in the following ways:

- 1.
- 2.
- 3.

Commented [e121]: Could you please add the supporting?

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

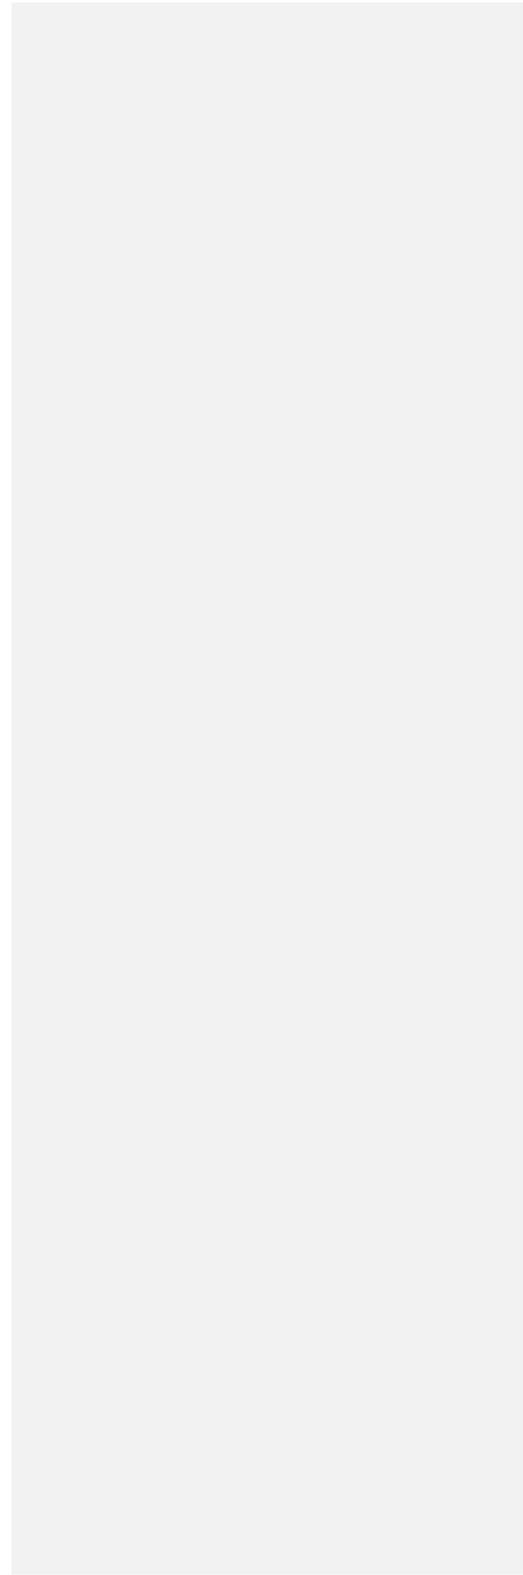

I'm very much looking forward to working closely with you on this 1-year research project and beyond as you continue to develop your surveillance zoonotic disease research program.

Best regards,

Eric Laing, Ph.D.

Assistance Professor

Uniformed Services University of the Health Sciences

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious

Diseases Clinical Centre (TRC-EIDCC),

King Chulalongkorn Memorial Hospital

Dear Dr. Srimuang & Mr. Sterling,

I am writing in support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

For my experience in 20 years to conduct the surveillance for novel virus in wildlife, human, and bats using molecular technology and multiplex serology panel (Luminex technology) will support them in the CREID Pilot Research Program. The research aim has the potential to have a strong impact on our approach to pathogen surveillance at high-risk human-animal interfaces. Given the understanding of the pathogen origin by using serologic and virus discovery in bats, humans, and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

As the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, I believe that this is a great opportunity for our Thailand team that can train in the characterization of memory B cells from peripheral blood mononuclear cells (PBMC) and serology surveillance in novel virus pathogens. Moreover, our laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases and communicable diseases such as Ebola, MERS, and COVID-19. I am also a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. With my experience to diagnose the first human MERS case in 2015 and the first human COVID-19 case outside China in January 2020, I will support multidisciplinary projects involving epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah, and Hendra viruses, Avian influenza, and novel viruses from bats. I am also the Thailand country coordinator for PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratorians. I will be given the strong knowledge to build capacity and capability in this project and our team in Thailand.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

The CREID Network and the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH) will support scientists in regions around the world where emerging and reemerging infectious disease outbreaks. Many Southeast Asian partnerships in EID-SEARCH have strong the potential to really drive forward innovations in this area.

I believe that Dr. Laing, and I will provide scientific skills, expertise, and networks for this project.

Towards that aim, I am committed to supporting your professional development in the following ways:

1. I will maintain regular bi-weekly meetings for the project progresses.
2. I will support the resources in our country and research team in this project.
3. I will create opportunities for scientists network to ensure the success of research project.
4. I will provide and share advice and technical expertise in specific knowledge for this project.

I'm very much looking forward to working closely with you on this 1-year research project and beyond as you continue to develop your surveillance zoonotic disease research program.

Best regards,

Supaporn Wacharapluesadee, Ph.D.

Subject: Letter of Support for CREID Network Pilot Research Program

Dear Dr. Srimuang,

I am writing to express my support for your CREID Network Pilot Research Program proposal titled, "Immune memory bait and capture to identify emerging henipavirus origins." Your preliminary data demonstrating immunoreactivity against Mojiang henipavirus in individuals sampled as part of the Emerging Infectious Diseases Southeast Asia Research Collaborative Hub (EID-SEARCH) center, provides compelling serologic evidence that novel henipaviruses spill over into human populations. Point-of-care diagnostics and nucleic acid-amplification tests rely on our present understanding of medically relevant pathogens. Thus, emergence of novel zoonotic viruses may go undetected. Serological profiling provides us an ability to measure the human infectome through broad-scale peptide arrays or targeted antigen-based detection.

The research activities conducted at the Thai Red Cross Emerging Infectious Diseases Clinical Center are complementary to the focus of the Vaccine Research Center's PREMISE (Pandemic REsponse REpository through Microbial and Immunological Surveillance and Epidemiology) program. PREMISE works closely with intramural and extramural NIH programs and in partnership with a global network of investigators and collaborators to achieve its objectives through 3 core activities: (1) genetic analysis of zoonotic reservoirs and symptomatic humans for pathogen discovery; (2) development of high throughput, multiplexed serologic and cellular assays; and (3) global blood sampling to identify antigen-specific and cross-reactive immune responses to known and previously unknown viruses of pandemic potential. Biological samples including serum and PBMC are obtained from broad-based population cohorts as well as targeted populations at risk from emerging infections. At the same time, sequence data from known and unknown (through virus discovery) pathogens are analyzed to design and express candidate antigenic proteins of interest. These proteins are then used in high throughput multiplexed assays to screen sera for antibody reactivity. Serum reactivity to candidate antigens is followed by further interrogation of the adaptive immune response at the cellular level using corresponding PBMC samples. Proteins used in the serological arrays are conjugated to fluorophores and used as probes to sort antigen-specific B cells by flow cytometry. In addition, the sequence of such candidate antigens provides the template for the design of overlapping peptide pools to assess T cell responses. Further analysis allows for the identification of

neutralizing antibodies specific for the target antigens as well as specific T cell epitopes which may be tested in animal models. Epitope identification informs and guides immunogen design. At the conclusion of this pipeline of assays and analysis, PREMISE delivers the following:

1. reagent and data resources for early detection and diagnosis
2. monoclonal antibodies with therapeutic potential
3. candidate immunogens for further vaccine development

Thus, PREMISE serves as a translational vehicle to integrate serologic and cellular immune discovery, targeting a broad array of pathogens, into product development, and constitutes an anticipatory reagent repository to accelerate the global response to pandemic threats.

As investigators in the Vaccine Research Center at the National Institute of Allergy and Infectious Diseases (NIAID), we are not eligible to be listed as a “co-investigator” on the application but look forward to participating as collaborators. All materials from us will be provided under an approved material transfer or other collaborative agreement. This collaboration is part of our official duties as employees at the NIAID, and no funds from the grant will be used in intramural research, neither will we accept any form of remuneration, whether in the form of salary, honoraria, or travel expenses. We will provide scientific input and mentoring but will not have any duties associated with programmatic stewardship, which will be performed by NIAID extramural program officials. Further, in keeping with the mission of NIAID to promote and facilitate biomedical research and the dissemination of new knowledge, we would supply requested research materials and technical expertise not only to you, but also to other interested and qualified parties for research purposes.

My group has met with Dr. Eric Laing (USU) one of the two mentors for this pilot research program to discuss ways we can collaborate and support your research application. We are enthusiastic about providing the technological and subject-expertise in immunology and translational therapeutic discovery afforded by the PREMISE program that would enhance your knowledge base and broaden your own scientific training.

Sincerely,

Daniel C. Douek

Project Abstract (250 words)

Prototypical henipaviruses (Hendra and Nipah virus) cause zoonotic diseases with high mortality and no effective vaccines or therapeutics and are hosted by Pteropus flying foxes. The recent detection of closely-related Mojiang and Langya viruses in rats and shrews, and an outbreak of acute febrile LayV illness in people, challenges the dogma that fruit bats are the key henipavirus reservoirs, and heightens their threat profile. The recently expanded henipavirus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascar fruit bat-borne Angovkeely virus. In this study, we have found serological evidence of a Mojiang-related virus in a community of Thai bat guano collectors with high exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic. We plan to identify seropositive human participants MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife. We will develop anti-RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus these will allow the serologic signature of related undiscovered henipaviruses to be identified.

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as Mentor for Dr. Krongkan and Spencer under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program.

Commented [e11]: For Eric

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Specific Aims (1-page limit)

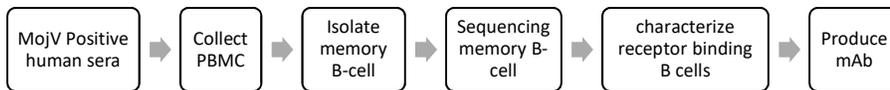

This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The hypothesis

1. Can the memory B-cell immune response be used as a tool for the discovery of novel henipaviruses?
2. Can the spatial relationships between henipaviruses receptor binding proteins be generated that would allow for an understanding of antigenic evolution and functional characterization.

Aim 1. Antibody-mediated bait & capture of Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Aim 2. Modeling antigenic relationships among known and unknown henipaviruses.

Defining antigenic relationships among these will allow the serologic signature of related undiscovered henipaviruses to be identified. We will develop anti-RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus.

Objective 1. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody production.

Objective 2. To capture unknown MojV-like viruses during syndromic surveillance in humans and routine surveillance in wildlife in Ratchaburi province, Thailand.

Objective 3: To generate antigenic maps using anti-henipavirus RBP standards.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Study Rationale (7-page limit)

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McLinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022).

HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genus of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, Gamak virus (GAKV), and Daeryong virus (DARV) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The Henipavirus genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L)

Commented [EL2]: Check date

Commented [el3]: cite

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australian (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV),	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	(Madera et al., 2022)

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

Research Gap

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus *Pteropus*, *Rhinolophus*, and *Hipposideros* (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in Rhinolophid bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected four members of a high-risk cohort with MojV-reactive serum, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus and to explore the novel MojV-like virus in Thailand.

Research Impact

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia is due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology to identify a novel virus that can aid in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

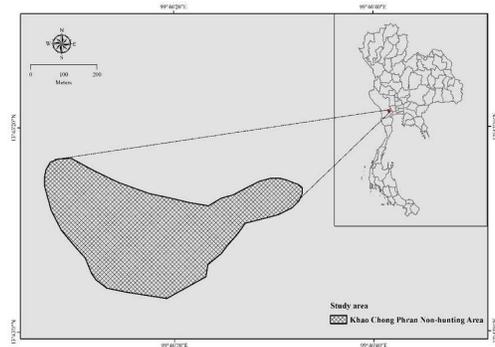

Aim 1. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific [mAbs](#).

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipaviruses, and LayV, depending on how well these cross react.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 1).

Commented [EL4]: Also propose to pull these out with MojV F.

And that you will test binding of these against LayV G and LayV F. To see cross reaction.

One antibody Broder has against MojV already has demonstrated cross reaction with a LayV protein.

David Veesler can do all the Cyro-EM to look at where these mAbs bind on the proteins.

Commented [EL5]: Show serological profile Figure

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

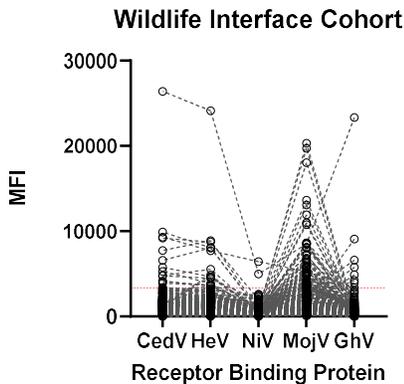

Figure 2: Seroprevalence of henipavirus proteins from a community with a large bat interface. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, the assay cutoff.

PBMC collection and Single Memory B Cell Isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes).

Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3⁻, CD14⁻, CD56⁻, IgM⁻, IgA⁻, CD19⁺, CD20⁺, CD27⁺). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor Amplicon Preparation

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced.

B cell receptor Data Analysis

After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline.

Recombinant Antibody Cloning, Production, and Purification

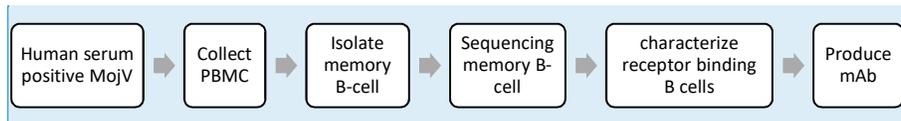

Commented [EL6]: Condense these subheadings

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression.

Functional assessment

Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. Next we will test the cross neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV (Duke NUS/LinFa should be able to do this, if they have LayV and are propagating it, they can use cell-cell fusion/CPE in a straight PRNT). Decide if you want to incorporate this.

Antigenic cartography

Antisera and monoclonal antibodies to henipavirus RBP, including the novel MojV-like henipavirus, will be generated and tested against all the known RBP. The resulting binding data will be compiled, and antigenic relatedness will be determined using RStudio.

Determination of envelope glycoprotein epitope binding

Isolated mAbs will be assessed for binding to MojV RBP and F proteins through multiplex binding serology. Further, the cross reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered [2 citations]. Thus, a functional assessment of cross neutralizing potential is not possible. However, through cryo-electron microscopy we can investigate binding epitopes between these mAbs and MojV and LayV envelope glycoproteins. Epitope identification can then be used to make predictions about neutralizing potential through deductions about the location of henipavirus RBP receptor-binding pockets.

Aim 2. Utility of Thai MojV-like mAbs for surveillance.

Serological profiling provides an indirect measurement of the infecting virus. Despite XX% (XX/XXX), seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. In addition to the translational application of mAbs as therapeutics, we intend to utilize these mAb as non-clinical diagnostics surveillance tools for virus/virus antigen capture.

Site wildlife samples collection

100 Rodents 100 bats, and 100 shrews in Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus. In this study, we can collect only one time for a limited grant and time.

Enrollment criteria: Random age, random weight, random sex.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Blood from animals will collect by using a needle in vein blood using serum to detect the undiscovered henipaviruses.

Human syndromic surveillance

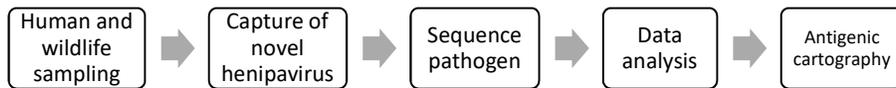

100 human samples will collect serum to detect henipa-like virus near Khao Chong Phran cave in Ratchaburi Province for 1 year.

Enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who have sick without any reason such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts wildlife or works with wildlife

Data analysis

Virus sequencing....after mAb pulldown.

Research Performance Sites (1-page limit)

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country.

We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

CREID Research Center Collaboration (1-page limit)

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Mentoring Plan (2-page limit)

1. Goals for Pilot study and Career

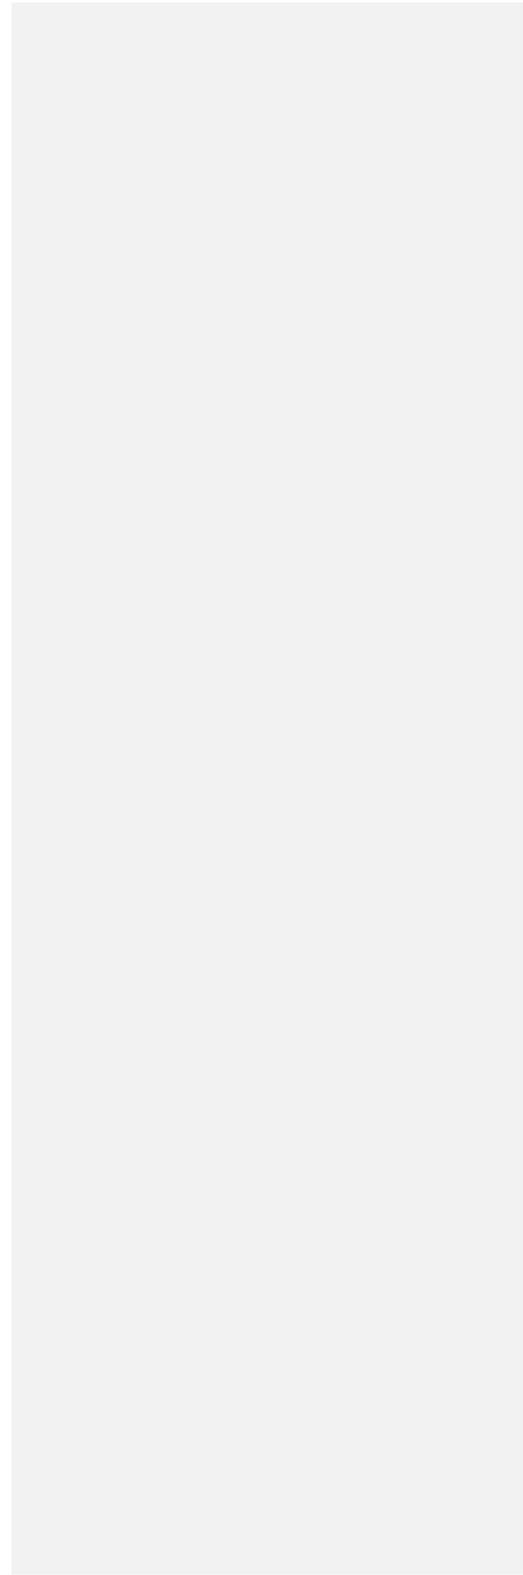

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand from for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

writing and project management skills. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Vertebrate Animals Section Requirements

1. Description of Procedures (Vertebrate Animals Section)

Animal samples will be collected in the Khao Chong Phran cave in Ratchaburi Province, including bats, rodents, and shrews as were approved by the IACUC for the project "Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia" (Animal Protocol #G2020-42). Moreover, the project has been approved by the Thai Department of National Park, Wildlife and Plant Conservation on 0907.4/28372.

1.1 Bats (order Chiroptera): Family Pteropodidae; Family Rhinopomatidae; Family Emballonuridae; Family Craseonycteridae; Family Megadermatidae; Family Rhinolophidae; Family Hipposideridae; Family Vespertilionidae; Family Molossidae; etc.

Random age, random weight, random sex, and total number 100.

1.2 Rodents (order Rodentia) *Maxomys whiteheadi*; *Rattus exulans*; *Rattus annandalei*; *Leopoldamys sabanus*; *Sundamys muelleri*; *Chiropodomys gliroides*; *Niviventer cremoriventer*; *Maxomys rajah*; *Hylomys suillus*; *Niviventer*; *Maxomys*; *Maxomys surifer*; *Rhizomys sumatrensis*; *Rhinosciurus laticaudatus*; *Callosciurus notatus*; *Rattus tiomanicus*; *Tupaia glis*; *Petaurillus hosei*; *Rattus tanezumi*; *Rattus norvegicus*; *Rattus rattus*; *Sundasciurus lowii*; *Tupaia longipes*; *Tupaia tana*; *Callosciurus prevostii*; *Sundasciurus hippurus*; *Tupaia minor*; *Hystrix crassispinis*; *Maxomys alticola*; *Rattus argentiventer*; *Trichys fasciculata*; *Dremomys everetti*; *Callosciurus adamsi*; *Rattus baluensis*; *Rattus losea*; *Bandicota indica*; *Mus cookie*; *Berylmys bowersi*; *Rattus nitidus*; *Mus caroli*; *Leopoldamys neilli*; *Leopoldamys edwardsi*; *Mus cervicolor*; *Mus fragilicauda*; *Niviventer confucianus*; *Niviventer fulvescens*; *Bandicota Savile*; etc.

Random age, random weight, random sex, and total number 100.

1.3 Shrews (order Soricomorpha) *Sorex isodon*; *Crocidura attenuate*; *Crocidura fuliginosa*; *Crocidura horsfieldii*; *Crocidura vorax*; etc.

Random age, random weight, random sex, and total number 100.

2. Justifications (Vertebrate Animals Section)

For our Aim 2. Modeling antigenic relationships among known and unknown henipaviruses. We will develop anti-Henipavirus RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus. We would like to survey all animals that could be reservoir hosts or intermediate hosts of novel henipaviruses that can be spillover to humans to increase the likelihood of detecting a novel virus. Therefore, the research goals be accomplished using an alternative model (e.g., computational, human, invertebrate, in vitro).

3. Minimization of Pain and Distress (Vertebrate Animals Section)

For animals requiring anesthesia- Blockage of visual stimulus, handling in cloth bags and other methods will be employed to keep handling procedures gentle and to minimize stress.

4. Method of Euthanasia

This study will not use methods of euthanasia in all animals.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Human Subjects Research

This project will enroll human subjects under the approved protocols by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64).

All applicants proposing human subjects research should address the following elements on the Protection of Human Subjects:

1. Risks to the subjects

Human blood will be collected by a needle from a vein in the arm (approximately 15 ml) into a heparin tube.

Having blood drawn may produce discomfort or minor bleeding and the possibility of bruising at the site of the needle puncture. There is also a slight risk of infection at the site of the

needle puncture. Although rare, some people have experienced nausea, light headedness, and fainting in association with a blood draw.

2. Adequacy of protection against these risks

Vital signs will be taken at each visit. Vital signs include measurements of your pulse (heart rate), respirations (breaths per minute), blood pressure, height, weight, and body temperature.

3. Potential benefits of the research to the subjects and others

There are no direct benefits to the research subjects. Indirect benefits to the research to subjects is the possible identification of undiscovered henipaviruses infections in this population. Detection can lead to correct diagnostics and proper treatment of the disease

4. Importance of the knowledge gained or to be gained

This study will bring opportunity, experience, and knowledge in immunology and serology to research staff in Thailand. Moreover, the new methods and techniques to identify novel pathogens by using memory B-cell can be used in the study of zoonotic reservoirs and pathogen origins. By using serologic and cellular immune discovery in humans and wildlife, we seek the ability for early detection and identification of novel pathogens to prevent the next pandemic.

5. Country- / institution-specific ethics / IRB regulations addressed

This project will enroll human subjects under the approved protocols by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64).

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Budget/Budget Justification

No.	Description	Budget (\$)	Unit cost (USD)	month	Unit	Cost
1	Personnel	63,600.00				19,400.00
	Krongkan Srimuang		1,000.00	12	month (20 hrs/month)	12,000.00

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cyclers, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), **cell sorting machine** and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country. Bats are considered protected wildlife in Thailand by Wildlife Conservation, Department of National Parks, Wildlife and Plant Conservation.

Computer:

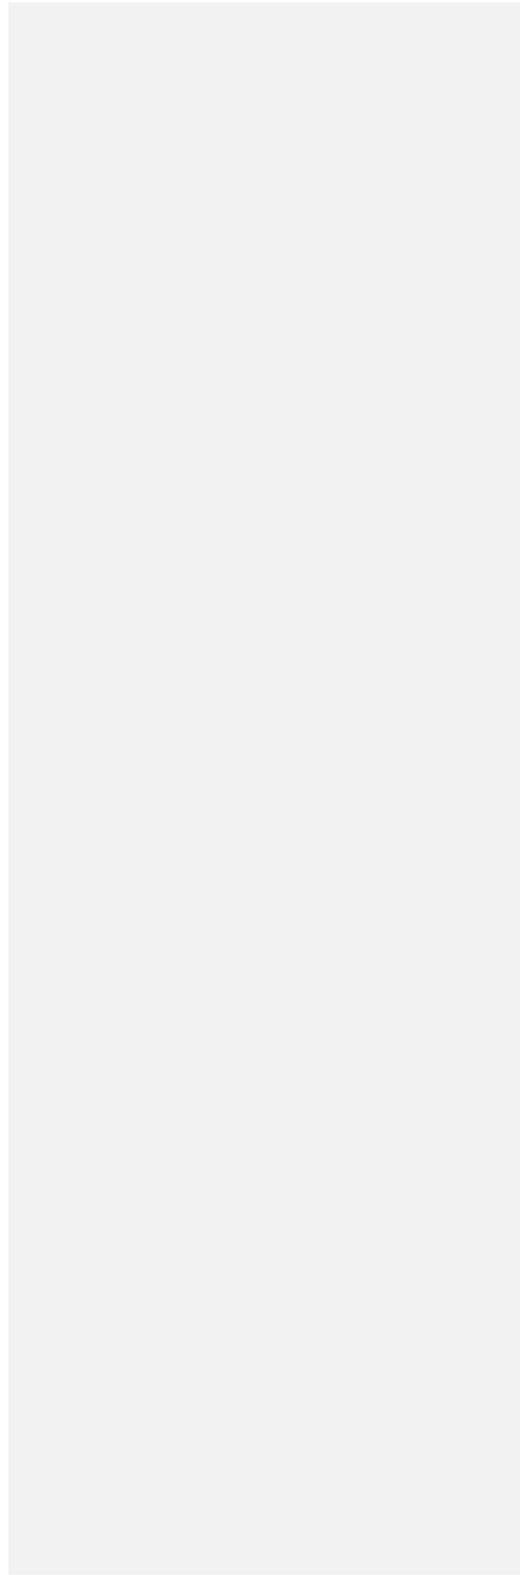

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

30 January 2023

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC),
King Chulalongkorn Memorial Hospital

Object: Thai Red Cross Emerging Infectious Diseases Clinical Center support for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

Dear Dr. Srimuang & Mr. Sterling,

Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC) is pleased to support your application to the **CREID Pilot Research Program**, entitled “Immune memory bait & capture to identify emerging henipavirus origins.” We are fully committed to executing the statement of work to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The work proposed in this project will be given a great opportunity and collaboration to our team, it serves very strong knowledge in serology and immunology for the detection of novel virus pathogens in Thailand using new technology and techniques. Moreover, the building capacity and capability of our laboratory and Faculty will access and support to make the success and completion of this project.

This letter expresses my strong interest and drives forward to making this application a success. I look forward to collaborating with you of this project. I wish you success in the CREID Pilot Research Program application.

Sincerely,

Assistant Professor Opass Putcharoen, MD, Msc

Head of Thai Red Cross Emerging Infectious Diseases Clinical Center

King Chulalongkorn Memorial Hospital

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

30th January, 2022

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious

Diseases Clinical Centre (TRC-EIDCC),

King Chulalongkorn Memorial Hospital

Dear Dr. Srimuang & Mr. Sterling,

I am writing this letter to express my support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled "Immune memory bait & capture to identify emerging henipavirus origins."

My experience in immunology and serology will support them in the CREID Pilot Research Program. The research aim has the potential to have a strong impact on our approach to pathogen surveillance at high-risk human-animal interfaces. Given the understanding of the pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

I believe that this is a great opportunity to use scientific knowledge and expertise to train the characterization of memory B cells from peripheral blood mononuclear cells (PBMC) and serology background to the team at Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital, Thailand. Our stronger partnerships have the potential to really drive forward innovations in this serology and immunology which include the implementation of novel techniques for pathogen surveillance as proposed in your pilot project application.

The CREID Network and the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH) will support scientists in regions around the world where emerging and reemerging infectious disease outbreaks. Many Southeast Asian partnerships in EID-SEARCH have strong the potential to really drive forward innovations in this area.

I believe that Dr. Wacharapluesadee, Co-PI, and I will provide scientific skills, expertise, and networks for this project.

Towards that aim, I am committed to supporting your professional development in the following ways:

- 1.
- 2.
- 3.

Commented [e111]: Could you please add the supporting?

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

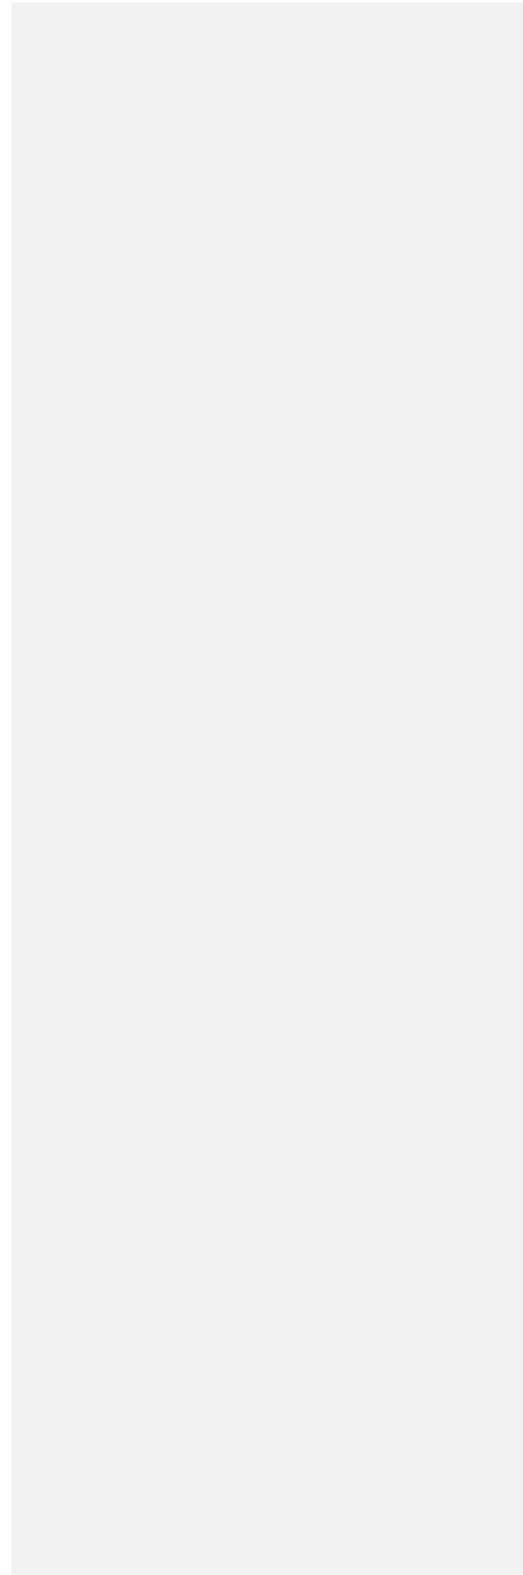

I'm very much looking forward to working closely with you on this 1-year research project and beyond as you continue to develop your surveillance zoonotic disease research program.

Best regards,

Eric Laing, Ph.D.

Assistance Professor

Uniformed Services University of the Health Sciences

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

30th January, 2022

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious

Diseases Clinical Centre (TRC-EIDCC),

King Chulalongkorn Memorial Hospital

Dear Dr. Srimuang & Mr. Sterling,

I am writing in support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

For my experience in 20 years to conduct the surveillance for novel virus in wildlife, human, and bats using molecular technology and multiplex serology panel (Luminex technology) will support them in the CREID Pilot Research Program. The research aim has the potential to have a strong impact on our approach to pathogen surveillance at high-risk human-animal interfaces. Given the understanding of the pathogen origin by using serologic and virus discovery in bats, humans, and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

As the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, I believe that this is a great opportunity for our Thailand team that can train in the characterization of memory B cells from peripheral blood mononuclear cells (PBMC) and serology surveillance in novel virus pathogens. Moreover, our laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases and communicable diseases such as Ebola, MERS, and COVID-19. I am also a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. With my experience to diagnose the first human MERS case in 2015 and the first human COVID-19 case outside China in January 2020, I will support multidisciplinary projects involving epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah, and Hendra viruses, Avian influenza, and novel viruses from bats. I am also the Thailand country coordinator for PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratorians. I will be given the strong knowledge to build capacity and capability in this project and our team in Thailand.

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

The CREID Network and the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH) will support scientists in regions around the world where emerging and reemerging infectious disease outbreaks. Many Southeast Asian partnerships in EID-SEARCH have strong the potential to really drive forward innovations in this area.

I believe that Dr. Laing, and I will provide scientific skills, expertise, and networks for this project.

Towards that aim, I am committed to supporting your professional development in the following ways:

1. I will maintain regular bi-weekly meetings for the project progresses.
2. I will support the resources in our country and research team in this project.
3. I will create opportunities for scientists network to ensure the success of research project.
4. I will provide and share advice and technical expertise in specific knowledge for this project.

I'm very much looking forward to working closely with you on this 1-year research project and beyond as you continue to develop your surveillance zoonotic disease research program.

Best regards,

Supaporn Wacharapluesadee, Ph.D.

Head Laboratory,

Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC),

King Chulalongkorn Memorial Hospital,

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

Pilot Program Application Submission Checklist – Final Application Submission

Title of Application: Immune memory bait & capture to identify emerging henipavirus origins

Submitted by: Krongkan Srimuang, Ph.D.

Submission Date: 1/30/2023

Full Application Submission Requirements

- Proposal Cover Sheet
- Title and Table of Contents
- Study Personnel (1-page limit)
- Main Application Body Section Requirements (7-page limit):
 - Research Aims & Objectives
 - Study Rationale/Research Gap/Impact
 - Significance and Approach
 - Research Methods
- Project Timeline (1-page limit)
- Research Performance Sites (1-page limit)
- CREID Research Center Collaboration (1-page limit)
- Mentoring Plan (2-page limit)
- Vertebrate Animals Section Requirements (3-page limit):
 - Description of Procedures**
 - Justifications**
 - Minimization of Pain and Distress**
 - Method of Euthanasia (Cover Page Supplement / PHS Fellowship Supplemental Form)**
- Human Subjects Research (3-page limit):
 - Summary of the parent study and IRB approval information for the study
 - Risks to the subjects
 - Adequacy of protection against these risks
 - Potential benefits of the research to the subjects and others
 - Importance of the knowledge gained or to be gained
 - Country / institution-specific ethics / IRB regulations addressed
- **Research, Related Project Information, and Budget/Budget Justification**
 - R&R Other Project Information Form
 - Full budget, with total costs of no more than \$150,000

Commented [e112]: How should we do about the budget?

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

- Budget justification which describes the labor and other direct costs
- If your institution does not have adequate funds for a cost-reimbursement award and requires pre-payment of funds during the award year, please note this in your budget justification and outline a payment schedule that will function for your project.
- Supporting Documentation
 - Biographical Sketch and Other Support. All applications must include:
 - Applicant PI Biographical Sketch (*4-page limit*)
 - Applicant PI Previous/Current/Pending Support (Include funding amounts, *no page limit*)
 - Mentor Biographical Sketch (*4-page limit*)
 - Mentor Current/Pending Support (*no page limit*)
 - Key Personnel Biographical Sketches (*4-page limit each*)
 - Key Personnel Current/Pending Support (*no page limit*)
 - Co-PI Plan (only needed if applying as Co-PIs) (*1-page limit*)
 - What each Co-PI will contribute to the proposed research study
 - How the Co-PIs will jointly work with the affiliated Research Center
 - How the Co-PIs will jointly manage the proposed study
 - References Cited (*no page limit*)
 - List of Abbreviations, Acronyms, and Symbols
 - Facilities, Existing Equipment, and Other Resources (*template provided*)
 - NIH Foreign Clearance form (*template provided*)
 - Letters of Organizational Support (*2-page limit per letter*)
 - Letter of Collaboration from CREID Research Center PI (*2-page limit per letter*)
 - Letter from Research Center Mentor (*2-page limit*)
 - Letter from Primary Scientific Mentor (if different than Research Center mentor) (*2-page limit*)

Commented [e113]: Dear Eric, this is your part.

Commented [e114]: Dear Eric, this is your part.

Hi Kio, Spencer, Eric,

Attached are

- Vertebrate Animals Section
- Human Subject Research
- Foreign Clearance
- Letter of Collaboration from CREID RC signed by Peter

You need to read through and edit based on the project activities, for example, sample types, enrollment of children or not, age group, and other relevant information.

Please also ensure the format, font, size, line spacing, margin, etc. are consistent and follow the guidance.

Let me know if you have any questions! Send me documents to review anytime.

Best,
Hongying

Dear Eric,

Please find attached the Pilot study including all documents.
If you need further information please let me know.

Thank you very much

Best regards,
KIO

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Wacharapluesadee, Supaporn

eRA COMMONS USER NAME (credential, e.g., agency login):

POSITION TITLE: Senior Researcher

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Chiang Mai University, Thailand	B.S.	02/1991	Medical Technology
Mahidol University, Thailand	M.S.	01/1994	Biochemistry
Chulalongkorn University, Thailand	Ph.D.	03/2006	Biomedical Sciences

A. Personal Statement

I have 29 years in public health research and 20+ years of experience in emerging viral zoonoses. I have managed many internationally funded research projects that involve working with and managing international and local interdisciplinary teams. Most of my research projects are diagnostics development, pathogen discovery, public health surveillance, field surveillance in wild mammals, human behavioral risk surveys, and clinical research. I conduct workshops on the development of novel diagnostic approaches, appropriate sample collection and handling for different pathogens, and viral characterization *in vitro* and *in vivo*. I am a senior researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, which conducts research on emerging zoonoses, clinical research, and public health surveillance research. My research background mainly focuses on understanding the process of zoonotic disease emergence, particularly viral zoonoses. This includes identifying the bat origin of Nipah virus, MERS-CoV, and SARS-CoV-2 and pathogenesis and diagnoses of Rabies. My studies on the emergence of novel betacoronaviruses found in Thai bats and Nipah virus have been published. My laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases, communicable diseases, and wastewater surveillance. I am the DDC instructor on the clinical sampling method and consultant for Ebola, MERS, and COVID-19 diagnosis. I am a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. I led the team to diagnose the first human MERS case in 2015 and the first human COVID-19 case outside China in January 2020. I have been the PI on six multidisciplinary research projects that use epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah, and Hendra viruses, Avian influenza, and novel viruses from bats. I am also the Thailand country coordinator for PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratorians.

B. Positions, Scientific Appointments, and Honors

Positions and Employment

- 1994 -97 Biochemical Technician, Department of Entomology, AFRIMS, Thailand
- 1997 Researcher, Department of Immunology, Chulabhorn Research Institute, Thailand
- 1997 -00 Medical Technologist, The HIV/AIDS Collaboration Thai-US, Thailand
- 2000 -16 Laboratory Chief, Neuroscience Centre for Research and Development & WHO Collaborating Centre for Research and Training on Viral Zoonoses, Faculty of Medicine, Chulalongkorn University Hospital, Thai Red Cross Society, Thailand
- 2016 -21 Deputy Chief of Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University Hospital
- 2021 - Senior Researcher, Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital
- Committee member, School of Global Health, Faculty of Medicine, Chulalongkorn University

Other Experience and Professional Membership

- 2010 -14 PREDICT Thailand Country Coordinator
- 2014 - Thai Ministry of Public Health (MOPH) Ebola Diagnostic Committee
- 2015 -19 PREDICT 2 Thailand Country Coordinator
- 2016 - Steering committee, Bat One Health Research Network, BTRP DTRA
- 2021 - WHO Scientific Advisory Group for the Origins on Novel Pathogens (SAGO)

C. Contributions to Science

1. **Research on One Health.** One Health is an integrated, unifying approach that aims to sustainably balance and optimize the health of people, animals, and ecosystems, as the definition by WHO. Our projects are multidisciplinary studies on human surveillance, wildlife surveillance, wastewater surveillance, and human behavior.
 - a. Tangwangvivat R, **Wacharapluesadee S**, Pinyopornpanish P, Petcharat S, Muangnoicharoen H. S, Thippamom N, Phiancharoen C, Hirunpatrawong P, Duangkaewkart P, Chaiden C, Wechsirisana W, Wandee N, Srimuang K, Paitoonpong L, Buathong R, Pawun V, Hinjoy S, Putcharoen O, Iamsirithaworn S. Assessment of SARS-CoV-2 variant wastewater detection strategies in the Bangkok Metropolitan region. **Preprint Research** 2023

- b. Keusch GT, Amuasi JH, Anderson DE, Daszak P, Eckerle I, Field H, Koopmans M, Lam SK, Das Neves CG, Peiris M, Perlman S, **Wacharapluesadee S**, Yadana S, Saif L. Pandemic origins and a One Health approach to preparedness and prevention: Solutions based on SARS-CoV-2 and other RNA viruses. **Proc Natl Acad Sci USA**. 2022 Oct 18;119(42):e2202871119. doi: 10.1073/pnas.2202871119. Yadana S, Cheun-Arom T, Li H, Hagan E, Mendelsohn E, Latinne A, Martinez S, Putcharoen O, Homvijitkul J, Sathaporntheera O, Rattanapreeda N, Chartpituck P, Yamsakul S, Sutham K, Komolsiri S, Pornphatthanankhom S, Petcharat S, Ampoot W, Francisco L, Hemachudha T, Daszak P, Olival KJ, **Wacharapluesadee S**. Behavioral-biological surveillance of emerging infectious diseases among a dynamic cohort in Thailand. **BMC Infect Dis**. 2022 May 16;22(1):472. doi: 10.1186/s12879-022-07439-7. PMID: 35578171; PMCID: PMC9109443.

2. Research on Public Health Surveillance in Thailand. Effective disease control programs rely on effective surveillance and response systems. Our laboratory collaborates with the Department of Diseases Control for active surveillance on syndromic surveillance and outbreak investigation. Both molecular and serology surveillance systems were conducted to identify the cause of the disease.

- a. Pliapat T, Buathong R, **Wacharapluesadee S**, Siriarayapon P, Pittayawonganon C, Sangsajja C, Kaewpom T, Petcharat S, Ponpinit T, Jumpasri J, Joyjinda Y, Rodpan A, Ghai S, Jittmittraphap A, Khongwichit S, Smith DR, Corman VM, Drosten C, Hemachudha T (2017). Imported case of Middle East respiratory syndrome coronavirus (MERS-CoV) infection from Oman to Thailand, June 2015. **Euro Surveill** 22(33):pii: 30598.
- b. Okada P, Buathong R, Phuygun S, Thanadachakul T, Parnmen S, Wongboot W, Waicharoen S, **Wacharapluesadee S**, Uttayamakul S, Vachiraphan A, Chittaganpitch M, Mekha N, Janejai N, Iamsirithaworn S, Lee RT, Maurer-Stroh S. Early transmission patterns of coronavirus disease 2019 (COVID-19) in travellers from Wuhan to Thailand, January 2020. **Euro Surveill**. 2020 Feb;25(8):2000097. doi: 10.2807/1560-7917.ES.2020.25.8.2000097. PMID: 32127124; PMCID: PMC7055038.
- c. Putcharoen O, **Wacharapluesadee S**, Chia WN, Paitoonpong L, Tan CW, Suwanpimolkul G, Jantarabenjakul W, Ruchisrisarod C, Wanthong P, Sophonphan J, Chariyavilaskul P, Wang LF, Hemachudha T. Early detection of neutralizing antibodies against SARS-CoV-2 in COVID-19 patients in Thailand. **PLoS One**. 2021 Feb 12;16(2):e0246864. doi: 10.1371/journal.pone.0246864. PMID: 33577615; PMCID: PMC7880427.
- d. Sangkakam A, Hemachudha P, Saraya AW, Thaweethee-Sukjai B, Cheun-Arom T, Latinne A, Olival KJ, **Wacharapluesadee S**. Detection of influenza virus in rectal swabs of patients admitted in hospital for febrile illnesses in Thailand. **SAGE Open Med**. 2021 Jan 22;9:2050312121989631. doi: 10.1177/2050312121989631. PMID: 33552519; PMCID: PMC7841862.

3. Research on diagnostic development. The molecular technique is a gold standard method for pathogen diagnosis and confirmation. The first COVID-19 case outside China in Thailand was primarily detected by family PCR and further confirmed by next-generation sequencing (NGS). The SARS-CoV-2 variants can be identified by the NGS technique or by identifying the mutation markers by MassARRAY technology.

Epub 2022 Sep 11. PMID: 36103950.
4. **Research on coronavirus prevalence in Thailand.** Numerous high-impact emerging viruses appear to have bat reservoirs. Our surveillance projects study the diversity of coronavirus (CoV) in bats in Thailand. We have isolated and characterized CoVs from many bat species and detected and sequenced CoV in bat guano collectors. Our surveillance studies continue to analyze the drivers of their emergence and risk factors for spillover.
- a. **Wacharapluesadee S**, Duengkae P, Chaiyes A, Kaewpom T, Rodpan A, Yingsakmongkon S, Petcharat S, Phengsakul P, Maneeorn P, Hemachudha T (2019). Longitudinal study of age-specific pattern of coronavirus infection in Lyle's flying fox (*Pteropus lylei*) in Thailand. **Virol J** 20;15(1):38.

The King Chulalongkorn Memorial Hospital and Faculty of Medicine, Thailand

Facilities and Equipment

The Thai Red Cross Emerging Infectious Diseases Clinical Center (EIDCC) has 100 square meters of office space, 200 square meters of molecular and serology lab spaces, and > 3,000 square meters of shared lab space with the faculty of Medicine (Chula Medical Research Center, MRC). There is twenty staff including 6 clinicians, 8 scientists, 1 bioinformatician 1 research nurse, and 4 admin staff. EIDCC lab supports molecular and serology diagnostics to the hospital and government partners, including Department of Diseases Control (DDC) and Department of National Parks, Wildlife, and Plant Conservation (DNP). EIDCC conducts research projects granted by the Thai government and international partners. The lab lead, Dr. Wacharapluesadee, has experience in emerging infectious zoonotic surveillance, especially from bats, for over 20 years. The research network includes the DDC, Faculty of the Veterinary Science, Chulalongkorn University and Faculty of Forestry, Kasetsart University.

The Chula MRC laboratory is equipped for virology, cell culture, serology, and molecular biology. There is one BSL-3 lab facility and 3 cell culture lab spaces. In addition, MRC has 8 PCR machines, 5 real-time PCR machines, 2 gel document imaging, 3 horizontal electrophoresis, 3 UV-visible spectrophotometers, 3 ultra-centrifuge, 2 high-speed centrifuge machines, 3 refrigerated centrifuge, 2 refrigerated incubator shakers, 5 autoclaves, 2 hot air oven, 6 upright microscopes, 3 inverted microscopes, 2 inverted microscopes with fluorescence, 9 CO₂ incubators, 5 Biosafety cabinets, freeze dryer, speed vacuum concentrator, extraction machine, ImmunoSpot ultimate analyzer, flow cytometer, Bio-plex multiplex suspension array system, microplate reader and washer, droplet digital PCR, automated electrophoresis system, dual fluorescence cell counter, NanoSight, florescence and phosphor imager, Chemiluminescence western blot scanner, CO₂ incubator with shaker, Automate Electrophoresis System, Automated Nucleic Acid and Protein Extraction System, Fluorescent Table and DNA analyzer.

The EIDCC lab is equipped for serology, molecular biology, and next-generation sequencing. There are 3 PCR machines, 4 deep Freezers, 3 freezers, 3 refrigerators, 4 Biosafety cabinets, 2 micro-centrifuge, 2 refrigerated centrifuges, 3 real-time PCR machines, automated gel electrophoresis, Next-generation sequencer (MiSeq system), NGS library preparation system, and MinION (Oxford Nanopore Technologies). The specimen repository system uses the "Pathogen Asset Control System, PACS" software supported by US DTRA. There are 4 PACS computers. The computer server of the faculty is available to access and use for genomic analysis.

Dear Eric,

Attached please find the NIH-biosketch of Dr. Supaporn, the facilities and equipment, and the excel file containing the number of animal and human sera samples we have at our EIDCC lab.

We would be grateful if you could send us a draft of the letter of support for Dr. Supaporn to sign.

Let me know if you require any additional information or if there is anything I can help with.

Best regards,
Bow

Hi Bow and Spencer,

I have sent the following info and attachments to Noam before, but just resending for your reference.

Attached please find the latest versions of relevant materials I have:

- Supapron's NIH-biosketch - this needs to be updated with the new format (no section D) <https://grants.nih.gov/grants/forms/biosketch.htm>
- Facilities and equipment
- Other support - this need to be updated with the new format and other grants <https://grants.nih.gov/grants/forms/othersupport.htm> - *but you will only need this for the Just-In-Time procedure, **not** now for proposal submission*

Other things you need from Chula are:

- Budget
- Budget justification

And if you need to fill in IRB approval information to use human samples under EID-SEARCH (on the cover page):

- US: Health Medical Lab Institutional Review Board (No. 894ECOH21b) on May 12, 2021
- Thailand: Institute Review Board of the Faculty of Medicine, Chulalongkorn University (No. 211/64) on June 8, 2021

Let me know if anything else I can help with.

Best,
Hongying

Hi Chu,

My lab is working on expanding our filo/henipa panel to a 28-plex, most of which should be available for further testing under EID-SEARCH. If this proposal is funded Noam and I would like to make sure that there are additional funds in this R01 proposal to support retesting in your lab.

Which groups of the samples (host species and project name) do you plan to test? Now I have moved to work at the new lab, and it isn't easy to access the old samples (before 2020). But it is possible.

For humans and wildlife, how many samples/species have you collected now and what is your projected target for the remainder of the EID-SEARCH POP? What would be really helpful would be a cost estimate for retesting all those samples under this R01 with the optimized in vitro and in silico serologic approaches.

We'd like to list you as a Co-Investigator, which means we'd need a biosketch, LOS, equipment/facilities pages, and that additional budget that we would include in YRS4-5 of this proposal to supplement additional testing. Spencer can be involved, just let me know whether salary support is coming from my end as HJF employee or whether he'd be listed as key personnel in your lab directly.

Best regards,
Eric

Subject: New NIH proposal on serology methods

Dear Supaporn,

Happy New Yea! I hope this finds you well. I'm writing because I am putting together a new NIH grant proposal at EcoHealth together with Eric Laing at USU that we wanted to include you in. The aim of the grant is to improve both lab and statistical methods for luminex serology. The main elements of the project would be to:

1) Develop statistical methods to simultaneously analyze multiplex serology to

quantify the probability that signals from multiple beads represent antibodies from exposures to different viruses, cross-reactions of viruses in the multiplex panel, or signals of new, previously unknown viruses.

2) Develop discovery-optimized panels for filoviruses and henipaviruses that mix high-specificity and high-sensitivity beads so as to maximize the ability to identify signals of novel viruses.

3) Re-test and re-analyze results from samples from previous serology surveillance studies that have ambiguous results to identify signals of exposure to previously unknown viruses, and conduct antigenic mapping to estimate where they fall phenotypically in relation to known viruses.

We anticipate sharing all our work across partners over the course of the project (if/when funded). However, we specifically hope to collaborate with you on #3 above. We'd like to use this to look deeper at EID-SEARCH results and ideally retest samples (such as the Mojiang-seropositive samples) to see what the new panels yield. For our proposed project, some of the new panels will be developed while EID-SEARCH is still running. If this new project is funded, we will work with you to determine what should be done concurrently with EID-SEARCH or after EID-SEARCH is completed and the best way to budget this (mind you, EcoHealth also hopes to get a continuation on our EID-SEARCH project so it is likely both will be concurrent). Assuming the best case, we submit this in February (Due date Feb 3, 2023) and start work in Fall 2023. Depending on how we stage our tasks, re-testing work could start as early as late 2024 or 2025.

One additional note – this project would be subject to new data sharing requirements NIH has enacted for projects starting 2023 or later. In short, all data we generate out of the project would be published at the end of the project period, whether or not publications are complete. We don't anticipate this would be an issue but want to make sure everyone is aware of this from the start of the grant so we can plan data and manuscript publication accordingly.

We'd like to have you as Key Personnel on this proposal. If you are interested, we'd love to have you aboard and get your thoughts and questions. Eric and I will also follow up next week with a proposal budget. We would also need an NIH Biosketch, Other Support form, and Facilities information from you by January 20. We have recent versions of all of these for EID-SEARCH, so we can send templates for you to modify and approve early next week.

Please let us know what you think, and we'd be happy to have a call to discuss.

Best,

Noam

Full Application Submission Requirements

- Proposal Cover Sheet
- Title and Table of Contents
- Study Personnel (1-page limit)
 - Main Application Body Section Requirements (7-page limit):
 - Research Aims & Objectives
 - Study Rationale/Research Gap/Impact
 - Significance and Approach
 - Research Methods
 - Project Timeline (1-page limit)
 - Research Performance Sites (1-page limit)
 - CREID Research Center Collaboration (1-page limit)
 - Mentoring Plan (2-page limit)
 - Vertebrate Animals Section Requirements (3-page limit):
 - Description of Procedures
 - Justifications
 - Minimization of Pain and Distress
 - Method of Euthanasia (Cover Page Supplement / PHS Fellowship Supplemental Form)
 - Human Subjects Research (3-page limit):
 - Summary of the parent study and IRB approval information for the study
 - Risks to the subjects
 - Adequacy of protection against these risks
 - Potential benefits of the research to the subjects and others
 - Importance of the knowledge gained or to be gained
 - Country / institution-specific ethics / IRB regulations addressed
 - Research, Related Project Information, and Budget/Budget Justification
 - R&R Other Project Information Form
 - Full budget, with total costs of no more than \$150,000
 - Budget justification which describes the labor and other direct costs
 - If your institution does not have adequate funds for a cost-reimbursement award and requires pre-payment of funds during the award year, please note this in your budget justification and outline a payment schedule that will function for your project.
 - Supporting Documentation
 - Biographical Sketch and Other Support. All applications must include:
 - Applicant PI Biographical Sketch (4-page limit)
 - Applicant PI Previous/Current/Pending Support (Include funding amounts, no page limit)
 - Mentor Biographical Sketch (4-page limit)
 - Mentor Current/Pending Support (no page limit)
 - Key Personnel Biographical Sketches (4-page limit each)
 - Key Personnel Current/Pending Support (no page limit)
 - Co-PI Plan (only needed if applying as Co-PIs) (1-page limit)

Commented [e11]: How should we do about the budget?

Proposed End Date	

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) cause zoonotic diseases with high mortality and no effective vaccines or therapeutics and are hosted by Pteropus flying foxes. The recent detection of closely-related Mojiang and Langya viruses in rats and shrews, and an outbreak of acute febrile LayV illness in people, challenges the dogma that fruit bats are the key henipavirus reservoirs, and heightens their threat profile. The recently expanded henipavirus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. In this study, we have found serological evidence of a Mojiang-related virus in a community of Thai bat guano collectors with high exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular</p>

Applicant(s) Name (Last, first, middle): (Srimuang, Krongkan)

immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic. We plan to identify seropositive human participants MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife. We will develop anti-RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus these will allow the serologic signature of related undiscovered henipaviruses to be identified.

Study Personnel (1-page limit)

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Commented [e1]: For Spencer

Dr. Eric Laing will act as Mentor for Dr. Krongkan and Spencer under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program.

Commented [e2]: For Eric

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Research Performance Sites (1-page limit)

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country.

We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

CREID Research Center Collaboration (1-page limit)

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Mentoring Plan (2-page limit)

1. Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand from for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant writing and project management skills. Additionally, Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has

mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Applicant Name (Last, first, middle):

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country. Bats are considered protected wildlife in Thailand by Wildlife Conservation, Department of National Parks, Wildlife and Plant Conservation.

Applicant Name (Last, first, middle):

Computer:

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Specific Aims (1-page limit)

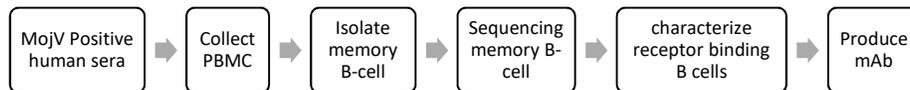

This project aims to study zoonotic reservoirs for pathogen origin by using serologic and cellular immune discovery in humans and wildlife applying to be used as a tool for early detection and identification of novel pathogens to prevent the next pandemic.

The hypothesis

1. Can the memory B-cell immune response be used as a tool for the discovery of novel henipaviruses?
2. Can the spatial relationships between henipaviruses receptor binding proteins be generated that would allow for an understanding of antigenic evolution and functional characterization.

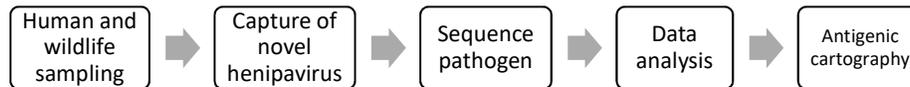

Aim 1. Antibody-mediated bait & capture of Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Aim 2. Modeling antigenic relationships among known and unknown henipaviruses.

Defining antigenic relationships among these will allow the serologic signature of related undiscovered henipaviruses to be identified. We will develop anti-RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus.

Objective 1. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody production.

Objective 2. To capture unknown MojV-like viruses during syndromic surveillance in humans and routine surveillance in wildlife in Ratchaburi province, Thailand.

Objective 3: To generate antigenic maps using anti-henipavirus RBP standards.

Study Rationale/Research Gap/Impact (7-page limit)

The genus Henipavirus is currently composed of nine viruses including Hendra virus (HeV), Nipah virus (NiV), Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McClinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022).

HeV was first identified in Australia in 1994 as a cause of encephalitis in humans and horses. NiV was identified in 1999 in Malaysia as a cause of encephalitis in humans, with swine determined to be the intermediate host. Additionally, annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap. Both viruses cause severe diseases with high mortality and there are currently no vaccines or therapeutics (Middleton and Weingartl, 2012). CedV was identified in Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV (Drexler, J. F., 2009). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). Recent investigations into Madagascan fruit bats detected a second African paramyxovirus, AngV. MojV, was identified during follow-up investigations into lethal pneumonia from three miners in 2012 in China. Multiple genus of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). Langya henipavirus (LayV), a close relative of MojV, was recently identified in febrile patients in eastern China and is closely linked to shrews (Zhang et al., 2022). The novel shrew-borne henipaviruses, Gamak virus (GAKV), and Daeryong virus (DARV) were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The Henipavirus genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australian (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012

Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV),	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	(Madera et al., 2022)

Viruses in the genus Henipavirus have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

The greatest bat diversity around the world especially appears to be found in the tropical rain forests of South East Asia. In Thailand, at least 138 species in 11 families and 45 genera of bats have been recorded, such as members of the genus Pteropus, Rhinolophus, and Hipposideros (Soisook et al., 2011). Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are Insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in Rhinolophid bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a Multiplex microsphere-based immunoassay (MMIA) have detected four members of a high-risk cohort with MojV-reactive serum, including one person with saturating levels of antibody from multiple years. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would to further identify and characterize the origin of the Mojiang virus and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B

cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S., 2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia is due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology to identify a novel virus that can aid in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

For aim 1. Antibody-mediated bait & capture of Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Human samples collection site

Human positive serum for MojV was found close to Khao Chong Phran in Ratchaburi Province, which has the largest colony of bats in Thailand (Figure 1).

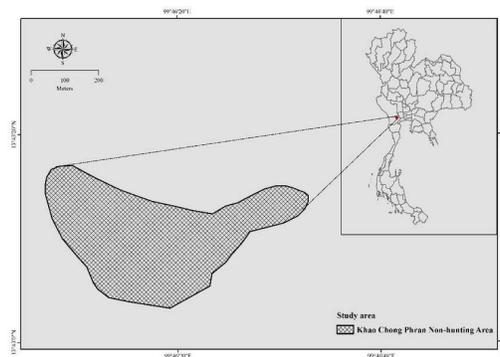

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Isolation PBMC

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes).

Single Memory B Cell Isolation

Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3⁻, CD14⁻, CD56⁻, IgM⁻, IgA⁻, CD19⁺, CD20⁺, CD27⁺). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will be synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor Amplicon Preparation

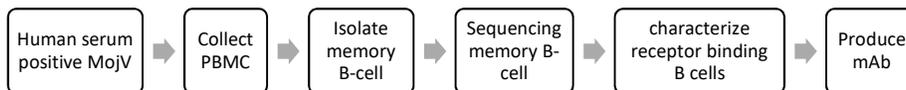

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced.

B cell receptor Data Analysis

After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline.

Recombinant Antibody Cloning, Production, and Purification

Heavy and light-chain sequences will be assembled into an expression vector and transfected into XXXXX cells for monoclonal antibody expression.

Aim 2. Modeling antigenic relationships among known and unknown henipaviruses.

Defining antigenic relationships among these viral species will allow the serologic signature of related undiscovered henipaviruses to be identified. We will develop anti-RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus.

Site wildlife samples collection

50 Rodents 50 bats, and 50 shrews in Khao Chong Phran cave in Ratchaburi Province will be collected for surveillance targeting the Mojiang-like virus.

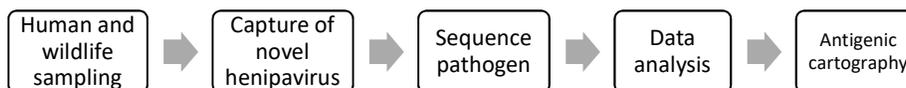

Human syndromic surveillance

50 patients who have Influenza-Like-Illness or Severe acute respiratory infection or respiratory tract infection will collect serum to detect henipa-like virus.

Antigenic cartography

Antisera and monoclonal antibodies to henipavirus RBP, including the novel MojV-like henipavirus, will be generated and tested against all the known RBP. The resulting binding data will be compiled, and antigenic relatedness will be determined using RStudio.

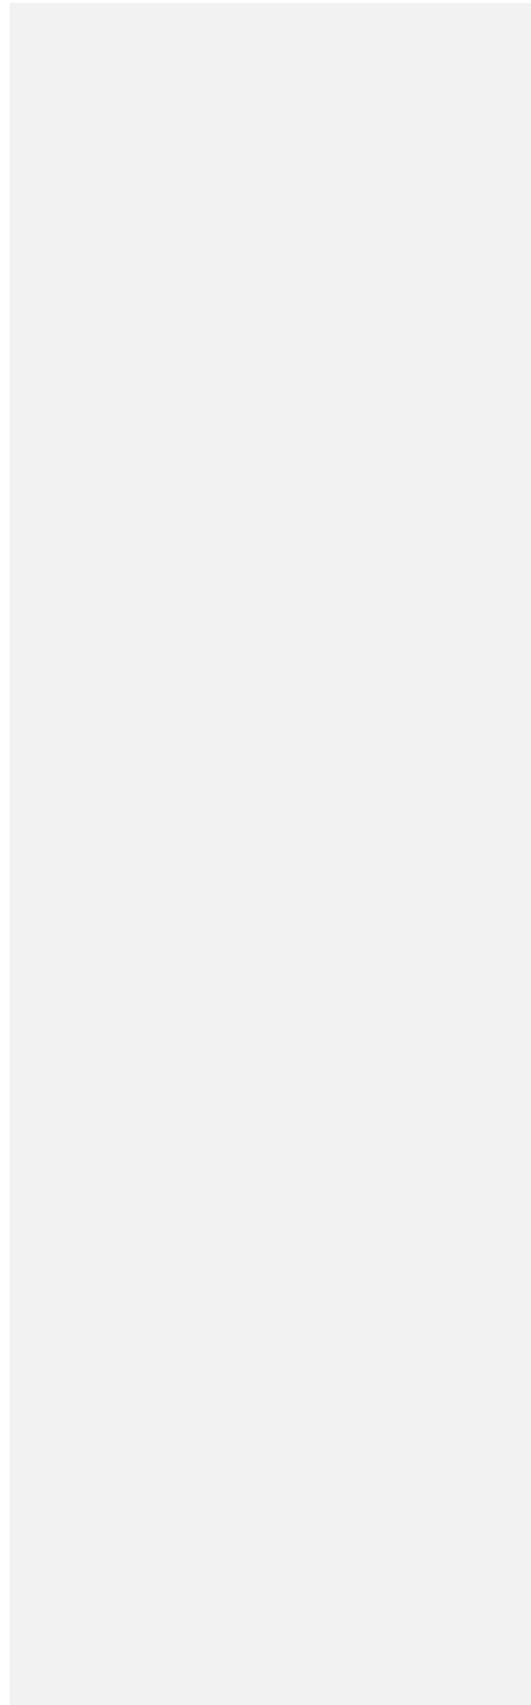

Data analysis

Commented [s1]: Will we take multiple sampling trips or just one?

Dear Hongying,

I and Spencer are writing the Pilot application.

We have some parts not finished which are labeled on the Submission Checklist.

I have attached files to this email for your consideration following;

1. Submission Checklist_Application
2. Proposal Cover Sheet
3. Study Personnel
4. Research Performance Sites
5. CREID Research Center Collaboration
6. Mentoring Plan
7. Facilities, Existing Equipment, and Other Resources
8. Research aim, methods
9. Research and Related Other Project Information_from BOW

I don't know what to do with the IRB part.

Can you give us some advice?

Thank you very much

Best regards,

KIO

The King Chulalongkorn Memorial Hospital and Faculty of Medicine, Thailand

Facilities

The Thai Red Cross Emerging Infectious Diseases Clinical Center (EID-CC) has 100 square meters of office space, 400 square meters of lab space, and more than 3,000 square meters of shared lab space with the faculty of Medicine (Chula Medical Research Center, MRC). There is twenty-one staff including 6 clinicians, 7 scientists, 1 bioinformatician, 2 research nurses, and 4 admin staff. EID-CC lab supports molecular and serology diagnostics to the hospital and government partners, including the Department of Diseases Control (DDC) and the Department of National Parks, Wildlife, and Plant Conservation (DNP). EID-CC conducts research projects granted by the Thai government and international partners. The lab leader, Dr. Wacharapluesadee, has experience in emerging infectious zoonotic surveillance, especially in bats, for over 20 years. The research network includes the Faculty of Forestry, Kasetsart University, DNP, DDC, and the faculty of the Veterinary Science Rajamangala University of Technology Srivijaya.

Equipment

The Chula MRC laboratory is equipped for virology, cell culture, serology, and molecular biology. There is one BSL-3 lab facility and 3 cell culture lab spaces. In addition, the Chula MRC has 8 PCR machines, 5 real-time PCR machines, 2 gel document imaging, 3 horizontal electrophoresis, 3 UV-visible spectrophotometers, 3 ultra-centrifuge, 2 high-speed centrifuge machines, 3 refrigerated centrifuge, 2 refrigerated incubator shakers, 5 autoclaves, 2 hot air oven, 6 upright microscopes, 3 inverted microscopes, 2 inverted microscopes with fluorescence, 9 CO₂ incubators, 5 Biosafety cabinets, freeze dryer, speed vacuum concentrator, extraction machine, immunoSpot ultimate analyzer, flow cytometer, Bio-plex multiplex suspension array system, microplate reader and washer, droplet digital PCR, automated electrophoresis system, dual fluorescence cell counter, NanoSight, fluorescence and phosphor imager, Chemiluminescence western blot scanner, CO₂ incubator with shaker, Automate Electrophoresis System, Automated Nucleic Acid and Protein Extraction System, Fluorescent Table and DNA analyzer.

The EIDCC lab is equipped for serology, molecular biology, and next-generation sequencing. There are 3 PCR machines, 4 deep Freezers, 3 freezers, 3 refrigerators, 4 Biosafety cabinets, 2 micro-centrifuge, 3 real-time PCR machines, automated gel electrophoresis, Nex-generation sequencer (MiSeq system), and NGS library preparation system. The specimen repository system uses the "Pathogen Asset Control System, PACS" software supported by US DTRA. There are 4 PACS computers. The computer server of the faculty of Medicine is available to access and use for genomic analysis.

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Wacharapluesadee, Supaporn

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Laboratory Chief

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Chiang Mai University, Thailand	B.S.	02/1991	Medical Technology
Mahidol University, Thailand	M.S.	01/1994	Biochemistry
Chulalongkorn University, Thailand	Ph.D.	03/2006	Biomedical Sciences

A. Personal Statement

I have 20+ years in research and 15+ years of experience in emerging viral zoonoses. I have managed many internationally funded research projects, that involves working with and managing international and local interdisciplinary teams. Majority of my research projects are field surveillance in wild mammals, human behavioral risk surveys, and clinical sampling. I conduct workshops on development of novel diagnostic approaches, appropriate sample collection and handling for different pathogens, and viral characterization *in vitro* and *in vivo*. I am the Deputy Chief of Thai Red Cross Emerging Infectious Diseases Health Science Centre which conducts research on emerging zoonoses. My research background is focused on understanding the process of zoonotic disease emergence, particularly viral zoonoses. This includes identifying the bat origin of Nipah virus and MERS-CoV, and pathogenesis and diagnoses of Rabies. My study on the emergence of novel betacoronaviruses found in Thai bats, as well as Nipah virus have been published. Our centre was the first laboratory to correctly diagnose the first human MERS case in Thailand, which led to swift execution of containment measures preventing a MERS outbreak in Thailand. We are now the government's reference laboratory for emerging infectious diseases. I have been the PI on 5 multidisciplinary research projects that use epidemiology, laboratory, field science and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah and Hendra virus, Avian influenza and novel viruses from bats. I am also the Thailand country manager for large contracts from USAID involving successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals and laboratorians.

B. Positions and Honors

Positions and Employment

- 1994 -97 Biochemical Technician, Department of Entomology, AFRIMS, Thailand
 1997 Researcher, Department of Immunology, Chulabhorn Research Institute, Thailand
 1997 -00 Medical Technologist, The HIV/AIDS Collaboration Thai-US, Thailand
 2000 -16 Laboratory Chief, Neuroscience Centre for Research and Development & WHO Collaborating Centre for Research and Training on Viral Zoonoses, Faculty of Medicine, Chulalongkorn University Hospital, Thai Red Cross Society, Thailand
 2016 - Deputy Chief of Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University Hospital

Other Experience and Professional Membership

- 2010 -14 PREDICT Thailand Country Coordinator
 2014 - Thai Ministry of Public Health (MOPH) Ebola Diagnostic Committee
 2015 - PREDICT 2 Thailand Country Coordinator
 2016 - Steering committee, Bat One Health Research Network, BTRP DTRA

C. Contribution to Science

1. Research on coronavirus prevalence in Thailand. Numerous high impact emerging viruses appear to have bat reservoirs. Our surveillance projects study the diversity of coronavirus (CoV) in bats in Thailand. We have isolated and characterized CoVs from many bat species, and detected and sequenced CoV in bat guano miner. Our surveillance studies continue to analyze the drivers of their emergence, and risk factors for spillover.

D. Additional Information: Research Support and/or Scholastic Performance

Ongoing Research Support

USAID Emerging Pandemic Threats Mazet (PI) 10/01/14 – 09/30/19
PREDICT-2

The goal is to conduct surveillance for novel pathogens in wildlife, livestock and people; characterize human risk behavior; analyze EID risk; and design interventions in >20 countries

Role: Thailand country coordinator

Multi-Echelon Diagnostics Wacharapluesadee (PI) 07/01/18 – 08/31/19

The goal is to support the Defense Threat Reduction Agency's (DTRA) Multi-Echelon Diagnostics evaluation program. Responsibilities include using the specified point-of-care diagnostic(s) through the procurement of supplies, enrollment of subjects according to inclusion and exclusion criteria, testing the samples, and reporting the data to the Naval Health Research Center (NHRC).

Pathogen Surveillance for Viral Zoonoses Wacharapluesadee (PI) 12/15/16 – 06/30/20

Disease surveillance analysis of wildlife-domestic animal-human interfaces, in coordination with PREDICT USAID project.

Surveillance for Emerging Infectious Disease Pathogens at the Animal-Human Interfaces in Thailand, in Coordination with PREDICT USAID Project and the Bat Serology Study

Wacharapluesadee (PI) 06/01/18 – 04/30/20

The goal of the study is to understand and mitigate zoonotic disease using multiplex serology developed by Utah State University (USU). This is also a disease surveillance analysis of wildlife-domestic animal-human interfaces, in coordination with PREDICT USAID project.

Completed Research Support (last 3 years only) out of 14 prior awards

NSTDA Viral Laboratory Network Wacharapluesadee (PI) 04/01/16 – 03/31/19

The goal of this study was to establish a viral laboratory network in Thailand for Emerging Infectious Disease preparedness among the university laboratories and government public health laboratory.

[Biosketch \(Wacharapluesadee,Supaporn\) EIDRC RFA-AI 19-028 \(PI-Daszak\) v02.docx](#)

Hi Bow and Spencer,

I have sent the following info and attachments to Noam before, but just resending for your reference.

Attached please find the latest versions of relevant materials I have:

- Supaporn's NIH-biosketch - this needs to be updated with the new format (no section D) <https://grants.nih.gov/grants/forms/biosketch.htm>
- Facilities and equipment
- Other support - this need to be updated with the new format and other grants <https://grants.nih.gov/grants/forms/othersupport.htm> - *but you will only need this for the Just-In-Time procedure, **not** now for proposal submission*

Other things you need from Chula are:

- Budget
- Budget justification

And if you need to fill in IRB approval information to use human samples under EID-SEARCH (on the cover page):

- US: Health Medical Lab Institutional Review Board (No. 894ECOH21b) on May 12, 2021
- Thailand: Institute Review Board of the Faculty of Medicine, Chulalongkorn University (No. 211/64) on June 8, 2021

Let me know if anything else I can help with.

Best,
Hongying

Hi Chu,

My lab is working on expanding our filo/henipa panel to a 28-plex, most of which should be available for further testing under EID-SEARCH. If this proposal is funded Noam and I would like to make sure that there are additional funds in this R01 proposal to support retesting in your lab.

Which groups of the samples (host species and project name) do you plan to test? Now I have moved to work at the new lab, and it isn't easy to access the old samples (before 2020). But it is possible.

For humans and wildlife, how many samples/species have you collected now and what is your projected target for the remainder of the EID-SEARCH POP? What would be really helpful would be a cost estimate for retesting all those samples under this R01 with the optimized in vitro and in silico serologic approaches.

We'd like to list you as a Co-Investigator, which means we'd need a biosketch, LOS, equipment/facilities pages, and that additional budget that we would include in YRS4-5 of this proposal to supplement additional testing. Spencer can be involved, just let me know whether salary support is coming from my end as HJF employee or whether he'd be listed as key personnel in your lab directly.

Best regards,
Eric

Subject: New NIH proposal on serology methods

Dear Supaporn,

Happy New Yea! I hope this finds you well. I'm writing because I am putting together a new NIH grant proposal at EcoHealth together with Eric Laing at USU that we wanted to include you in. The aim of the grant is to improve both lab and statistical methods for luminex serology. The main elements of the project would be to:

- 1) Develop statistical methods to simultaneously analyze multiplex serology to quantify the probability that signals from multiple beads represent antibodies from exposures to different viruses, cross-reactions of viruses in the multiplex panel, or signals of new, previously unknown viruses.
- 2) Develop discovery-optimized panels for filoviruses and henipaviruses that mix high-specificity and high-sensitivity beads so as to maximize the ability to identify signals of novel viruses.
- 3) Re-test and re-analyze results from samples from previous serology surveillance studies that have ambiguous results to identify signals of exposure to previously unknown viruses,

and conduct antigenic mapping to estimate where they fall phenotypically in relation to known viruses.

We anticipate sharing all our work across partners over the course of the project (if/when funded). However, we specifically hope to collaborate with you on #3 above. We'd like to use this to look deeper at EID-SEARCH results and ideally retest samples (such as the Mojiang-seropositive samples) to see what the new panels yield. For our proposed project, some of the new panels will be developed while EID-SEARCH is still running. If this new project is funded, we will work with you to determine what should be done concurrently with EID-SEARCH or after EID-SEARCH is completed and the best way to budget this (mind you, EcoHealth also hopes to get a continuation on our EID-SEARCH project so it is likely both will be concurrent). Assuming the best case, we submit this in February (Due date Feb 3, 2023) and start work in Fall 2023. Depending on how we stage our tasks, re-testing work could start as early as late 2024 or 2025.

One additional note – this project would be subject to new data sharing requirements NIH has enacted for projects starting 2023 or later. In short, all data we generate out of the project would be published at the end of the project period, whether or not publications are complete. We don't anticipate this would be an issue but want to make sure everyone is aware of this from the start of the grant so we can plan data and manuscript publication accordingly.

We'd like to have you as Key Personnel on this proposal. If you are interested, we'd love to have you aboard and get your thoughts and questions. Eric and I will also follow up next week with a proposal budget. We would also need an NIH Biosketch, Other Support form, and Facilities information from you by January 20. We have recent versions of all of these for EID-SEARCH, so we can send templates for you to modify and approve early next week.

Please let us know what you think, and we'd be happy to have a call to discuss.

Best,

Noam

Overview of proposed research project	
Pathogen(s) focus	Mojiang Virus, Henipavirus, Paramyxovirus
Country(ies) where work will be conducted	Thailand
Research Aims and Objectives (250 words)	
<p>Prototypical henipaviruses (Hendra and Nipah virus) cause zoonotic diseases with high mortality and no effective vaccines or therapeutics and are hosted by Pteropus flying foxes. The recent detection of closely-related Mojiang and Langya viruses in rats and shrews, and an outbreak of acute febrile LayV illness in people, challenges the dogma that fruit bats are the key henipavirus reservoirs, and heightens their threat profile. We have found serological evidence of a Mojiang-related virus in a community of Thai bat guano collectors with</p>	

Updated: 10/28/22

high exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts.

Aim 1. Antibody-mediated bait & capture of Thai MojV-like virus

In collaboration with NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific MAbs will be generated and used for direct antibody-mediated virus capture in people and wildlife.

Aim 2. Modeling antigenic relationships among known and unknown henipaviruses.

The henipavirus genus has recently expanded to include LayV, MojV, two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. Defining antigenic relationships among these will allow the serologic signature of related undiscovered henipaviruses to be identified. We will develop anti-RBP standards to explore the antigenic spatial relationships between all known rodent- and bat-borne HPVs, and the Thai MojV-like virus.

If you are proposing a human subjects' or animal research study, please describe the already approved study it is nested within and your plan to obtain an IRB or IACUC modification for the proposed study within 2 months of award.

This project will enroll human subjects under the approved protocols by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64). We will obtain an IRB amendment approval for peripheral blood mononuclear cells (PBMCs) collection within two months of award.

If you are proposing a study involving a select agent, indicate the select agent and address the issue identified in the Call for Applications, Section 1.2 about prior approval.

Not applicable.

BIOGRAPHICAL SKETCH

NAME: Krongkan Srimuang

eRA COMMONS USER NAME (credential, e.g., agency login):

POSITION TITLE: Research Scientist

EDUCATION/TRAINING (Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Chulalongkorn University, Bangkok, Thailand	B.Sc.	03/2012	Medical Technology
Mahidol University, Bangkok, Thailand	Ph.D.	04/2017	Molecular Tropical Medicine and Genetics

A. Personal Statement

I am a medical technologist. My undergraduate training has provided me with a background in multiple biological disciplines including molecular biology, microbiology, and genetics. During my Ph.D., I conducted research with Dr. Mallika Imwong focused on Malaria. My thesis was entitled "Exploring the molecular mechanism of mefloquine resistance in *Plasmodium falciparum*". I conducted research on drug resistance to malaria in Southeast Asia. Specifically, my focus was on molecular techniques in identifying the genetic mutations involved with drug resistance. Moreover, I got experience in *Plasmodium falciparum* malaria culture. After my Ph.D., I worked at the genetics laboratory at Jetanin Institute of Assisted Conception. My responsibilities included Preimplantation Genetic Testing (PGT) is screen embryos for genetic abnormalities such as chromosome copy number gains or losses (PGT-A, aneuploidy screening), single gene disorders (PGT-M, monogenic or single-gene disease), or structural rearrangement (PGT-SR, structural rearrangement to identify embryos with chromosome imbalanced) by using Next Generation Sequencing. Additionally, I conducted genetic screening in couples for detecting carrier diseases such as glucose-6-phosphate dehydrogenase (G6PD), Alpha thalassemia, Beta thalassemia, and Spinal muscular atrophy (SMA) by using molecular genetics techniques. Currently, I am a Research Scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC EIDCC), King Chulalongkorn Memorial Hospital where I investigate emerging infectious diseases under the guidance of Dr. Supaporn Wacharapluesadee. The research focuses on detecting, identifying, and characterizing pathogens and human genome segments using molecular and serology techniques, including Next Generation Sequencing and Multiplex serology assays as a part of EID-SEARCH project. Additionally, I am the laboratory sequencing lead on the Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) project from patients in Thailand as part of a collaboration with the Department of Disease Control.

B. Positions, Scientific Appointments, and Honors

Positions and Scientific Appointments:

02/2022 – Present	Medical research scientist, Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital
05/2017 - 01/2022	Scientist, Genetics Laboratory, Jetanin Institute for Assisted Reproduction
10/2015 - 03/2016	Fellowship at Laboratory of Molecular and Cellular Parasitology, Department of Microbiology and Immunology, National University of Singapore, Singapore.
11/2011 – 02/2012	Training Medical Technology Programs at Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Honors:

2012 -2017	Scholarship for Ph.D. from the Royal Golden Jubilee, Ph.D. Grant (14th Batch).
------------	--------------------------------------------------------------------------------

C. Contributions to Science

Undergraduate Research: I participated in research activities under Dr. Attakorn Palasuwan to study in human genetic variants in proteins, such as G6PD, as they relate to the effect of exercise on the reduction of free radicals in the body. We conducted the multiplex PCR to identify the G6PD variants and found 8 variants including Vanua Lava, Mahidol, Mediterranean, Coimbra, Viangchan, Union, Canton, and Kaiping.

Graduate Research: I continued to studies under Dr. Mallika Imwong in the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University. My thesis, "Exploring the molecular mechanism of mefloquine resistance in *Plasmodium falciparum*", focused on the evolution of resistance to mefloquine, which is commonly used in Southeast Asia in Malaria treatment. The mechanism of mefloquine resistance remains unknown, but I focused on the *Pfmdr1* gene which is involved in the drug resistance mechanism in *Plasmodium falciparum*. I found mutations and polymorphisms in *Pfmdr1* gene.

1. **Srimuang K**, Miotto O, Lim P, Fairhurst RM, Kwiatkowski DP, Woodrow CJ, Imwong M; Tracking Resistance to Artemisinin Collaboration. "Analysis of anti-malarial resistance markers in *pfmdr1* and *pfcr1* across Southeast Asia in the Tracking Resistance to Artemisinin Collaboration" *Malar J.* 2016 Nov 8;15(1):541.

Post-graduate Research: I was a scientist in genetics lab at Jetanin, a holistic center for infertility, offering counseling and treatment with Assisted Reproductive Technologies such as IVF, ICSI, and Preimplantation Genetic Testing (PGT). My work included the development of standard operating procedures for the lab, including Next Generation Sequencing, for detecting and identifying chromosomes in blastocyst growth to an embryo. Additionally, we assisted couples who had a family history of genetic diseases for screening before pregnancy. The carrier screening focused on highly prevalent diseases in Thailand such as alpha thalassemia, beta thalassemia, G6PD, and SMA. Currently, I am a Research Scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital. I am currently tasked with using molecular and serological techniques in the surveillance of novel, exotic, and known pathogens in wildlife and humans.

B. Positions, Scientific Appointments, and Honors

05/22-present Visiting Scientist, King Chulalongkorn Medical Hospital, Bangkok, Thailand. Advisors: Dr. Supaporn Wacharapluesadee, Dr. Opass Putchaeron, and Dr. Eric D. Laing.

02/22-present Scientific Project Coordinator, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisors: Dr. Christopher C. Broder and Dr. Eric D. Laing

- 08/20-02/22 Research Associate 2, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 08/19-08/20 Senior Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 06/15 – 08/19 Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 01/14-08/14 Laboratory research internship, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder

C. Contributions to Science

1. **Post-Baccalaureate:** My post-baccalaureate research works primarily targeted understanding the adaptive immune response to emerging zoonotic viruses as a tool for virus discovery. As part of the assay development team, I designed and expressed soluble, native-like filovirus and henipavirus attachment glycoproteins and developed the monoclonal antibodies and antisera used as standards in the assay. I have led technical training for international projects and assisted in data analysis
 - a. Laing ED, Mendenhall IH, Linster M, Low DHW, Chen Y, Yan L, **Sterling SL**, et al. “Serologic evidence of fruit bat exposure to filoviruses, Singapore, 2011–2016”. (2018). *Emerg Infect Dis.* 24(1):114-117. doi: 10.3201/eid2401.170401. PMID: 29260678.

2. **Professional Studies:** While employed, I continued my studies by pursuing a Master’s in Public Health with a focus on Epidemiology. Immediately preceding my thesis work, COVID-19 was declared a pandemic, and I worked along side Dr. Eric Laing to develop and standardize a human coronavirus serological panel to track the serological response to SARS-CoV-2 infections and vaccinations among a military cohort. For my thesis, I evaluated the humoral immune response to SARS-CoV-2 patients as it related to the severity of the disease, where we observed significantly more robust antibody responses in people with more severe disease.

Dear Prof.Linfa Wang

I applied the NIH pilot study in title “Immune memory bait & capture to identify emerging henipavirus origins” last week, please find the attached file.
This includes the PBMC study in Mojiang antibody positive from human in Ratchaburi. Dr. Eric is the mentor in this study.
Please advice how three labs can collaborate on this study.

Thank you very much

Best regards,
Krongkan Srimuang

2. **Professional Studies:** While employed, I continued my studies by pursuing a Master’s in Public Health with a focus on Epidemiology. Immediately preceding my thesis work, COVID-19 was declared a pandemic, and I worked along side Dr. Eric Laing to develop and standardize a human coronavirus serological panel to track the serological response to SARS-CoV-2 infections and vaccinations among a military cohort. For my thesis, I evaluated the humoral immune response to SARS-CoV-2 patients as it related to the severity of the disease, where we observed significantly more robust antibody responses in people with more severe disease.

**CREID Pilot Research Program
2023 Letter of Intent**

Please use this template to submit your Letter of Intent (LOI) for the 2023 Pilot Research Program. Be sure to also submit a Biosketch for the applicant PI and the co-PI if one is included.

LOIs are due December 5, 2022, 5pm ET.

Project Title	Seizing immune memory to identify emerging henipaviruses
Principal Investigator Name	Krongkan Srimuang, Ph.D.
Position/Title	Research scientist
Department	Thai Red Cross Emerging Infectious Diseases Clinical Center
Institution Name	King Chulalongkorn Memorial Hospital
Street	1873, Rama 4 Road, Pathumwan Sub-district, Pathumwan District
City, State, Zip Code	Bangkok 10330
Country	Thailand
Email	Krongkan.sr@gmail.com
Phone	+66 (0) 92-453-0808
CREID Research Center affiliation	The Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH)
The category of eligibility of the applicant(s) (see Section 1.3 of Call for Applications)	LMIC Applicants
Co-Principal Investigator Name (If applicable)	Spencer Sterling, MPH
Position/Title	Scientific Project Coordinator
Department	Microbiology and Immunology
Institution Name	Uniformed Services University of the Health Sciences
Street	Jones Bridge Road
City, State, Zip Code	Bethesda, MD 20814
Country	USA
Email	spencer.sterling.ctr@usuhs.edu
Phone	+66 (0) 83-494-5980
CREID Research Center affiliation	The Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH)
The category of eligibility of the applicant(s) (see Call for Applications, Section 1.3)	

Name of Mentor	Eric Laing, Ph.D.
Mentor Institution	Uniformed Services University of the Health Sciences
Institution Address	Microbiology and Immunology, Uniformed Services University of the Health Sciences, 4301 Jones Bridge Road, Bethesda, MD 20814
Permanent location of Mentor	4301 Jones Bridge Road, Bethesda, MD 20814
Mentor email	eric.laing@usuhs.edu
Mentor phone	(301) 980-8192

Overview of proposed research project	
Pathogen(s) focus	Mojiang Virus, Henipavirus, Paramyxovirus
Country(ies) where work will be conducted	Thailand
Research Aims and Objectives (250 words)	
<p>The recent isolation of Langya virus, a novel henipavirus, from patients with acute febrile illness has provided further evidence that henipaviruses remain an emerging zoonotic virus threat to public health. The prototypical henipaviruses, Hendra virus and Nipah virus, are zoonotic viruses hosted by flying foxes (Pteropus genus) across mainland south/southeast Asia and Australia. The detection of henipaviruses, Mojiang virus and Langya virus, infections in rats and shrews changed the standing dogma that fruit bats were the primary wildlife reservoirs of henipaviruses. Continued vigilant zoonotic virus surveillance of sentinel populations remains critical to detect and identify novel henipaviruses before outbreaks of clinical disease that facilitate virus isolation. However, the</p>	

detection of viremia and virus isolation from wildlife populations remains elusive for these emerging rodent-borne henipaviruses.

Aim 1. Antibody-mediated capture of the Thai MojV-like virus and discovery

Utilize the MojV RBP antigen to bait and capture MojV-like virus specific memory B cells from seropositive human participants. With support from NIH PREMISE, MojV RBP-reactive B cell receptors will be sequenced to generate monoclonal antibodies specific to the MojV-like virus. These monoclonal antibodies will be used for direct antibody-mediated virus capture in ongoing human and wildlife surveillance.

Aim 2. Multidimensional spatial modeling to characterize antigenic relationships between known and unknown henipaviruses.

In addition to LayV and MojV the henipavirus genus has expanded to include two other shrew-borne viruses, Gamak virus and Daeryong virus, and a Madagascan fruit bat-borne Angovkeely virus. Defining the antigenic relationships of these henipaviruses remains a valuable tool for characterizing the serologic signature of related undiscovered henipaviruses. Anti-RBP standards will be developed and utilized to explore serogroups and the antigenic spatial relationships between known rodent-borne, known bat-borne, and the Thai MojV-like virus.

If you are proposing a human subjects' or animal research study, please describe the already approved study it is nested within and your plan to obtain an IRB or IACUC modification for the proposed study within 2 months of award.

This project will collect samples under approved protocols (**EcoHealth Alliance**) and (**King Chulalongkorn Medical Hospital**): (**Protocol Numbers**). We will seek an IRB amendment for human sampling so that we can collect peripheral blood mononuclear cells (PBMC) during the serological sampling for use in Aim 1.

If you are proposing a study involving a select agent, indicate the select agent and address the issue identified in the Call for Applications, Section 1.2 about prior approval.

Dear All,

Thank you for confirming your availability, let's have a quick meeting on:

Wednesday, Nov 30 at 8:00 AM (BKK time)

Tuesday, Nov 29 at 8:00 PM (Eastern time)

We will discuss the general idea to confirm the information for the LOI (template attached)

I have sent you a calendar invite, also including the Zoom link below, look forward to speaking with you!

Eric - it will be helpful if you're free to join the discussion.

Best regards,
Hongying

Dear Krongkan and Spencer,

Thanks for sharing the proposal abstract!

Peter and Kevin reviewed all proposed ideas and think this one perfectly aligns with EID-SEARCH's research objectives and will help answer some important questions.

However, can we meet to further discuss the title and writing regarding the significance of this work? The current text sounds a bit like adding additional lab procedures that have already been covered by current EID-SEARCH work, so we need to make it sound more significant...And please read through the instruction here for the proposal preparation https://creid-network.org/documents/pilot-program/2023/CREIDPilotProgram_CallforApplications_2023.pdf to see the research and objective priorities (e.g., well-defined hypothesis, and human subject research in LOI, etc.)

Please let me know when you will be available for a quick *call anytime next Monday or Tuesday*.

I'm re-attaching two successful applications, as well as some LOIs examples for your reference.

Best,
Hongying

Thank you, Bow!

Kio and Spencer,

Attached are the two successful applications for 2021 and 2022 for your reference.

And can you please quickly write up one paragraph of your proposed idea (like the abstract) **before Monday next week**? We have received eight requests to collaborate this year, so Kevin, Peter, and I need to review all of them together on Monday to decide which three to support, and it would be great if you can send something written-down.

Best,
Hongying

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Vincent J. Munster

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Chief, Virus Ecology Unit

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Utrecht University	MSc	1999 - 2001	Molecular Microbiology
Erasmus University	PhD	2002 - 2006	Molecular Virology
Erasmus Medical Center	Postdoctoral	2006 - 2009	Influenza transmission
Rocky Mountain Laboratories, NIH/NIAID	Postdoctoral	2009 - 2012	Virus Ecology

A. Personal statement

Past outbreaks of bat-borne zoonotic viruses such as coronaviruses, henipaviruses and filoviruses, have had an enormous impact on human and wildlife health. The unpredictability of the zoonotic introductions of these bat-borne limits the potential for effective intervention strategies. One of the main reasons for the absence of successful pre-emptive strategies is our lack of understanding of the ecology, evolution and interaction with the immune system of these pathogens in their respective natural reservoirs. I have gained extensive laboratory and field experience. I have expanded my expertise over the last year towards the field of bat-borne zoonotic diseases (Ebola, Marburg, Nipah and MERS-CoV), conducting field studies in the Republic of Congo and Mali and experimental studies at the Rocky Mountain Laboratories high and maximum containment facility (BSL3 and BSL4). Within the NIAID Virus Ecology unit (http://www.niaid.nih.gov/labsandresources/labs/aboutlabs/lv/virusecology/Pages/default.aspx#niaid_inlineNav_Anchor) my work focuses on natural reservoirs of emerging viruses and elucidation of the underlying biotic and abiotic drivers of zoonotic and cross-species transmission events. Over two decades, I have a demonstrated record of accomplished and productive research resulting in over 190 peer-reviewed publications.

B. Positions and Honors**Positions**

2013 – Present Chief, Virus Ecology Unit, Laboratory of Virology, Rocky Mountain Laboratories, NIAID/NIH
2009 – 2012 Post-doctoral fellow, Disease Modelling and Transmission Section, NIAID/NIH.
2006 – 2009 Postdoctoral research fellow at the Department of Virology, Erasmus Medical Center.

Other Experiences and Professional Memberships

2021 Member WHO virus evolution working group
2020 Member WHO animal working group
2020 Member Operation Warp Speed / CAG
2020 NIAID coronavirus response
2018 DRC Ebola Outbreak: NIAID Internal Coordination Working Group
2018 NIAID Viral Pathogen Preparedness Working Group
2018 Scientific Advisory Board, DTRA Western Asia bat research project
2017 FAO-OIE-WHO global technical meeting on MERS-CoV, Geneva
2017 WHO Global Outbreak and Alert Network workshop meeting, Hong Kong
2017 WHO Environmental Contamination of MERS-CoV meeting, Hong Kong
2016 Graduate faculty appointment, Marshall University, Joan C. Edwards School of Medicine

2016 PhD thesis examiner, University of Melbourne, Australia
 2015-2016 Member the Scientific Advisory Group of the NIAID workshop on MERS animal models
 2015 Member the Scientific Advisory Group organizing the NIAID workshop on MERS animal models.
 2015 Member of the ASPR SPIRiT Ebola environmental working group.
 2015 Member of the ASPR Science Disaster Preparedness working group.
 2014-2015 Team lead of the combined WHO - CDC/NIH diagnostic laboratory during the Ebola virus outbreak, Monrovia, Liberia.
 2014 American Society for Virology, Program Planning Committee.
 2014 Moderator, IOM/NRC Workshop on Research Priorities to Inform Public Health and Medical Practice for Domestic Ebola Virus Disease, Institute of Medicine of the National academy of Sciences.
 2014 Organizer of the fifth ESWI Influenza Conference in Riga, Latvia.
 2014 Scientific organizing committee of the Endemic and Emerging Viral Diseases of Priority in the Middle East and North Africa.
 2013 WHO-ISARIC joint MERS-CoV Outbreak Readiness Workshop.
 2013 Member Coronavirus Therapeutics Interagency Working Group (NIH, CDC, BARDA and DoD).
 2013 Moderator, NIAID MERS-CoV Research: Current Status and Future Priorities Meeting.
 2013 Editor for PLoS One, One Health and Frontiers in Cellular and Infection Microbiology
 2011-2014 Board member of the European Scientific Working group on Influenza.
 2008 Member of the OIE ad hoc Group on Wildlife Disease Surveillance.
 2005-present Reviewer for journals including: Lancet Infectious Diseases, Nature, Nature Medicine, PNAS and Science.

Grant application reviewer

2019 AAAS for the Saudi Arabia's Ministry of Education Research
 2018 BBSRC, UK
 2018 Italian Ministry of Health
 2017 BBSRC (Biotechnology and Biological Sciences Research Council), UK
 2016 USAID Combating Zika and Future Threats Grand Challenge
 2016 FINOVI Foundation, France
 2015 Italian Ministry of Health
 2015 Referee Panel for Health and Medical research Fund, HKSAR
 2015 Human Frontier Science Program
 2012 Referee Panel for Health and Medical research Fund, HKSAR
 2008-2009 National Medical Research Council, Singapore
 2008 Minnesota Center of Excellence for Influenza Research and Surveillance, USA
 2007 Department for Environment, Food and Rural Affairs, UK

Miscellaneous

2014-2015 Team lead of the combined CDC/NIH diagnostic laboratory under GOARN/WHO during the Ebola virus outbreak, Monrovia, Liberia, providing diagnostic services to several Ebola treatment units in the Monrovia area
 2015-2018 Thompson Reuters / Clarivate highly cited researcher 2015, 2016, 2017 and 2018

Honors

2020 AAAS Golden Goose award, COVID-19 response
 2016 European Society for Virology young investigator award
 2015 NIH Director's award, in recognition of the establishment and running of diagnostic field laboratory during the Ebola virus outbreak in West Africa.
 2014 NIAID merit award for the development of a nonhuman primate disease model and a treatment strategy for MERS-CoV
 2014 ASM IAAC young investigator award
 2014 NIH Director's award, in recognition of the exceptional and rapid response to the emergence of MERS-coronavirus.
 2011 European Scientific Working group on Influenza, Best Body of Work award for Young Scientists.

C. Contributions to Science

1 During my PhD working on avian influenza at Erasmus Medical Center, it became clear to me that there was a lack of integration between bench virology and fieldwork. Being trained as a "classical" molecular virologist I could very well answer questions on what mutations would make a virus more pathogenic, but the translation of this knowledge to real world situations remained elusive. Integrating various disciplines helped me to understand the ecology and drivers of avian influenza and pandemic influenza outbreaks.

2 My research group at the Rocky Mountain Laboratories of the NAID/NIH is built around the concept of complete integration of fieldwork, experimental work and computational modeling to allow study of emerging viruses in their natural, intermediate and human hosts. It is clear that past outbreaks of zoonotic viruses have had an enormous impact on human and wildlife health and that the unpredictability of cross-species transmission events limits the potential for effective intervention strategies. My lab aims to identify the underlying changes in virus-host ecology that allow these viral pathogens to cross the species barrier. Recognizing the strengths and weaknesses of a unilateral focus on field research on one hand and experimental research on the other, we have combined both approaches in one research program. This integrated approach has contributed greatly to the rapid advancements in our knowledge on the emergence of MERS-CoV. Using a combination of fundamental concepts of host species restriction of MERS-CoV and protein-protein binding interaction modeling we predicted potential MERS-CoV host species, which were tested in experimental infections. Our field studies in the Middle East confirmed camels as the primary reservoir for MERS-CoV.

3 My research group was directly involved in the response to several outbreaks including the Ebola virus outbreak in West Africa by providing diagnostic support at the request of the WHO for several Ebola treatment units in Monrovia, Liberia and SARS-CoV-2. The emergence of Ebola virus in West Africa highlighted significant gaps in our knowledge, including fundamental ecological questions surrounding zoonotic and human-to-human transmission. In order to understand the drivers of transmission, we examined the stability of the virus within tissues and on body surfaces and determined the potential for transmission. The results from this study directly aided the interpretation of epidemiologic data collected from human corpses and are also applicable to interpreting samples collected from remains of wildlife infected with Ebola virus, especially nonhuman primates, and helped to assess the risk of zoonotic transmission. With the current COVID19 pandemic we are actively involved in the development of medical countermeasures and providing critical experimental data supporting direct public health decisions and interventions.

Subject: [EXTERNAL] NIH Biosketch for Liberia R01 proposal

Hello, all!

Can you please send me your current NIH-formatted biosketches for inclusion in the Liberia R01 proposal? I would like to collect them before the holidays, so if you could send them by December 21st, that would be excellent.

I've attached the current format (and here is the [NIH biosketch webpage](#)). Please let me know if I can answer any questions.

Thank you,
Madeline

Project Abstract
<p>Viet Nam sits within a critical Southeast Asian emerging infectious disease hotspot with diverse wildlife and a rapidly increasing human population. In this region, wildlife farming is a growing but inadequately regulated industry that exhibits many features thought to contribute to increased risks of cross-species transmission and zoonotic disease emergence. We will focus on a key zoonotic disease pathway that was involved in the emergence of Nipah virus, SARS-CoV, and potentially SARS-CoV-2 – the spillover of viruses from wildlife to multi-species farms, and subsequently to people. We will test a key hypothesis: viral diversity and cross-species transmission will increase with species</p>

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

diversity on mixed-species farms, and this pattern will be further amplified by the presence of wildlife species. We will access a previously untouched sample set from 64 mixed-species farms in a biodiverse region of central Viet Nam where wildlife and domestic species are farmed both together and separately. We will characterize viral diversity in single- and mixed-species farms using metagenomics and PCR, identify their zoonotic potential using ecological and phylogenetic methods, and estimate risk of emergence by analyzing distribution and prevalence. To inform the local community of our results, we will develop a two-way dialogue with farmers and government stakeholders in Viet Nam regarding potential disease risks associated with wildlife and mixed-species farming. Importantly, this project builds capacity for emerging infectious disease research in Southeast Asia by supporting the in-country development of analytically robust, hypothesis-driven research into the ecology and evolution of emerging infectious diseases.

Title

Mixed-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Study Personnel

The PI on this project, Dr. Cuong Nguyen, is ideally suited to conduct and manage this project. Dr. Nguyen is trained as a veterinarian and will be defending his PhD thesis (Open University, United Kingdom (UK)) focused on veterinary epidemiology and antimicrobial usage on farms in Viet Nam on 15 March 2021. Dr. Nguyen possesses experience in performing both laboratory- and field-based research, as well as translating research outcomes into locally-relevant interventions and policy recommendations. These efforts have resulted in 20 peer-reviewed publications since 2018. Dr. Nguyen has worked with the Oxford University Clinical Research Unit (OUCRU) since 2011, during which time he acted as a coordinator of veterinary fieldwork for the Wellcome Trust-funded Vietnamese Initiative for Zoonotic Infections (VIZIONS) project, which ended in 2016, and under which the samples for the proposed project were collected. Dr. Nguyen will be responsible for project coordination, data analysis, public engagement, and presentation/publication of the research conducted under the proposed project. He will be allocated 100% protected time to work on this project and his professional development over the one-year period. To ensure that the proposed research can be accomplished on time and within budget, all laboratory work will be completed by a Senior Research Assistant who will be supervised directly by Dr. Nguyen within the Molecular Epidemiology group at OUCRU. Several members of this research group were part of the VIZIONS team and are familiar with the sampling and laboratory protocols required to ensure the completion of this study in a timely manner.

As co-lead of OUCRU's Molecular Epidemiology research group, Dr. Maia Rabaa will be a collaborator on this project and will supervise Dr. Nguyen's research throughout the proposed project. Dr. Rabaa is a molecular epidemiologist with eight years of experience working at OUCRU, and contributed to the design, implementation, and analysis of data related to the VIZIONS project. Dr. Rabaa and her team have access to the relevant samples, were involved in the design and conduct of the VIZIONS project, have significant expertise in sequencing and phylogenetic analysis, and will provide additional support and advice during Dr. Nguyen's laboratory work, analysis, and writing. As the group lead, Dr. Rabaa will also supervise Dr. Nguyen's progress and administrative tasks and assist in the further development of his budget and human resources management skills as he progresses toward scientific independence.

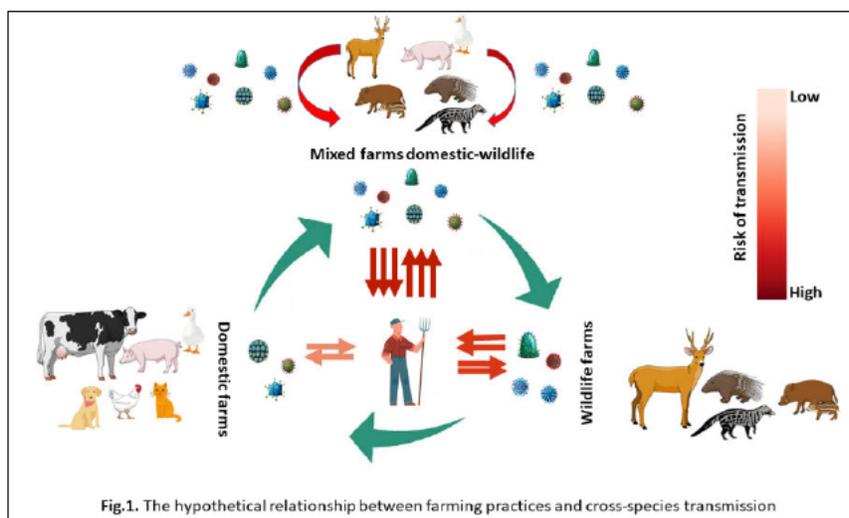

Dr. Cadhla Firth will act as Mentor for Dr. Nguyen under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Firth is Senior Research Scientist and Program Coordinator at EcoHealth Alliance (EHA), which houses the Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH) program. Dr Firth has more than 15 years' experience conducting research on emerging infectious diseases, with a focus on the ecology and evolution of viruses in animal populations. Dr. Firth's expertise in study design, molecular biology, metagenomic sequencing, and the analysis of metagenomic and ecological data match well with Dr. Nguyen's interests and the proposed project. Dr. Firth will provide scientific guidance, analytical training, mentoring, and career advice, as well as networking opportunities that support Dr. Nguyen's progression toward independence.

As colleagues on the VIZIONS project, Dr. Nguyen and Dr. Rabaa have built a strong collaborative foundation that complements the peer mentorship that Dr. Rabaa and Dr. Firth established in 2008 during their respective PhD studies under Prof Edward Holmes, and which continues to this day. With Dr. Firth's recent move to EHA, Dr. Rabaa's promotion to Group Head and subsequent collaboration with EHA, and the completion of Dr. Nguyen's PhD work, this team is now in an advantageous position to deliver a strong research project with tangible outcomes under the CREID Pilot Research Program.

Research Aims and Objectives

This project aims to answer the question: “How does species diversity influence viral diversity and the risk of cross-species transmission on mixed-species farms?”.

We hypothesize that: (i) viral diversity and cross-species transmission will increase with species diversity on mixed-species farms, (ii) the presence of both wildlife and livestock species on a farm will be associated with increased viral diversity, and (iii) the diversity of viruses with zoonotic potential will

increase with species diversity on mixed-species farms. To test these hypotheses, we will access a unique sample set from farms in the Central Highlands of Viet Nam, where a variety of wildlife (e.g., deer, bamboo rats, civets, wild boars, rabbits, porcupines) and domestic species (e.g., chickens, ducks, cats, pigs, goats) are farmed both together and separately. Mixed-species farms create new interfaces between wildlife, domestic animals, and

people that may provide opportunities for cross-species transmission of viruses to occur (Figure 1).

The proposed project has three aims:

AIM 1: Estimate the frequency of viral sharing between animals of different species under mixed- and single-species farming conditions and identify ‘risky’ viruses that commonly cross the species barrier under each of these conditions.

AIM 2: Identify environmental and ecological factors associated with variations in viral prevalence, diversity, or rates of cross-species transmission of ‘risky’ viruses.

AIM 3: Identify farm management policies and practices to increase awareness and reduce the risk of cross-species transmission of viruses associated with mixed-species farms.

The proposed project has three objectives:

OBJ 1: Characterize the viral diversity present in samples from animals housed on single and mixed-species farms using a combination of metagenomics and polymerase chain reaction (PCR)-based screening.

OBJ 2: Identify viruses with known or predicted zoonotic potential using ecological and phylogenetic methods. Estimate the distribution, prevalence, and relatedness of these viruses across animal species and farms.

OBJ 3: In collaboration with the policy and public engagement departments at OUCRU, engage in two-way dialogues with government stakeholders and the farming community in the Central Highlands about potential disease risks associated with wildlife and mixed-species farming.

Study Rationale/Research Gap/Impact

On July 23, 2020, the Prime Minister of Viet Nam issued a new directive (Directive 29/CT-TTg) [1] calling for increased enforcement of legislation regarding the control of wildlife hunting and trade, which has been widely interpreted as a move toward a complete ban on wildlife trading [2]. This follows similar legislation passed in China in February 2020, which introduced new regulations banning almost all consumption and trade of terrestrial wild animals in the country, and which is expected to cause knock-on policy effects across Asia [3]. Commercial wildlife farming has been proposed as a potential solution to problems caused by a ban on wildlife hunting and trade by creating a regulated and monitored source for wildlife products, while supporting conservation efforts and addressing cultural, economic, and food security issues that may otherwise drive these practices into unregulated marketplaces [4–6]. However, wildlife have also been associated with the emergence of many zoonotic diseases, and several features of wildlife or mixed-species farms suggest that they may pose a greater risk to people than domestic farms alone [7–10].

More than 175 wildlife species are farmed in Viet Nam, including those previously associated with zoonotic transmission risks (e.g., civets, primates, rodents) [11]. However, a recent survey of more than 4000 wildlife farms in southern Viet Nam revealed that 70% of farms also raised domestic species (including livestock) [11]. Critically, pathogens with broad host ranges are significantly more likely to emerge in human populations, which suggests that the presence of multiple species (both wild and domestic) on the same farms may be cause for concern due to the potential for cross-species transmission and viral amplification [12–15]. The risks posed by wildlife farming are further complicated by the high frequency of wildlife laundering, which was the dominant form of wildlife production on 26 Vietnamese farms surveyed between 2014 and 2015 [4]. The frequent movement of wildlife from the natural environment into a domestic setting creates a conduit for the emergence of novel pathogens, including those with zoonotic potential. In addition, the majority of farmed wildlife are raised for food, yet there is a lack of veterinary oversight and infection control measures on Vietnamese wildlife farms that is not mirrored in the farming of domestic species in the region. In a census of more than 4000 wildlife farms in southern Viet Nam, an absence of veterinary care was noted in nearly all cases, along with high numbers of sick and dead animals from unknown causes [11].

Despite the clear risks associated with wildlife farming in Viet Nam, there is very limited understanding of the impacts of wildlife and mixed-species farming practices on viral diversity, virus sharing, and zoonotic transmission [15]. However, the renewed interest in wildlife hunting, farming, and trading that has resulted from the hunt for the origin of SARS-CoV-2 has led to a resurgence in effort to understand the impacts of the policies and practices around wildlife farm management. Although a stated aim of this work is to reduce human and animal disease risk, and zoonotic transmission in particular, there remains an extreme paucity of data related to the risks posed by wildlife farming, or specific farming practices that contribute to this risk. For the first time in the proposed project, we will explicitly test the relationships between species diversity and composition, viral diversity, and cross-species transmission on wildlife and mixed-species farms.

Thus, in line with the goals of the CREID network and the EID-SEARCH team, we aim to use previously collected samples from Vietnamese farms to systematically characterize the diversity and transmission of viruses within animal populations on mixed-species farms. We will assess the risk these viruses may pose to human and animal populations, and use these data to assist in the development of farm management practices and policies to mitigate such risks.

Significance and approach

Wildlife farming, hunting, and trade have repeatedly been associated with the emergence of new zoonotic diseases, including SARS-CoV, SARS-CoV-2, monkeypox virus, and Ebola and Marburg filoviruses [16]. However, strikingly little is known about the drivers of disease emergence from wildlife, particularly with respect to the food chain, including wildlife farms. Previous studies on virus diversity and viral sharing along wildlife supply chains have relied exclusively on consensus PCR-based virus detection or have focused on only a single animal species, even on mixed-species farms [15,17,18]. In contrast, this project will use cutting-edge genomic approaches in ecology and evolution within a hypothesis-driven framework to reveal the determinants of viral diversity, abundance, and transmission within mixed-species farms. To our knowledge, this will be the first data-driven project with the goal of providing a foundation for understanding the roles of mixed-species farming, wildlife farming, and species-species interactions as drivers of disease emergence.

Data collected as part of the VIZIONS project represents a unique opportunity to build a holistic picture of the links between wildlife farming practices, viral diversity, and cross-species transmission. VIZIONS, which ended in 2016, involved international research institutions collaborating with Vietnamese governmental organizations and hospitals to collect samples at three sites across Viet Nam to study clinical illness, epidemiology, pathogen diversity, and social and behavioral factors within a One Health framework. The VIZIONS project had two fundamental components: 1) a hospital disease surveillance program to characterize endemic infections, novel infections, and diseases of unknown origin in humans, and 2) a high-risk human sentinel cohort (HRSC) to assess zoonotic disease incidence and cross-species transmission through sampling of both HRSC members and the animals with which they had contact [19]. Most HRSC cohort members (72.8%) were individuals living on farms, with 53.7% of members in Dak Lak Province reporting exposure to farmed wildlife, including deer, bamboo rats, civets, wild boars, rabbits, and porcupines [20]. We have access to untouched animal samples from this unique dataset from Dak Lak Province, which are linked to publicly available metagenomic data [21,22] from co-located samples from farm workers, and to questionnaire data designed to assess zoonotic disease risk. This provides an unprecedented opportunity to examine multiple dimensions of risk in a complex and highly topical system.

This study also provides an opportunity to link zoonotic disease research back to the communities most at risk of novel disease emergence, including the farmers and government health officials who make daily decisions that directly influence disease risk. Community and government engagement activities were key components of the VIZIONS project and these relationships have been maintained by the OUCRU public engagement team. This will enable a dialogue between the project team and a network of key stakeholders (i.e., farmers, provincial and regional animal health officers, public health officials, and representatives of the Departments of Agriculture and Forestry), through which we can identify potential risks associated with mixed-species farming and wildlife trade in these communities. The result of this engagement activity will be an understanding of how policy is implemented at the local level, and the identification of avenues for future collaborative research and engagement that will benefit the community and expand the CREID and EID-SEARCH networks to improve our understanding and response to the risk of zoonotic virus emergence in Viet Nam and across the region.

Research Methods

Site and sample selection.

Our metagenomic analysis will use animal samples previously collected as part of a three-year high-risk cohort study conducted across Dak Lak Province in Viet Nam's Central Highlands (Figure 2). From March 2012 to September 2015, human and animal samples were collected from 64 farms across Dak Lak at multiple time points (median of five visits per farm), including during reported episodes of human illness. Human samples included nasopharyngeal swabs, rectal swabs, and sera, and were associated with questionnaire data to assess human-animal contact and potential risk factors for zoonotic transmission. Human samples collected during illness have been previously analyzed by metagenomic analysis [21,22], and the data are available for comparison with the results of this study. Animal samples primarily included feces and/or rectal swabs (N = 3675), nasal and/or throat swabs (N = 2499), and sera (N = 1245), which were collected from 2251 live animals, comprised of 19 species (12 domestic species, seven wildlife species). These uninterrogated animal samples have been stored at OUCRU in -80°C freezers since the time of collection and are available for metagenomic sequencing in this study.

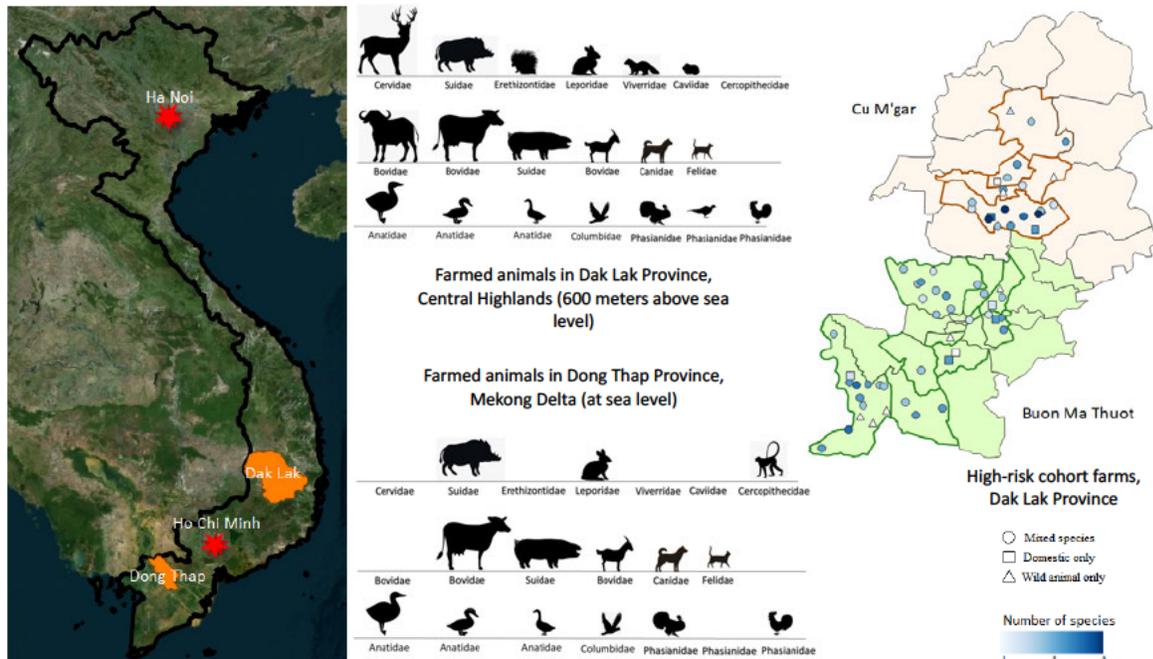

Figure 2. Summary of farmed animals sampled within the VIZIONS project (Dak Lak & Dong Thap Provinces), and distribution of domestic, wildlife, and mixed farms in Dak Lak Province, Viet Nam.

Of the 64 farms sampled as part of the cohort study, 67% contained both domestic and wildlife species, 27% contained domestic species only, and 6% contained wildlife only. The number of species per farm ranged from one to nine, with a median value of five species/farm. To explore the relationships between mixed-species farming, viral diversity, and cross-species transmission, we will select a subset of sampled farms for metagenomics that best capture a gradient of farming intensity in this region. These will include farms with low, medium and high species diversity, as well as farms with and without wildlife (Figure 3). Farms will also be selected to achieve maximum overlap in species composition, whereby the species sampled on low diversity farms are also represented on high diversity farms. As such, we will initially target the most frequently sampled domestic (e.g., chickens, ducks, pigs, cats) and wildlife species (e.g., porcupines, rabbits, wild boar, deer) across farms.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Figure 3. The number of animal species sampled per sampling trip, according to species (select data shown). For example, in the top left corner, wild boar were the only species present on a farm at two sampling events, while one or more other species was sampled on all other sampling involving wild boar. Different shapes and colors differentiate farm types (domestic, wild, and mixed wild/domestic). Additional images illustrate farming practices and species diversity on Dak Lak farms.

RNA isolation and metagenomic sequencing.

It has been estimated that only a very small fraction of viral diversity on earth has been described, such that our ability to contextualize disease emergence and cross-species transmission is strongly skewed towards viral families that have already been well-characterized [23]. This bias is further amplified by the widespread use of ‘consensus PCR’ assays as a mechanism of virus discovery, as this approach attempts to detect new viruses by using sequences from conserved regions of the genome (i.e., primers) of known viruses. As such, this method is likely to be unable to detect viruses that are significantly divergent from those which are already known. In contrast, many recent studies have demonstrated that a metagenomic approach has the ability to reveal the entire virus composition of a sample (i.e., the virome), as well as the relative abundances of each virus [23,24]. We will use this approach to provide a comprehensive view of all viruses present in our dataset.

To comprehensively characterize viromes at both the farm and species level, high quality total ribonucleic acid (RNA) will be extracted from 1000 fecal samples and/or rectal swabs, and 1000 nasal and/or throat swabs (henceforth respiratory swabs) from animals sampled from the subset of farms described above. Fecal samples were selected due to their association with high viral diversity (e.g., coronaviruses, picornaviruses) and the potential importance of fecal-oral transmission in viral emergence and spread [25–27]. Respiratory swabs were selected due to the potential to detect respiratory viruses, which have been associated with multiple significant emerging viral diseases (e.g., SARS, COVID-19, influenza) in the past [28,29]. Extracted RNA will be quantified and samples will be pooled by sample type, species, and farm to achieve a total of 120 pools with a maximum of 10

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

samples/pool. When animal numbers on a farm are low, pooling will be by taxonomic order (e.g., Rodentia, Carnivora, Artiodactyla), rather than by species. Sequencing libraries will be generated from each pool using the Stranded Total RNA Prep with Ribo-Zero Plus kit (Illumina), which includes a ribosomal RNA depletion step to reduce the amount of animal and bacterial RNA sequenced. Libraries will be assessed for quality on the Agilent 2100 Bioanalyzer and sequenced using the Illumina HiSeq-2500 platform at Macrogen (South Korea).

Sequence analysis.

Raw sequencing reads from each pool will be filtered for quality and assembled *de novo* using Trinity RNA-Seq [30]. Assembled sequences will be identified and annotated by comparing them to the complete nonredundant nucleotide and protein databases available through GenBank using E-value cutoffs of 1E-10 and 1E-4, respectively, and the program Diamond [31]. Sequences representing viral genomes will be further characterized using phylogenetic analysis targeting conserved domains (e.g., the RNA polymerase) that will include related viruses from GenBank to estimate evolutionary relationships. Phylogenies will be inferred using the maximum likelihood method implemented in IQ-Tree, employing the best-fit amino acid substitution models for each virus family [32]. The resultant phylogenies will be used along with the Virus-Host DB [33] to identify putative host species for viruses found in feces or rectal swabs, which commonly also contain plant and invertebrate viruses ingested as part of an animal's diet. Only viruses predicted or known to infect vertebrate animals will be investigated in downstream analyses.

PCR-based screening.

A subset of viruses identified from the metagenomic data will be selected for additional analyses based on phylogenetic relationships and host associations, as described above. As a priority, we will select: (i) viruses with known or predicted zoonotic potential (e.g., coronaviruses, paramyxoviruses), and (ii) viruses found at high prevalence and in multiple species that will facilitate the analysis needed to achieve AIM 2. Primers will be designed from the metagenomic data and used to screen relevant individual samples (i.e., not pools). An effort will be made to target regions of the genome likely to contain enough genetic diversity to support phylogenetic resolution at the farm and species level (e.g., the capsid gene, glycoprotein genes). Positive PCRs will be sequenced in both forward and reverse directions using Sanger sequencing technology (Macrogen) and assembled *de novo* using Geneious [34].

Assessing viral sharing.

To address AIM 1, the prevalence of each known or putative vertebrate virus will be estimated for all pools using the reference mapping software BWA, with RNA polymerase sequences from the metagenomic data as a reference [35]. The abundance of each vertebrate virus within a pool will be estimated from the sequencing data using RNA-Seq by Expectation-Maximization (RSEM) [36], implemented in Trinity. These data will be used to compare viral community structure across farms and host species using standard measures from community ecology, including species richness, alpha diversity, and beta diversity, which will be calculated using a range of R packages [37]. Permutational multivariate analysis of variance tests (permanova) will be used to assess differences in virome composition between farms and species.

For a more detailed analysis of the processes underlying viral sharing, the sequence data generated from our PCR-based screening on individual samples will be used to infer virus-specific phylogenetic trees, using maximum likelihood methods (as above) as well as Bayesian inference where phylogenetic resolution is high. Unlike our previous analysis, these phylogenies will contain only samples from this study and will reflect viral genetic variation across individuals, host species, and farms. To assess phylogenetic clustering and cross-species transmission at the farm and species level, we will utilize statistical frameworks developed for the phylogenetic analysis of discrete character states. These will

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

include association indices [38], parsimony scores [39], and maximum exclusive single-state clade sizes [40]. Further, we will impose models of discrete trait evolution [41], often utilized in phylogeographical analyses, to investigate viral sharing and the directionality of cross-species transmission between host species and between farms.

For AIM 2, we will use non-metric multidimensional scaling (NMDS) to ordinate each farm based on a set of ecological and environmental variables using R [37]. This analysis will be performed at two scales – local and regional. The local analysis will include data about each farm that was acquired during sampling or from questionnaires, such as the abundance and diversity of animal species, the presence of sick animals (and type of illness), and human activities previously associated with increased disease risk (e.g., butchering/slaughtering, selling wild animals, eating raw meat, etc.) [42]. In addition, the regional analysis will include variables representing the environmental and ecological context of each farm, which will be estimated from publicly available databases. Examples of these variables include average rainfall, average temperature, the mean normalized difference vegetation index (using LANDSAT data [43]), distance to an urban area, distance to water, and an index of wild mammal diversity (using International Union for Conservation of Nature [IUCN] data). Critically, the regional analysis will also include virus data previously generated and published from farms in Dong Thap Province (**Figure 2**) in the Mekong Delta, which were sampled under the same protocols (ENA accession numbers PRJEB6505, PRJEB26687, PRJEB27881) [18,44,45]. The addition of this second sampling location will allow us to separate the effects of farming practices on viral sharing (local scale) from the impacts of the surrounding environment (regional scale). The ordination axes resulting from the NMDS performed at each scale will be used as predictor variables in independent generalized linear models (GLMs) to examine their influence on virus presence and abundance for the subset of prioritized viruses using R. Model fit will be assessed using the Hosmer-Lemeshow goodness of fit test. The resulting models will be used to identify behavioral, environmental, and ecological factors that best predict the presence of ‘risky’ viruses on mixed-species farms.

Community and policy engagement.

To address AIM 3, we will utilize the results from the above analyses to identify potentially ‘risky’ farming practices, such as high farm-level species diversity, specific host-virus interactions, or interactions between farming practices and the surrounding environment, to engage stakeholders in discussions about the perception and management of risk in mixed-species farming. We will first organize meetings to engage stakeholders responsible for animal health, human health, and farm management within Dak Lak Province. These include provincial and regional animal and human health officials, and provincial representatives of the Departments of Agriculture (overseeing domestic farm management) and Forestry (overseeing wildlife farm management). We will use these meetings to create a two-way dialogue around these issues and better understand how recommendations on farm health and management are disseminated through public policy and farm management structures. Where recommendations on farm management can be made from our findings, we (with the OUCRU public engagement and policy teams) will work within the identified structures to determine the best practices with which to disseminate these findings to animal health workers and farming communities.

Working with these government stakeholders, we will identify opportunities to engage former members of the Dak Lak HRSC from the VIZIONS project in order to share our findings and better understand current perceptions of the risks associated with wildlife farming, particularly in light of potential links to the COVID-19 pandemic. With the OUCRU public engagement team, we will design surveys to initiate future discussions (extending beyond the scope of this proposal) that consider questions related to bans on wildlife farming and consumption at the policy level and their potential economic impacts, as well as perceived risks and approaches to protecting animal and human health at the farm level.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Research Performance Sites

OUCRU in Ho Chi Minh City (HCMC) was the primary site of the VIZIONS project, which ran from 2012-2016. This project involved two components: 1) hospital-based surveillance of pathogens causing selected human illnesses and 2) three cohorts (~300 humans/cohort) of individuals considered at high occupational risk of contracting zoonotic infections. These cohorts were sampled over three years, along with the animals with which they were in contact. The proposed project will focus on animal samples collected under component 2 of the VIZIONS project in Dak Lak Province. All samples needed for this work have been maintained in OUCRU HCMC laboratory freezers at -80°C from the time of collection and can be easily linked to human questionnaire, serological, and pathogen data collected from the human cohorts within OUCRU's in-house data management system (CliRes).

These unique samples and data are available only at OUCRU, which is committed to facilitating the proposed research. Leadership and several staff members within OUCRU's Molecular Epidemiology group (including Dr. Nguyen) were involved in the design and conduct of the VIZIONS project, and will facilitate access to samples and data, as well as assist in sample processing and analysis. Expertise in molecular biology, viral surveillance, phylogenetics, and molecular epidemiology within the research group will ensure that Dr. Nguyen has the support necessary to complete the proposed project.

OUCRU have established state-of-the-art clinical diagnostics, as well as basic and applied research laboratories that will facilitate successful completion of all aspects of the proposed project. Laboratory facilities include: clinical laboratories (ISO 15189:2012 certified), Biosafety level (BSL) 2 and BSL3 laboratories, and a bio-archiving facility. The laboratories are equipped with safety cabinets (fume hoods, biosafety category II and III), shaking & stationary incubators, refrigerated centrifuges, thermocyclers, real-time quantitative PCR machines, a gel imaging platform (chemiluminescence, ultraviolet, and visible light), gel boxes, water baths, mixing devices, capillary DNA sequencers, Illumina MiSeq sequencers, Oxford Nanopore MinION sequencers, an ultra-centrifuge, a Luminex Flexmap 3D, -80°C freezers, -20°C freezers, refrigerators, liquid nitrogen tanks, ice machines, and autoclaves.

Molecular epidemiology research at OUCRU is conducted in facilities across the laboratories, including a specimen processing facility, molecular diagnostic facility, genomics facility, and an immune-biology facility with serology and cell culture capabilities. High-risk laboratory processes are conducted in the BSL3 laboratory. OUCRU maintains a bio-archiving facility (-20°C, -86°C, liquid nitrogen storage facility) containing 2.5 million samples with continuous temperature monitoring and sample tracking (Lab guard system, Freezerworks system, and biometric access control). Dr. Nguyen will have access to all of the infrastructure and support associated with these facilities to complete the proposed project.

All OUCRU employees have around-the-clock access to computer servers, a virtual private network (VPN), encryption software, information technology (IT) support, and all necessary software including: Git and Github (hosted software revision/audit service), Oracle Virtualbox virtual machines, Google Apps (hosted email and collaboration web-based software), Python, NodeJS, and R programming languages, Meteor (Javascript framework), Jenkins (Continuous Integration server), Microsoft Office, and Adobe CS6. OUCRU also has a dedicated 150+ core Linux server with 8 terabyte (TB) hard drives, and the Molecular Epidemiology group has two dedicated 16-core Mac Pro Servers with 4TB hard drives. Either server individually or in combination may be used for intensive sequence analysis, computational modeling and/or database processing by Dr. Nguyen to ensure successful completion of the project.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

CREID Research Center Collaboration

The goals and objectives of the proposed research project, *“Mixed-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam”*, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Viet Nam, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and its OUCRU partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the OUCRU research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between Dr. Nguyen and our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Dr. Nguyen’s professional development and strengthen research capacity in the region. Dr. Cathla Firth, Senior Scientist at EID-SEARCH and the project Mentor, has an established relationship with both Dr. Nguyen and his supervisor, Dr. Maia Rabaa, and will act as the liaison between EID-SEARCH and the OUCRU research team. An expected outcome of this research project will be pilot data to support a joint funding application in the future, led by Dr. Nguyen.

Furthermore, we expect this research to not only improve scientific understanding of zoonotic disease emergence, but also to raise risk awareness among government and local stakeholders and help inform local policies. EID-SEARCH has a team with a strong policy and social science background and extensive experience working with communities and engaging local governments. The EID-SEARCH team will support this project by helping the OUCRU team to develop locally-relevant evidence-based messages, and will strengthen multi-sectoral collaboration in developing practical risk-mitigation strategies. Dr. Nguyen has nearly ten years of experience engaging with local officials and farming communities to develop locally-acceptable research and One Health interventions on the ground in Viet Nam. These relationships Dr. Nguyen has cultivated during his time at OUCRU will facilitate the establishment of a sustainable scientific platform for ongoing research in emerging infectious diseases in Southeast Asia, as well as provide a direct pathway for policy impacts under the EID-SEARCH program.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Mentoring Plan

Although I am scheduled to complete my PhD on March 15, 2021 (viva date), I have been actively involved in research as a veterinarian and Program Coordinator at OUCRU since 2011. As a result, I have a broad understanding of the challenges involved in developing and implementing a research project, and a clear idea of how I would like to progress my career. My overall research goal is to improve the health of people in Viet Nam using a One Health approach that will allow me to maximize the impacts of both my veterinary and academic training. However, my aspirations are not just limited to the creation of scientific knowledge; instead, I wish to actively use this knowledge to address social issues in Viet Nam, as demonstrated by the focus of my PhD research on antimicrobial stewardship on poultry farms.

My previous community engagement experiences have focused primarily on highlighting the need for data-driven policy, and I have had only limited experience working with political agencies to translate scientific evidence into laws and regulations. Through the public engagement aim of the proposed project, I will be able to strengthen my relationships with government and local stakeholders, grow my network across Viet Nam, and enable my long-term success using data-driven, community-led research to generate real-world impacts. By working closely with members of EHA, who have a strong background in community engagement and policy development, and the recently formed Policy Engagement group at OUCRU, I feel that this project will provide the perfect opportunity for me to develop my career vision as an independent scientist.

Throughout my career, I have had experience and training in veterinary medicine, laboratory-based science, program coordination, and epidemiology. However, it is clear that genomics (and metagenomics) is now an increasingly common aspect of emerging infectious disease research. There is a pressing need for increased capacity in this field in Viet Nam, as well as in many other lower- and middle-income countries, to ensure that we have access to the best methods and analytical tools available to support a thriving science industry. I believe that, given the opportunity to further strengthen my analytical skills to include metagenomic data analysis, I will be in possession of a comprehensive skillset that will allow me to transition from a junior scientist to an independent science leader in Viet Nam, capable of initiating and delivering hypothesis-driven research to solve locally relevant problems.

With more than 15 years' experience working on emerging infectious diseases, Dr. Firth (my Mentor) has built a research program with a strong multi-disciplinary focus that is only enhanced by her recent appointment as Senior Scientist with EHA. Her expertise includes nearly 10 years' experience in the generation and analysis of metagenomic sequence data, which she has used in both clinically relevant and veterinary contexts, as well as to address a range of ecological and evolutionary questions [25,46–50]. Dr. Firth also has significant experience with field and laboratory science and has led or participated in projects in multiple countries, including Malaysia, Viet Nam, Australia, Brazil, The United States, and Canada. As a result, she has a broad scientific network that involves global leaders in infectious disease research, including those within Southeast Asia (e.g., Prof. Linfa Wang, Director, Emerging Infectious Diseases Program at Duke-NUS Medical School, Singapore; Prof. David Perera, Director, Institute of Health & Community Medicine, UNIMAS). Dr. Firth will actively create opportunities for me to interact with Prof. Wang and other leading scientists through the proposed research project, which will greatly increase my research network. A two-week visit to Prof. Wang's laboratory has been budgeted as part of the proposed project and will provide me with the opportunity to learn cutting-edge laboratory techniques, as well as interact directly with members of his lab. Dr. Firth has also committed to creating opportunities for me to discuss my metagenomic data directly with Prof. Edward Holmes (a world leader in virus discovery and metagenomics), who is highly supportive of the proposed project.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

In addition to her scientific skills and network, Dr. Firth has previous experiences training and mentoring scientists in lower- and middle-income countries. This should increase the effectiveness of her mentorship since I am also a junior scientist from one of these countries in Southeast Asia. Dr. Firth also has a close personal relationship with my in-country project supervisor and long-term collaborator, Dr. Maia Rabaa, who is co-lead of OUCRU’s Molecular Epidemiology research group. Drs. Firth and Rabaa completed their PhD degrees together and have maintained a strong relationship focused on peer mentorship since that time. As a result of their joint commitment to both this research project and my professional development, I will have access to an extremely high level of support and mentorship both locally and internationally. The combined mentoring, experience, and expertise I will gain through the CREID Pilot Research Program will assist me in my progression toward scientific independence by providing opportunities to develop my grant writing, budgeting, study management, and networking skills, in addition to the new scientific skills I will gain. The data generated as a result of the proposed project will also provide critical pilot data for future grant applications that will form the foundation of a long-term collaborative relationship with EHA.

Through the process of writing the application for the CREID Pilot Research Program, Dr. Firth and I have already established the foundation for an effective communication plan that will continue throughout the project. We have created a WhatsApp group that also includes Dr. Rabaa, which we use to communicate in an informal setting and in real-time. This has been invaluable for sharing ideas, asking questions, and facilitating the development of a good personal relationship that is a pre-requisite for effective mentorship. We have also agreed to a regularly scheduled Zoom meeting that will occur every two weeks, be agenda-driven, and focused on a topic or issue of direct relevance to the research project. Both Dr. Firth and I will be responsible for setting the agenda and following up on action items. I will also attend weekly academic meetings at OUCRU and EHA (over Zoom), which will expose me to the breadth of research at these institutions, and which I have found to be extremely useful for me in the past. Dr. Firth and I have also agreed to extend my visit to the United States to attend the annual CREID meeting to include a visit to EHA in New York City. The timing of this visit will allow me to bring some metagenomic data from the project with me and work through data analysis with Dr. Firth and other EHA scientists. Finally, Dr. Firth, Dr. Rabaa, and I will travel to Dak Lak province in Viet Nam at the end of the project to present the study outputs to the community members that participated in the VIZIONS study, as part of the public engagement aim.

	06/20	07/20	08/20	09/20	10/20	11/20	12/20	01/21	02/21	03/21	04/21	05/21

Vertebrate Animals Section Requirements

No new animal sampling will be conducted in the proposed research study. All samples and data to be used in the proposed research project were previously obtained as part of the VIZIONS project, which concluded in 2016. Samples were collected under a protocol approved by the Oxford Tropical Research Ethics Committee (OxTREC code 157-12), and were locally reviewed and approved by the ethical review board of the Hospital for Tropical Diseases in HCMC, with local review and acceptance at all sites. Viet Nam did not have an animal ethics review board at the time that the VIZIONS project was conducted.

Details on the VIZIONS project are available in a 2015 publication [19].

The principal aims of the VIZIONS project were:

1. To establish a model international collaborative consortium with an integrated approach to human and animal health research.
2. To estimate the burden of viral and zoonotic diseases in Viet Nam.
3. To investigate the disease epidemiology of specified clinical syndromes and infections in a cohort of high-risk individuals occupationally exposed to animals, with targeted sampling from domestic animals and wildlife associated with these individuals.
4. To elucidate the etiology of infectious diseases of unknown origin in the human population and provide a repository of putative pathogens for further study.
5. To characterize genetic diversity within virus populations on either side of the species barrier to understand cross-species transmission and disease emergence.
6. To identify socio-demographic, environmental, and behavioral drivers for disease emergence.
7. To create a platform and resource for further research on zoonotic disease agents.

Key in-country partners on the VIZIONS project included:

- Hospitals (The Hospital for Tropical Diseases, HCMC; Dong Thap General Hospital, Cao Lanh City, Dong Thap Province; Dak Lak General Hospital, Buon Ma Thuot City, Dak Lak Province; Khanh Hoa General Hospital, Nha Trang City, Khanh Hoa Province; Hue Central Hospital, Hue City, Thua Thien Hue Province; National Hospital for Tropical Diseases, Ha Noi; Ba Vi District Hospital, Ha Noi)
- Academic institutions (OUCRU, HCMC; OUCRU, Ha Noi; Hanoi Medical University)
- Regional Animal Health Offices (RAHO5, Buon Ma Thuot City, Dak Lak Province)
- Sub-departments of Animal Health (sDAH) (Dak Lak sDAH, Buon Ma Thuot City, Dak Lak Province; Dong Thap sDAH, Cao Lanh City, Dong Thap Province)
- Preventive Medicine Centers (PMCs) (Dak Lak PMC, Buon Ma Thuot City, Dak Lak Province; Dong Thap PMC, Cao Lanh City, Dong Thap Province; Ba Vi District PMC, Ha Noi)
- Ba Vi District Veterinary Station

Budget Justification

In total, we request \$149,970.57 for Dr. Nguyen for this one-year project, starting 1 June 2021, including: \$50,878.00 for personnel, \$1,200.00 for regulatory fees, \$1,000 for equipment, \$76,473.76 for consumables, \$9,309.88 for travel, and \$11,108.93 for indirect costs. Detailed expenses are calculated as follows:

A. Personnel (\$50,878.00)

Dr. Nguyen, PI, will commit 12 months (1 FTE) per year to this project for study design, supervising the laboratory work, training in new analytical methods, and conducting the metagenomic and epidemiological analyses. Dr. Nguyen is a veterinary epidemiologist specializing in pathogen surveillance at the human-animal interface and will have just completed his PhD studies (15 March 2021). We request \$28,563.00 total salary for Dr. Nguyen for the period of 12 months.

We also request funding for a senior research assistant who will commit 12 months (1 FTE) per year to this project to perform laboratory work and assist in the development of community engagement activities and materials. The research assistant will have significant experience working with and performing virus surveillance/sequencing on samples collected under the VIZIONS project, and will have experience participating in public engagement projects in Viet Nam. We request \$22,315.00 total salary for this research assistant for the period of 12 months.

B. Regulatory fees (\$1,200.00)

An import license from the Ministry of Health will be required for importation of any consumables, equipment, reagents, and biological materials related to this project, at the cost of \$1,200.00.

C. Equipment (\$1,000.00)

No equipment will be purchased with the exception of one laptop computer for Dr. Nguyen. We request budget (\$1,000.00) for one laptop computer for use by Dr. Nguyen.

D. Consumables (\$76,437.76)

RNA Extractions (\$29,170.00). We request (\$29,170.00, \$14.59 per sample) for RNA extractions. This total covers the cost of all kits, reagents, and consumables (MagNA Pure 96 DNA and Viral NA SV Kits, MagNA Pure 96 Processing Cartridges, MagNA Pure 96 Filter Tips, MagNA Pure 96 System Fluid, MagNA Pure 96 Sealing Foil, MagNA Pure 96 Output Plates, Qubit™ RNA HS Assay Kits, Qubit™ Assay Tubes, and TURBO™ DNase) for 2000 extractions.

Metagenomics (\$32,500.00). We request (\$32,500.00, \$270.83 per 10-sample pool) for metagenomic sequencing. This total covers the cost of reagents and consumables for library prep (Illumina Stranded Total RNA Prep with Ribo-Zero Plus kit, Illumina Sequencing Adapters, Agilent AMPure Beads, RNA Clean XP) and sequencing on a HiSeq-4000 at Macrogen (South Korea), for 120 pools.

Follow-up PCRs (\$14,173.56). We request (\$14,173.56, \$11.81 per sample) for targeted RT-PCR following results of the metagenomic analysis. This total covers the cost of all kits, reagents, and consumables (LightCycler 480 Multiwell Plates, 96-Well Half Skirt PCR Plates, Bubble Strip Caps for PCR Strips, SuperScript III One-Step RT-PCR, Primers, Agarose, SYBR™ Safe DNA Gel Stain, DNA Clean & Concentrator-5, Amplicon Sequencing) to cover 1200 reactions.

Other reagents & consumables (\$630.21). We request (\$630.21) to cover miscellaneous consumables. This total covers the cost of tubes, tips, personal protective equipment, and other consumables (varied

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Axygen™ Aerosol Filter Tips, Water - Molecular Biology Reagent, Absolute Ethanol, LoBind Eppendorf tubes, nitrile gloves) required to process samples in the laboratory.

E. Travel (\$9,309.88)

International Travel (\$8,229.00). We request: 1) \$4,335.00 for one trip to the United States for Dr. Nguyen to the CREID meeting in Rockville, Maryland. This total covers one round-trip flight (\$1,600.00), lodging and per diem for 4 days/nights (\$250 per day; total \$1,000), ground transportation costs (\$150.00), insurance and visas (\$185.00), and quarantine costs for 14 days on return to Viet Nam (\$100.00 per day; total \$1,400.00). Additional costs for travel to New York City, lodging, and subsistence during this trip will be covered by EHA. 2) We also request an additional \$3,894.00 for one trip to meet and train with EID-SEARCH partners in Singapore. This total covers one round-trip flight (\$400.00), lodging and per diem for 14 days/nights (\$140.00 per day; total \$1,960.00), ground transportation costs (\$100.00), insurance (\$34.00), and quarantine costs for 14 days on return to Viet Nam (\$100.00 per day; total \$1,400.00).

Inter-province Travel (\$1080.88). We request \$1080.88 for Dr. Nguyen and two OUCRU staff members (one from the Molecular Epidemiology group and one from the Public Engagement team) to travel to Buon Ma Thuot city, Dak Lak Province for discussions with stakeholders and engagement planning activities. This total covers three round-trip flights (\$200.00 per person; total \$600.00), lodging and per diem for 3 people for 3 days (\$43.43 per person per day; total \$390.88), and ground transportation costs (\$30.00). Additional costs for engagement activities will be covered by internal OUCRU funding for Public Engagement activities.

Additional travel

EID-SEARCH (EcoHealth Alliance) will provide additional funding for international travel costs related to additional face-to-face meetings and collaborative work periods for Dr. Nguyen and Dr. Firth.

F. Indirect costs (\$11,108.93)

We are requesting 8% indirect costs on all direct costs (total \$11,108.93).

BIOGRAPHICAL SKETCH

NAME: Nguyen, Cuong, Van

eRA COMMONS USER NAME (credential, e.g., agency login): N/A

POSITION TITLE: Project coordinator

EDUCATION/TRAINING

INSTITUTION AND LOCATION	DEGREE	Completion Date	FIELD OF STUDY
Agriculture and Forestry University (VN)	DVM	09/2008	Veterinary Medicine
University of Paris XI (France)	MSc	09/2011	Biotechnology (Genome, Cells)
The Open University (UK) (thesis submitted, viva March 2021)	PhD	03/2021	Life, Health and Chemical Sciences

A. Personal Statement

I have strong motivation to lead a research project characterizing viral diversity across multiple animal species, particularly in wildlife/domestic mixed species farms. I was involved in the implementation within the VIZIONS project from 2012-2016, acting as a research assistant and field coordinator. My research interests are focused on community-based studies investigating high potential zoonotic diseases and antimicrobial resistance at the animal-human interface. My primary research work during the VIZIONS study was coordinating the collection of high-quality data and samples, as well as establishing critical community partnerships in both the human and animal health sectors. Beyond my field coordinator role, I also processed and tested for the presence of known viruses in animal samples from the VIZIONS project. These studies collected and have reported on varied sources of data (i.e. epidemiological, clinical, laboratory, genomic, and behavioral data) to better understand the epidemiology and emergence of viral zoonoses. I currently coordinate an intervention project (ViParc: Vietnamese Platform for Antimicrobial Reduction in Chicken production) that aims to reduce antimicrobial usage in chicken production in southern Viet Nam. I now have nearly completed my PhD work characterizing antimicrobial usage in chicken production. I have delivered a number of high impact publications focused on key issues in veterinary epidemiology. I am also committed to providing training for local veterinary students on statistics and epidemiology, veterinary public health, and animal welfare (visiting university lecturer).

B. Positions and Honors

YEAR(S)	POSITION
2011-2013	Research Assistant, Oxford University Clinical Research Unit (OUCRU), Viet Nam
2014-2016	Senior Research Assistant, VIZIONS Field Coordinator, OUCRU, Viet Nam
2017-2021	PhD candidate, ViPARC project coordinator, OUCRU, Viet Nam
2020-present	Visiting University Lecturer at the Applied Science Institute, Ho Chi Minh University of Technology (HUTECH), Viet Nam

C. Contributions to Science

1. Zoonotic transmission at the human-animal interface

I played a crucial role in implementing a community-based study of zoonotic infections in Viet Nam under the VIZIONS project. By coordinating high quality data and sample collection, I contributed to the success and unique study design of many VIZIONS-related studies, driving a number of sub-studies investigating pathogen evolution and epidemiology. These studies provided insight into viral, bacterial, and parasitological zoonotic infections presenting in communities in Viet Nam. I played multiple roles on the project, including field work and sampling, laboratory-based screening, and complex epidemiological investigations of pathogen diversity in domestic and wild animal farms, as well as in wild animal populations (capturing bats in the jungle and rats in rice fields).

2. Usage and drivers of antimicrobial resistance in animal production

Antimicrobial resistance (AMR) is a global threat to the health and wealth of nations. The AMR crisis has been attributed to the overuse and misuse of antimicrobials. Excessive use of antimicrobials in animal production is one of the contributing factors to this global threat. In my PhD work, I characterized antimicrobial usage (AMU) in small-scale chicken farms in the Mekong Delta region of Viet Nam. This includes consumption of antimicrobials mixed with water by the farmer as well those included in commercial feeds as antimicrobial growth promoters (AGPs). The epidemiological data that I gathered in

this project was used to investigate the relationship between AMU and disease. Results from this thesis suggest that efforts to promote responsible use of antimicrobials and limit excessive AMU are effective in reducing AMU in animal production, and thus should focus on: 1) educating farmers on good farming practices and simple veterinary diagnostics, and 2) strengthening veterinary systems, including farm audits and provision of effective advice from animal health experts. These studies have also shown that the probability of effective treatment is often very low. My research concluded that the message 'prophylactic AMU does not reduce the probability of disease in flocks' should be further disseminated to poultry farming communities to reduce unnecessary AMU on farms.

3. Understanding AMR in commensal and pathogenic microorganisms in animal production

A better understanding of AMR in both commensal and pathogenic microorganisms in animal production is vital to improve treatment and control, particularly in the context of preventing those bacterial infections in animals as well as the transfer of their genes into human pathogenic bacteria. Epidemiological data from my studies have shown that high levels of AMU resulted in high levels of AMR in both commensal and pathogenic bacteria. These data have resulted in improved treatment and diagnostic policies for animal production across Viet Nam.

A. Personal Statement

I am a molecular and evolutionary biologist who has been working on emerging infectious diseases for almost 15 years. In my current research, I explore the ecological and evolutionary dynamics of emerging zoonoses at the human-animal interface, with a focus on rapidly changing environments. I have more than seven years' experience leading independent research projects in this field, including collaborations with industry and local government. Over time, I have been responsible for the successful completion of every aspect of these studies, including project design, funding acquisition, implementation, and reporting/publishing. In 2015 I initiated a research program to investigate the response of zoonotic pathogens to urbanization in Malaysian Borneo using metagenomics, landscape ecology, and population genomics. This research has a strong multi-disciplinary component that includes evolutionary biology, molecular ecology, virology, pathogen genetics and genomics, field biology, and public health, and has required me to become adept at combining and analyzing multiple types of data, including environmental, ecological, and genomic data. As such, my experience, skills, and training are ideally suited to the proposed research project, which builds naturally on my previous work. I also have a strong track record in the generation and use of genetic and genomic data to explore the transmission dynamics and evolution of emerging viruses, with more than 20 publications in this field, seven of which have been cited more than 100 times since 2010. The mastery of phylogenetic and phylodynamic methods I have developed throughout my career are directly applicable to the proposed research. Further, I am strongly committed to supporting diversity and equity both within the scientific community and in the communities we serve, and have led several projects and initiatives aimed at improving science education and health service delivery for underserved communities in tropical northern Australia. I am also committed to providing training and mentorship for low- and middle-income country scientists and scholars, and in my previous role worked to develop protocols and bioinformatics pipelines to enable portable metagenomic sequencing in rural and remote regions in Australia and the Pacific. I am currently supervising three PhD students and three postdoctoral researchers (James Cook University, AUS).

B. Positions and Honors**Positions and Employment**

2001-2006	Research Assistant, Department of Zoology, The University of Guelph, Guelph, CAN
2006-2010	PhD Scholar, The Pennsylvania State University, State College, PA
2010-2012	Postdoctoral Fellow, Center for Infection and Immunity, Columbia University, New York, NY
2013	Associate Research Scientist, Center for Infection and Immunity, Columbia University, New York, NY

2013-2017	Research Scientist/ Australian Research Council (ARC) Discovery Early Career Research Fellow, Health and Biosecurity, The Commonwealth Scientific and Industrial Research Organization, Geelong, AUS
2017-2018	Australian Research Council (ARC) Discovery Early Career Research Fellow, School of BioSciences, The University of Melbourne, Parkville, AUS
2018-2020	HOT North Career Development Fellow, Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, AUS
2021-	Senior Research Scientist and Program Coordinator, EcoHealth Alliance, New York, NY
Honors	
2003-2005	Ontario Graduate Scholarship, The Province of Ontario (Canada)
2006-2009	Postgraduate Scholarship, Natural Science and Engineering Research Council of Canada
2015-2018	Discovery Early Career Researcher Award, The Australian Research Council
2019-2021	HOT North Career Development Fellowship, Northern Australia Tropical Disease Collaborative Research Programme, National Health and Medical Research Council (AUS)

C. Contributions to Science

Throughout my career, my research has focused on many aspects of infectious disease emergence and has encompassed evolutionary biology, molecular ecology, virology, pathogen genetics and genomics, field biology, and public/veterinary health. My most significant contributions include:

1. The use of genomic and metagenomic sequencing techniques to discover new pathogens, study their evolution, and explore microbial diversity.

I have successfully developed and used cutting-edge metagenomic techniques and bespoke bioinformatics pipelines for: (i) pathogen discovery, including a case of acute encephalitis in an immune-suppressed patient, (ii) studies of viral diversity, including coronaviruses and flaviviruses in bats; and (iii) genomics, including the epizootology of bluetongue virus, the evolution of rhabdoviruses, and the characterization of Australian bunyaviruses. I have also co-authored two perspectives on the utility of next-generation sequencing for pathogen discovery in people and animals. These included an invited submission that described an updated framework for proof of causation in the genomics era and discussed the emerging integration of on-the-ground metagenomics-based diagnostics with molecular epidemiology.

In 2013, I initiated a study that used metagenomics to characterize the viruses and bacteria carried by New York City rats across a range of habitats, with a focus on the built environment. At the time, little was known about the range of potential pathogens carried by urban rodents or the risk factors associated with zoonotic transmission in a city environment. To begin to address this, I designed the first comprehensive molecular survey of rodent-borne microbes in a U.S. city, and demonstrated that urban rats frequently carry a range of zoonotic pathogens. We also found evidence of substantial heterogeneity in pathogen distribution within and between cities, suggesting that the associated risks of human disease may be similarly heterogeneous.

2. I have helped develop the emerging field of urban zoonotic disease ecology.

In 2015, I pioneered an ongoing research program to investigate the response of zoonotic pathogens to urbanization using metagenomic sequencing, landscape ecology, and population genomics. Using a multi-disciplinary approach, this research explores how changes in the environment (e.g., land-use changes, microclimates, etc.), and host community and population structure (e.g., biodiversity, connectivity, density), influence pathogen community composition and zoonotic potential. Initial results of this work indicate that while mammalian diversity decreases with increasing urbanization, connectivity between populations increases, as does microbial species richness and the prevalence of known zoonotic pathogens. This suggests that some features of the built environment may inadvertently support pathogen persistence and spread, and as a result, some zoonotic pathogens may be more likely to emerge with intensifying urbanization. My reputation as an emerging researcher in this field has led to multiple invitations to present as a plenary or symposium speaker at national and international meetings, including the Ecological Society of Australia's Annual Conference (2019) and the Annual Meeting of the American Society of Mammalogists (2019), and the Joint Conference of the Asian Society of Conservation Medicine and the Wildlife Disease Association Australasia (2018).

3. I challenged established beliefs about the ecological and evolutionary processes linked to viral disease emergence, and the timescale over which they occur.

During my PhD, I was able to make significant contributions to this field by questioning the idea that viruses evolve either by cross-species transmission (spillover) or by co-evolution with their hosts, but rarely both. My work demonstrated that viruses with many genomic structures are capable of jumping species barriers, and that evolution through both co-divergence and cross-species transmission may be a

general trend of many virus systems. This has since been supported by numerous subsequent studies that have highlighted the complex evolutionary dynamics of both RNA and DNA viruses.

- a. Pagan I, **Firth C**, Holmes EC. 2010. Phylogenetic analysis reveals rapid evolutionary dynamics in the plant RNA virus genus tobamovirus. *Journal of Molecular Evolution* 71: 298-307. PMID: [20838783](#)

* Name changed from Ramsden to Firth in 2009

4. I was among the first to apply novel phylodynamic approaches to reconstruct the spatiotemporal processes behind disease emergence events.

Phylodynamic methods enable the synthesis of epidemiological, geographic, and phylogenetic data to reconstruct the processes behind infectious disease emergence and spread through time and space. These methods are of particular use for investigating the emergence and spread of viruses, as they have a rapid evolutionary rate that closely matches the timescale of virus transmission. I began to explore these approaches during my PhD and have now successfully used them to: (i) explore the genetics underpinning the rapid emergence and spread of human enterovirus 68; (ii) examine the patterns and processes that influence the diversity and geographic distribution of New World hantaviruses; (iii) explore the epizootology of porcine circovirus 2; iv) understand the evolutionary and ecological drivers behind the distribution of bluetongue virus in Australia; and (v) assess the likely origins of hepatitis C virus.

<https://www.ncbi.nlm.nih.gov/myncbi/1pcDCsap4HMk2/bibliography/public/>

Role: Co-Investigator. My role was to sequence the genomes of SARS-CoV-2 from patients and perform relevant analyses.

Goal: To predict clinical outcomes from SARS-CoV-2 infection using a combination of immunological and pathogen data collected from nasopharyngeal swabs, blood, and urine samples.

Tropical Australian Academic Health Centre Research Assistance Brown J (PI) 2020

Title: Building Research Support for Cairns Hospital.

Role: Co-Investigator. My role was to collaborate with and support clinicians engaging in infectious disease research, and help build a culture that fosters scientific research.

Goal: Cairns Hospital is a regional facility serving as a referral hospital for remote communities across Far North Queensland, yet does not have a strong culture of scientific research. This grant supported collaborations between academics and clinicians working in emerging infectious diseases in this region to improve research output for rural/remote Australia.

HOT North Pilot Project Grant Firth C (PI) 2019-2020

Title: Portable genome sequencing as a point-of-care diagnostic test in remote tropical Australia

Role: Principal Investigator. My role was to design the patient and sampling strategies, design a laboratory workflow suitable for uptake in a clinical diagnostic lab, assist in the development of novel bioinformatics pipelines for clinical metagenomics, and validate the approach.

Goal: To develop a clinical metagenomics ID diagnostic platform suitable for use in rural and remote hospitals and health services in tropical Northern Australia.

Australian Research Council Discovery Early Career Researcher Firth C (PI) 2015-2018

Title: Characterizing the impact of urbanization on viral diversity, ecology and disease emergence

Role: Principal Investigator. My role was project design and management, fieldwork and sample collection, metagenomic sequencing, data analysis and interpretation.

Goal: This project examined the viral response to changes in reservoir host and vector population structure and dynamics that occur as a result of urbanization, and identified viral characteristics associated with survival in an urban environment in Southeast Asia.

NIEHS Center for Environmental Health Pilot Project Grant Firth C (PI) 2013

Title: Identification of rodent-borne human pathogens in an urban environment and the features that influence their presence and prevalence

Role: Principal Investigator. My role was project design and management, fieldwork and sample collection, metagenomic sequencing, data analysis, and interpretation.

Goal: To characterize the zoonotic pathogens present in rats and their ectoparasites in New York City.

A. Personal Statement

I have the experience, expertise, training, and motivation needed to successfully support the proposed research project to analyze viral diversity and cross-species transmission on mixed-species farms in Viet Nam. I am a molecular epidemiologist at OUCRU Viet Nam. I have 8 years of experience in the design and implementation of research in human and animal health in Viet Nam, with a focus on emerging infections, viral zoonoses and antimicrobial resistance. I currently lead the Molecular Epidemiology group at OUCRU: a group of 28 staff (including one postdoctoral scientist, PhD students, clinicians, research assistants and technicians, nurses, and experienced project coordinators).

My primary research interests are laboratory, community, and hospital-based studies investigating the epidemiology, ecology, and evolution of pathogens in human populations and at the animal-human interface. My postdoctoral work focused on the development and implementation of a countrywide study of virus epidemiology and viral zoonoses, called VIZIONS, in which I designed and implemented scientific research and assisted in the management of collaborations across 7 Vietnamese hospitals and 3 local and regional animal health offices. I am now the PI on laboratory work and analyses of samples collected within the VIZIONS study, including identification of pathogens in farmed and wild animal populations. These studies use genomics, epidemiology, clinical, laboratory, and field science to test hypotheses on the emergence of viral zoonoses. Project coordinators currently on my team also worked on the VIZIONS study and maintain valuable links to collaborating institutions focused on human and animal health across the country. My team's previous experience and our nationwide network of collaborators will facilitate a scientifically rigorous study with important buy-in from local communities and health authorities. I have managed various institutional grants and delivered a number of significant and highly visible publications focused on a portfolio of varied pathogens and public health issues.

Further, I am committed to providing training and mentorship for low- and middle-income country researchers. In addition to junior research staff, I have supervised 3 PhD students to completion (University of Oxford [UK], Open University [UK]), and am currently supervising 2 PhD students (University of Oxford [UK]) and 1 postdoctoral scientist.

2007-2008	Research Associate at the Fogarty International Center, U.S. National Institutes of Health, Maryland, USA
2008-2009	Campbell Distinguished Graduate Fellowship, The Pennsylvania State University, USA
2009-2012	Graduate Research Fellowship, National Science Foundation, USA
2012-2015	Postdoctoral Research Fellow at the University of Edinburgh, Edinburgh, UK
2012-2020	Lead Molecular Epidemiologist at OUCRU, Ho Chi Minh City, VN
2015-2020	Research Fellow at the Nuffield Department of Medicine, University of Oxford, UK
2020-present	Molecular Epidemiology Research Group Head at OUCRU, Ho Chi Minh City, VN
2020-present	University Research Lecturer at the Nuffield Department of Medicine, University of Oxford, UK

C. Contributions to Science

1. Pathogen diversity and exchange at the human-animal interface

With Southeast Asia considered a hub of zoonotic transfer, I, with colleagues at OUCRU, the University of Edinburgh, and the Sanger Institute, sought to track the frequency and risks for pathogen transfer at the human-animal interface. I played a pivotal role in designing and implementing a national hospital- and community-based study of zoonotic infections in Viet Nam, driving a number of substudies and conducting analyses investigating pathogen evolution and epidemiology. These studies have uncovered frequent zoonotic infections presenting in clinical settings, and I am now the PI for several continuing analyses using archived samples and data to perform virological and serological investigations of zoonotic infections, as well as investigations of pathogen diversity in farmed and wild animal populations, including bats.

2. Evolution and epidemiology of flaviviruses

In my PhD and postdoctoral work, I performed detailed phylogenetic and epidemiological analyses of flavivirus populations to identify the determinants of novel flavivirus emergence in endemic and epidemic settings. This research showed the utility of connecting epidemiological and genomic data in understanding the spread of vector-borne disease, identifying risk factors (population connectivity, immunity, and climate) for flavivirus emergence at various spatial scales. Genomic studies of viruses sampled during phase III dengue vaccine trials showed that dengue virus genetics play a limited role in determining vaccine efficacy and identified genomic regions of the virus that may be under selection for vaccine escape. In these studies, I designed sampling strategies and conducted analyses of sequence data, clinical and epidemiological surveillance data, and geographical, climatological, and census data.

3. Mechanisms and determinants of antimicrobial resistance (AMR) emergence

Continual emergence of antimicrobial resistance is among the greatest threats to public health. As lead molecular epidemiologist at OUCRU, I have led various investigations of the genetics of AMR and its global spread. Working with collaborators across Asia, I drive both computational and lab-based experimental evolution studies to determine the drivers of the emergence and maintenance of AMR in human and animal populations. These studies have shown that plasmid transfer from healthy human gut microbiota can drive the emergence of resistance in pathogenic *Shigella*, and that inappropriate antimicrobial usage may enhance the frequency of plasmid transfer. Our studies also identify South and Southeast Asia, where inappropriate antimicrobial usage is rampant, as important hotspots of AMR emergence.

4. Typhoid epidemiology, genomics, and the role of carriage in transmission

A better understanding of the role of genetics in typhoid epidemiology is needed to improve diagnostics, treatment, and control, particularly in the context of introduction of typhoid conjugate vaccine in endemic regions. I have recently led and collaborated on studies that have utilized bacterial genomics to investigate the relationships between treatment failure, AMR, and vaccination, as well as to identify the selective pressures induced by gallbladder carriage and to better characterize the potential roles of typhoid carriers in typhoid transmission following large-scale vaccination. Our studies have shown that novel emerging clades of AMR *Salmonella* Typhi can rapidly undermine accepted treatment regimens; these data have resulted in improved treatment and diagnostic policies across Nepal. Novel studies of gallbladder carriage are expected to inform typhoid surveillance, including the identification and treatment of typhoid carriers, thus aiding elimination efforts.

BIOGRAPHICAL SKETCH

NAME: Rabaa, Maia Anita

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: University Research Lecturer in Medicine, Molecular Epidemiology Group Head

D. Additional Information: Research Support and/or Scholastic Performance

Pending Research Support

NIAID/NIH (Grant 13220428) Daszak (PI) 07/2021 – 06/2026

Title: Analyzing the potential for future bat coronavirus emergence in Southeast Asia

Goal: The overall goal of this study is to build a platform to pinpoint the risk of future coronavirus emergence in a region where COVID-19 likely originated, inform strategies to intervene and prevent future pandemics, and provide critical reagents, therapeutic interventions, and recombinant viruses for public health preparedness against future SARS- and COVID-like events.

Role: Co-Investigator (country PI)

Pfizer (Investigator Sponsored Research: Pre-clinical/Clinical) Pham (PI) 03/2021 – 03/2023

Title: The bacterial etiology and antimicrobial susceptibility patterns of lower respiratory and intra-abdominal infections in Viet Nam

Goal: The goal of this study is to characterize and compare the microbiology, antimicrobial resistance patterns, and clinical outcomes of lower respiratory tract and intra-abdominal infections in 6 metropolitan hospitals in Viet Nam between 2019 and 2020.

Role: Co-Investigator

Current Research Support

COVID-19 Research Response Fund, University of Oxford Baird (PI) 05/2020 – 03/2021

Title: Validating GeneXpert platform for SARS-CoV-2 diagnosis for remote sites in Eastern Indonesia

Goal: The goal is to validate the GeneXpert platform using various sample types and to estimate the prevalence of SARS-CoV-2 infection among patients seeking treatment for febrile illness in Sumba, Indonesia.

Role: Co-Investigator

Research grant, Oxford University Clinical Research Unit Rabaa (PI) 02/2020 – 12/2021

Title: Molecular epidemiology of *K. pneumoniae* in bloodstream infections

Goal: The goal is to investigate the epidemiology and evolution of *K. pneumoniae* causing bloodstream infections in southern Viet Nam from 2010-2019.

Role: PI

Research grant, Oxford University Clinical Research Unit Rabaa (PI) 02/2020 – 12/2021

Title: A novel molecular assay for simultaneous detection of pathogen and AMR genes

Goal: The goal is to develop a rapid, inexpensive assay that will allow for rapid screening and pathogen/AMR diagnostics for bloodstream infections in resource-poor hospitals.

Role: PI

Facilities, Existing Equipment, and Other Resources

Laboratory:

OUCRU, in partnership with the Hospital for Tropical Diseases, have established state-of-the-art clinical diagnostic, basic, and applied research laboratories. The laboratory facilities include: clinical laboratories (ISO 15189:2012 certified), BSL2 research laboratories (GLP and GCLP compliance), BSL3 laboratories (MoH, Viet Nam certified), and a bio-archiving facility (Biosecurity compliance). OUCRU laboratories in HCMC and Hanoi are collectively equipped with 29 safety cabinets (fume hoods, biosafety category II and III), 21 shaking and stationary incubators, 36 centrifuges including refrigerated centrifuges that accommodate swinging bucket and fixed angle rotors, six refrigerated microfuges, 12 thermocyclers, five real-time PCR machines, four UV/Visible microplate readers, a gel imaging platform (chemiluminescence, UV, and visible light), gel boxes, water baths, and mixing devices, 11 water-jacketed CO₂ incubators, five inverted microscopes, three fluorescence-activated flow cytometers (one with cell sorting capability), three capillary DNA sequencers, two Illumina MiSeq sequencers, Oxford Nanopore MinION sequencers, two HPLC systems, one GenXpert machine, one ultra-centrifuge, two Chef Mapper XA Systems, one Luminex Flexmap 3D, one Bio-Plex Suspension Array System, 26 -80°C freezers, 77 -20°C freezers, 33 refrigerators, eight liquid nitrogen tanks, a liquid nitrogen shipper, ice machines, autoclaves, and film developers. Molecular Epidemiology research is conducted in several facilities across the laboratories including a specimen processing facility, a molecular diagnostic facility (GeneXpert and RT-PCR based diagnosis), a genomics facility (NGS facility using Illumina MiSeq and Oxford Nanopore MinION systems), and an immune-biology facility (ELISA, Luminex, FACS Lyrics system, Fluoresce microscopy, and cell culture facility). High-risk laboratory processes are conducted in the BSL3 laboratory. OUCRU maintains a bio-archiving facility (-20°C, -80°C, and liquid nitrogen storage facility) containing 2.5 million samples with continuous temperature monitoring and sample tracking system (Lab guard system, Freezerworks system and biometric access control system).

Clinical:

NA

Animal:

NA

Computer:

OUCRU employees have around-the-clock access to servers, VPN, encryption software, IT support, and all necessary software including: Git and Github (Hosted software revision/audit service), BBEdit text editors, Oracle Virtualbox virtual machines, Google Apps (Hosted email and collaboration web based software), Python, NodeJS, and R programming languages, Meteor (Javascript framework), Bash shell scripts, Jenkins (Continuous Integration server), Microsoft Office and Adobe CS6 running on Apple Mac OS X, Ubuntu Linux, and Windows Operating Systems. OUCRU has a dedicated 150+ core Linux server with 8TB hard drives, and the Molecular Epidemiology group has two dedicated 16-core Mac Pro Servers with 4TB hard drives. Either server individually or in combination may be used for intensive sequence analysis, computational modeling and/or database processing by Dr. Nguyen. Access to supercomputing services is maintained by a dedicated staff member from the IT team.

Office:

The applicant will have a dedicated desk in the office of the Molecular Epidemiology Group under the supervision of Drs. Maia Rabaa and Duy Pham Thanh, with expertise in both wet and dry laboratory research.

Letter of Organizational Support

28th February 2021

Dear CREID pilot research program funding committee,

Proposal from Nguyen Van Cuong

As Director of the Oxford University Clinical Research Unit (OUCRU) in Vietnam I would like to confirm my strongest possible support for the application from Nguyen Van Cuong.

Cuong has worked at OUCRU in Ho Chi Minh City since 2011, first as a Research Assistant and Project Coordinator for the Wellcome Trust funded Vietnam Initiative on Zoonotic infections (VIZIONS) project, and since 2017 as a PhD student and Project Coordinator for the ViPARC project (a Veterinary Intervention to Reduce Antimicrobial Usage in Animal Production). He has submitted an excellent PhD thesis (Open University, UK) and is scheduled to defend it on 15 March, 2021. In Cuong's tenure at OUCRU, he has developed strong skills in veterinary epidemiology, project coordination, and biostatistical analysis, along with varied wet laboratory skills. He will make an excellent post-doctoral researcher.

As Cuong moves into his postdoctoral career, the CREID pilot research program presents an excellent opportunity for him to grow in his independence as a scientist while gaining new scientific and program management skills as principal investigator of the proposed project. The proposed project will allow Cuong to develop additional expertise in study design, metagenomic sequencing, and bioinformatics. Additionally, the built-in mentorship program and regional and global networks that will be established through this collaboration with EcoHealth Alliance and the EID-SEARCH team will aid Cuong in designing and developing future impactful research on emerging infectious diseases at the human-animal interface, a topic that is in line with both Cuong's personal scientific agenda and the mission of OUCRU.

If funding is obtained for Cuong's proposal from the CREID pilot research program, OUCRU is committed to providing sufficient support to complete the project. Under this scheme, Cuong will have 100% protected time to complete the laboratory and analytical work to achieve the aims of this 1-year study, while working as a postdoctoral researcher within the OUCRU Molecular Epidemiology group, jointly led by Drs. Maia Rabaa and Duy Pham Thanh.

Cuong will have access to a remarkable collection of archived samples and data from the VIZIONS project for screening and downstream laboratory work, dedicated laboratory and office space within the OUCRU Molecular Epidemiology group, and access to shared laboratory spaces, computational resources, and equipment needed to complete the project. His research will be aided by existing laboratory and analytical expertise in the Molecular Epidemiology group, and a research assistant with experience in viral screening and sequencing will be employed to assist in sample processing and data management. As a member of the Molecular Epidemiology group, Cuong will participate in biweekly lab meetings, with regular opportunities to present and receive feedback on his work. He will also benefit from participation in extensive unit-wide academic and training programs.

I believe that the CREID pilot program will provide Cuong with a unique platform from which to develop veterinary epidemiology research within Viet Nam and across Southeast Asia. He would utilize the

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

knowledge and experience gained under this program to encourage and mentor future cohorts of scientists, veterinarians, and animal health officials in the pursuit of emerging infectious disease and OneHealth research and interventions to improve human and animal health in Viet Nam. He has my complete support.

Yours Faithfully,

(b) (6)

Professor Guy Thwaites FRCP FRCPath FMedSci
Director, Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam;
Professor of Infectious Diseases, University of Oxford

Letter of Collaboration from CREID Research Center PI

Dr. Nguyen Van Cuong
Project Coordinator
Oxford University Clinical Research Unit
Ho Chi Minh City, Viet Nam

Dear Dr. Nguyen,

The Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH) at EcoHealth Alliance is extremely interested in working with you and your collaborators at the Oxford University Clinical Research Unit (OUCRU) in Viet Nam on the proposed research: *“Multi-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam”*.

This collaboration will significantly contribute to the goal of the CREID Network and EID-SEARCH to develop in-country research capacity and build the research network for emerging infectious diseases in Southeast Asia. It will also form the foundation for new partnerships among EID-SEARCH, OUCRU and other in-country stakeholders in Viet Nam, which will strengthen international and multi-sectoral cooperation for emerging infectious disease research in Southeast Asia. Further, the networking, training, and mentorship opportunities embedded within the Pilot Research Program will develop your own skills in mentorship, project management, and supervision within a supportive framework, and grow your network both within and outside of Viet Nam.

Beyond capacity and network building, the proposed research strongly aligns with the core of EID-SEARCH’s scientific goals by exploring links between wildlife farming and several determinants of spillover risk, including farming practices and wildlife species diversity. By using an unbiased approach to virus surveillance and targeting a high-risk human-animal interface (wildlife farming), the proposed work has the potential to make a significant contribution to our understanding of the drivers behind cross-species transmission and infectious disease emergence. I am confident that this work will lead to at least one high-quality publication on the highly relevant topic of wildlife and emerging infectious diseases, particularly given the links between hunting, farming, and trading wildlife and the emergence of new zoonotic diseases, as highlighted by the ongoing COVID-19 pandemic.

I have high expectations for this collaborative research project and expect that this will only be the beginning of our work together. Members of EID-SEARCH (including myself and Dr Kevin Olival as PI and CI of EID-SEARCH, respectively) are committed to working closely with you to develop the research project and support the efforts needed for the success of this application and project implementation. Our Senior Research Scientist, Dr. Cadhla Firth, has enthusiastically joined the project as your Mentor to advise on study design, data collection, and analysis throughout the project. Dr Firth is committed to providing relevant and timely career advice to assist in your professional development, and brings a well-established network across Southeast Asia, Australia, and North America, which includes world leaders in the ecology and evolution of emerging infectious diseases. You will be invited to join all trainings conducted by EID-SEARCH and EcoHealth Alliance on emerging infectious disease field surveillance and statistical analysis to build your skillset, and Dr Firth will work closely with you to develop your skills in pathogen genetics and genomics. EID-SEARCH will also commit funding and arrange exchange opportunities for you to visit our partners in Singapore to expand your skill set in

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

sequencing and serology. You will be supported to present the results of this research at international conferences, as well as meetings with CREID Network and external partners, and to produce high-quality publications from this research.

I am confident that the proposed research collaboration represents a genuine opportunity for your professional development, particularly as you will have successfully defended your PhD on March 15 2021, and are ready to transition to a role with more scientific independence. I am particularly impressed with your extensive work history at the human-animal interface of emerging infectious disease, including as a Program Coordinator with the VIZIONS project, and am confident that you have already begun to emerge as a future leader in this field in Viet Nam.

This letter conveys my strong interest and commitment to making this application a success, and I look forward to working with you on this research project.

Sincerely,

A black rectangular redaction box covers the signature area. Inside the box, the text "(b) (6)" is written in large, bold, red font.

Letter from Mentor

Dr. Nguyen Van Cuong
Project Coordinator
Oxford University Clinical Research Unit
Ho Chi Minh City, Viet Nam

Dear Dr. Nguyen,

This letter is to express my support as your Mentor for your application to the CREID Pilot Research Program, entitled "*Mixed-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam.*"

I am extremely excited that you have chosen me to be your Mentor for the proposed project. The research question is timely and important, and your work has the potential to have a strong impact on our understanding of potential disease risks associated with wildlife farming. Given what we understand to be the likely origins of SARS-CoV-2, there has never been a more pressing need to examine the links between our interactions with wildlife and emerging zoonotic diseases.

I would be hard-pressed to think of a more appropriate applicant to lead this project, given your background in veterinary medicine, epidemiology, and project management. The skills you have acquired during your previous work on the VIZIONS project and throughout your PhD will be enhanced by the Mentorship plan we have developed together. It has become clear to me as we have worked on the Pilot Project application that you are ready to make the transition from a junior scientist to an independent researcher capable of driving your own research projects, and I look forward to the opportunity to support you in this process. Towards this aim, I commit to supporting your professional development in the following ways:

- I will actively work to maintain the healthy, open, and informal dialogue we have established while drafting the project proposal, and I will seek feedback from you on a regular basis to ensure that our communication plan continues to meet your needs as the project progresses.
- I will engage with your current and future in-country collaborators in a supportive and inclusive manner.
- I will create opportunities for you to interact with scientists across my network through your research project to widen your exposure to people with a range of expertise.
- I will give you timely feedback on all material in the manner that works best for you.
- I will provide you with opportunities to present your work to my colleagues at EcoHealth Alliance during our academic meetings and include you in any relevant trainings.
- I will share my scientific and technical expertise with you to help ensure the success of the project. When skills outside my area are required, I will assist you in accessing this expertise from scientists within my network.
- I will assist you in career planning, providing advice and support as required to maximize your opportunity to succeed.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

One of the likely outcomes from the proposed research project will be the generation of pilot data that can form the basis for additional funding applications. The President of EcoHealth Alliance, Peter Daszak, has already expressed his support for a joint funding application that will follow on from the proposed project, with you as the lead PI. This will present the perfect opportunity for you to complete the transition to an independent scientist, and I am committed to assisting you through the process of writing your first funding applications as lead investigator.

There is significant overlap between your research interests and skills, the overall goals of OUCRU, and those of EcoHealth Alliance and the EID-SEARCH team. This pilot project presents a real opportunity for you to become a liaison between these organizations, and to help drive forward future collaborative research projects in Viet Nam. I am thrilled to be able to support you at this critical stage in your career and am genuinely convinced that you have the potential to become a science leader in Southeast Asia in the very near future.

Sincerely,

(b) (6)

Cadhla Firth, PhD
Senior Scientist and Program Coordinator
EcoHealth Alliance

Proposed End Date	30/04/2023

Project Abstract (250 words)
<p>The ability to quickly assess risk of emerging infectious diseases at points of high exposure or contact is paramount for early warning systems and preventative actions. In addition, maintenance of surveillance systems in individual animals is costly and time consuming and prevents widespread coverage. One way to address this issue is to incorporate environmental sampling into surveillance programs to cast a wider net at high-risk interfaces and on a longitudinal basis. To this end, we have begun to incorporate environmental sampling at high-risk human-animal interfaces, including live animal markets, slaughterhouses, and domestic/wild animal interfaces. However, these samples have only been tested for specific pathogens of interest by conventional or real-time PCR, limiting their utility. The ability to use these samples for metagenomic surveillance and pathogen discovery would not only increase surveillance capacity, but also contribute to our understanding of new or emerging pathogens at these high-risk interfaces. Therefore, in the proposed project, we will: (1) utilize existing environmental samples from longitudinal pathogen surveillance to build metagenomic sequencing and bioinformatics capacities and capabilities; (2) assess the suitability of environmental metagenomics as an early warning system for endemic and emerging infectious diseases at high-risk interfaces in Cambodia; and, (3) potentially discover new, emerging, or zoonotic pathogens of concern in high-risk interfaces in Cambodia. Overall, the results from this study will potentially help to improve surveillance systems through rapid and broad pathogen detection, reduced cost, lowered occupational risk, and diminished animal and environmental impact.</p>

Study Personnel

Jurre SIEGERS, Ph.D., (Postdoctoral Researcher) is a postdoctoral researcher in the Virology Unit at IPC in charge for planning and conducting research on zoonotic viral diseases, including avian influenza and coronaviruses. Dr. Siegers currently oversees all avian influenza virus surveillance efforts of IPC. Dr. Siegers has been vital in implementing COVID-19 sequencing at Institut Pasteur du Cambodge. Dr. Siegers will plan, oversee and conduct sample processing, data collection, and analysis for this proposal. He will also be instrumental in preparing data and publications stemming from this work. He will meet with the mentors and technical personnel on a twice-weekly basis to discuss results, issues and future work. Dr. Siegers's commitment to this project constitutes 25% of his total professional effort for the year (3 calendar months).

Vireak HEANG, MS.c., is a research engineer at sequencing platform at IPC in charge of providing sequencing service to other scientists across the unit at IPC. Mr. Heang has an extensive experience over 15 years on molecular biology technique including PCR, Sanger sequencing and NGS. Prior to move to IPC Mr. Heang was working at US Naval Medical Research Unit. 2 (NAMRU-2), the place where he went through various training programs, on-the-job experiences and finally developed a deep understanding of molecular techniques and how it can be used in detection, characterization, and epidemiological modelling of pathogens. When he moved to IPC July last year, Mr. Heang managed to pull all the resources together to make the Illumina Miseq system functioning and he made this happen through his effort and the result was several runs of COVID-19 and Malaria specimens successfully sequenced. Mr. Heang will handle logistic, laboratory work and data analysis of this project. He will meet with the mentors and technical personnel on a twice-weekly basis to discuss results, issues and future work. Mr. Heang will be allocated 25% of his work to this proposed project.

Erik KARLSSON, Ph.D., is a Senior Research Scientist (Assistant Professor equivalent) and acts as the Deputy Head of the Virology Unit at Institut Pasteur du Cambodge. He is an expert on Respiratory Viruses, including SARS-CoV-2, and will act as the Primary Scientific Mentor for Dr. Siegers and Mr. Heang. He is the Director of the National Influenza Center in Cambodia, Director of the WHO Regional H5 Reference Laboratory, and Coordinator of the WHO Global COVID-19 Reference Laboratory housed in the Virology Unit. He is also Co-PI of the Sequencing Mini-Platform formed at IPC in 2021. He will meet regularly with the co-PIs to review experimental progress, troubleshoot issues, interpret data, and participate in preparation of publications resulting from this research.

Cadhla FIRTH, Ph.D., is part of the CREID EID-SEARCH Research Center and will act as the Research Mentor for Dr. Siegers and Mr. Heang. Dr. Firth is Senior Research Scientist and Program Coordinator at EcoHealth Alliance and holds a position as an Adjunct Senior Research Fellow at James Cook University in Australia. Dr. Firth has more than 15 years' experience conducting research on emerging infectious diseases, with a focus on the ecology and evolution of zoonotic pathogens at human-animal interfaces. Dr. Firth's expertise in molecular biology, metagenomic sequencing, and the analysis of genomic and metagenomic data match well the goals of the proposed project. Dr. Firth will provide methodological and analytical guidance, mentoring and career advice, and networking opportunities that support the co-PIs progression toward independence, as well as assisting in the preparation of publications or future funding applications that may arise from this work.

Research Aims & Objectives

The ability to quickly assess zoonotic disease risk at potential points of high exposure or contact is of paramount importance for effective early warning systems and the initiation of preventative actions. Therefore, **this pilot project aims to answer the question: “Can metagenomic pathogen discovery on environmental samples improve the speed, comprehensiveness, and cost of existing pathogen surveillance programs?”**

In Cambodia, current pathogen surveillance systems rely primarily on sampling and testing individual animals – a practice that is both costly and time consuming, and prevents widespread coverage of all high-risk areas. **One way to address this issue is the incorporation of environmental sampling (ES) into surveillance programs.** ES includes samples or swabs taken from soil, water sources (drinking, carcass wash, lakes and ponds), feeding sources, feathers, air, and surfaces such as cages, chopping boards, and defeathering machines. As such, **environmental pathogen surveillance casts a wide net at high-risk interfaces, potentially improving surveillance coverage and supporting expanded sampling on a longitudinal basis.** After collection, samples are currently tested using a series of molecular diagnostics targeting a range of pathogens, another cost- and time-limiting factor. We hypothesize that utilizing metagenomic pathogen discovery with ES can: **(i)** improve, expand and simplify existing methods of pathogen surveillance; **(ii)** reduce the cost of pathogen surveillance programs; **(iii)** reduce direct contact between people and large numbers of animals, thereby improving biosafety, animal welfare, and reducing occupational exposure risks; and **(iv)** set a precedent for lower-middle income countries (LMICs) to conduct broad pathogen surveillance cost-effectively.

To test these hypotheses, we will utilize a **large and unique biobank** from Cambodia that includes previously collected **paired samples** from individual animals and ES. These samples originate from ongoing longitudinal surveillance studies for: **(i)** avian influenza viruses in live bird markets (LBMs); **(ii)** swine influenza and Nipah virus in swine abattoirs **(iii)** bat-borne viruses from caves, roosts, and guano farms.

The proposed project has *three aims*:

AIM 1: To assess the suitability of environmental metagenomics as an early warning system for endemic and emerging infectious diseases at high-risk interfaces in Cambodia.

AIM 2: To utilize biobank environmental samples from longitudinal pathogen surveillance programs in Cambodia to build metagenomic sequencing and bioinformatics capacities and capabilities in Cambodia.

AIM 3: To discover new, emerging, or zoonotic pathogens of concern at high-risk interfaces in Cambodia.

The proposed project has *four objectives*:

Objective 1: Characterize and compare the viral diversity present in samples from individual animals (poultry, swine, bat guano/urine) and environmental samples (wash water, air samples, cage swabs), using a combination of metagenomics and polymerase chain reaction (PCR)-based screening methods. **Endpoint:** Comparison of 129 animal samples with 207 ES across 3 species for 3000+ viral targets

Objective 2: Assess whether a surveillance system that incorporates both environmental sampling and virus detection through metagenomics is sensitive and specific enough to replace or support conventional virus surveillance programs. **Endpoint:** Comparative sensitivity (detecting the same virus) in metagenomic versus previously detected pathogens by RT-PCR.

Objective 3: Discover previously undetected, (re)-emerging, and/or zoonotic pathogens of concern at high-risk interfaces in Cambodia. **Endpoint:** Sequencing 2M reads/sample to ensure coverage and maintain cost-effectiveness.

Objective 4: Build capacity and capability in metagenomic sequencing and bioinformatics at Institute Pasteur du Cambodge. **Endpoint:** Successful implementation of a user-friendly metagenomic sequencing and analysis platform.

Study Rationale/Research Gap/Impact

Emerging infectious diseases are a major and ongoing threat to global health and the economy as illustrated by the ongoing SARS-CoV-2 pandemic and a record-breaking avian influenza outbreak across Asia, Europe, the Middle East, and North America. Asia, especially Southeast Asia, is a hotspot of endemic and emerging infectious diseases, including avian influenza viruses (AIVs), and bat-borne viruses such as coronaviruses and henipaviruses with pandemic potential¹⁻⁴.

Cambodia is a resource poor, lower-middle income country in tropical Southeast Asia with a large socio-economic dependence on agriculture⁵. Since 2011, Institut Pasteur du Cambodge (IPC) has maintained active longitudinal pathogen surveillance programs at key live bird markets (LBMs), farms/slaughterhouses/storage facilities (poultry and pigs), and at locations where a diverse range of Cambodian bat species roost. These locations represent high-risk human-animal interfaces, where known zoonotic pathogens circulate and novel disease emergence events are likely to occur^{6,7}. Sentinel and research pathogen surveillance systems are conducted by IPC for the early detection/warning of known emerging infectious disease to support and inform Cambodian public health systems and the global virus community. Currently, these surveillance programs use PCR-based pathogen detection, which relies on specific or pan-virus primers to amplify conserved genomic targets from an individual virus family. While this approach has led to the successful identification of novel viruses in the past, reliance on conserved genomic targets limits detection of sufficiently divergent pathogens, including those that arise through recombination or reassortment^{8,9}. These surveillance efforts are also labor intensive, expensive, limited to known hotspots, and highly species-specific (both animal and viral family). To this end, we have begun to supplement our traditional surveillance methods, which depend on sampling directly from animals, with ES at high-risk human-animal interfaces. These samples include water, swabs, and air samples, which are collected alongside samples taken from individual animals, enabling a direct comparison of pathogens identified from environmental samples with those collected from individuals.

Despite the clear risks associated with Cambodian LBMs, pig farms/slaughterhouses, bat guano farms and caves, there is very limited understanding of virus diversity at these sites. However, the hunt for the origin of SARS-CoV-2 has led to a renewed interest in the viruses present at live animal markets and across the wildlife supply chain, as well as in viruses carried by bats. Hence, improved surveillance of poultry, pigs, bats and other wildlife (as putative reservoirs and intermediate hosts of zoonotic viruses) will be key for the development of early and effective disease prevention and intervention measures by identifying viruses with known or predicted zoonotic potential at high-risk interfaces, where pathogen spillover is most likely to occur. The ability to use environmental samples for metagenomic pathogen surveillance and discovery would not only increase surveillance capacity, but also contribute to our understanding of new or emerging pathogens at these high-risk interfaces. Environmental sampling has several benefits compared to individual animal sampling: 1) **Biosafety benefits**. Handling animals for sampling is risky, both for the animal (discomfort and distress) and the handler (increased exposure to zoonotic infections, trauma from bites/scratches, etc.); 2) **Economic benefits**. Sampling individual animals requires increased sample numbers, trained personnel, more personal protective equipment, increased number of molecular tests, and time which are costly. Short-term and long-term storage of individual samples requires additional space in -80 freezers and/or liquid nitrogen. 3) **Increased comprehensiveness**. Environmental sampling expands the source of sampling to include animal excretions from multiple animals and/or species (urine, feces, saliva), contact material, and aerosolized particles. As many zoonotic diseases are effectively transmitted through the environment (i.e., respiratory viruses, enteric viruses), sampling from these sources may more directly represent human disease risk at key interfaces.

Significance and Approach

Backyard livestock farms, LBMs, and wildlife farms often have limited biosafety measures in place despite representing potentially risky human-livestock-wildlife interfaces, and as a result, have repeatedly been associated with the (re-)emergence of zoonotic diseases¹⁻⁴. Therefore, developing early warning systems at these high-risk locations will be critical for monitoring and preventing zoonotic diseases from generating the next pandemic. Previous pathogen surveillance and virus diversity studies at human-livestock-wildlife interfaces in Cambodia have relied heavily on consensus PCR-based virus detection, and/or focused on only a single animal species¹⁰. These methods are time consuming and costly and may result in delayed disease detection and reporting. Every second counts between first detection and response. Indeed, the total cost of an outbreak grows exponentially as time from detection increases, making identification critical at emergence or early stages of spread¹¹. It is critical to get “left of sneeze.”

To this end, the proposed project will use and evaluate cutting-edge metagenomic approaches for multiple viral pathogens on broad coverage samples as a modern alternative to pathogen surveillance at high-risk interfaces. Comparison to standard methods will be conducted under a hypothesis-driven framework to reveal the diversity, abundance, and zoonotic potential of viruses circulating in high-risk locations for emergence. To our knowledge, this is the first data-driven project with the goal of providing a foundation for the role of metagenomic ES in monitoring virus prevalence and emergence in Cambodia.

Like much of South/Southeast Asia, Cambodia is a hotspot of endemic and emerging infectious diseases. However, despite active, longitudinal surveillance efforts, outbreaks still frequently occur and data on virus diversity at high-risk human-animal interfaces are still lacking¹²⁻¹⁴. Additionally, as a Least Developed Country, the economic impacts of endemic agricultural and human seasonal pathogens are high, making surveillance for novel emerging pathogens at the animal-human interface a costly lower priority. Furthermore, it is increasingly difficult to obtain samples and/or data from some countries in the region, increasing the importance of Cambodia as a critical location for monitoring zoonotic disease emergence. The unique biobank of samples we have collected as part of active, longitudinal surveillance programs represents a remarkable opportunity to compare standard pathogen surveillance using individual animals and PCR with metagenomic ES to determine viral diversity and viral abundance.

Outcomes from this pilot study will provide invaluable data on improved and cost-effective surveillance practices within a “One Health” perspective. This is critical, as viruses will likely jump to new hosts from the water they drink, the surfaces they touch, and the air they breathe - less likely because they are kissing a chicken. **Environmental sampling reduces occupational risk, improves animal welfare, and can have non-invasive or reduced impact on market trade and wildlife habitats.** Improving our ability to monitor multiple pathogens in the environment will increase our capacity to develop and communicate key biosecurity practices and guidelines to reduce risk, and influence policy. Environmental sampling with multiple pathogen detection will also reduce the overall cost of surveillance systems, which is a key consideration in resource-limited settings. Expanded pathogen detection with reduced sampling means being able to conduct surveillance over a broader area and/or more frequently, greatly enhancing the ability to detect a potentially pandemic-level pathogen at a high-risk interface. Indeed, rough estimations from the budget of this pilot project alone predict surveillance could double in length or breadth for a single pathogen itself, let alone the 3000+ targets included in each enhanced metagenomic run.

Thus, in line with the goals of the CREID network and the EID-SEARCH team (to improve the detection and surveillance of important emerging viruses), we will use previously collected samples from high-risk human-animal interfaces in Cambodia to systematically characterize and compare viral diversity within and between environmental and animal samples from the same locations. We will evaluate the benefits of incorporating ES into existing surveillance programs as a means to broaden pathogen

surveillance efforts without increasing the cost of these programs at high-risk interfaces and on a longitudinal basis. We will develop and utilize user-friendly protocols and analysis pipelines **allowing for broad implementation in a resource-limited country.**

Research Methods

A total of 334 (129 animal pools and 205 ES pools/individual) will be analyzed in this pilot research project.

Poultry Surveillance – 224 samples (120 animal pools/104 ES pooled and individual)

Our metagenomic analysis will use environmental and animal samples previously collected as part of AIV surveillance programs at Cambodian LBMs and farms/slaughterhouses/storage facilities for poultry and pigs, which occurred from 2018 to April, 2022⁹. Sampling was performed at two major LBMs – Orussey Market in Phnom Penh province and Takeo Market in Takeo province (**Figure 1**). The LBM at Orussey Market is the largest LBM in Cambodia and the most extensively studied. The LBM at Takeo market is often associated with the emergence of new influenza subtypes, possibly due to its proximity to Viet Nam and the absence of biosafety and biosecurity measures^{5,15}. Sampling at these markets occurred 16 times/year, and wash water samples (N=152), and cage swabs (N=55) were collected along with a multitude of individual animal samples from chickens (N=2240), ducks (N=2240), and other poultry. Air sampling using the Thermo Scientific™ AerosolSense™ Sampler was also conducted at three locations in and around the LBMs (N=33). **From this biobank we will select 10 paired ES and animal sampling sessions for metagenomic sequencing and analysis.** Together, this provides us with a unique sample set to observe virus diversity in animal versus ES samples in heavily sampled LBMs.

Figure 1. Overview live bird market (LBM) at Orussey Market, Phnom Penh province. A) Defeathering machines. B) Paired throat and cloacal sample collection. C) Air sampling machine at the poultry holding facility. D) Air sampling machine at poultry slaughter site.

Pig Surveillance – 54 samples (9 animal pooled/45 ES pooled and individual)

Ongoing pig surveillance studies are funded by NIAID/NIH - Centers for Excellence in Influenza Research and Response (CEIRR; 2021-2028) and include individual animal samples and environmental samples (air, cage swabs, and water) collected in three different provinces across Cambodia. Sampling locations were pig farms at high-risk interfaces (slaughterhouses) with minimal biosafety measures in place (**Figure 2**). A total of 45 individual pigs were sampled over three sessions, along with air samples, cage swabs, and wash water samples.

Bat Surveillance – 56 samples (35 animal ES individual/21 air ES individual)

Bat sampling sites for this proposal were chosen based on previous research efforts by IPC in Phnom Penh, Kampong Cham, Stung Treng, Kampot, Kandal, and Battambang provinces (Figure 2)^{10,16,17}. Our standard pathogen surveillance protocol for bats focuses on the collection of urine and guano; here, these will be referred to as animal samples, although it is worth bearing in mind that they may be representative of multiple animals in some cases. Sample collection for this project is performed under the FAO-USAID and includes air, guano, and urine samples collected in and around seven locations of bat caves, roosting sites, and/or guano farms. Air samplers (N = 21) are deployed at cave entrances, roosting trees, and bat guano farms where large groups of individual bats congregate, maximizing the capacity to sample many individuals collectively. In parallel, air samplers were fitted with a sterile plastic cover (2m x 2m) to collect urine and feces (N = 35) to compare the viruses identified in air samples with those from bat excretions.

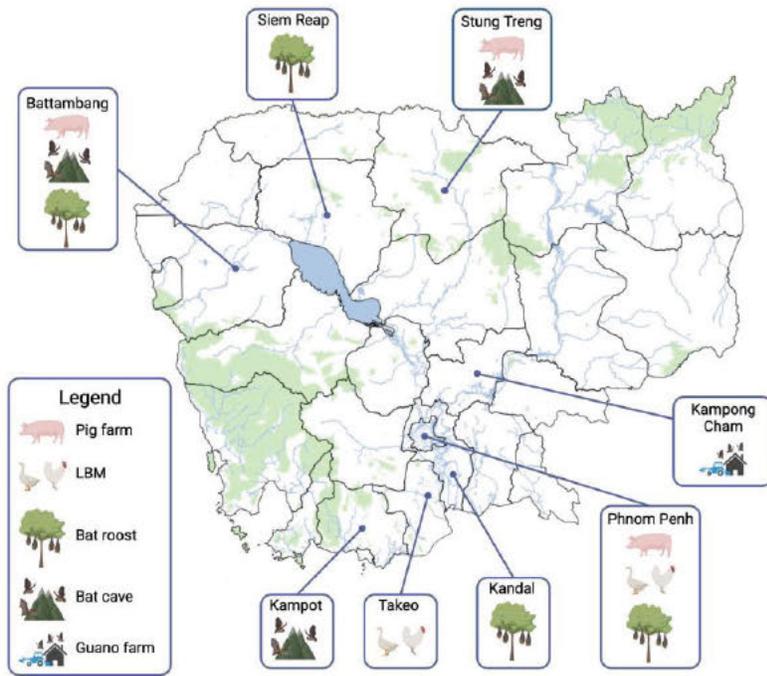

Figure 2. Location and type of sample previously collected in Cambodia and readily available for the proposed study.

Metagenomic Sequencing. While the advent of metagenomic sequencing was a significant step forward as a tool for pathogen detection and discovery, it remains relatively expensive and lacks the analytical sensitivity required for a true pathogen surveillance platform. Target enrichment panels were developed in response to this issue, but, until recently, were unable to facilitate the detection of highly divergent strains or novel viruses^{10,18}. In this project, we will use a cutting-edge hybridization-based target enrichment approach - The Twist Comprehensive Viral Research Panel (CVRP) – that was designed to explicitly address this need¹⁹. The CVRP contains more than a million probes covering the

genomes of 15,488 strains from 3,153 unique viruses (including animal viruses), and is tolerant to mismatches between virus and probe, supporting the detection of novel zoonoses. These include ssRNA, dsRNA, ssDNA, and dsDNA viruses belonging to every virus family capable of infecting people. Thus, target enriched metagenomics represents an ideal balance between the promise of unbiased virus detection and the feasibility of the standard tool of public health surveillance programs everywhere – quantitative PCR.

Prior to preparation for metagenomic sequencing, individual animal samples will be pooled by sampling session: 10 samples will be pooled for chickens and ducks per market (2 markets) per visit (10 selected visits), respectively; five samples will be pooled from pigs. Bat guano/urine will be run individually (Table 1). Wash water samples will be pooled by sampling session (N=2/session), as will cage swabs (N=5/session), while all air samples will be processed individually. Wash water samples will be pelleted and concentrated using ultrafilters²⁰ prior to RNA extraction.

In this project, we will follow the manufacturer’s recommended protocol for the generation of hybridization-enriched sequencing libraries, under the guidance of Prof. Linfa Wang at Duke-NUS, who

has been involved in the development and implementation of target enriched metagenomic sequencing for several years (see attached letter of support). Briefly, high quality total RNA will be extracted from

Table 1. Sample types and numbers (pools) from paired sampling locations selected for target enriched metagenomic sequencing.

System	Animal sample type	Animal number	sample	Environmental sample type	Environmental sample number
Poultry	Cloacal swab	Chicken: 600 (60)		Wash water	120 (60)
	Cloacal swab	Duck: 600 (60)		Cage swabs	55 (11)
				Air samples	33
Pigs	Nose/snout swab	45 (9)		Wash water	18 (9)

each (pooled) environmental and animal sample using the RNeasy PowerMicrobiome Kit (Qiagen). RNA will be quantified and converted to cDNA using ProtoScript II First Strand cDNA Synthesis kit and random primers (New England Biolabs). The NEB Next Ultra II Non-Directional RNA second Strand Synthesis kit (New England Biolabs) will be subsequently used to convert single-stranded cDNA to dsDNA, and Illumina TruSeq-compatible libraries will be generated using the Twist Library Preparation Enzymatic Fragmentation kit (Twist Bioscience). These libraries will be hybridized for 16 hours with the set of 120 base pair biotinylated probes contained within the CVRP (Twist Bioscience) and sequenced with 2x75 bp paired-end reads on an Illumina MiSeq platform housed at IPC. Twelve target enriched libraries will be sequenced per run to achieve approximately 2 million reads/sample.

Metagenomic data analysis. For target enriched metagenomics to have utility as a public health surveillance tool, data analysis must be user-friendly and understandable to a non-expert in bioinformatics. Towards this aim, we will assess the performance and user-experience of two leading cloud-based metagenomics platforms for virus detection and compare the results to those generated by our bespoke bioinformatics pipeline²¹. Analysis of data generated by the CVRP is supported by One Codex software, a cloud-based platform for microbial genomics that will be used for preliminary data analysis and visualization²². One Codex uses a rapid, highly sensitive k-mer classification algorithm that maps sequencing reads to their custom database, which consists of more than 115k microbial genomes. The raw classification results are filtered through several statistical post-processing steps designed to eliminate false positive results caused by contamination or sequencing artifacts. We will analyze the same data using Genome Detective, a web-based platform that sorts sequence reads into bins prior to *de novo* assembly and compares the assembled contigs to the NCBI RefSeq and Swissprot UniRef90 databases, respectively, for virus identification²³. Each of these platforms is contained within a point-and-click, web-based interface and reports results using easy-to-understand visualizations, with click-through options for additional details should the user wish to perform analyses beyond pathogen detection. Finally, we will analyze these same data with our bespoke bioinformatics pipeline (representing the gold standard approach), which uses Trinity RNA-Seq for *de novo* assembly²¹, followed by comparisons with the complete non redundant nucleotide and protein databases available through GenBank using E-value cutoffs of 1E-10 and 1E-4, respectively, and the program Diamond²⁴. Additional full genome assembly will be attempted for all known or potentially zoonotic viruses identified by any of the three analysis approaches using either metaSPAdes (for *de novo assembly* of highly divergent viruses), or BWA MEM for reference mapping of known viruses^{25,26}. Sequences representing viral genomes will be further

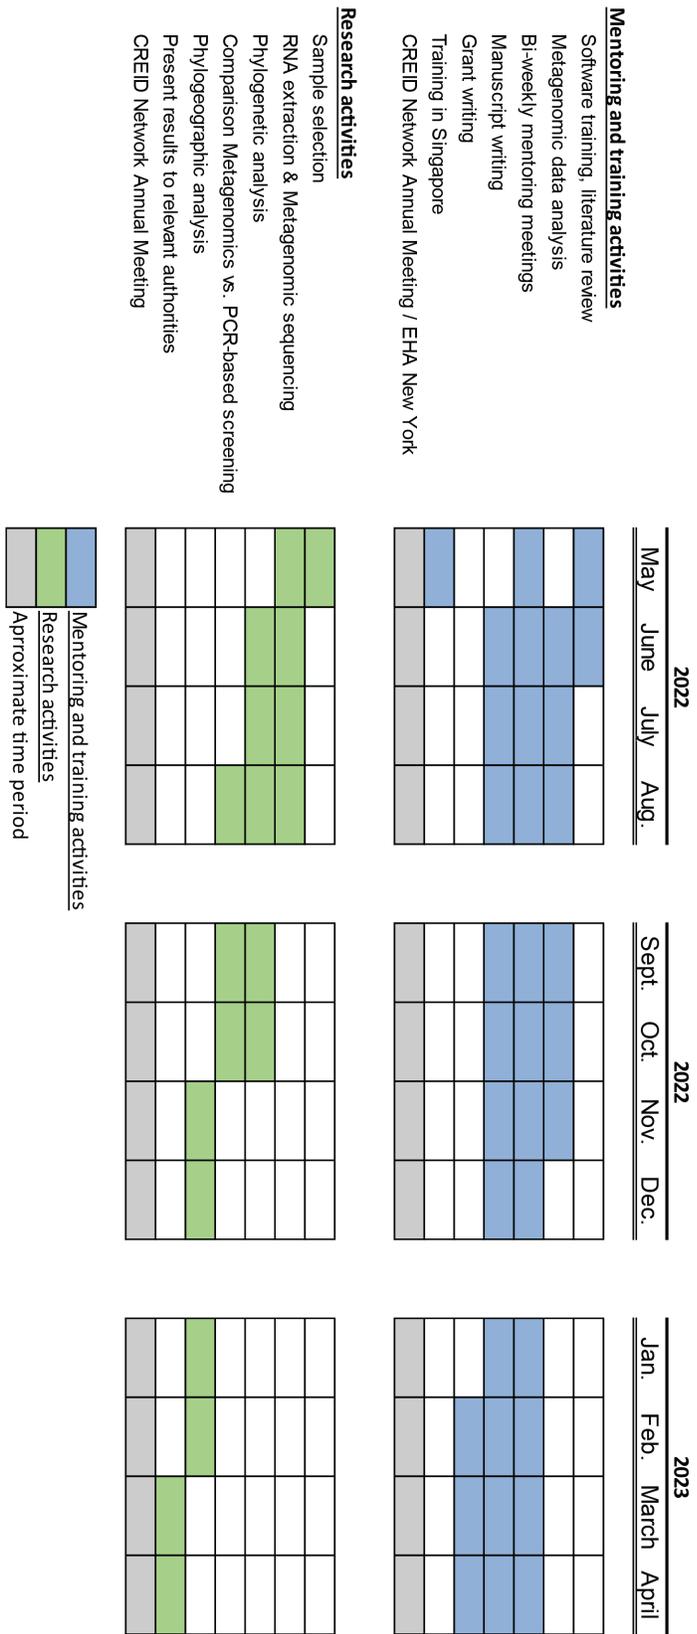

characterized using phylogenetic analysis targeting conserved domains (e.g, the RNA polymerase) that will include related viruses from GenBank to estimate evolutionary relationships and infer potential zoonotic disease risk. Phylogenies will be estimated using the maximum likelihood method implemented in IQ-Tree 2, employing the best-fit amino acid substitution models for each virus family²⁷. The resultant phylogenies will be used along with the Virus-Host DB²⁸ to identify putative host species for viruses found in environmental samples, where genetic material from multiple host species may be present.

Assessing the utility of target-enriched environmental metagenomics for pathogen surveillance. First, we will interrogate the utility of ES as a tool for pathogen surveillance by comparing metagenomic data from environmental samples with metagenomic data from animal samples collected at the same time and location. From each sequencing library, we will calculate the following metrics: number (and identity) of virus families identified, number (and identity) of unique viruses identified, and percent genome coverage for each virus. These will be combined by sample type and sampling session (as replicates) to provide a snapshot of circulating viral diversity at each time/place. The metrics associated with each environmental sample type will be compared to those from the corresponding animal samples from the same time and location. This will allow us to assess what proportion of virus diversity in a host population is detectable from the environment, as well as to identify any taxon-specific biases in environmental sampling, if present. We will also compare viral community structure across sample types using standard measures from community ecology, including species richness, alpha diversity, and beta diversity, which will be calculated using a range of R packages²⁹. Permutational multivariate analysis of variance tests (permanova) will be used to assess differences in virome composition between sample types.

Next, we will examine the utility of target enriched metagenomics as an alternative to traditional molecular diagnostics (qRT-PCR and consensus PCR). As part of our routine pathogen surveillance efforts, individual animal samples from these same sampling sessions have previously been tested for the following pathogens: **Poultry** – AIV and Newcastle disease virus; **Pigs** – influenza, African swine fever virus, classical swine fever virus, Nipah virus, and porcine reproductive and respiratory syndrome virus; **Bats** – coronaviruses, Nipah virus, orthomyxoviruses. The results of these tests will be compared to the metagenomic results from environmental and animal samples to evaluate how well this approach recapitulates the results from standard pathogen surveillance efforts.

Potential Pitfalls and Alternative Plans: Overall, this is a straight forward study using novel and readily accessible samples. Any resultant data will be extremely useful in understanding the benefits of ES over animal sampling for pathogen surveillance. No issues are foreseen with utilizing retrospective samples for metagenomic sequencing; however, storage and collection issues can affect sample quality. If insufficient samples are available, IPC plans to continue surveillance activities throughout the period of this project and fresh samples can be collected for analysis. In addition, given the need to maintain cost-effectiveness, only 2M reads will be collected per sample using CVRP. A series of spike-in experiments will be conducted to ensure sequencing reads and dept is adequate for known viruses before conducting sequencing on precious samples to ensure detectability (not funded through this project). At the current time, no internationally recognized guidelines exist on the use of environmental sampling (ES) and data management. It is hopeful these studies will contribute to future guidelines surrounding the use of ES in surveillance sampling.

Project Timeline

Research Performance Sites (1-page limit)

The Institut Pasteur in Cambodia, established in 1953, is a non-profit research institution operating under the auspice of the Cambodian Ministry of Health (MoH) and the Institut Pasteur in Paris, France. IPC missions are: **(i)** to conduct innovative life science and health research on infectious and emerging disease in Cambodia; **(ii)** to provide public health services; **(iii)** to contribute to training and capacity building in the field of biomedical and life science.

IPC constitutes a strong team and a state-of-the-art facility with modern, secured and standardized laboratories appropriate for experiment with hazardous pathogens. These laboratories include biosafety level (BSL) 2 and 3. The BSL3 facility comprises four modules dedicated to different and separate activities including a safety cabinet with gloves box allowing BSL3+ safety conditions. The proposed project will take place within The Virology Unit at IPC, which serves as the reference laboratory for COVID-19, Influenza, Arboviruses, and Rabies for Cambodia, and conducts surveillance and research on endemic, emerging, and zoonotic pathogens. To respond to the COVID-19 pandemic, the Virology Unit at IPC has recently increased its sequencing capacity to include both Oxford Nanopore (GridION and MinION) and Illumina MiSeq technologies.

The Virology Unit works closely with the Epidemiology/Public Health, Entomology, Bacteriology, and Malaria Units at IPC, as well as national and international partners, to conduct One Health-focused surveillance and studies in Cambodian people, domestic animals, and wildlife. As such, IPC is continually searching for new and innovative ways to expand and improve surveillance activities. IPC also serves as a model for state-of-the-art research in a Least Developed Country/Low-Middle Income Country and successful studies at IPC can inform future work in the region.

All samples needed for this work have been maintained in IPC laboratory freezers at -80°C from the time of collection and can be easily linked to collection and pathogen metadata. These unique samples and data are available only at IPC, which is committed to facilitating the proposed research. Please see “12.10 - Facilities and Resources” for a more detailed description of infrastructure and equipment available at IPC to ensure the success of this project.

CREID Research Center Collaboration (1-page limit)

The goals and objectives of the proposed research project, “In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on improving, expanding and simplifying existing surveillance efforts to cast a wider net for pathogen surveillance and monitor virus diversity at key human-animal interfaces and on a longitudinal basis we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, uses archival samples, and includes a robust individual development and capacity building component that together corresponds to the overall research strategy of CREID and EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of applying metagenomics to pathogen surveillance and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on robust surveillance networks to timely identifying emerging zoonotic threat at key human-animal interfaces the proposed research is both timely and likely to yield highly-cited, impactful publications and policy recommendations for EID-SEARCH and its IPC partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic, genomic, and bioinformatics analyses, who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the IPC research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between Dr. Jurre Siegers and Vireak Heang and our partners in Southeast Asia (based in Singapore, Australia and the US) that will facilitate Dr. Jurre Siegers and Vireak Heang professional development and strengthen research capacity in the region. Dr. Cadhla Firth, Senior Scientist at EID-SEARCH and the project Mentor, has an established relationship with both Dr. Jurre Siegers and his supervisor, Dr. Erik Karlsson, and will act as the liaison between EID-SEARCH and the IPC research team. An expected outcome of this research project will be pilot data to support a joint funding application in the future, led by Dr. Jurre Siegers.

Mentoring Plan

The co-PIs, Vireak Heang and Jurre Siegers, are at different stages of their respective careers with discrete professional development goals. This Mentoring Plan allows the co-PIs to pursue independent professional goals while working as a team to achieve the learning and development objectives associated with the proposed project.

1. Developing Leadership and Independence

Vireak Heang: My long-term goal is to train the next generation of Cambodian scientists. I can pass on my knowledge in my native language, Khmer, providing greater educational opportunity to all Cambodians. The opportunity for future scientists to learn in their native language is a critical step towards rebuilding the scientific infrastructure of my country. Prior to joining IPC, much of my work was technical, with limited experience in project management. However, at IPC, my Scientific Mentor, Dr. Karlsson, took an immediate interest in my professional development and is actively involving me in the entire scientific process – from conception, to study design, implementation, and analysis. As a result, we have developed a strong mentoring relationship built on trust and mutual respect that will continue across this project to improve my scientific career. My Research Center Mentor, Dr. Firth, has a broad scientific network, and regularly interacts with scientists across Southeast Asia in her role as a Project Coordinator for EID-SEARCH. To strengthen my ability to communicate complex scientific topics, both Mentors will actively provide opportunities for me to interact with and present my research to other scientists across Southeast Asia and through their respective global networks of research partners.

Jurre Siegers: My overall research goal is to improve the health of people, animals, and ecosystems using a “One Health” approach that will allow me to maximize my academic training, and scientific and personal interests. I wish to develop my skills in novel diagnostic tools, such as metagenomics, to contribute to improved surveillance and research capacity in the field of emerging viruses at human-animal interfaces. However, my aspirations are not just limited to the generation of scientific knowledge, methods, and policies. Instead, I wish to actively use my knowledge in virology (Ph.D. training) and emerging infectious diseases (Postdoctoral) to train the next generation of Cambodian scientists that will one day be local leaders in the field of emerging infectious diseases. As my Scientific Mentor, Dr. Karlsson has already demonstrated his commitment to my scientific progress by providing me with opportunities to develop project management skills and improve my scientific writing. Both Mentors will continue to mentor me in this capacity. Both Mentors have also been actively guiding me in grant writing (including with this proposal) and will continue to provide hands-on instruction. Both Mentors will support my attendance and participation at (inter)national conferences on emerging zoonotic diseases and provide opportunities to present my work to scientists at IPC, EcoHealth Alliance (EHA), and across EID-SEARCH/CREID. Both Mentors will also provide me with networking opportunities from across their respective networks as they support my development to become a more independent leader in the field of emerging infectious disease research.

2. Building Expertise in Metagenomics

Vireak Heang: My extensive experience and training in laboratory-based sciences has developed a deep understanding of molecular techniques and how they can be used in the detection, characterization, and epidemiological modeling of pathogens. While my work has primarily dealt with shotgun and amplicon-based sequencing, metagenomics is a critical tool for pathogen detection and discovery. In Cambodia, this

capacity is very limited; however, we recently set up the IPC Sequencing Mini-Platform (Illumina MiSeq and ONT technologies) and are exploring the full potential of this system. Given the opportunity to strengthen my hands-on and analytical skills to include metagenomics, will broaden my skillset, and further transition me to scientific independence in Cambodia, capable of using cutting-edge genomics techniques to solve locally relevant problems. Dr. Firth has more than 15 years' experience in the generation and analysis of genomic and metagenomic data in the context of zoonotic disease detection, discovery, and characterization (including BSL3), and is experienced in training and mentoring scientists from LMICs in Southeast Asia. She is therefore an ideal mentor in this area and will work closely with me to develop laboratory SOPs and workflows for metagenomics that are fit-for-purpose at IPC. In addition, Dr. Firth has arranged for me and Dr. Siegers to visit Prof Linfa Wang's laboratory at Duke-NUS Medical School in Singapore for training in cutting-edge molecular techniques, as well as to interact directly with members of his lab.

Jurre Siegers: In Cambodia and other LMICs, there is a pressing need for increased capacity in the field of (meta)genomics, which is becoming increasingly common in emerging infectious disease surveillance and research. Given the opportunity to further strengthen my analytical skills to include genomic and metagenomic data analysis, I will be in possession of a skillset that will allow me to make significant career steps as a junior scientist, capable of initiating and delivering hypothesis-driven research at the forefront of virology and emerging diseases. I will also actively work to disseminate this knowledge to local scientists and staff to ensure that these methods and tools are available to Cambodian scientists, and to support national and international surveillance efforts. Dr. Firth has a wealth of experience in viral sequence analysis, phylogenetics, and phylodynamics, and a broad network of experts in this field. She will work closely with me to develop my technical skills in this area and will facilitate interactions across her network as needed to achieve the analytical goals of the project and build my expertise in this area.

3. Communication Plan

Through the process of writing the application for the CREID Pilot Research Program, the four of us have established the foundation for an effective communication plan that will continue throughout the project. We have already created a WhatsApp group used to communicate in a real-time, informal setting. This has been invaluable for sharing ideas, asking questions, and facilitating development of good interpersonal relationships - the foundations of effective mentorship. We have also agreed to regularly scheduled Zoom meetings (every two weeks) that are agenda-driven, and focused on a topic or issue of direct relevance to the research project. Both the Co-PIs and the Mentors will set the agenda and follow-up on action items. Co-PIs will meet weekly in-person with Dr. Karlsson to discuss project developments, troubleshoot, and develop skills in project and budget management. In addition, the Co-PIs will attend weekly academic meetings at IPC in person and at EHA (remote), which will expose them to the breadth of research and broaden their knowledge base.

Finally, we have scheduled two in-person visits between Dr. Firth and the Co-PIs. The first will coincide with the CREID annual meeting and will include a visit to EHA's headquarters in New York City. This visit will focus on learning relevant analytical techniques, performing preliminary data analysis, and networking with EHA's scientists and staff. Towards the end of the project, Dr. Firth will join us in Cambodia to assist in preparing and analyzing our data for publication and will discuss future directions and plans for future funding following on from this project.

Vertebrate Animals Section Requirements

Projects involving animal samples were collected (2019-2021) under a protocol approved by National Ethics Committee for Health Research under the Ministry of Health, Cambodia (NECHR143, NECHR149, and NECHR320); however, Cambodia did not have a specific animal ethics review board at the time the collections were conducted. Continuing ethics approvals (NECHR013) for projects involving further animal sample collections in 2022 are in revision and projected to be approved in February 2022.

Human Subjects Research

This proposal will not involve experimental procedures with or on human subjects and is therefore not applicable.

A. Personal Statement

I first began conducting research in 2006 when I was hired by the US Naval Medical Research Unit No. 2 (NAMRU-2) in Phnom Penh Cambodia and I am now working at Institute Pasteur of Cambodia as a Research Engineer for the sequencing platform. My first position at NAMRU-2 was as a Molecular Biology Laboratory Technician. In this role, I was introduced to the exciting world of infectious disease surveillance in one of the global hotspots of these diseases. Over the next 15 years, I rose to become the Head of Molecular Diagnostics where I oversaw a diverse team of 10 people that conducted molecular detection and characterization of pathogens. Utilizing technologies such as RT-PCR, Sanger sequencing, and Next Generation Sequencing (NGS), we collected and analyzed data on infectious pathogens that was critical not only for the US Department of Defense, but also for the Cambodian Ministry of Health, and the Cambodian Armed Forces. Through various training programs and on-the-job experiences, I have developed a deep understanding of molecular techniques and how they can be used in the detection, characterization and epidemiological modeling of pathogens. In 2017, the NAMRU-2 laboratory was chosen by the Global Emerging Infectious Surveillance and Response System (GEIS) to be one of the NGS and Bioinformatics (BI) Consortiums. The goal was to rapidly detect and characterize known, emerging, and novel infectious agents through the establishment of a harmonized Department of Defense laboratory capability that uses data from NGS and BI to inform armed forces health protection decision making. As part of the consortium, each laboratory was sent a set of blinded specimens and we were to run, analyze, and send the report back to the consortium. My role was to set up and manage the plan for running and analyzing those blinded specimens using our in-house techniques, and we correctly identified 85% of the pathogens that the consortium sent us. I have since managed to sequence a variety of specimens - from bacteria isolates to clinical specimens - using Illumina Miseq, including Escherichia coli, Salmonella spp., Shigella spp., influenza virus, Chikungunya virus, and Dengue virus. In my current role, I am a designated expert on Illumina sequencing and assist scientists from across all different units at IPC, regardless of discipline. Recently, I managed to successfully sequence 96 respiratory specimens for SARS-CoV-2 using the Illumina Miseq ARTIC protocol.

My work has encompassed all aspects of infectious diseases from human-specific diseases to analyzing zoonotic transmission at the animal-human interface. From these experiences, I have come to understand the “whole” of health as it applies to animal and environmental reservoirs and the dynamics of transmission. I also have experience across multiple levels of research – from hands-on work at the bench, to team lead, to leading an entire department executing multiple projects. Through these varied responsibilities, I have developed a keen knowledge of how to manage both projects and teams, excellent communication skills, and programmatic expertise. My personal goals are to continue to expand my knowledge and abilities in molecular science. I am keenly interested in the dynamic relationship that microorganisms, especially pathogens, have with their hosts, including natural reservoirs and spillover hosts. By understanding these interactions, I feel we can develop better protections against disease, whether those be through enhanced detection, novel prophylactics, or targeted therapeutics.

B. Positions, Scientific Appointments and Honors

2020-Present	Research Engineer, Institute Pasteur of Cambodia.
2013-2020	Molecular Biology Project Manager, US Naval Medical Research Unit.2
2010-2013	Laboratory Technician, US Naval Medical Research Unit.2
2006-2008	Laboratory Technician, US Naval Medical Research Unit.2, Contractor
2001-2006	Laboratory/X-ray Technician, International SOS clinic.

C. Contributions to Science

1. My early publications focused on the reemergence of Zika virus in Cambodia. My work first began by detecting and describing a case report of Zika infection in a Cambodian citizen in 2010. The identification of this index case signaled that ZIKV was still circulating in Cambodia. Continuing the investigation, we sequenced the Cambodian isolate with four other isolates from across the globe, expanding the number of characterized isolates in Cambodia from two to seven. Our results demonstrated that there appeared to be two distinct lineages of ZIKV circulating, one originating in Africa and one from Asia.

PMID: 22389730; PMCID: PMC3289602
 - c. Ladner JT, Wiley MR, Prieto K, Yasuda CY, Nagle E, Kasper MR, Reyes D, Vasilakis N, **Heang V**, Weaver SC, Haddow A, Tesh RB, Sovann L, Palacios G. Complete Genome Sequences of Five Zika Virus Isolates. *Genome Announc.* 2016 May 12;4(3):e00377-16. doi: 10.1128/genomeA.00377-16. PMID: 27174284; PMCID: PMC4866861.
2. A second focus of my work has been the detection and characterization of drug resistance in bacterial pathogens circulating in Cambodia. Cambodia lacks regulation in the use of antibiotics and thusly the use of incorrect antibiotics and/or improper dosing is common. This has led to a rise in multi-drug resistant strains of bacteria across the country. My worked has helped detect the presence of antibiotic resistance in Cambodia and characterize the mechanisms of resistance using molecular techniques.

PMID: 32824772; PMCID: PMC7460656.
3. Finally, I have also contributed to broad topics including drug resistance in malaria and observational studies into the causes of sepsis. Cambodia has experienced malaria treatment failures to multiple frontline drugs, creating great concern should these resistant strains continue to proliferate. My work helped to evaluate the efficacy of new combinations of drugs in the treatment of malaria. Sepsis continues to be a significant cause of morbidity and mortality, especially in areas with a rudimentary health care system such as Cambodia. I contributed to the seminal description of the causes of sepsis in Cambodia through the use of next generation sequencing techniques for pathogen detection and characterization.

A. Personal Statement

I am virologist who has been working in the field of emerging infectious diseases since 2013. During my PhD training in the Department of Viroscience at the Erasmus Medical Center in Rotterdam, the Netherlands, I studied the extra-respiratory tract complications of (zoonotic) influenza A virus infection using a wide range of disciplines that included virology, immunology, molecular biology and pathology. Following completion of my Ph.D., I began to pursue a research career focused on emerging respiratory viruses at the human-animal interface in Cambodia that incorporates surveillance, viral evolution, host-pathogen interactions, and pathogenesis. As a postdoctoral scientist at Institut Pasteur du Cambodge (IPC) in Phnom Penh, Cambodia, I coordinate and oversee all daily activities related to seasonal human and avian influenza viruses. These include molecular surveillance for influenza-like illness (ILI-surveillance), avian influenza surveillance in Cambodian live bird markets and wild birds, phylogenetics, cell culture work at BSL-2 and BSL-3 level for virus isolation, and serology. Furthermore, I am in charge of implementing novel virus characterization methods at the BSL-2 and BSL-3 lab facilities. Of particular relevance to the proposed project, I also oversee all management, development, and training related to routine sequencing at IPC Virology Unit using Oxford Nanopore technologies.

My research portfolio has a strong multi-disciplinary component that includes virology, immunology, pathology, pathogen genetics and genomics, field work, and public health, and has required me to become adept at combining and analyzing multiple types of data, including experimental, environmental, and genomic data. I also have a strong track record in the discovery/identification and characterization of emerging viruses, with 6 publications in this field, four of which have been cited more than 10 times since 2013 (total citation: 161). Adding pathogen metagenomics to my portfolio would advance my career significantly by becoming an expert in the field of emerging viruses, capable of performing initial pathogen discovery as well as primary virus characterization. As such, my experience, skills, and training are ideally suited to the proposed research project, which builds naturally on my previous work. Further, I am strongly committed to supporting diversity and equity both within the scientific community and in the communities we serve by improving science education and good/safe farming practices for underserved communities in rural Cambodia. I am also committed to providing training and mentorship for low- and middle-income country scientists and scholars.

B. Positions and Honors

Positions and Employment

2020-	Postdoctoral Scientist, Institut Pasteur du Cambodge, Phnom Penh, Cambodia
2015-2020	PhD Candidate, Erasmus Medican Center, Rotterdam, the Netherlands
2015	Volunteer. Clinical Laboratory Technician (Ebola Virus Diagnostics). Koidu, Sierra Leone
2014	Research Asissant, Murdoch Children's Research Institute, Melbourne, Australia

Other Experience, Commissions of Trust and Professional Memberships

2018-	Membership. American Society for Virology
2014-	Ad Hoc Reviewer. Peer reviewer for different journals including Neuron, the Lancet, Journal of Virology.

Honors

2021	Young Scientist Fund, The eight ESWI conference, Virtual
2020	Young Scientist Fund, The seventh ESWI conference, Virtual
2019	Travel grant award. CADDE Genomic Epidemiology Workshop, Sao Paulo, Brazil
2018	Travel grant award. Visiting Scientist, University of Queensland, Australia
2017	Young Scientist Fund, The sixth ESWI conference, Riga, Latvia
2017	Travel grant award, European Seminar in Virology, Bertinoro, Italy
2016	Travel grant award, Options XI for the control of Influenza, Chicago, US
2015	Best poster award, Young Predigone (Predemix/Antigone), Rotterdam, the Netherlands
2015	Best abstract award, 7th Orthomyxovirus Research Conference, Toulouse, France
2015	Travel grant award, 7th Orthomyxovirus Research Conference, Toulouse, France
2013	Travel grant award, 100th American Association for Immunologist (AAI), Hawaii, US

C. Contributions to Science

I have authored 18 publications (published or in press) in the fields of influenza, respiratory viruses, infectious disease, and immunology, nine of which (50%) are first author publications. The primary theme of my work is understanding the emergence, prevalence, transmission, and pathogenesis of viruses at the human-animal interface. *As of this dossier, Google Scholar: **Total citations:** 374, **h-index:** 10, **i10-index:** 11

1. **Immunologic consequences of chronic diseases in humans.** The start of my scientific career began during my bachelor's degree internship at the Murdoch Children's Research Institute in Melbourne Australia where I started a new line of research within the Cell & Gene Therapy group. This research shed light on the mechanism that underlies the increased susceptibility to bacterial infections observed in patients suffering from the genetic blood disorder beta-thalassemia. I identified that neutrophils of beta-thalassemia patients are functionally abnormal due to a block in neutrophil maturation. My interest in the field of immunology and infectious disease grew during this internship and led me to pursue a MSc degree in infection & immunity. During one of my MSc internships at the department of Hematology, Erasmus Medical Center Rotterdam, the Netherlands, I examined the role of the cytokine IL-22 and the IL-22 receptor in rheumatoid arthritis and identified IL-22 as an important enhancer of the germinal center reaction, which are essential for the production of autoantibody-secreting plasma cells.
 - V. Reduced PU.1 expression underlies aberrant neutrophil maturation and function in β -thalassemia mice and patients. Epub 2016 May 12.
2. **Characterization of emerging (respiratory) viruses.** After exploring immunology, it was time to pursue my biggest interest, the world of emerging viruses. I was able to contribute scientific knowledge and advancements related to the novel avian-origin H7N9 virus, where I first reported on the attachment pattern of this potentially pandemic virus to the respiratory tract of five different animal models frequently used in influenza virus research. In addition, I showed that in humans, H7N9 viruses attach to cells in both the upper and lower respiratory tract, something never before observed for an avian-origin influenza virus. In terms of virus discovery, I described the first identification and genetic characterization of a dolphin rhabdovirus and during the Zika virus outbreak, a re-emerging virus, I contributed by describing fundamental intrinsic *in vitro* differences between the African and Asian lineage Zika viruses in neuronal cells. Finally, I contributed to the identification of zinc-embedded polyamide fabrics as a suitable "passive" inactivation of SARS-CoV-2 virus that could be used in personal protective equipment.

3. **Pathogenesis of seasonal, pandemic, and zoonotic influenza A virus associated extra-respiratory complications.** My PhD project focused on the extra-respiratory complications of influenza virus infection where I made significant contributions to our understanding of the pathogenesis of extra-respiratory disease. First, I described the pathogenesis and extra-respiratory complications of pandemic 1918 H1N1 virus in a ferret animal model and provided new insights into the significant pathogenicity of this virus. Second, I provided new insights into the impact of chronic metabolic diseases (excess weight/obesity) on the

development of influenza virus-associated extra-respiratory disease. Third, I described the intrinsic differences - viral and host factors - in the ability of seasonal, pandemic, and zoonotic influenza A viruses to replicate in cells of the central nervous system, and proposed a potential mechanism. Finally, I evaluated the efficacy of vaccination and pre-exposure prophylaxis antivirals in the development of extra-respiratory tract disease associated with highly pathogenic avian influenza H5N1 virus infection in ferrets.

4. **Emerging respiratory viruses at human-animal interface.** My current postdoctoral training is focused on emerging (respiratory) viruses at the human-animal interface in Cambodia and includes - but is not limited to - influenza, coronaviruses, and paramyxoviruses. Using a “One Health” approach I contribute to understanding the dynamics of avian influenza at Cambodian live bird markets and in wild birds, the epidemiology of seasonal influenza, and the emergence of zoonotic viruses in humans. Thus far, I have identified the first human A/H9N2 infection in Cambodia and performed genetic and antigenic characterization of an influenza A(H3N2) outbreak in Cambodia during the COVID-19 pandemic.

A. Personal Statement

I am a molecular and evolutionary biologist who has been working on emerging infectious diseases for 15 years. In my current research, I explore the ecological and evolutionary dynamics of emerging zoonoses at the human-animal interface, with a focus on rapidly changing environments in Southeast Asia. I have more than eight years' experience leading independent research projects in this field, including collaborations with industry and local government. Over time, I have been responsible for the successful completion of every aspect of these studies, including project design, funding acquisition, implementation, and reporting/publishing. In 2015 I initiated a research program to investigate the response of zoonotic pathogens to urbanization in Malaysian Borneo using metagenomics, landscape ecology, and population genomics. This research has a strong multi-disciplinary component that includes evolutionary biology, molecular ecology, virology, pathogen genetics and genomics, field biology, and public health, and has required me to become adept at combining and analyzing multiple types of data, including environmental, ecological, and genomic data. This work has already resulted in three last-author publications, with a fourth currently in revisions at *Proceedings of the National Academy of Sciences of the USA*. As such, my experience, skills, and training are ideally suited to the proposed research project, which builds naturally on my previous work. I also have a strong track record in the generation and use of genetic and genomic data to explore the transmission dynamics and evolution of emerging viruses, with more than 20 publications in this field, nine of which have been cited more than 100 times since 2010. The mastery of genomic, phylogenetic, and phylodynamic methods I have developed throughout my career are directly applicable to the proposed research. Further, I am strongly committed to supporting diversity and equity both within the scientific community and in the communities we serve and have led several projects and initiatives aimed at improving science education and health service delivery for underserved communities in tropical northern Australia. I am also committed to providing training and mentorship for low- and middle-income country scientists and scholars, and in my previous role worked to develop protocols and bioinformatics pipelines to enable portable metagenomic sequencing in rural and remote regions in Australia and the Pacific. I am currently supervising two PhD students (James Cook University, AUS) and formally mentor a postdoctoral scientist, Dr. Nguyen Van Cuong, at the Oxford University Clinical Research Unit (OUCRU) in Viet Nam as part of my activities within the Centres for Research in Emerging Infectious Diseases (CREID) network.

B. Positions, Scientific Appointments, and Honors

Positions and Employment

2020-Present	Senior Research Scientist and Program Coordinator, EcoHealth Alliance, New York, NY
2020-Present	Adjunct Senior Research Fellow, College of Public Health, Medical & Vet Sciences, James Cook University, Cairns, AUS
2018-2020	HOT North Career Development Fellow, Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, AUS
2017-2018	Australian Research Council (ARC) Discovery Early Career Research Fellow, School of BioSciences, The University of Melbourne, Parkville, AUS
2013-2017	Research Scientist/ Australian Research Council (ARC) Discovery Early Career Research Fellow, Health and Biosecurity, The Commonwealth Scientific and Industrial Research Organization, Geelong, AUS
2013	Associate Research Scientist, Center for Infection and Immunity, Columbia University, New York, NY
2010-2012	Postdoctoral Fellow, Center for Infection and Immunity, Columbia University, New York, NY
2006-2010	PhD Scholar, The Pennsylvania State University, State College, PA
2001-2006	Research Assistant, Department of Zoology, The University of Guelph, Guelph, CAN

Honors

2019-2021	HOT North Career Development Fellowship, Northern Australia Tropical Disease Collaborative Research Programme, National Health and Medical Research Council (Australia)
2015-2018	Discovery Early Career Researcher Award, The Australian Research Council
2009-2010	Jeanette Ritter Mohnkern Graduate Student Scholarship in Biology, The Pennsylvania State University
2006-2009	Postgraduate Scholarship, Natural Science and Engineering Research Council of Canada
2006-2008	Braddock Graduate Fellowship, The Pennsylvania State University
2003-2005	Ontario Graduate Scholarship, The Province of Ontario (Canada)
1999	Undergraduate Entrance Scholarship, The University of Guelph

C. Contributions to Science

Throughout my career, my research has focused on many aspects of infectious disease emergence and has encompassed evolutionary biology, molecular ecology, virology, pathogen genetics and genomics, field biology, and public/veterinary health. My most significant contributions include:

- 1. The use of genomic and metagenomic sequencing techniques to discover new pathogens, study their evolution, and explore microbial diversity.** I have successfully developed and used cutting-edge metagenomic techniques and bespoke bioinformatics pipelines for: (i) pathogen discovery, including a case of acute encephalitis in an immune-suppressed patient, (ii) studies of viral diversity, including coronaviruses and flaviviruses in bats; and (iii) genomics, including the epizootology of bluetongue virus, the evolution of rhabdoviruses, and the characterization of Australian bunyaviruses. I have also co-authored two perspectives on the utility of next-generation sequencing for pathogen discovery in people and animals. These included an invited submission that described an updated framework for proof of causation in the genomics era and discussed the emerging integration of on-the-ground metagenomics-based diagnostics with molecular epidemiology. In 2013, I initiated a study that used metagenomics to characterize the viruses and bacteria carried by New York City rats across a range of habitats, with a focus on the built environment. At the time, little was known about the range of potential pathogens carried by urban rodents or the risk factors associated with zoonotic transmission in a city environment. To begin to address this, I designed the first comprehensive molecular survey of rodent-borne microbes in a U.S. city, and demonstrated that urban rats frequently carry a range of zoonotic pathogens. We also found evidence of substantial heterogeneity in pathogen distribution within and between cities, suggesting that the associated risks of human disease may be similarly heterogeneous.

Related Pre-print available: <https://doi.org/10.1101/2021.04.30.442218>

2. **I have helped develop the emerging field of urban zoonotic disease ecology.** In 2015 I pioneered an ongoing research program to investigate the response of zoonotic pathogens to urbanization using metagenomic sequencing, landscape ecology, and population genomics. Using a multi-disciplinary approach, this research explores how changes in the environment (e.g., land-use changes, microclimates, etc.), and host community and population structure (e.g., biodiversity, connectivity, density), influence pathogen community composition and zoonotic potential. Initial results of this work indicate that while mammalian diversity decreases with increasing urbanization, connectivity between populations increases, as does microbial species richness and the prevalence of known zoonotic pathogens. This suggests that some features of the built environment may inadvertently support pathogen persistence and spread, and as a result, some zoonotic pathogens may be more likely to emerge with intensifying urbanization. My reputation as an emerging researcher in this field has led to multiple invitations to present as a plenary or symposium speaker at national and international meetings, including the Ecological Society of Australia's Annual Conference (2019) and the Annual Meeting of the American Society of Mammalogists (2019), and the Joint Conference of the Asian Society of Conservation Medicine and the Wildlife Disease Association Australasia (2018).

3. **I challenged established beliefs about the ecological and evolutionary processes linked to viral disease emergence, and the timescale over which they occur.** During my PhD, I was able to make significant contributions to this field by questioning the idea that viruses evolve either by cross-species transmission (spillover) or by co-evolution with their hosts, but rarely both. My work demonstrated that viruses with many genomic structures are capable of jumping species barriers, and that evolution through both co-divergence and cross-species transmission may be general trend of many virus systems. This has since been supported by numerous subsequent studies that have highlighted the complex evolutionary dynamics of both RNA and DNA viruses.

4. **I was among the first to apply novel phylodynamic approaches to reconstruct the spatiotemporal processes behind disease emergence events.** Phylodynamic methods enable the synthesis of epidemiological, geographic, and phylogenetic data to reconstruct the processes behind infectious disease emergence and spread through time and space. These methods are of particular use for investigating the emergence and spread of viruses, as they have a rapid evolutionary rate that closely matches the timescale of virus transmission. I began to explore these approaches during my PhD and have now successfully used them to: (i) explore the genetics underpinning the rapid emergence and spread of human enterovirus 68; (ii) examine the patterns and processes that influence the diversity and geographic distribution of New World hantaviruses; (iii) explore the epizootology of porcine circovirus 2; iv) understand the evolutionary and ecological drivers behind the distribution of bluetongue virus in Australia; (v) assess the likely origins of hepatitis C virus; and (vi) understand the global emergence of community-associated MRSA and MSSA.

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Erik Albert KARLSSON

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Deputy Head of Unit, Director of National Influenza Center of Cambodia, Director of WHO Regional H5 Reference Laboratory, Coordinator of WHO Global COVID-19 Reference Laboratory, Virology Unit, Institut Pasteur du Cambodge

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
University of North Carolina, Chapel Hill	B.S.	05/2005	Biochemistry
University of North Carolina, Chapel Hill	Ph.D.	05/2010	Nutrition
St. Jude Children's Research Hospital	Postdoctoral	06/2016	Virology

A. Personal Statement

During my doctoral work in the Department of Nutrition at the Gilling's School of Global Public Health, University of North Carolina at Chapel Hill, I studied the effect of nutrition, especially diet-induced obesity, on immune responses to viral pathogens. Following completion of my Ph.D., I began to pursue a research career focused on understanding surveillance, viral evolution, host-pathogen interactions, and immune responses. I began working as a Postdoctoral Research Associate with Dr. Stacey Schultz-Cherry and collaborators at St Jude Children's Research Hospital to expand my knowledge of virology, viral pathogenesis, co-infection, immunology (primary and vaccine-induced), and infectious disease surveillance. I became a Staff Scientist in Dr. Schultz-Cherry's laboratory, focusing further on the interaction of nutrition and infectious disease as well as helping to oversee influenza surveillance at the animal-human interface worldwide. I currently serve as a Senior Researcher (Assistant Professor equivalent) at Institut Pasteur du Cambodge (IPC) in Phnom Penh, Cambodia. I am the Deputy Head of the Virology Unit and in charge of all ongoing activities related to respiratory viruses, including human seasonal and zoonotic viruses, and am the Director of the National Influenza Center and the Regional WHO H5 Reference lab. I am integral in the COVID-19 response in Cambodia and worldwide and serve as the Coordinator for the WHO Global COVID-19 Reference Laboratory in the Virology Unit. I also serve as the Co-PI of the newly developed Sequencing Platform at IPC. My work at IPC focuses on surveillance of endemic and emerging viruses in Cambodia, including developing Early Warning systems against the next pandemic. I also frequently consult for UN organizations (FAO and WHO) and am the founder of a research think-tank named: "CANARIES: Consortium of Animal market Networks to Assess Risks of emerging Infectious diseases through Enhanced Surveillance."

B. Positions and Honors**Positions and Employment**

2016-2017 Staff Scientist, Department of Infectious Diseases, St. Jude Children's Research Hospital, Memphis, TN

2017-2020 Senior Researcher, Virology Unit, Institut Pasteur du Cambodge, Phnom Penh, Cambodia

2020- Deputy Head, Virology Unit, Institut Pasteur du Cambodge, Phnom Penh, Cambodia

Other Experience, Commissions of Trust, and Professional Memberships (since 2011)

2011-	American Society for Virology
2011-	Ad Hoc Reviewer. Peer reviewer for 60+ journals Full review record available on Publons: https://publons.com/author/737520/erik-albert-karlsson#profile
2012-2013	Secretary. Nutritional Immunology RIS. American Society for Nutrition
2013-2015	Chair Elect. Nutritional Immunology RIS. American Society for Nutrition.
2015-2016	Chair. Nutritional Immunology and Inflammation RIS. American Society for Nutrition
2015-	Editorial Board Member. Journal of Nutritional Biochemistry
2017-	Editorial Board Member. Virus Genes
2019-	Founder. Consortium of Animal market Networks to Assess Risks of emerging Infectious diseases through Enhanced Surveillance (CANARIES; http://www.canarieshmhp.org).
2020-	Consultant, Laboratory Technical Advisor, Emergency Centre for Transboundary Animal Diseases, Food and Agriculture Organization of the United Nations, Regional Office for Asia and the Pacific.
2020-2021	Consultant, Scientific Expert. World Health Organization. Global Influenza Surveillance and Response System.
2021-	Consultant, Technical Expert – Genomic Surveillance. World Health Organization, European Region, Turkey.

Honors Since 2011

2011	ASV 2011 Postdoctoral Fellow Travel Award. American Society for Virology General Meeting 2011, Minneapolis, MN
2011	Travel Award. ISIRV-AVG Conference: Influenza Antivirals: Efficacy and Resistance. Rio de Janeiro, Brazil. November, 2011
2012	Travel Award. Nutritional Immunology Research Interest Section. American Society for Nutrition. Experimental Biology 2012, San Diego, CA
2012	Young Investigator Travel Award. Palm Beach Infectious Disease Research Institute. PBIDI Symposium 2012, Palm Beach, FL
2012	Travel Award. 6 ^h Orthomyxovirus Research Conference. Bromont, Quebec, Canada. September, 2012
2012	Travel Award. Obesity Research Interest Section. American Society for Nutrition. Experimental Biology 2012, San Diego, CA
2013	Promising Young Investigator Scholarship. Options for the Control of Influenza VII. Cape Town, South Africa. September 2013.
2015	Young Investigator Travel Award. 3 rd ISIRV International Symposium on Neglected Influenza Viruses. Athens, Georgia, USA. April, 2015.
2015	Merck Junior Investigator Award - Best Speaker. 3 rd ISIRV International Symposium on Neglected Influenza Viruses. Athens, Georgia, USA. April, 2015.
2018	Francis Crick Institute Best Poster Award. ISIRV Symposium – Influenza 2018: Centenary of the 1918 Pandemic. London, UK. June, 2018.

C. Contributions to Science

As of this submission, I have authored 70+ publications (published or in press) in the fields of nutrition, influenza, respiratory viruses, and infectious disease: 28 (40%) first author publications and 7 (10%) senior author publications. Full list available at: <https://scholar.google.com/citations?user=lq1f7K0AAAAJ&hl=en>

*As of this dossier: **Total citations:** 3,395, **h-index:** 31, **i10-index:** 53

1. **Global avian influenza virus surveillance and response in domestic poultry and wild birds.** Avian influenza virus is a major concern worldwide. Aside from seasonal epidemics and occasional pandemics, avian influenza viruses continue to cause human infections. I have been involved in influenza virus surveillance in wild and domestic poultry in Africa, South America, and Southeast Asia. These studies have defined new hotspots of influenza, determined seasonal patterns, and even helped to define policy recommendations. Selected References:

d)

4. **Defining the risk of emerging viruses and the bottlenecks overcome to cross species barriers.** A major concern with zoonotic viruses, especially avian influenza virus, is the risk of zoonotic transmission. These studies seek to define factors (host-related, bacteriological, and virological) which can help to predict risk of zoonotic transmission and severity of viruses and emerging diseases. Selected References:

*Title: Understanding the establishment and persistence of community associated methicillin-resistant Staphylococcus aureus (CA-MRSA) in resource-limited, high-burden settings: How can we reduce the burden of disease?

Major Goals: To determine the clinical impact of MRSA-related acute hematogenous osteomyelitis (AHO) in the PNG highlands and identify interventions to reduce the burden and impact of this infection. We will evaluate the feasibility of point-of-care diagnosis of MRSA, determine the persistence and transmission pathways of CA-MRSA, and determine the diversity and phylodynamics of MRSA strains circulating in PNG highland communities and their association with AHO cases.

*Title: CREID COVID Supplement: Support for COVID Sequencing in Cambodia. PICREID.

Major Goals: The major goals of this project are to further support sequencing and analysis of SARS-CoV-2 genomes in Cambodia as part of the national response to COVID-19.

*Status of Support: Active

Project Number:

Name of PD/PI: Karlsson, Erik

*Source of Support: NIH/NIAID

*Primary Place of Performance: Institut Pasteur du Cambodge

Project/Proposal Start and End Date: (MM/YYYY) (if available): 11/2021 – 05/2022

* Total Award Amount (including Indirect Costs): \$107,266

* Person Months (Calendar/Academic/Summer) per budget period.

Applicant Name (Karlsson, Erik):

Year (YYYY)	Person Months (##.##)
1. [2022]	0.5 calendar

PENDING

*Title: Novel detection and sampling techniques for surveillance of bat-borne zoonoses in Cambodia

Major Goals: This project will utilize novel field technologies (RT-PCR, sequencing) in conjunction with novel sampling strategies (air, environment) to develop better ways to sample bats across Cambodia.

*Status of Support: Pending LoA

Project Number:

Name of PD/PI: Karlsson, Erik

*Source of Support: FAO-USAID

*Primary Place of Performance: Institut Pasteur du Cambodge

Project/Proposal Start and End Date: (MM/YYYY) (if available): 01/2022 – 11/2022

* Total Award Amount (including Indirect Costs): \$77,000

* Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)
1. [2022]	1.8 calendar

*Title: One Health understanding of small-holder swine value chain in Cambodia

Major Goals: This study aims to enhance the health and livelihood of small-holder swine value chain stakeholders through cost-effective intervention measures following a One-Health approach. We believe that small-holder pig producers play a key role in the spread of several important zoonotic diseases, including food borne diseases. Applying cost-effective interventions and risk-based surveillance along the value chain will reduce risk and enhance the livelihood of the stakeholders. The project will tackle gender-related inequalities in the roles assigned along the pig-value chain in risk awareness, mitigation and exposure, and identify solutions to empower women in this system.

*Status of Support: Pending

Project Number:

Name of PD/PI: Karlsson, Erik

*Source of Support: ACIAR (Australia), IDRC (Canada)

*Primary Place of Performance: Institut Pasteur du Cambodge

Project/Proposal Start and End Date: (MM/YYYY) (if available): 07/2022 – 07/2025

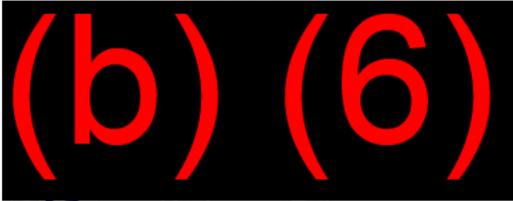

* Total Award Amount (including Indirect Costs): \$698,700

Applicant Name (Karlsson, Erik):

Co-PI Plan (only needed if applying as Co-PIs):

As stated in the Mentoring Plan, the co-PIs, Vireak Heang and Jurre Siegers, are at different stages of their respective careers and have discrete professional development goals. This Co-PI Plan was developed to maximize the strengths of each PI, provide opportunities to learn from each other, and create a supportive environment where they can pursue their independent professional goals while working as a team to achieve the project objectives.

Overall, the proposed research project will be jointly and equally managed by Dr. Siegers and Mr. Heang. Dr. Siegers will plan, oversee, and conduct sample management and processing. He will also lead the data analysis aspects of the work. Mr. Heang will be responsible for the technical aspects of metagenomic sequencing, including logistics and protocol development, laboratory work, and initial data curation and quality control. He will work closely with the Research Center Mentor, Dr. Cadhla Firth, to develop these aspects of the project. As the project progresses, Dr. Siegers will be exposed to the technical aspect of metagenomics, including how to prepare and load samples onto the sequencing platform, by learning from Mr. Heang. Likewise, Mr. Heang will develop skills in upstream sample preparation and handling and will have the opportunity to participate in downstream data analysis, as he learns from Dr. Siegers. This collaboration will ensure that both individuals gain technical skills in areas where they have less experience, and each will become a more well-rounded scientist as a result of their joint efforts. While Mr. Heang will be more involved with the technical aspects of sequencing and data generation, Dr. Siegers will take the lead to work with EcoHealth Alliance's modeling experts to explore the virological data and the meaning for potential surveillance efforts.

Both PIs will jointly manage data curation, analysis, and dissemination for this proposal. In addition, the Co-PIs will jointly manage the project budget with oversight from their Scientific Mentor, Dr. Erik Karlsson. The PIs will receive a budget code in the IPC system on which they can charge reagents and supplies, as well as manage spending, and purchases will be co-signed by Dr. Karlsson. In terms of specific reagents, Mr. Heang will oversee the ordering of supplies needed for sequencing, and Dr. Siegers will be responsible charges related to sample preparation. Both PIs will jointly book and conduct travel. While Mr. Heang will be more involved in generating metagenomic sequencing data in the lab, Dr. Siegers will lead the initial drafting of reports and publications that will result from this research. However, both authors will contribute to the writing and publication of any manuscripts and will jointly share authorship. The Co-PIs will work closely with both Mentors on all aspects of the project and will regularly attend IPC and EcoHealth Alliance scientific meetings to present work and progress.

Facilities and Resources

Laboratory:

The Institut Pasteur in Cambodia (IPC) is an institution of public utility engaged with the Royal Government of Cambodia by a convention and under the patronage of the Ministry of Health to meet the challenges of the future in the areas of scientific research, public health and education. It is a member of the Institut Pasteur International Network with which it develops ongoing collaborations, with 33 member institutes spread across the globe, which facilitates collaboration and scientific exchanges. Visiting scientists from Institut Pasteur Paris can provide expertise to setup specific assays and collaborations with Institut Pasteur Paris enable access state-of-the-art equipment if needed for the proposed research.

The Virology Unit at the Institut Pasteur du Cambodge (IPC) has been instrumental in public health responses in Cambodia, especially against respiratory viruses such as avian influenza. As such, IPC has served as the National Influenza Centre (NIC) for Cambodia since 2006 and was designated as a WHO H5 Reference Laboratory in October 2014 (H5RL), as part of the WHO Global Influenza Surveillance and Response System (GISRS). In addition, IPC serves as a reference laboratory for a number of other pathogens. Programs and procedures are also in place to identify, diagnose, and sequence numerous other emerging and zoonotic pathogens, such as Coronavirus (CoV). The IPC Virology Unit was designated by the Cambodian Ministry of Health as first line laboratory for diagnosis of COVID-19 and currently acts as the National Reference Laboratory for COVID-19. In April 2020, IPC Virology Unit was recently named a WHO Global Reference Laboratory for COVID-19.

The virology laboratory space covered by the Virology Unit contains all equipment needed for virology research. Biological Level 1 and 2 space (200 m²) is dedicated for sample acquisition, processing and storage, serology, extraction, post-amplification procedures, molecular biology and PCR. Separate BSL2 spaces are also dedicated to human samples (23 m²), animal samples (24 m²), cell maintenance (12 m²) and cell culture work (35 m²). In response to A/H5N1 circulation in Cambodia the Virology Unit was upgraded in 2008 to include a BSL3 facility (142 m²). The BSL3 facility comprises four modules dedicated to different and separate activities: arboviruses, emerging viruses (including a safety cabinet with gloves box allowing BSL3+ safety conditions) and mycobacterium (activity handled by the IPC clinical laboratory). The last module includes isolators for animal experiments.

Equipment includes: CO₂ incubators (n=3 dedicated to cell maintenance and cell culture work in a dedicated BSL2 spaces and n=2 dedicated to cell culture work in BSL3), automated extraction (n=4), real time qRT-PCR machines (n=7 BioRad CFX96), conventional PCR machines (n=8 BioRad T100), a Sanger sequencing (ABI 3500xL Genetic analyzer), 2x MinION next generation sequencer (Oxford Nanopore), 1x GridION next generation sequencer (Oxford Nanopore), 1x MiSeq next generation sequencer (Illumina), a gel imaging system (BioRad ChemiDoc WRS+), a capillary electrophoresis device (Qiagen QIAxcel advanced system), light microscopes (n=2 direct light; n=4 inverted light), a fluorescent microscope, bench top centrifuges, three ELISA washers (BioRad), two ELISA readers (BioRad and ThermoFisher Scientific) and Qubit fluorometer.

Applicant Name (Last, first, middle): Siegers, Jurre, Ynze and Heang, Vireak

The sequencing mini-platform at IPC is a newly established platform intended to provide the sequencing services to all scientists within the institute regardless of their discipline. The sequencing mini-platform is situated in the Regional Research Platform-ASIA (PRR) building and contains all the equipment needed to perform sequencing. We have 20m² dedicated for library preparation and another 20m² for the instruments. Equipment includes: 1 Illumina Miseq, 1 Tapestation 4150, 1 Qubit 4.0, 1 Thermocycler.

Clinical:

The medical analysis laboratory of IPC has received ISO NF 15189 accreditation for all its applications for the analysis of clinical biology, biochemistry, hematology, and microbiology in 2018.

Animal:

A conventional mouse facility and dedicated BSL2 and BSL3 level space for animal experiments are available at IPC; however, they will not be utilized in this proposal.

Computer:

Information technology access: Since the Institute is located in a low-income country, we are eligible for the Hinari Access to Research for Health Programme of the world health organization (WHO), providing us online access to all major journals in biomedical research. Both the laboratories and PI's office are equipped with MacIntosh and PC computers and printers. Computers are protected by enterprise antivirus software. Email solution is Microsoft Exchange 2010 server. Local network is managed with Cisco catalyst switches, linked with fiberoptics or network cables, with redundant paths. VLANs are used to segregate research units, enabling more confidentiality. Two telco links provide access to the internet: primary/nominal with fiberoptics Online operator, with 8 Mbit/s bandwidth and 24/7 support. IPC has a reliable internet connection with 35Mbs download and 35Mbs upload speeds. Backup link is operated by OpenNet with 4 Mbit/s bandwidth.

The computational resources for generating, analyzing, storing and managing sequencing data are available locally. IPC acquired two Ubuntu server compute nodes (each equipped with 64 cores, 128GB of RAM, and a high-end NVIDIA GPU) connected over 10Gbs switches to 222 TB of shared networked storage.

Applicant Name (Last, first, middle): Siegers, Jurre, Ynze and Heang, Vireak

Office:

Office space is separated from the laboratory space with dedicated offices for postdoctoral researchers, students, PI's and technicians.

Other:

Biological sample storage and access: All samples will be stored in -80°C freezers and liquid nitrogen tanks housed within the IPC biobanking system. The IPC biobank is a multisite biological resource center (BRC), which collects, transforms, analyses, stores and provides resources according to specific pre-requirements and manages associated data. All the activities of preparation, analysis and biological resource (BR) processing are realized according to stringent quality requirements. For long-term security and confidentiality, Biobank Management Software has been implemented and established and used to manage the BR and associated data from different laboratories and research units at IPC. Only the PI and relevant key personnel has access to the samples. The biobank includes human, animal and pathogenic samples.

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Dr. Jurre SIEGERS and Mr. Vireak HEANG
Project Title:	<i>In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.</i>
Institution:	Institut Pasteur du Cambodge
Foreign Research Site:	Phnom Penh, Cambodia
Point of Contact for Research Site:	Dr. Jurre SIEGERS Virology Unit, Institut Pasteur du Cambodge 5 Monivong Blvd, PO Box #983 Phnom Penh, Cambodia email: jsiegers@pasteur-kh.org

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goals of this project are: (1) to assess the suitability of environmental metagenomics as an early warning system for endemic and emerging infectious diseases at high-risk interfaces in Cambodia; (2) to utilize biobank environmental samples from longitudinal pathogen surveillance programs in Cambodia to build metagenomic sequencing and bioinformatics capacities and capabilities in Cambodia; and, (3) To discover new, emerging, or zoonotic pathogens of concern at high-risk interfaces in Cambodia.

To achieve these goals, investigators and primary Scientific Mentor on site will collaborate with EcoHealth Alliance and their CREID partners as part of the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH). The EID-SEARCH team will support this project by helping the Institut Pasteur du Cambodge (IPC) team conduct and analyze metagenomic sequencing on Cambodian samples.

\$147,675.96 of grant funds will be sent to IPC for these studies.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will coordinate and/or perform all laboratory work and data analyses necessary for the proposed project (including metagenomic sequencing).

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - IRB approval number for parent study: **Not Applicable**
 - IRB approval date:
 - Human Subject Assurance Number:
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - **No**
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - **No**
 - How many subjects provided the existing samples to be used? **Not Applicable**

- Will human subjects be recruited (Yes or No)
 - No
 - Number of human subjects that will be recruited: **Not Applicable**
- Population parameters: **Not Applicable**
 - Gender:
 - Age Group:
 - Race/Ethnicity:
- Sample collection will include: **Not Applicable**
 - Blood:
 - Urine:
 - Tissues:
 - Other samples (describe):
- Sample collection will be completed in how many visits: **Not Applicable**
- Will samples be de-identified (Yes or No)? If No, describe how they will be protected.
 - **Not Applicable**
- Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.
 - **Not Applicable**
- Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.
 - **Not Applicable**
- Will samples be brought back to the US (Yes or No)?
 - **Not Applicable**
- Will data be brought back to the US (Yes or No)?
 - **Not Applicable**

Animal Subjects (1 word or 1 sentence per bullet):

- Parent study IACUC approval
 - IACUC approval number for parent study: ○ Projects involving animal samples were collected (2019-2021) under a protocol approved by National Ethics Committee for Health Research under the Ministry of Health, Cambodia (NECHR143, NECHR149, and NECHR320); however, Cambodia did not have a specific animal ethics review board at the time the collections were conducted. Continuing ethics approvals (NECHR013) for projects involving further animal sample collections in 2022 are in revision and projected to be approved in February 2022.
 - IACUC approval date: **Not Applicable**
Animal Welfare Assurance Number: **Not Applicable**
- Does this study require a modification to the IACUC approval of a parent study (Yes or No)?
 - **No**
- Will existing samples from animal subjects will be used: (Yes or No)?
 - **Yes**
 - How many animal subjects provided the existing samples to be used? **2445**
- Will vertebrate animals be collected (Yes or No)?
 - **No**

- **Species of animals (e.g. rats, mice, rabbits, monkeys):** Not Applicable
- **Animal parameters:**
 - **Total number of animals:**
 - **Gender:**
 - **Age range:**
 - **Lab strain (e.g. Sprague-Dawley rats, Balb/C mice):**
 - **Wild animals procured in country (e.g. Rhesus monkeys from a reserve):**
- **What will be done to them or with them and how often?**
 - Not Applicable
- **What are the follow-ups?**
 - Not Applicable
- **What will be their fate at the end of the experiments – will they be euthanized?**
 - Not Applicable
- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - Not Applicable
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EcoHealth Alliance/EID-SEARCH for relevant analysis.

Phnom Penh, January 31, 2022

O/Ref.: N°034/IPC/DIR/2022

Dr. Jurre Siegers & Mr. Vireak Heang
Institut Pasteur du Cambodge
Phnom Pehn, Cambodia

Object: Institutional Support for your application to the CREID Pilot Research Program, entitled “In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.”

Dear Dr. Siegers & Mr. Heang,

The Institut Pasteur du Cambodge (IPC) is pleased to support your application to the **CREID Pilot Research Program**, entitled “In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.” We are fully committed in executing the statement of work utilizing next-generation metagenomics techniques for emerging zoonoses and potentially developing novel methods of expanding our surveillance in Cambodia.

The work proposed in this project will be given the highest priority and complements nicely to all of the other endemic and emerging virus research being conducted at IPC. In addition, it serves very nicely to bring together our long-standing Virology Unit with the newly created Sequencing Mini-Platform to build capacity and capability not only in our institution, but also for the next generation of Cambodian scientists.

As such, IPC asserts that all necessary time, facilities, and resources required for the project will be made fully available to you to successfully complete the work proposed in this project.

Sincerely,

Prof. André SPIEGEL
Director

Prof André SPIEGEL

Dr. Jurre Siegers, Mr. Vireak Heang
Institut Pasteur du Cambodge
No. 5 Monivong Boulevard
P.O Box. 983
Phnom Penh, Cambodia

Dear Jurre and Vireak,

The Emerging Infectious Disease-Southeast Asia Research Collaboration Hub (EID-SEARCH) at EcoHealth Alliance is highly interested in working with you and your collaborators at the Institut Pasteur du Cambodge in Cambodia on the proposed project titled: *“In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.”*

This project will significantly contribute to the goals of the CREID Network and EID-SEARCH to build in-country research capacity and an international research network for emerging infectious diseases in Southeast Asia. It will develop a foundation for new collaborations among EID-SEARCH, Institut Pasteur du Cambodge, and other in-country stakeholders, strengthening the multi-sectoral cooperation for emerging infectious diseases in Cambodia. Furthermore, the process to develop and implement this project will help develop your skills in project management, provide training and networking opportunities with scientists from EID-SEARCH and the CREID Network, and most importantly, expand your skills in metagenomics, to prepare you to be independent researchers leading emerging infectious disease research both within and outside of Cambodia.

Beyond capacity and network building, the proposed project strongly aligns with the EID-SEARCH’s scientific objectives and research strategies by conducting surveillance among humans and animals to identify emerging pathogens with zoonotic potential at the high-risk human-animal interfaces and develop an early-warning system for zoonotic disease emergence. The research sites of this project - live animal markets, bat caves, slaughterhouses, animal farms – represent scenarios where zoonotic spillover are mostly concerned that require further in-depth investigation to reveal the spillover pathways. In addition, the innovative approach to conduct surveillance among environmental samples will not only expand our knowledge in viral discovery from the environment but also promote the One Health surveillance by establishing a validated sampling and analysis method that will significantly contribute to the disease surveillance and prevention strategies in Cambodia through collaborative and coordinative cooperation among a variety of stakeholders.

I am optimistic that this collaborative research project will bring valuable insights to advance disease surveillance and early warning systems for endemic and emerging infectious diseases in Cambodia. Members of EID-SEARCH are committed to working closely with you to develop the research project and support the efforts necessary for the success of this project. Our Senior Research Scientist, Dr. Cadhla Firth, has enthusiastically joined the project as your Mentor to advise on the study design, data collection, and analysis throughout the project. Dr. Firth will work closely with Dr. Erik Karlsson, a mentor from your IPC Virology Unit, to provide pertinent and timely career advice to assist in your professional development and brings a well-established network with leaders and experts in the ecology and evolution of infectious diseases across Southeast Asia, North America, and Australia. You will be invited to join all training conducted by EID-SEARCH and EcoHealth Alliance regarding emerging infectious disease fields, surveillance, and statistical analysis to build your skillset. In addition, Dr. Linfa

EID-SEARCH

Emerging Infectious Diseases
South East Asia Research Collaboration Hub

Wang, Co-Investigator from the EID-SEARCH, will support you on the metagenomics analysis by advising on the project and providing training or exchange opportunities at the Duke-NUS Medical School. You will be supported to present the findings of this research at international conferences, CREID Network meetings, and external partners and produce high-quality publications from this research.

I am confident that this proposed project will bring genuine opportunities for your professional development. The interdisciplinary expertise, a hallmark of “One Health”, in virology, genomics, public health, extensive experience working with sequencing platforms from Dr. Siegers and Mr. Heang, and the improved environmental metagenomics methods and skills through this research will make this a successful and purposeful project to bring public health impacts in a broad region with the similar social and cultural context.

This letter conveys my strong interest and commitment to making this application a success. I look forward to collaborating with you and your team on all phases of this proposed project. I wish you success in the CREID Pilot Research Program application.

Sincerely,

A black rectangular redaction box covering the signature area. The text "(b) (6)" is written in red across the box, indicating a FOIA exemption.

Jurre Siegers, Vireak Heang
Institut Pasteur du Cambodge
No. 5 Monivong Boulevard
P.O Box. 983
Phnom Penh Cambodia

Dear Jurre and Vireak,

I am writing this letter in support of your CREID Network Pilot Research Program application “In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance” conducted at the Institut Pasteur du Cambodge.

I and my group at Duke-NUS Medical School have long experience working on the emerging infectious diseases associated with bats and other animals. Your current proposal complements and expands this scope to identify the at-risk groups and the risk factors of viral spillover from wildlife to human populations.

I also work with the Emerging Infectious Diseases - South East Asia Research Collaboration Hub (EID-SEARCH) to develop serological tests and conduct virus characterization. I am very much looking forward to participating in this research to contribute my expertise, advise and provide relevant laboratory training.

This letter conveys my strong interest and commitment to making this application a success. I am excited to be part of the research to build scientific evidence to better predict zoonotic disease emergence, and I look forward to working with you on this research.

Yours sincerely,

(b) (6)

Linfa (Lin-Fa) WANG, PhD FTSE
Professor in Programme in Emerging Infectious Diseases

30th January, 2022

Dr. Jurre Siegers & Mr. Vireak Heang
Institut Pasteur du Cambodge
Phnom Pehn, Cambodia

Dear Dr. Siegers & Mr. Heang,

This letter is to express my support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled “*In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.*”

I am extremely excited that you have chosen me to be one of your Mentors for the proposed project. The research question is timely and important, and your work has the potential to have a strong impact on our approach to pathogen surveillance at high-risk human-animal interfaces. Given what we understand to be the likely origins of SARS-CoV-2, there has never been a more pressing need to improve the efficiency, sensitivity, and cost-effectiveness of zoonotic disease surveillance in emerging infectious disease hotspots.

I would be hard-pressed to think of two more appropriate applicants to co-lead this project, given your combined expertise in pathogen surveillance, molecular diagnostics, next-generation sequencing, and emerging respiratory viruses. Although you each have unique longer-term personal and professional goals, you also have a shared vision of using your scientific knowledge and expertise to train the next generation of Cambodian scientists, while building intellectual and scientific capacity around emerging infectious diseases in the country. I believe that increased access to the CREID Network, and to the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), in particular, will greatly help facilitate these goals by increasing your access to other scientists working on similar research questions across Southeast Asia. Many Southeast Asian countries face similar challenges in preventing and mitigating the impacts of emerging zoonotic diseases, and stronger regional partnerships have the potential to really drive forward innovations in this area. These include the implementation of novel, cost-effective approaches to pathogen surveillance, as proposed in your pilot project application.

The well-established relationship you each have with your chosen Primary Scientific Mentor for this project, Dr. Erik Karlsson, will provide an excellent foundation for the proposed work that will be enhanced by the joint Mentorship Plan we have developed together. I believe that Dr. Karlsson and I have distinct but complementary scientific skills, expertise, and networks that will maximize your professional and scientific development throughout the duration of the project, and I look forward to working more closely with all of you. I can see multiple opportunities for this new collaboration between the four of us to develop into a fruitful, long-term scientific partnership. Towards that aim, I am committed to supporting your professional development in the following ways:

- I will actively work to maintain the healthy, open, and informal dialogue we have established while drafting the project proposal, and I will seek feedback from you on a regular basis to ensure that our communication plan continues to meet your needs as the project progresses.

EcoHealth Alliance

- I will engage with your current and future in-country collaborators in a supportive and inclusive manner.
- I will create opportunities for you to interact with scientists across my network through your research project to widen your exposure to people with a range of expertise.
- I will give you timely feedback on all material in the manner that works best for you.
- I will provide you with opportunities to present your work to my colleagues at EcoHealth Alliance and across EID-SEARCH during our academic meetings and will include you in any relevant training or networking opportunities.
- I will share my scientific and technical expertise with you to help ensure the success of the project. When skills outside my area are required, I will assist you in accessing this expertise from scientists within my network.
- I will assist you in career planning, providing advice and support as required to maximize your opportunity to succeed.

Finally, I believe that the data you will collect about the potential zoonotic pathogens circulating in live bird markets, swine abattoirs, and bat roosts and guano farms in Cambodia will lead to a wealth of new research questions and hypotheses that could form the basis for additional research projects. This will present the perfect opportunity for you to continue the transition towards scientific independence, and I am committed to assisting you through the process of conceptualizing and writing your first funding applications as lead investigators.

There is significant overlap between your research interests and skills, the overall goals of the Institut Pasteur du Cambodge, and those of EcoHealth Alliance and the EID-SEARCH team. This pilot project presents a real opportunity for you to increase collaboration between these organizations, and to help drive forward future research projects on emerging zoonoses at high-risk interfaces in Cambodia. I am thrilled to be able to support you at these stages in your careers and am genuinely convinced that you both have the potential to become scientific leaders in Southeast Asia in the very near future.

Sincerely,

(b) (6)

Cadhla Firth, PhD
Senior Scientist and Program Coordinator
EcoHealth Alliance

30th January, 2022

Dr. Jurre Siegers & Mr. Vireak Heang
Institut Pasteur du Cambodge
Phnom Penh, Cambodia

Object: Support as Primary Scientific Mentor for your application to the CREID Pilot Research Program, entitled *“In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.”*

Dear Dr. Siegers & Mr. Heang,

This letter is to express my support as Primary Scientific Mentor for your application to the CREID Pilot Research Program, entitled *“In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.”*

I am proud to be able to continue to mentor both of you as one of your Mentors for the proposed project. I serve as both your mentor in the Institut Pasteur du Cambodge (IPC) Virology Unit (Dr. Siegers) and in the IPC Sequencing Mini-Platform (Mr. Heang). You are both in the top 1% of individuals I have ever had the pleasure to mentor/supervise. I have observed you both as extremely organized, productive, proactive, and responsive. You have never failed in any challenge placed in front of you and always deliver extra in your work. You are always willing to learn and adapt to new situations, and you both have extremely good leadership qualities, which will make your excellent PIs in the future.

As you well know, IPC serves as a major institution in the Institut Pasteur International Network and has been involved in research and diagnosis of human and animal infectious diseases in the Kingdom of Cambodia since 1953. IPC serves as a research institute, non-profit foundation for vaccination, diagnosis, and treatment, and is part of the Cambodian Ministry of Health (MoH). The Virology Unit at IPC was opened in 1996 and serves as the reference laboratory for Influenza, Arboviruses, and Rabies for Cambodia, as well as conducting surveillance and research on endemic, emerging, and zoonotic pathogens. The unit opened the first, and only, BSL3+ laboratory in the country in 2008. The Virology Unit works in close collaboration with the Epidemiology/Public Health, Entomology, Bacteriology, and Malaria Units at IPC as well as national and international partners to conduct One Health-focused surveillance and studies in Cambodian humans, domestic animals, and wildlife. In 2021, we opened the IPC Sequencing Mini-Platform to further increase these studies through advances in next generation sequencing equipment and support.

The research question proposed in this pilot program is both timely and important, and the work has great potential for increasing capacity and capability at IPC and in Cambodia as a whole. Indeed, the research proposed has significant potential to impact our approach to pathogen surveillance at high-risk human-animal interfaces. Indeed, the project will also serve to further link the Virology Unit and the Sequencing Mini-Platform at IPC with scientists in the CREID Network, specifically the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), which will allow future work across Southeast Asia and positively influence your networking and future careers. There is significant overlap between this proposal, the overall mission of the Institut Pasteur du Cambodge, and the goals of EcoHealth Alliance and the EID-SEARCH team. Therefore, this pilot project presents a real opportunity for you to increase

Télécopie : +855 23 725 606

collaboration, and to spearhead future research projects on emerging zoonoses at high-risk interfaces in Cambodia. In addition, I am completely supportive of your vision to utilize the knowledge you gain from this proposal to train the next generation of Cambodian scientists, a critical part of our mission at IPC.

I fully support your choice of Research Center Mentor for this project, Dr. Cadhla Firth. Dr. Firth and I feel that our distinct but complementary scientific skills, expertise, and networks will maximize your professional and scientific development throughout the duration of the project. In the future, I see multiple opportunities for this new collaboration to develop into long-term scientific partnership. Indeed, I believe the data collected in this proposal regarding new ways to survey potential zoonotic pathogens circulating in Cambodia will lead to scientific independence and further lead investigator applications for you on novel research questions and hypotheses.

Therefore, I am committed to supporting your professional development in the following ways:

- I will continue to actively maintain the healthy, open, and informal mentoring relationship we have established as your mentor at IPC
- I will continue to meet with you on scheduled and *ad hoc* basis to support whatever needs you might have regarding this project, other ongoing projects, and future projects
- I will continue to provide (and ensure the institution provides) the time and resources needed to complete all research activities proposed in this pilot project
- I will continue to engage with our current and future in-country collaborators in a supportive and inclusive manner and promote your engagement with them
- I will continue to give you timely feedback on all material in the manner that works best for you
- I will continue to support and promote opportunities to interact with other scientists through your research project to widen your exposure to people with a range of expertise.
- I will continue to share my scientific and technical expertise with you to help ensure the success of the project. When skills outside my area are required, I will continue to assist (and encourage) you in accessing this expertise from scientists within my network.
- I continue to assist you in career planning, providing advice, and any other support as needed to maximize your opportunity to succeed.

Overall, I am thrilled you have chosen me as Primary Scientific Mentor on this project and I look forward to working with you on this project and throughout your careers.

Pilot Program Application Submission Checklist – Final Application Submission

Title of Application: In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance

Submitted by: Siegers, Jurre, Ynze and Heang, Vireak

Submission Date: 1/31/2022

Full Application Submission Requirements

- Proposal Cover Sheet
- Title and Table of Contents
- Study Personnel (*1-page limit*)
- Main Application Body Section Requirements (*7-page limit*):
 - Research Aims & Objectives
 - Study Rationale/Research Gap/Impact
 - Significance and Approach
 - Research Methods
- Project Timeline (*1-page limit*)
- Research Performance Sites (*1-page limit*)
- CREID Research Center Collaboration (*1-page limit*)
- Mentoring Plan (*2-page limit*)
- Vertebrate Animals Section Requirements (*3-page limit*):
 - Description of Procedures
 - Justifications
 - Minimization of Pain and Distress
 - Method of Euthanasia (Cover Page Supplement / PHS Fellowship Supplemental Form)
- Human Subjects Research (*3-page limit*):
 - Summary of the parent study and IRB approval information for the study
 - Risks to the subjects
 - Adequacy of protection against these risks
 - Potential benefits of the research to the subjects and others
 - Importance of the knowledge gained or to be gained
 - Country / institution-specific ethics / IRB regulations addressed
- Research, Related Project Information, and Budget/Budget Justification
 - R&R Other Project Information Form
 - Full budget, with total costs of no more than \$150,000
 - Budget justification which describes the labor and other direct costs
 - If your institution does not have adequate funds for a cost-reimbursement award and requires pre-payment of funds during the award year, please note this in your budget justification and outline a payment schedule that will function for your project.

Supporting Documentation

- Biographical Sketch and Other Support. All applications must include:
 - Applicant PI Biographical Sketch (*4-page limit*)
 - Applicant PI Previous/Current/Pending Support (Include funding amounts, *no page limit*)
 - Mentor Biographical Sketch (*4-page limit*)
 - Mentor Current/Pending Support (*no page limit*)
 - Key Personnel Biographical Sketches (*4-page limit each*)
 - Key Personnel Current/Pending Support (*no page limit*)

Pilot Program Application Submission Checklist – Final Application Submission

Title of Application: In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance

Submitted by: Siegers, Jurre, Ynze and Heang, Vireak

Submission Date: 1/31/2022

- Co-PI Plan (only needed if applying as Co-PIs) (*1-page limit*)
 - What each Co-PI will contribute to the proposed research study
 - How the Co-PIs will jointly work with the affiliated Research Center
 - How the Co-PIs will jointly manage the proposed study
- References Cited (*no page limit*)
- List of Abbreviations, Acronyms, and Symbols
- Facilities, Existing Equipment, and Other Resources (*template provided*)
- NIH Foreign Clearance form (*template provided*)
- Letters of Organizational Support (*2-page limit per letter*)
- Letter of Collaboration from CREID Research Center PI (*2-page limit per letter*)
- Letter from Research Center Mentor (*2-page limit*)
- Letter from Primary Scientific Mentor (if different than Research Center mentor) (*2-page limit*)

cuongnv@oucru.org

Re: Letter of Intent, CREID Network Pilot Research Program

Dear Review Committee:

This letter is to inform you that I, Nguyen Van Cuong, intend to submit an application for the CREID Network Pilot Research Program by the 12th of March, 2021. The title of my application will be: **'Multi-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam'**.

The project team will include myself, my long-term collaborator, Dr. Maia Rabaa (Group Head, Molecular Epidemiology, Oxford University Clinical Research Unit, Viet Nam), and my chosen Mentor, Dr. Cadhla Firth (Senior Research Scientist and Program Coordinator, EcoHealth Alliance). I will collaborate closely with the Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH), who will provide training and exchange opportunities within its network to achieve the research goals. This project will form the foundation of a new collaboration between the CREID Research Center, EID-SEARCH, and the Oxford University Clinical Research Unit in Viet Nam, which will focus on zoonotic diseases and the animal-human interface whilst building the emerging infectious disease research collaborative network in Southeast Asia.

In the proposed project, I will use samples and metadata previously collected (but not analyzed) as part of a three-year high-risk cohort study that has now come to an end. Animal samples were collected from more than 15 species present in farms and slaughterhouses across Dak Lak province in the Central Highlands of Viet Nam between 2012 and 2015. Serum samples from 300 people in contact with these animals were collected simultaneously, along with questionnaire data to assess risk. Using sequence data generated from these animal samples, we will explore how species diversity in Central Highland farms contributes to viral diversity and viral sharing between animal species (i.e., cross-species transmission). If time and resources permit, human questionnaire data and serum samples will also be analyzed to identify potential risk factors for zoonotic transmission associated with the viruses circulating on multi-species farms.

The proposed project will have three aims:

1. Estimate the frequency of viral sharing between animals of different species and identify viruses that commonly cross the species barrier under mixed-farming conditions.
2. Identify environmental and ecological factors associated with variations in viral prevalence and diversity, or rates of cross-species transmission, of zoonotic viruses on multi-species farms.
3. Identify risk factors for zoonotic infection on multi-species farms (time permitting).

The proposed project will have three objectives:

1. Characterize the viral diversity present in samples from animals housed on multi-species farms using a combination of metagenomics and PCR-based screening.
2. Identify viruses with known or predicted zoonotic potential using ecological and phylogenetic methods. Estimate the distribution, prevalence and relatedness of these viruses across animal species and farms.
3. Correlate human behavioral and demographic characteristics from existing questionnaire data with evidence of zoonotic infection from targeted serological analyses (time permitting).

All samples for this project have been previously collected under approved Research Ethics and IRB protocols. No additional samples or engagements with individuals will be required for the successful completion of this project.

All work required for completion of the project will be performed at the Oxford University Clinical Research Unit in Ho Chi Minh City, Viet Nam. The samples were previously collected from Dak Lak province and are all currently stored and available for use in the Oxford University Clinical Research Unit laboratories in Ho Chi Minh City.

Sincerely,

(b) (6)

Nguyen Van Cuong

Object: Letter of Intent, CREID Network Pilot Research Program

Dear Review Committee:

This letter is to inform you that we, Vireak Heang and Jurre Siegers, intend to submit an application as **co-PIs** for the CREID Network Pilot Research Program by 31st of January 2022. The title of our application will be: *'In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance'*.

The project team will include ourselves (Vireak Heang, a Category 1 LMIC applicant with a master's degree and 15 years of experience; and Jurre Siegers, a Category 2 postdoctoral applicant with a PhD in Virology), and two Mentors: Dr. Erik Karlsson (Deputy Head, Virology Unit, Institut Pasteur du Cambodge) and Dr. Cadhla Firth (Senior Research Scientist, EcoHealth Alliance). We will collaborate closely with the CREID Research Center 'Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH)', who will provide training and exchange opportunities within its network to achieve the research goals. This project will form the foundation of a new collaboration between EID-SEARCH, and the Institut Pasteur du Cambodge (IPC), which will focus on zoonotic disease research at high-risk animal-human interfaces.

The proposed project will take place within The Virology Unit at IPC, which serves as the reference laboratory for COVID-19, Influenza, Arboviruses, and Rabies for Cambodia, and conducts surveillance and research on endemic, emerging, and zoonotic pathogens. The Virology Unit works closely with the Epidemiology/Public Health, Entomology, Bacteriology, and Malaria Units at IPC, as well as national and international partners, to conduct One Health-focused surveillance and studies in Cambodian people, domestic animals, and wildlife. As such, IPC is continually searching for new and innovative ways to expand and improve surveillance activities. **The ability to quickly assess risk at points of high exposure or contact is paramount for early warning systems and preventative actions.** In addition, maintenance of surveillance systems in individual animals is costly and time consuming and prevents widespread coverage in all high-risk areas. **One way to address this issue is the incorporation of environmental sampling into surveillance programs to cast a wider net for pathogen surveillance at high-risk interfaces and on a longitudinal basis.**

To this end, we have begun to incorporate environmental sampling at high-risk human-animal interfaces, including live animal markets, slaughterhouses (poultry/swine), and domestic/wild animal interfaces (lakes, bat caves, farms). These samples include water (environmental and direct wash water), swabs (surfaces and other contact areas), and air samples (live animal markets, slaughterhouses, bat caves), which have been collected along with swabs from individual animals, enabling a direct comparison of pathogens identified from environmental samples with those collected from individuals. However, these samples have only been tested for specific pathogens of interest by conventional or real-time PCR, limiting their utility for pathogen surveillance. The ability to use these samples for metagenomic surveillance and pathogen discovery would not only increase surveillance capacity, but also contribute to our understanding of new or emerging pathogens at these high-risk interfaces. To respond to the COVID-19

pandemic, the Virology Unit at IPC has recently increased its sequencing capacity to include both Oxford Nanopore (GridION and MinION) and Illumina MiSeq technologies. We now have the capability to perform metagenomic surveillance; however, these systems are still primarily used for amplicon-based sequencing. As such, their full potential as tools for pathogen surveillance has not yet been realized.

In the proposed project, we will use previously and prospectively collected environmental and animal samples from high-risk human-animal interfaces across Cambodia (e.g., live animal markets, slaughterhouses, farms, and bat caves) to assess the utility of environmental metagenomics as a tool for pathogen surveillance, while building capacity in this area at IPC.

The proposed project will have three aims:

- 1) To utilize existing and prospective environmental samples from longitudinal pathogen surveillance to build metagenomic sequencing and bioinformatics capacities and capabilities.
- 2) To assess the suitability of environmental metagenomics as an early warning system for endemic and emerging infectious diseases at high-risk interfaces in Cambodia.
- 3) To discover new, emerging, or zoonotic pathogens of concern in high-risk interfaces in Cambodia.

This project will use previously and prospectively collected environmental samples and PCR data from swabs taken from animals collected under approved protocols from the National Ethics Committee for Health Research (NECHR) of Cambodia: NECHR143, NECHR149, and NECHR320. No new animal sampling will occur as part of this project. No human sampling or engagement with individuals will be performed as part of this project.

Dear Krongkan and Spencer,

Thanks for sharing the proposal abstract!

Peter and Kevin reviewed all proposed ideas and think this one perfectly aligns with EID-SEARCH's research objectives and will help answer some important questions.

However, can we meet to further discuss the title and writing regarding the significance of this work? The current text sounds a bit like adding additional lab procedures that have already been covered by current EID-SEARCH work, so we need to make it sound more significant...And please read through the instruction here for the proposal preparation https://creid-network.org/documents/pilot-program/2023/CREIDPilotProgram_CallforApplications_2023.pdf to see the research and objective priorities (e.g., well-defined hypothesis, and human subject research in LOI, etc.)

Please let me know when you will be available for a quick *call anytime next Monday or Tuesday*.

I'm re-attaching two successful applications, as well as some LOIs examples for your reference.

Best,
Hongying

Thank you, Bow!

Kio and Spencer,

Attached are the two successful applications for 2021 and 2022 for your reference.

And can you please quickly write up one paragraph of your proposed idea (like the abstract) **before Monday next week**? We have received eight requests to collaborate this year, so Kevin, Peter, and I need to review all of them together on Monday to decide which three to support, and it would be great if you can send something written-down.

Best,
Hongying

Abstract: Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles and little circulation but lower seroprevalence amongst adults. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

Keywords: bats; Nipah virus; filovirus; Rubulavirus; *Pteropus medius*; Bangladesh; serology; disease dynamics; generalized additive models

Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics¹⁻³. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses^{4,5} including close relatives of SARS-CoV-2⁶, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses^{1,2,7}.

Bat species can carry diverse viruses which circulate simultaneously within single populations⁸⁻¹¹. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire-virus have also been detected in this bat in Central Africa, suggesting that it may play a role in the circulation of multiple filoviruses^{12,13}. In addition to these filoviruses, a novel zoonotic and pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations¹⁴.

Commented [NRI]: Please check that your affiliation is as it should be!

Commented [EL2]: Cara Brook has a nice article about bats and virulent viruses

46 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to
47 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity¹⁵. Various
48 surveillance efforts have found diverse viruses from with the same viral family in various bat
49 species^{5,16,17}, and other studies have used metagenomic approaches to look broadly at viral diversity
50 within individual bat species^{9,11,18-21}.

51 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of
52 viruses and their relationships to specific hosts^{6,22} and inform public health strategies²³. However,
53 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated
54 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or
55 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other
56 species, including domestic animals and humans²⁴. For these, more detailed demographic and
57 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect
58 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics²⁵⁻²⁷.
59 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral
60 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been
61 observed to have annual shedding patterns²⁸, whereas Hendra virus, which is closely related to
62 Nipah virus and is carried by multiple pteropodid bat species in Australia, has asynchronous and non-
63 periodic cycles which appear to be influenced by localized factors such as specific bat species
64 abundance and climatic factors²⁹. Bi-annual pulses of Marburg virus shedding were observed in
65 Uganda, coinciding with synchronous birth pulses in *R. aegyptiacus*³⁰. Serological data is often
66 valuable in understanding disease dynamics and transmission³¹⁻³³, especially in cases where direct
67 detection and incidence rates of viruses are low³⁴.

68 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, ~~lethal neurotropic~~
69 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus³⁵⁻³⁷. In Bangladesh and India,
70 *P. medius* is a reservoir of Nipah virus, ~~a lethal neurotropic zoonotic virus - which that~~ has spilled over
71 to human populations repeatedly³⁸. Viruses from eight other viral families have been detected in *P.*
72 *medius* in Bangladesh⁹. The epidemiology of these other viruses is far less characterized, and little is
73 known about their interactions or zoonotic potential.

74 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,
75 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in
76 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-
77 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of
78 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral
79 circulation. We find that Nipah virus circulates primarily among adults without distinct seasonality,
80 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by
81 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also
82 circulated in juveniles but exhibited distinct patterns antibody waning and limited maternal
83 inheritance.

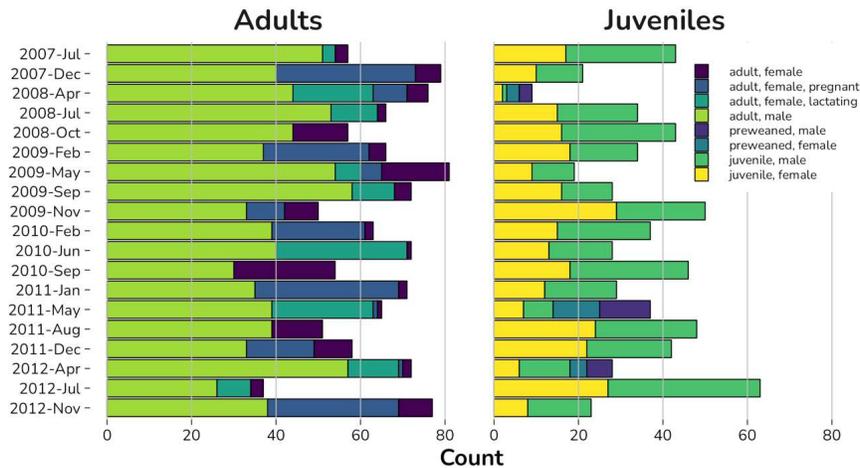

84 2. Results

85 *Bat dynamics and demographics*

86 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly from a roost
87 complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies sampling bats
88 monthly from roosts in Chakhoria and Ramnagar, Bangladesh. In the five-year study, we sampled
89 and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39 weaning juveniles
90 (captured attached to adult females) over 19 sampling events (Figure 1). During the one-year studies,
91 919 bats were sampled: 435 in Chakhoria (251 adults, 144 free-flying juveniles and 40 weaning
92 juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning juveniles (Figure
93 S1). Nearly all juveniles (as determined by examination of maturation of sex organs) were 14 months
94 old or less and could be assigned to a birth cohort based on size. Pregnant and juvenile bats were
95 captured more frequently during the late spring and summer months. Mother-pup pairs were all

Commented [EL3]: Only 2/5 listed are lethal, only 3 have been isolated. Add in Gamak, Daeryong, Angovkeely, LayV.

96 captured during April and May in the five-year study whilst in the one-year-studies a small number
 97 were also captured in June and July. Pregnant females were captured between November and
 98 April/May. Lactating females were found between April and July.
 99

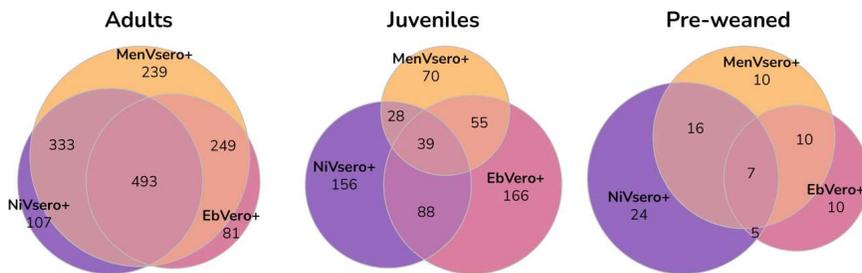

100 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured
 101 in months from November to June, lactating females were captured in months from April to July.
 102 Females with pre-weaning juveniles attached were found from April to May.

103 *Patterns of Immunity and Co-immunity*

104 We found bats were seropositive for antibodies against the Nipah virus (NiVsero+), a filovirus
 105 (EBObVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the
 106 rubulavirus were common; 1,314 of 1752 adult bats were MenVsero+. Antibodies against Nipah virus
 107 or filovirus were less common – 1,031 were NiVsero+ and 921 were EBObVsero+. Among the 921
 108 juveniles, 192 were MenVsero+, 311 were NiVsero+ and 348 were EBObVsero+. Of the 122 pre-
 109 weaned juveniles, 43 were MenVsero+, 52 were NiVsero+, and 32 were EBObVsero+.

110 Co-exposure to multiple viruses was common (Figure 2). Over half (1,173) of the 1752 adults had
 111 antibodies against more than one of the three viruses, and 493 had antibodies against all three.
 112 Among the 921 juveniles, 210 had antibodies against more than one, and 39 had antibodies all three.
 113 38 of 122 pre-weaned juveniles had more than one of the three antibodies, with seven having all three.

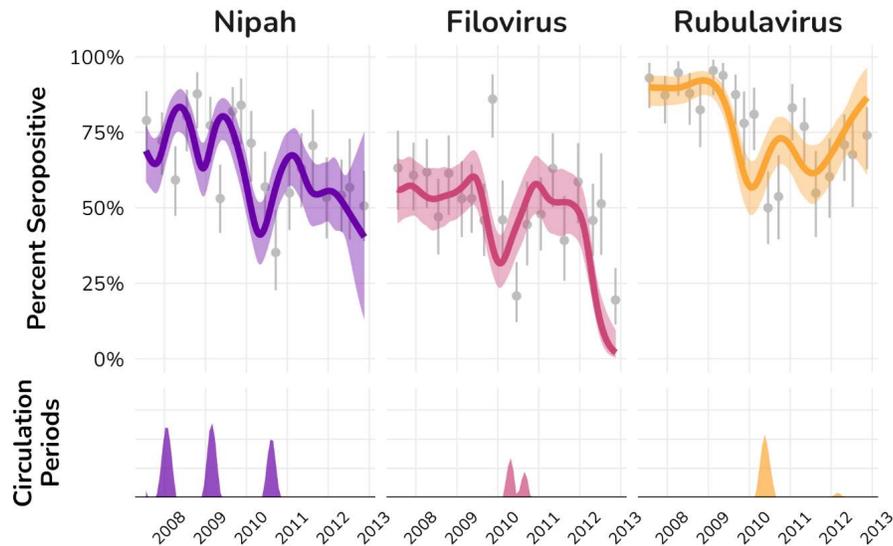

114 We found correlations [between](#) serostatus between all three pairs of viruses in a model
 115 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other
 116 more than would be expected than if they were distributed independently among bats. Nipah virus
 117 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).
 118 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of
 119 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had a covariance of 0.23 (0.17-0.29).

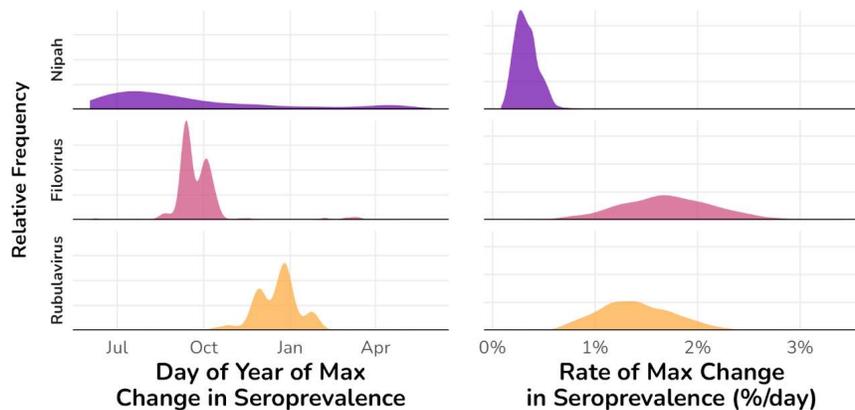

120 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn
 121 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,
 122 filovirus, and rRubulavirus. Numbers under labels are counts of bats with only those viruses,
 123 numbers in overlapping areas represent number of bats detected with multiple viruses.

124 *Serodynamics*

125 Dynamics of population seroprevalence were different across the viral types. In adults,
 126 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)
 127 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-
 128 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very
 129 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in [Epstein, et al. 34](#)).
 130

131 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population
 132 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey
 133 points and bars represent measured population seroprevalence from individual sampling events on

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah virus) (Fig. 3). Filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

Among juveniles within the average year, filovirus seroprevalence started very low in June –at 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it consistently occurred in December or January. The average date with the greatest rate of seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day (4.5%/day-9.9%/day).

Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74% (62%-84%), though there were some temporary periods of decline. There were distinct periods of increasing circulation in early 2010 and early 2012. Only for the rubulavirus did adult seroprevalence exhibit patterns of seasonality. Periods of increasing seroprevalence in adults exhibited strong seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean peak date occurring on Dec 15 (Oct 15-Feb 1)

In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in the youngest bats in June, though in individual years this could range from 7%-43%. In all years juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%) The peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and occurred Jan 9 (Dec 21-Mar 16).

187

Spatial Comparisons

188

189

190

191

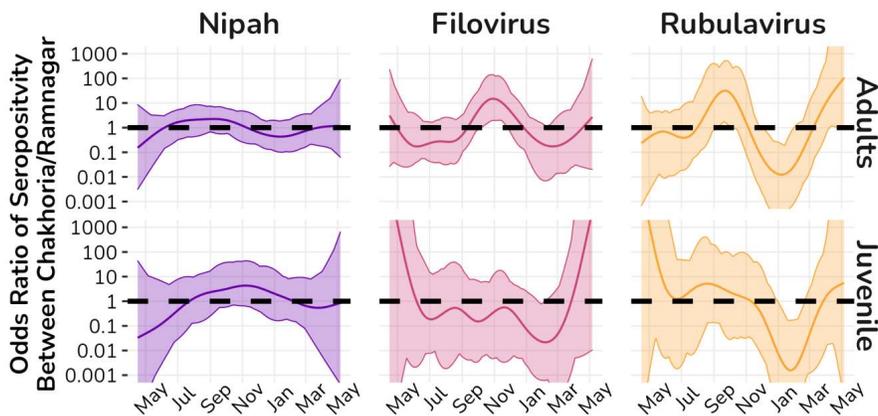

Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2). In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

192 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-61%) in April 2010, rising to
 193 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over
 194 the same period. The trend in juveniles was as described for the five-year study.

195 For the filovirus, the seroprevalence in the one-year studies was higher than the reported
 196 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-
 197 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of
 198 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the
 199 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the
 200 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,
 201 there were two periods of increasing seroprevalence in adults over the course of the year. The first of
 202 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August
 203 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the
 204 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)
 205 between early March 2011 to late April 2011.

206 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from
 207 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in
 208 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December
 209 2010/January 2011 in Chakhoria. These decreases were followed by rapid increases back to high
 210 seroprevalence, coincident with increasing levels in juveniles. The pattern in juveniles was as
 211 described in the five-year study, with seroprevalence estimates in yearlings in April 2011 of 80%
 212 (28%-99%) in both locations.

213 Comparison of the seroprevalence trends within each age group and virus between the two one-
 214 year study locations did not support spatial differences in the timing of changes in seroprevalence
 215 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between
 216 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at
 217 the end of 2010.

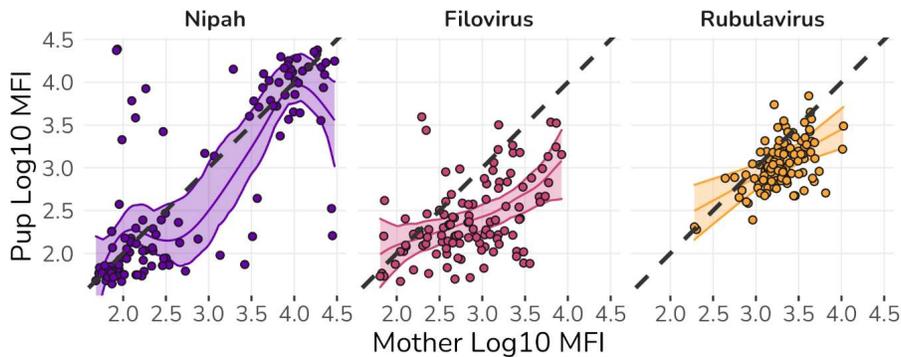

218
 219 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**
 220 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference
 221 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.
 222 Where the confidence interval excludes zero, there is evidence for a significant difference in the
 223 serodynamics between the Ramnagar and Chakhoria populations over that period.

224 *Maternal Inheritance of antibodies*

225 We examined the relationship between mother and pup antibody titers, as measured by our
 226 [Luminex-antibody](#) assays (see Methods). This relationship varied between viruses (Figure 7). For

Commented [EL4]: Use serology or antibody assays.

227 Nipah virus, the relationship was nonlinear due to clustering at high and low values, but largely
 228 followed a 1:1 relationship between mother and pup antibody titers. For the rubulavirus the
 229 relationship was near-linear and near 1:1. For the filovirus, though, the relationship between MFI
 230 values measured in mothers and their pups fell well below the 1:1 line, indicating pups having low
 231 inheritance of antibodies against the filovirus relative to the other two viruses.

232
 233 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for
 234 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the
 235 predicted mean relationship between the two and their associated 95% confidence intervals.

236 **3. Discussion**

237 We found serological evidence for regular circulation of multiple viruses in *P. medius*
 238 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to
 239 humans in the region, as well as a filovirus and a Rubulavirus. It was common for bats to have
 240 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity
 241 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance
 242 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types
 243 being positively correlated within bats.

244 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The
 245 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations
 246 inherit maternal antibodies against the Rubulavirus, which wane over the first six months of their
 247 life, after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in
 248 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the
 249 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence
 250 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating
 251 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of
 252 the rubulavirus to be strongest in the late winter and early spring months in these populations.
 253 Mortlock et al.³⁹ found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via
 254 PCR detection in pooled urine samples), including a peak during a period of presumed antibody
 255 waning, though only within a one-year study.

256 An outstanding question is how the rubulavirus is maintained in the population despite high
 257 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent
 258 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*⁴⁰, Hendra virus in
 259 *P. Medius*⁴¹, and Lagos bat lyssavirus and an African henipavirus in *Eidolon helvum*⁴². Another
 260 possibility is re-importation. In concurrent work with this study, we found that bat home ranges

261 overlapped with nearby colonies so as to form a meta-population³⁴, allowing occasional infection
262 from outside bats, as has been shown to maintain Hendra virus in [Australian](#) *Pteropus* populations^{33,44}.

263 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle
264 virus, which has been found in *P. medius* in Australia^{45,46}. At least 11 distinct Paramyxoviruses have
265 been found in *P. medius* in Bangladesh alone: Nipah virus and ten uncharacterized species, including
266 six ~~r~~Rubulaviruses closely related to Menangle virus and ~~the~~ Tioman virus^{9,47}. It is possible that the
267 serological patterns observed represent antibodies against a complex of multiple ~~r~~Rubulaviruses,
268 though the regular interannual patterns in seroprevalence would indicate that they are operating
269 similarly.

270 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with
271 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some
272 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup
273 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults
274 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,
275 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah
276 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by
277 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years²⁸.
278 ~~On the other hand, Human-~~Nipah virus [infections of humans outbreaks](#) in Bangladesh ~~on the other~~
279 ~~hand,~~ exhibit seasonality associated with the palm-sap consumption, the most likely spillover
280 mechanism⁴⁸.

281 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-~~Zaire~~
282 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have
283 been found in *R. leschenaultii* in the country⁴⁹. This could be one of several known filoviruses or an
284 unknown species. There have been several recent findings of new ~~Ebola-like~~ filoviruses in bats
285 extending across Africa and Asia~~-, including These include~~ Bombali virus in Sierra Leone⁵⁰ and
286 [Kenya \[cite\]](#), and Měnglà virus in *Rousettus* bats in China⁵¹. ~~Ebola~~-Reston virus was found in multiple
287 bat species (*M. australis*, *C. brachyotis* and *Ch. plicata*) in the Philippines⁵². Marburg virus and Ebola-
288 ~~Zaire~~ virus may have been detected in Sierra Leone and Liberia (unpublished,^{53,54}). Serological
289 evidence of filoviruses in bats has been found in multiple bat species in Central^{12,55} and Western⁵⁶
290 African countries, Singapore⁵⁷, [India \[cite\]](#), China⁵⁸, as well as Trinidad⁵⁹. Our finding here adds to
291 the evidence of broad host and geographic host ranges for filoviruses.

292 Several components of the serological patterns of filovirus antibodies are of interest. Young
293 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months
294 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite
295 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult
296 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period
297 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase
298 among juveniles. One possible hypothesis explaining this pattern is that the filovirus may exhibit low
299 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.
300 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain
301 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was
302 found to be rapid, but bats retained protective immunity even with very low antibody titers^{60,61}. If a
303 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite
304 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles
305 following the peak is consistent with this explanation.

306 However, if adults remain immune to the filovirus despite low antibody titers, this immunity
307 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and
308 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the
309 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly
310 differential maternally derived immunity. If pups derive weaker immunity from dams than for other
311 viruses, this may provide another mechanism for maintenance of the virus. ~~It~~ possible that patterns
312 in filovirus antibody detection are an artifact of our test, specific to Ebola-~~Zaire~~-virus, and that

313 temporal trends are in part reflective of differential cross-reaction with viruses in this bat population.
314 However, while this may modify estimates of overall seroprevalence, the differential pup/dam
315 antibody-MFI relationship, and consistent rise in seroprevalence among young juveniles, would
316 require the test to exhibit differential sensitivity by age.

317 Serodynamics in our two one-year studies were broadly similar to those found in the five-year
318 study. We found weak evidence for differences in serodynamics between sites for the filovirus in
319 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the
320 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study³⁴,
321 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their
322 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are approximately 225
323 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible
324 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or
325 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple
326 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

327 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-
328 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from
329 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or
330 transmission, via competition for host nutritional or cellular resources, or via immune-mediation
331 involving cross-immunity or antibody-dependent enhancement, and these interactions structure
332 viral communities²⁶. These interactions can have complex, even opposite effects when scaled to the
333 population²⁷. Here, we found positive correlations between serostatus against different viruses.
334 External factors may also affect these relationships. For instance, all three viruses appear to have
335 circulated in adults in mid-2010. It is possible that common factors like population density and/or
336 nutrition availability³² affected transmission of multiple viruses.

337 While rich observational serological data reveal these patterns, greater study is required to
338 characterize these viruses and their effects on the host population and potential for spillover, as well
339 as the degree and mechanisms of interactions. Our inferred periods of viral circulation point to
340 optimal sub-populations and times to sample this population to detect viral shedding and isolate
341 these viruses, and potentially capture co-infected hosts.

342 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term
343 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and
344 shedding, but establishing patterns or variation in seasonality requires extended, multi-year
345 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was
346 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The
347 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.
348 Similarly, we were able to understand these patterns far better by separating juvenile and adult
349 patterns, which we would be unable to distinguish in pooled samples.

350 While such extended individual-capture longitudinal studies are resource-intensive,
351 understanding the joint circulation of multiple viruses can be accomplished via multiplex
352 immunoassays such as those used here. The continuous measures from these assays also have the
353 potential to identify key patterns such as the differential inheritance of filovirus antibodies we
354 identified here. Interpretation of these values is challenging and the relationship between immune
355 status, antibody titer, and measured IgG levels-fluorescence is complex³², but they have much
356 potential to shed light on mechanistic drivers of disease circulation.

357 **Methods**

358 *Field collection*

359 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-
360 year studies in different locations, sampling monthly. All capture and sampling methods were
361 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol
362 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as

Commented [EL8]: This is a good limitation – not sure what the shadow filovirus is so could be cross-reactions to 1 or more.

Commented [EL9]: IgG?

363 previously described in Epstein, et al. ³⁴ The area of the roost complex consists of patchy forest
364 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July
365 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst
366 roosts within the 80km² roost complex over the period of the study. Sampling occurred at the largest
367 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex
368 across consecutive sampling nights if required to capture a sufficient number of individuals.

369 Approximately 100 bats were captured at each sampling event, which lasted 7-10 days. We
370 captured bats with a 10x15m mist net between 11pm and 5am each night as bats returned from
371 foraging until the count of 100 was reached.

372 In the one-year longitudinal studies, sampling was undertaken in two roost complexes in
373 Ramnagar and Chakhoria, Bangladesh between April 2010 and May 2011. Monthly sampling of
374 approximately 40 bats in each location was performed to obtain data at a finer temporal scale. Details
375 of collection are otherwise as described for the five-year study.

376 For each study, we recorded each bat's age class, reproductive status, weight, size, and body
377 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with
378 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box
379 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and
380 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton
381 Cryogenics, NJ, USA).

382 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal
383 swabs and pooled urine samples from under colonies. Further details can be found in Epstein, et al.
384 ³⁴

385 *Serological Assays*

386 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and
387 gamma irradiated upon receipt. We used a ~~bead-based-microsphere~~³⁴ ~~multiplex~~ ~~microsphere-based~~
388 ~~immunoassay~~ that specifically detects antibodies to ~~native-like the recombinant envelope soluble~~
389 ~~attachment glycoprotein ectodomains~~ ^{s^{57,63,64}} ~~for~~ ~~from~~ a panel of viruses. ~~Glycoprotein-coupled~~
390 ~~microspheres~~ ~~Beads coated with each protein~~ were mixed with sera at a dilution of 1:100.
391 Biotinylated Protein A/G and Streptavidin-PE were then used to detect bound ~~antigen-antibody~~
392 ~~complexes~~. Beads were interrogated by lasers in a BioRad BioPlex ~~200 multiplexing system~~ ~~machine~~
393 and the results recorded as the ~~m~~Median ~~f~~Fluorescent ~~i~~Intensity (MFI) of 100 beads. We report here
394 ~~serology~~ results for Nipah ~~virus~~, Ebola-~~Zaire virus~~, and Menangle ~~virus~~, the only three for which we
395 established regular positive results.

396 While the Nipah virus has been detected in this population⁶⁵ and the specificity of the Nipah
397 ~~virus~~ test ~~more is well-established~~⁶⁶, the Ebola-~~Zaire virus~~ and Menangle virus ~~are less qualified and~~
398 ~~tests are~~ cross-reactions^{ve} with other ~~Asiatic Ebola-filoviruses~~ and rubulavirus-~~specieses remains~~
399 ~~possible~~ ^{67,68}. ~~f~~Thus we refer to these as tests for filovirus and ~~r~~Rubulavirus.

400 *Data Analysis*

401 We determined individual bat serostatus using Bayesian mixture models⁶⁹ fit on pooled data
402 across all three longitudinal studies, calculating a cutoff of log-MFI as the point of equal probability
403 between the smallest and second-smallest cluster of equal distributions for each assay.

404 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian
405 multivariate probit model^{70,71} which allows estimation of the joint outcomes (serostatus against each
406 virus) and the correlation between the outcomes. We included age and sex variables to account for
407 these effects on serostatus.

408 To examine time-varying changes in population seroprevalence, we fit binomial generalized
409 additive mixed models (GAMMs)^{72,73} to the time-series of serostatus measurements. For the five-year
410 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit
411 a model for seroprevalence dynamics over the course of the whole study. This treats the adult
412 population as a single unit, though individuals within the population may turn over via migration,

413 death and recruitment. We included both long-term and annual cyclic components for the multi-year
414 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate
415 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile
416 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles
417 over their first year. To estimate periods of peak viral circulation within the population, we calculated
418 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior
419 distributions and classified periods with >95% of samples with positive derivatives - that is,
420 increasing population seroprevalence - as periods of viral circulation. We also calculated strength
421 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date
422 at which this maximum occurred, again sampling these values from the model posterior, and
423 calculating mean and high-density posterior interval (HDPI) values.

424 For the one-year studies, we fit models primarily to detect differences in time-varying changes
425 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus
426 measurements with separate models for each immunoassay. We included a separate, fixed-term
427 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in
428 serodynamics for each virus in each age group were compared between locations to test for spatial
429 differences⁷⁴. Juveniles identified as being from the previous year's cohort were excluded from the
430 analysis.

431 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI
432 between adult lactating females and their attached pups for each viral assay. We limited these to data
433 from the five-year longitudinal study.

434 **Data Availability:** Raw data from this study and reproducible code used to perform analyses is available at the
435 Zenodo Scientific Archive [Zenodo DOI to be generated] and also on GitHub at
436 <https://github.com/ecohealthalliance/bangladesh-bat-serodynamics>

Hey Noam,

I made some edits on a recent flight but completely lost track of the document. If you are still working on this my edits are attached.

Hi Noam,

Apologies for my absence, you have my focus now.

Here are my follow-up items:

- ***I'd like to have a conversation with you about nuts and bolts and budgeting.*** I'm headed out for vacation Friday afternoon through Labor day. ***If you want to chat tomorrow or Friday pick a time*** at this link, if not I will write when I return: <https://calendly.com/noamross/60-minute-chat-extended-hours>
Can we touch base next Tuesday Sept 6th? I'm free after 1pm EST. I'd like to go over some of the assays mentioned in the pdf you attached.

- ***I'll get you a draft*** with a bulleted section on this stuff that you and Spencer can make sound like a virologist who knows what they are talking about. I expect this ***around September 12.***
Sounds good.

- I think it would be good for me to ***come down to USU for a day or two in early-mid September*** for us to work through some of this stuff if you agree and have the time. If so, let's schedule that.
Yes, I'll be out of town from Sept 18 - 22, but in town until that date.

Hi Eric,

Hi! I hope you are well. I had a call with Spencer yesterday about this grant as I know you've been away for family reasons. (CC'ing him to chat with you about this when he has the chance). We discussed things that we could write into the grant on your side, notably validation/calibration testing using the Filovirus standard coming out of Oxford, and also running tests on the sera from experimental infections that are at BSL-4 labs at RMN, UTMB, and maybe South Africa. These could be used to model how we expect real responses to look in related virus and host species.

Here are my follow-up items:

- *I'd like to have a conversation with you about nuts and bolts and budgeting.* I'm headed out for vacation Friday afternoon through Labor day. *If you want to chat tomorrow or Friday pick a time* at this link, if not I will write when I return: <https://calendly.com/noamross/60-minute-chat-extended-hours>

- *I'll get you a draft* with a bulleted section on this stuff that you and Spencer can make sound like a virologist who knows what they are talking about. I expect this *around September 12.*

- I think it would be good for me to *come down to USU for a day or two in early-mid September* for us to work through some of this stuff if you agree and have the time. If so, let's schedule that.

Best,
Noam

Hi Eric,

After many false starts, I really am planning to submit an R01 on bioinformatics and statistical methods for Luminex serology in the next cycle (due Oct 6). Everyone came back from the BatID conference really jazzed about this. I still think it works best with you and I as co-PIs. If you are still game, want to have a call about it? I'd still like to come down to USU for a day in the next month, too, if you'd like to spend a day working on it and other related issues.

Schedule a call on my calendar here: <https://calendly.com/noamross/60-min-chat>

Last draft of specific aims attached.

Best,

Noam

(see Between Session slides)

-
- Investigation of ecological drivers of sarbecoviruses spillover in Myanmar and Nepal | Ohnmar Aung (EEIDI)
 - Vector surveillance in context of urban transmission and spread of Crimean-Congo hemorrhagic fever virus (CCHFV), Karachi Pakistan | Najia Ghanchi (UWARN)
 - In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance | Jurre Siegers and Vireak Heang (EID-SEARCH)
 - Pathogenic Mammarenaviruses and Orthohantaviruses in Argentina | María Martín and Carina Sen (WAC-EID)
 - Surveillance for known and novel viruses with zoonotic potential at the interface between humans and livestock in Kenya | Stephanie Seifert and Isaac Ngere (CREID-ECA)
 - Characterization of the mosquito microbiome and its role in arbovirus emergence and maintenance in Senegal | Laura Dickson and Alioune Gaye (WAC-EID)
-

Lightning Talk Concurrent Session Details

Day 3 | Friday, September 23 | 13:00-14:30

Concurrent Session A: Ecology, Entomology and Field Methods

Location: Fitzgerald B/C & Zoom

Session Chair: Peter Dascal (EID-SEARCH)

Session Co-Chair: Tierra Smiley (EEIDI)

- Building capacity for ecological surveillance and molecular diagnostics of mosquito-borne viruses in Sierra Leone | Robert Cross on behalf of Aiah Lebbie (WAC-EID)
- Active surveillance to detect low-level Rift Valley Fever Virus transmission in humans in East and Central Africa | Jeanette Dawa (CREID-ECA)
- [The use of satellite imagery to create robust geospatial sampling designs and examine landscape dynamics across an urban to rural gradient in Managua, Nicaragua](#) |  Kathryn Hacker (A2CARES)
- Higher infestation indices of the vector *Aedes aegypti* in rural areas than in urban areas in Managua, Nicaragua | Jose Victor Zambrana (A2CARES)
- [Rainfall and the prevalence of *Aedes aegypti* in northern coastal Ecuador](#) |  Jessica Uruchima (A2CARES)
- Setting the standard for field biosafety at the human-animal interface | Marc Valitutto (EID-SEARCH)
- [Effective Recruitment Strategies during an Infectious Disease Surveillance Study at Rural Health Facilities in Liberia; WARN-ID Liberia Team Experience](#) |  Bode Shobayo (WARN-ID)
- Environmental surveillance of informal sewage systems reveals community SARS-CoV-2 transmission dynamics | Joshua Levy (WARN-ID)
- Mosquito ecology and risk of arboviral infectious disease spillover in southwestern Uganda | Jalika Joyner (EEIDI)
- Report of arbovirology surveillance prospective cohort as model of early detection of viral circulation | Mauricio Nogueira (CREATE-NEO)
- Towards the laboratory maintenance of *Haemagogus janthinomys*, the major neotropical vector of sylvatic yellow fever | Adam Hendy (CREATE-NEO)

Lightning Talk Concurrent Session Details, continued

Concurrent Session B: One Health and Zoonotic Surveillance

Location: Fitzgerald A North & Zoom

Session Chair: Christine Johnson (EEIDI)

Session Co-Chair: Isaac Ngere (2022 Pilot Awardee, CREID-ECA)

- [One Health Pathogen Surveillance in the Bwindi Impenetrable Forest Region of Uganda](#) | [John Kayiwa \(EEIDI\)](#)
- [Use of molecular epidemiological, serological and experimental approaches to study COVID-19 transmission in Hong Kong](#) | [Leo Poon \(CREID-ESP\)](#)
- Evidence of Bourbon virus in ticks and humans in St. Louis Missouri, USA | Ishmael D. Aziati (CREID-ESP)
- Potential reservoirs hosts zoonotic pathogens in Senegal including emerging viruses such arboviruses, Lassa, Ebola, coronaviruses and henipaviruses | Mawlouth Diallo (WAC-EID)
- [A One Health investigation framework for zoonotic and vector-borne disease outbreaks](#) | [Soledad Colombe \(CREID-ECA\)](#)
- Coronavirus Circulation in Peridomestic Rodent Populations in Sierra Leone | Allison Smither (WAC-EID)
- One Health surveillance of Lassa fever in rodents and human close contacts in North Central Nigeria | Nathan Shehu on behalf of Pam Luka (WAC-EID)
- Plasmodium vivax infection in two non-human primates in the Amazon | Marcus Lacerda (CREATE-NEO)
- YF-neutralizing antibodies in pied tamarins (Saguinus bicolor) captured in Amazon Rainforest fragments in the urban area of Manaus, Brazil | Marcus Lacerda (CREATE-NEO)
- CREATE-NEO arboviral surveillance in mosquitoes, febrile humans and non-human primates in transition zones in Panama and Darien | Sandra Lopez-Verges (CREATE-NEO)
- Late Breaker: Predicting the zoonotic capacity of mammals to transmit SARS-CoV-2 | Barbara Han (CREATE-NEO)
- [Late Breaker: Coronavirus surveillance among farmed collared peccaries \(Dicotyles tajacu\) and caretakers in the Peruvian Amazon](#) | [Carlos Calvo-Mac \(EEIDI\)](#)
- Late Breaker: SARS-CoV-2 Genomic Variant Surveillance in Human and Non-Human Primates in Peru | Mariana Leguía (EEIDI)

Concurrent Session C: Clinical and Laboratory Science

Location: Fitzgerald A South &

Zoom

Session Chair: Rob Brieman (CREID-ECA)

Session Co-Chair: Bronwyn Gunn (2021 Pilot Awardee, CREID-ECA)

- [Acute Neurologic Syndromes associated with Chikungunya virus infections in Salvador, Brazil](#) | [Lorena Martins on behalf of Mateus Santana do Rosário \(UWARN\)](#)
- Predictors of severity in dengue-suspected pediatric patients during 2019 dengue epidemic in Brazil | Mauricio Nogueira (CREATE-NEO)
- Influence of previous Zika virus exposure on Brazilian dengue outbreak in 2019 | Cassia Fernanda Estofolete (CREATE-NEO)
- Immune escape mutations in the Spike protein of an endemic SARS-CoV-2 variant in Panama | Sandra Lopez-Verges (CREATE-NEO)
- The highly conserved stem-loop II motif is important for the lifecycle of astroviruses but dispensable for SARS-CoV-2 | David Wang (CREID-ESP)
- Antibody fucosylation predicts disease severity in secondary dengue infection | Tineke Cantaert (PICREID)
- Unexpected Acute Viral Fever Mimicking Dengue-Like Illness in Major City of Pakistan | Najeeha Talat Iqbal (UWARN)
- [Comparison of the Immunogenicity of five COVID-19 vaccines in Sri Lanka](#) | [Chandima Jeewandara \(A2CARES\)](#)
- SARS-CoV-2 Variant Detection and Surveillance with an Economical and Scalable Molecular Protocol | Jesse Waggoner (A2CARES)
- [Multiplexed detection of respiratory viruses and SARS-CoV-2 variants with mCARMEN](#) | [Nicole Welch \(WARN-ID\)](#)
- Developing Rapid Antigen Diagnostics for Emerging Viruses using Antibodies Cloned from Sorted Single Memory B-cells | Lee Gehrke (CREATE-NEO)

- A simplified Cas13-based assay for the identification of SARS-CoV-2 and its variants | Jon Artizti Sanz (WARN-ID)
- Late Breaker: Dynamics of infectious virus neutralization from convalescent and vaccine cohorts across global SARS-CoV-2 variant lineages reveals boost protection and novel monoclonal antibody efficacy against Omicron strains | Michael Gale (UWARN)

Concurrent Session D: Epidemiology and Surveillance Across the Americas

Location: Warfields &

Zoom

Session Chair: Wes Van Voorhis (UWARN)

Session Co-Chair: Daniel Aguiar, 2021 Pilot Awardee (CREATE-NEO)

- [A Dengue outbreak in Panama, 2022](#) | [Luis Felipe Rivera \(CREATE-NEO\)](#)
- [Seroprevalence of Zika, Dengue, and Chikungunya viruses in a rural area in Brazil](#) | [Marcos Vinicius Lima de Oliveira Francisco \(UWARN\)](#)
- Zika virus infection surveillance in Manaus, Amazonas state | Marcus Lacerda (CREATE-NEO)
- Real-time genomic surveillance of DENV-1 and DENV-2 in Brazil: improving public health outbreaks response | Luiz Alcantara (UWARN)
- [Surveillance and evolutionary analysis of Dengue viruses to understand the epidemiological dynamics of dengue outbreaks, São José do Rio Preto, São Paulo, Brazil](#) | [Livia Sacchetto \(CREATE-NEO\)](#)
- Monitoring the genetic diversity of reemerging chikungunya virus in Brazil | Luiz Alcantara (CREATE-NEO)
- Genomic and epidemiological monitoring of YFV reemergence in Brazil: unveiling the corridor of spread and the geographic hot spots for predicting and preventing other possible spillover events | Marta Giovanetti (UWARN)
- Genomic surveillance of SARS-CoV-2 in symptomatic vaccinated and unvaccinated asymptomatic patients in Brazil | Luiz Alcantara (UWARN)
- [SARS-CoV-2 genomic surveillance and the impact of different lineages circulation in the epidemiological landscape of São José do Rio Preto, São Paulo, Brazil](#) | [Cecília Artico Banho \(CREATE-NEO\)](#)
- Genomic epidemiology reveals the impact of national and international restrictions on the SARS-CoV-2 epidemic in Brazil | Marta Giovanetti (UWARN)
- Occurrence of SARS-CoV-2 reinfections at regular intervals in Ecuador | Paul Cardenas (A2CARES)
- [Genomic characterization of SARS-CoV-2 during the COVID-19 pandemic in Nicaragua](#) | [Cristhiam Cerpas \(A2CARES\)](#)

Concurrent Session E: Epidemiology and Surveillance Across Africa and Asia

Location: Grason & Zoom

Session Chair: Anavaj Sakuntabhai (PICREID)

Session Co-Chair: Robert Langat, 2021 Pilot Awardee (CREID-ECA)

- Flaviviruses and Lassa fever in febrile patients in North Central Nigeria: A cross-sectional study | Nathan Shehu (WAC-EID)
- [Double Stigma and discrimination: A qualitative study of Lassa fever and hearing loss in Northern Nigeria](#) | [Kachollom Best \(WAC-EID\)](#)
- A brief chronicle of SARS-CoV-2 genomic surveillance in Cambodia | PICREID Representative on behalf of Erik Karlsson (PICREID)
- [Identification of Genetic Variations of SARS-CoV-2 Omicron Strain and their Clinical Significance in Karachi, Pakistan](#) | [Aqsa Khalid \(UWARN\)](#)
- Genetic characterization of Norovirus strains from an unusual diarrheal outbreak in the community in Thailand | Krongkan Srimuang (EID-SEARCH)
- Factors associated with changing Dengue case numbers during the COVID-19 pandemic in Sri Lanka | Dinuka Ariyaratne (A2CARES)
- SARS-CoV-2 genomic epidemiology in Sierra Leone | John Demby Sandi (WARN-ID)
- Yellow Fever outbreak in eastern Senegal, 2020–2021 | Moussa Diagne (WAC-EID)
- [The evolving SARS-CoV-2 epidemic in Africa: Insights from rapidly expanding genomic surveillance](#) | [Houriiyah Tegally \(UWARN\)](#)

- Detection and Characterization of Variants of Concern: Insights from the South African Epidemic | James Emmanuel San (UWARN)
- Emergence of novel combinations of SARS-CoV-2 spike receptor binding domain variants in Senegal | Amroise Ahoudi (UWARN)
- [COVID-19 laboratory surveillance at IRESSEF in Senegal](#) | [Cheikh Ibrahim Lo \(UWARN\)](#)
- [Dynamics of Variants of Concern \(VOC\) during the different waves of COVID-19 in Senegal](#) | [Abdou Padane \(UWARN\)](#)

Acronyms and Abbreviations

A2CARES	American and Asian Centers for Arboviral Research and Enhanced Surveillance
BV-BRC	Bacterial and Viral Bioinformatics Resource Center
CEPI	Coalition for Epidemic Preparedness Innovations
CREATE-NEO	Coordinating Research on Emerging Arboviral Threats Encompassing the Neotropics
CREID	Centers for Research in Emerging Infectious Diseases
CREID CC	CREID Coordinating Center
CREID-ECA	Center for Research in Emerging Infectious Diseases – East and Central Africa
CREID-ESP	Center for Research in Emerging Infectious Diseases – Epidemiology, Surveillance and Pathogenesis
CSPH	Colorado School of Public Health
DMID	Division of Microbiology and Infectious Diseases
EEIDI	EpiCenter for Emerging Infectious Disease Intelligence
EID-SEARCH	Emerging Infectious Diseases: South East Asia Research Collaboration Hub
NIAID	National Institute of Allergy and Infectious Diseases
NIBSC	National Institute for Biological Standards and Controls
NIH	National Institutes of Health
PICREID	Pasteur International Center for Research on Emerging Infectious Diseases
PREMISE	Pandemic Response Repository through Microbial and Immunological Surveillance and Epidemiology
RC	Research Center
TGHN	The Global Health Network
UWARN	United World Antiviral Research Network
WAC-EID	West African Center for Emerging Infectious Diseases
WARN-ID	West African Research Network for Infectious Diseases
WRCEVA	World Reference Center for Emerging Viruses and Arboviruses

Subject: RE: CREID Scientific Meeting Day 1

Date: Wednesday, September 21, 2022 1:26:52 PM

Attachments: [CREIDAqenda_Detailed_Scientific_v2.pdf](#)

Hi all,

Please find an updated agenda with scientific meeting zoom link attached.

Thank you,

Aaron

Aaron Macoubray
RTI International
Public Health Analyst

Subject: CREID Scientific Meeting Day 1

When: Wednesday, September 21, 2022 1:00 PM-5:00 PM (UTC-05:00) Eastern Time (US & Canada).

Where:

Hello CREID Scientific Meeting Attendees,

Please plan to join the **Scientific Meeting on Day 1** of the Annual Meeting. Final agenda and materials will be shared on Monday, September 19.

In-person attendees, please go to **Fitzgerald B/C**.

Virtual attendees, please use the following zoom link for this meeting:

<https://explorepsa.zoomgov.com/j/1619281154?pwd=T0JLL1FHK3p2cU9nQ3h2TzFLaHdhQT09>

Thank you,

Aaron

CREID Coordinating Center Project Coordinator

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Application Cover Sheet

Project Title	Mixed-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam
Principal Investigator Name	Nguyen Van Cuong
Position/Title	Project Coordinator and PhD candidate (viva data: 03/15/21)
Department	Centre for Tropical Medicine
Institution Name	Oxford University Clinical Research Unit
Street	764 Vo Van Kiet, Ward 1, District 5
City, State, Zip Code	Ho Chi Minh City, TP Ho Chi Minh, 700000
Country	Viet Nam
Email	cuongnv@oucru.org
Phone	+84 8 39237954
Country(ies) where work will be conducted	Viet Nam
Pathogen(s) focus	Zoonoses, Coronaviruses, Paramyxoviruses

Collaborating CREID Research Center	The Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH)
Contact PI	Peter Daszak
CREID RC Primary Point of Contact	Hongying Li
CREID RC Primary Point of Contact Location or Institution	EcoHealth Alliance (EHA)

Name of Mentor	Cadhla Firth
Mentor Institution	EcoHealth Alliance
Institution Address	520 Eighth Avenue, Ste. 1200 New York, NY 10018
Permanent location of Mentor	New York, NY
Mentor email	firth@ecohealthalliance.org
Mentor phone	+61 447 361 669

Total Budget	\$149,970.58
Direct Costs	\$138,861.64
Indirect Costs	\$11,041.17
Proposed Start Date	06/01/2021
Proposed End Date	05/31/2021

Project Abstract
<p>Viet Nam sits within a critical Southeast Asian emerging infectious disease hotspot with diverse wildlife and a rapidly increasing human population. In this region, wildlife farming is a growing but inadequately regulated industry that exhibits many features thought to contribute to increased risks of cross-species transmission and zoonotic disease emergence. We will focus on a key zoonotic disease pathway that was involved in the emergence of Nipah virus, SARS-CoV, and potentially SARS-CoV-2 – the spillover of viruses from wildlife to multi-species farms, and subsequently to people. We will test a key hypothesis: viral diversity and cross-species transmission will increase with species</p>

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

diversity on mixed-species farms, and this pattern will be further amplified by the presence of wildlife species. We will access a previously untouched sample set from 64 mixed-species farms in a biodiverse region of central Viet Nam where wildlife and domestic species are farmed both together and separately. We will characterize viral diversity in single- and mixed-species farms using metagenomics and PCR, identify their zoonotic potential using ecological and phylogenetic methods, and estimate risk of emergence by analyzing distribution and prevalence. To inform the local community of our results, we will develop a two-way dialogue with farmers and government stakeholders in Viet Nam regarding potential disease risks associated with wildlife and mixed-species farming. Importantly, this project builds capacity for emerging infectious disease research in Southeast Asia by supporting the in-country development of analytically robust, hypothesis-driven research into the ecology and evolution of emerging infectious diseases.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Title

Mixed-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Study Personnel

The PI on this project, Dr. Cuong Nguyen, is ideally suited to conduct and manage this project. Dr. Nguyen is trained as a veterinarian and will be defending his PhD thesis (Open University, United Kingdom (UK)) focused on veterinary epidemiology and antimicrobial usage on farms in Viet Nam on 15 March 2021. Dr. Nguyen possesses experience in performing both laboratory- and field-based research, as well as translating research outcomes into locally-relevant interventions and policy recommendations. These efforts have resulted in 20 peer-reviewed publications since 2018. Dr. Nguyen has worked with the Oxford University Clinical Research Unit (OUCRU) since 2011, during which time he acted as a coordinator of veterinary fieldwork for the Wellcome Trust-funded Vietnamese Initiative for Zoonotic Infections (VIZIONS) project, which ended in 2016, and under which the samples for the proposed project were collected. Dr. Nguyen will be responsible for project coordination, data analysis, public engagement, and presentation/publication of the research conducted under the proposed project. He will be allocated 100% protected time to work on this project and his professional development over the one-year period. To ensure that the proposed research can be accomplished on time and within budget, all laboratory work will be completed by a Senior Research Assistant who will be supervised directly by Dr. Nguyen within the Molecular Epidemiology group at OUCRU. Several members of this research group were part of the VIZIONS team and are familiar with the sampling and laboratory protocols required to ensure the completion of this study in a timely manner.

As co-lead of OUCRU's Molecular Epidemiology research group, Dr. Maia Rabaa will be a collaborator on this project and will supervise Dr. Nguyen's research throughout the proposed project. Dr. Rabaa is a molecular epidemiologist with eight years of experience working at OUCRU, and contributed to the design, implementation, and analysis of data related to the VIZIONS project. Dr. Rabaa and her team have access to the relevant samples, were involved in the design and conduct of the VIZIONS project, have significant expertise in sequencing and phylogenetic analysis, and will provide additional support and advice during Dr. Nguyen's laboratory work, analysis, and writing. As the group lead, Dr. Rabaa will also supervise Dr. Nguyen's progress and administrative tasks and assist in the further development of his budget and human resources management skills as he progresses toward scientific independence.

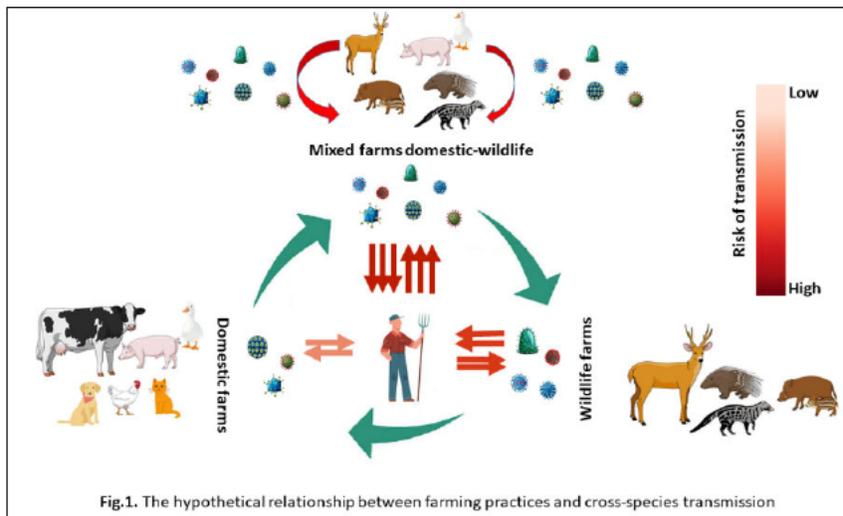

Dr. Cadhla Firth will act as Mentor for Dr. Nguyen under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Firth is Senior Research Scientist and Program Coordinator at EcoHealth Alliance (EHA), which houses the Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH) program. Dr Firth has more than 15 years' experience conducting research on emerging infectious diseases, with a focus on the ecology and evolution of viruses in animal populations. Dr. Firth's expertise in study design, molecular biology, metagenomic sequencing, and the analysis of metagenomic and ecological data match well with Dr. Nguyen's interests and the proposed project. Dr. Firth will provide scientific guidance, analytical training, mentoring, and career advice, as well as networking opportunities that support Dr. Nguyen's progression toward independence.

As colleagues on the VIZIONS project, Dr. Nguyen and Dr. Rabaa have built a strong collaborative foundation that complements the peer mentorship that Dr. Rabaa and Dr. Firth established in 2008 during their respective PhD studies under Prof Edward Holmes, and which continues to this day. With Dr. Firth's recent move to EHA, Dr. Rabaa's promotion to Group Head and subsequent collaboration with EHA, and the completion of Dr. Nguyen's PhD work, this team is now in an advantageous position to deliver a strong research project with tangible outcomes under the CREID Pilot Research Program.

Research Aims and Objectives

This project aims to answer the question: “How does species diversity influence viral diversity and the risk of cross-species transmission on mixed-species farms?”.

We hypothesize that: (i) viral diversity and cross-species transmission will increase with species diversity on mixed-species farms, (ii) the presence of both wildlife and livestock species on a farm will be associated with increased viral diversity, and (iii) the diversity of viruses with zoonotic potential will

increase with species diversity on mixed-species farms. To test these hypotheses, we will access a unique sample set from farms in the Central Highlands of Viet Nam, where a variety of wildlife (e.g., deer, bamboo rats, civets, wild boars, rabbits, porcupines) and domestic species (e.g., chickens, ducks, cats, pigs, goats) are farmed both together and separately. Mixed-species farms create new interfaces between wildlife, domestic animals, and

people that may provide opportunities for cross-species transmission of viruses to occur (Figure 1).

The proposed project has three aims:

AIM 1: Estimate the frequency of viral sharing between animals of different species under mixed- and single-species farming conditions and identify ‘risky’ viruses that commonly cross the species barrier under each of these conditions.

AIM 2: Identify environmental and ecological factors associated with variations in viral prevalence, diversity, or rates of cross-species transmission of ‘risky’ viruses.

AIM 3: Identify farm management policies and practices to increase awareness and reduce the risk of cross-species transmission of viruses associated with mixed-species farms.

The proposed project has three objectives:

OBJ 1: Characterize the viral diversity present in samples from animals housed on single and mixed-species farms using a combination of metagenomics and polymerase chain reaction (PCR)-based screening.

OBJ 2: Identify viruses with known or predicted zoonotic potential using ecological and phylogenetic methods. Estimate the distribution, prevalence, and relatedness of these viruses across animal species and farms.

OBJ 3: In collaboration with the policy and public engagement departments at OUCRU, engage in two-way dialogues with government stakeholders and the farming community in the Central Highlands about potential disease risks associated with wildlife and mixed-species farming.

Study Rationale/Research Gap/Impact

On July 23, 2020, the Prime Minister of Viet Nam issued a new directive (Directive 29/CT-TTg) [1] calling for increased enforcement of legislation regarding the control of wildlife hunting and trade, which has been widely interpreted as a move toward a complete ban on wildlife trading [2]. This follows similar legislation passed in China in February 2020, which introduced new regulations banning almost all consumption and trade of terrestrial wild animals in the country, and which is expected to cause knock-on policy effects across Asia [3]. Commercial wildlife farming has been proposed as a potential solution to problems caused by a ban on wildlife hunting and trade by creating a regulated and monitored source for wildlife products, while supporting conservation efforts and addressing cultural, economic, and food security issues that may otherwise drive these practices into unregulated marketplaces [4–6]. However, wildlife have also been associated with the emergence of many zoonotic diseases, and several features of wildlife or mixed-species farms suggest that they may pose a greater risk to people than domestic farms alone [7–10].

More than 175 wildlife species are farmed in Viet Nam, including those previously associated with zoonotic transmission risks (e.g., civets, primates, rodents) [11]. However, a recent survey of more than 4000 wildlife farms in southern Viet Nam revealed that 70% of farms also raised domestic species (including livestock) [11]. Critically, pathogens with broad host ranges are significantly more likely to emerge in human populations, which suggests that the presence of multiple species (both wild and domestic) on the same farms may be cause for concern due to the potential for cross-species transmission and viral amplification [12–15]. The risks posed by wildlife farming are further complicated by the high frequency of wildlife laundering, which was the dominant form of wildlife production on 26 Vietnamese farms surveyed between 2014 and 2015 [4]. The frequent movement of wildlife from the natural environment into a domestic setting creates a conduit for the emergence of novel pathogens, including those with zoonotic potential. In addition, the majority of farmed wildlife are raised for food, yet there is a lack of veterinary oversight and infection control measures on Vietnamese wildlife farms that is not mirrored in the farming of domestic species in the region. In a census of more than 4000 wildlife farms in southern Viet Nam, an absence of veterinary care was noted in nearly all cases, along with high numbers of sick and dead animals from unknown causes [11].

Despite the clear risks associated with wildlife farming in Viet Nam, there is very limited understanding of the impacts of wildlife and mixed-species farming practices on viral diversity, virus sharing, and zoonotic transmission [15]. However, the renewed interest in wildlife hunting, farming, and trading that has resulted from the hunt for the origin of SARS-CoV-2 has led to a resurgence in effort to understand the impacts of the policies and practices around wildlife farm management. Although a stated aim of this work is to reduce human and animal disease risk, and zoonotic transmission in particular, there remains an extreme paucity of data related to the risks posed by wildlife farming, or specific farming practices that contribute to this risk. For the first time in the proposed project, we will explicitly test the relationships between species diversity and composition, viral diversity, and cross-species transmission on wildlife and mixed-species farms.

Thus, in line with the goals of the CREID network and the EID-SEARCH team, we aim to use previously collected samples from Vietnamese farms to systematically characterize the diversity and transmission of viruses within animal populations on mixed-species farms. We will assess the risk these viruses may pose to human and animal populations, and use these data to assist in the development of farm management practices and policies to mitigate such risks.

Significance and approach

Wildlife farming, hunting, and trade have repeatedly been associated with the emergence of new zoonotic diseases, including SARS-CoV, SARS-CoV-2, monkeypox virus, and Ebola and Marburg filoviruses [16]. However, strikingly little is known about the drivers of disease emergence from wildlife, particularly with respect to the food chain, including wildlife farms. Previous studies on virus diversity and viral sharing along wildlife supply chains have relied exclusively on consensus PCR-based virus detection or have focused on only a single animal species, even on mixed-species farms [15,17,18]. In contrast, this project will use cutting-edge genomic approaches in ecology and evolution within a hypothesis-driven framework to reveal the determinants of viral diversity, abundance, and transmission within mixed-species farms. To our knowledge, this will be the first data-driven project with the goal of providing a foundation for understanding the roles of mixed-species farming, wildlife farming, and species-species interactions as drivers of disease emergence.

Data collected as part of the VIZIONS project represents a unique opportunity to build a holistic picture of the links between wildlife farming practices, viral diversity, and cross-species transmission. VIZIONS, which ended in 2016, involved international research institutions collaborating with Vietnamese governmental organizations and hospitals to collect samples at three sites across Viet Nam to study clinical illness, epidemiology, pathogen diversity, and social and behavioral factors within a One Health framework. The VIZIONS project had two fundamental components: 1) a hospital disease surveillance program to characterize endemic infections, novel infections, and diseases of unknown origin in humans, and 2) a high-risk human sentinel cohort (HRSC) to assess zoonotic disease incidence and cross-species transmission through sampling of both HRSC members and the animals with which they had contact [19]. Most HRSC cohort members (72.8%) were individuals living on farms, with 53.7% of members in Dak Lak Province reporting exposure to farmed wildlife, including deer, bamboo rats, civets, wild boars, rabbits, and porcupines [20]. We have access to untouched animal samples from this unique dataset from Dak Lak Province, which are linked to publicly available metagenomic data [21,22] from co-located samples from farm workers, and to questionnaire data designed to assess zoonotic disease risk. This provides an unprecedented opportunity to examine multiple dimensions of risk in a complex and highly topical system.

This study also provides an opportunity to link zoonotic disease research back to the communities most at risk of novel disease emergence, including the farmers and government health officials who make daily decisions that directly influence disease risk. Community and government engagement activities were key components of the VIZIONS project and these relationships have been maintained by the OUCRU public engagement team. This will enable a dialogue between the project team and a network of key stakeholders (i.e., farmers, provincial and regional animal health officers, public health officials, and representatives of the Departments of Agriculture and Forestry), through which we can identify potential risks associated with mixed-species farming and wildlife trade in these communities. The result of this engagement activity will be an understanding of how policy is implemented at the local level, and the identification of avenues for future collaborative research and engagement that will benefit the community and expand the CREID and EID-SEARCH networks to improve our understanding and response to the risk of zoonotic virus emergence in Viet Nam and across the region.

Research Methods

Site and sample selection.

Our metagenomic analysis will use animal samples previously collected as part of a three-year high-risk cohort study conducted across Dak Lak Province in Viet Nam's Central Highlands (Figure 2). From March 2012 to September 2015, human and animal samples were collected from 64 farms across Dak Lak at multiple time points (median of five visits per farm), including during reported episodes of human illness. Human samples included nasopharyngeal swabs, rectal swabs, and sera, and were associated with questionnaire data to assess human-animal contact and potential risk factors for zoonotic transmission. Human samples collected during illness have been previously analyzed by metagenomic analysis [21,22], and the data are available for comparison with the results of this study. Animal samples primarily included feces and/or rectal swabs (N = 3675), nasal and/or throat swabs (N = 2499), and sera (N = 1245), which were collected from 2251 live animals, comprised of 19 species (12 domestic species, seven wildlife species). These uninterrogated animal samples have been stored at OUCRU in -80°C freezers since the time of collection and are available for metagenomic sequencing in this study.

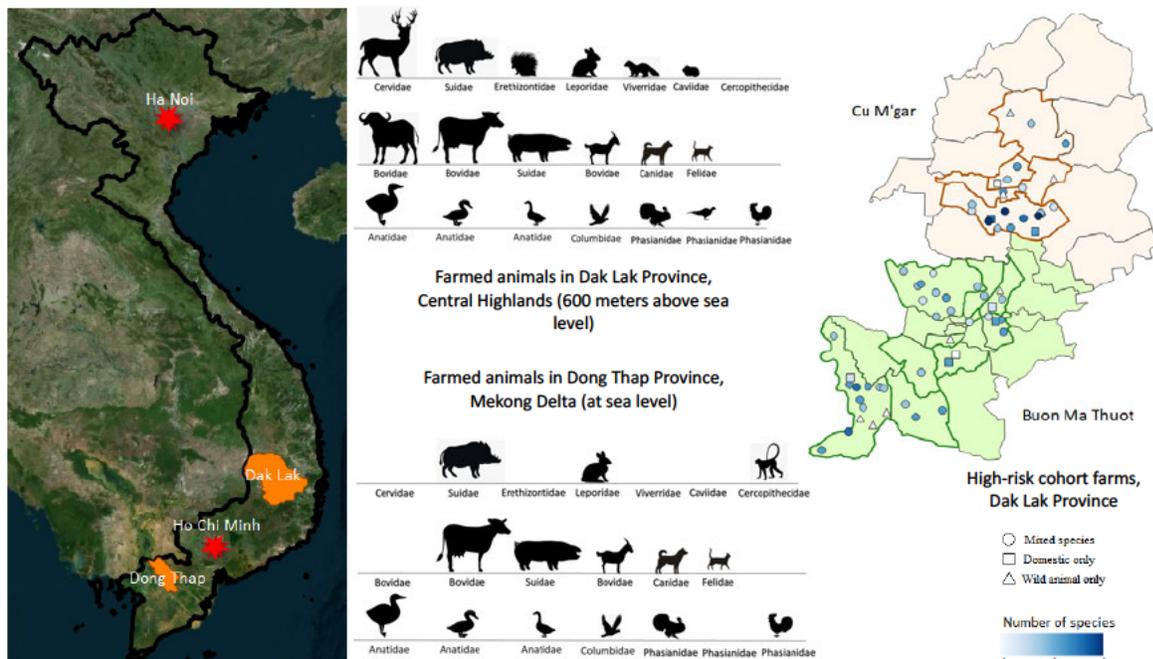

Figure 2. Summary of farmed animals sampled within the VIZIONS project (Dak Lak & Dong Thap Provinces), and distribution of domestic, wildlife, and mixed farms in Dak Lak Province, Viet Nam.

Of the 64 farms sampled as part of the cohort study, 67% contained both domestic and wildlife species, 27% contained domestic species only, and 6% contained wildlife only. The number of species per farm ranged from one to nine, with a median value of five species/farm. To explore the relationships between mixed-species farming, viral diversity, and cross-species transmission, we will select a subset of sampled farms for metagenomics that best capture a gradient of farming intensity in this region. These will include farms with low, medium and high species diversity, as well as farms with and without wildlife (Figure 3). Farms will also be selected to achieve maximum overlap in species composition, whereby the species sampled on low diversity farms are also represented on high diversity farms. As such, we will initially target the most frequently sampled domestic (e.g., chickens, ducks, pigs, cats) and wildlife species (e.g., porcupines, rabbits, wild boar, deer) across farms.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Figure 3. The number of animal species sampled per sampling trip, according to species (select data shown). For example, in the top left corner, wild boar were the only species present on a farm at two sampling events, while one or more other species was sampled on all other sampling involving wild boar. Different shapes and colors differentiate farm types (domestic, wild, and mixed wild/domestic). Additional images illustrate farming practices and species diversity on Dak Lak farms.

RNA isolation and metagenomic sequencing.

It has been estimated that only a very small fraction of viral diversity on earth has been described, such that our ability to contextualize disease emergence and cross-species transmission is strongly skewed towards viral families that have already been well-characterized [23]. This bias is further amplified by the widespread use of ‘consensus PCR’ assays as a mechanism of virus discovery, as this approach attempts to detect new viruses by using sequences from conserved regions of the genome (i.e., primers) of known viruses. As such, this method is likely to be unable to detect viruses that are significantly divergent from those which are already known. In contrast, many recent studies have demonstrated that a metagenomic approach has the ability to reveal the entire virus composition of a sample (i.e., the virome), as well as the relative abundances of each virus [23,24]. We will use this approach to provide a comprehensive view of all viruses present in our dataset.

To comprehensively characterize viromes at both the farm and species level, high quality total ribonucleic acid (RNA) will be extracted from 1000 fecal samples and/or rectal swabs, and 1000 nasal and/or throat swabs (henceforth respiratory swabs) from animals sampled from the subset of farms described above. Fecal samples were selected due to their association with high viral diversity (e.g., coronaviruses, picornaviruses) and the potential importance of fecal-oral transmission in viral emergence and spread [25–27]. Respiratory swabs were selected due to the potential to detect respiratory viruses, which have been associated with multiple significant emerging viral diseases (e.g., SARS, COVID-19, influenza) in the past [28,29]. Extracted RNA will be quantified and samples will be pooled by sample type, species, and farm to achieve a total of 120 pools with a maximum of 10

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

samples/pool. When animal numbers on a farm are low, pooling will be by taxonomic order (e.g., Rodentia, Carnivora, Artiodactyla), rather than by species. Sequencing libraries will be generated from each pool using the Stranded Total RNA Prep with Ribo-Zero Plus kit (Illumina), which includes a ribosomal RNA depletion step to reduce the amount of animal and bacterial RNA sequenced. Libraries will be assessed for quality on the Agilent 2100 Bioanalyzer and sequenced using the Illumina HiSeq-2500 platform at Macrogen (South Korea).

Sequence analysis.

Raw sequencing reads from each pool will be filtered for quality and assembled *de novo* using Trinity RNA-Seq [30]. Assembled sequences will be identified and annotated by comparing them to the complete nonredundant nucleotide and protein databases available through GenBank using E-value cutoffs of 1E-10 and 1E-4, respectively, and the program Diamond [31]. Sequences representing viral genomes will be further characterized using phylogenetic analysis targeting conserved domains (e.g., the RNA polymerase) that will include related viruses from GenBank to estimate evolutionary relationships. Phylogenies will be inferred using the maximum likelihood method implemented in IQ-Tree, employing the best-fit amino acid substitution models for each virus family [32]. The resultant phylogenies will be used along with the Virus-Host DB [33] to identify putative host species for viruses found in feces or rectal swabs, which commonly also contain plant and invertebrate viruses ingested as part of an animal's diet. Only viruses predicted or known to infect vertebrate animals will be investigated in downstream analyses.

PCR-based screening.

A subset of viruses identified from the metagenomic data will be selected for additional analyses based on phylogenetic relationships and host associations, as described above. As a priority, we will select: (i) viruses with known or predicted zoonotic potential (e.g., coronaviruses, paramyxoviruses), and (ii) viruses found at high prevalence and in multiple species that will facilitate the analysis needed to achieve AIM 2. Primers will be designed from the metagenomic data and used to screen relevant individual samples (i.e., not pools). An effort will be made to target regions of the genome likely to contain enough genetic diversity to support phylogenetic resolution at the farm and species level (e.g., the capsid gene, glycoprotein genes). Positive PCRs will be sequenced in both forward and reverse directions using Sanger sequencing technology (Macrogen) and assembled *de novo* using Geneious [34].

Assessing viral sharing.

To address AIM 1, the prevalence of each known or putative vertebrate virus will be estimated for all pools using the reference mapping software BWA, with RNA polymerase sequences from the metagenomic data as a reference [35]. The abundance of each vertebrate virus within a pool will be estimated from the sequencing data using RNA-Seq by Expectation-Maximization (RSEM) [36], implemented in Trinity. These data will be used to compare viral community structure across farms and host species using standard measures from community ecology, including species richness, alpha diversity, and beta diversity, which will be calculated using a range of R packages [37]. Permutational multivariate analysis of variance tests (permanova) will be used to assess differences in virome composition between farms and species.

For a more detailed analysis of the processes underlying viral sharing, the sequence data generated from our PCR-based screening on individual samples will be used to infer virus-specific phylogenetic trees, using maximum likelihood methods (as above) as well as Bayesian inference where phylogenetic resolution is high. Unlike our previous analysis, these phylogenies will contain only samples from this study and will reflect viral genetic variation across individuals, host species, and farms. To assess phylogenetic clustering and cross-species transmission at the farm and species level, we will utilize statistical frameworks developed for the phylogenetic analysis of discrete character states. These will

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

include association indices [38], parsimony scores [39], and maximum exclusive single-state clade sizes [40]. Further, we will impose models of discrete trait evolution [41], often utilized in phylogeographical analyses, to investigate viral sharing and the directionality of cross-species transmission between host species and between farms.

For AIM 2, we will use non-metric multidimensional scaling (NMDS) to ordinate each farm based on a set of ecological and environmental variables using R [37]. This analysis will be performed at two scales – local and regional. The local analysis will include data about each farm that was acquired during sampling or from questionnaires, such as the abundance and diversity of animal species, the presence of sick animals (and type of illness), and human activities previously associated with increased disease risk (e.g., butchering/slaughtering, selling wild animals, eating raw meat, etc.) [42]. In addition, the regional analysis will include variables representing the environmental and ecological context of each farm, which will be estimated from publicly available databases. Examples of these variables include average rainfall, average temperature, the mean normalized difference vegetation index (using LANDSAT data [43]), distance to an urban area, distance to water, and an index of wild mammal diversity (using International Union for Conservation of Nature [IUCN] data). Critically, the regional analysis will also include virus data previously generated and published from farms in Dong Thap Province (**Figure 2**) in the Mekong Delta, which were sampled under the same protocols (ENA accession numbers PRJEB6505, PRJEB26687, PRJEB27881) [18,44,45]. The addition of this second sampling location will allow us to separate the effects of farming practices on viral sharing (local scale) from the impacts of the surrounding environment (regional scale). The ordination axes resulting from the NMDS performed at each scale will be used as predictor variables in independent generalized linear models (GLMs) to examine their influence on virus presence and abundance for the subset of prioritized viruses using R. Model fit will be assessed using the Hosmer-Lemeshow goodness of fit test. The resulting models will be used to identify behavioral, environmental, and ecological factors that best predict the presence of ‘risky’ viruses on mixed-species farms.

Community and policy engagement.

To address AIM 3, we will utilize the results from the above analyses to identify potentially ‘risky’ farming practices, such as high farm-level species diversity, specific host-virus interactions, or interactions between farming practices and the surrounding environment, to engage stakeholders in discussions about the perception and management of risk in mixed-species farming. We will first organize meetings to engage stakeholders responsible for animal health, human health, and farm management within Dak Lak Province. These include provincial and regional animal and human health officials, and provincial representatives of the Departments of Agriculture (overseeing domestic farm management) and Forestry (overseeing wildlife farm management). We will use these meetings to create a two-way dialogue around these issues and better understand how recommendations on farm health and management are disseminated through public policy and farm management structures. Where recommendations on farm management can be made from our findings, we (with the OUCRU public engagement and policy teams) will work within the identified structures to determine the best practices with which to disseminate these findings to animal health workers and farming communities.

Working with these government stakeholders, we will identify opportunities to engage former members of the Dak Lak HRSC from the VIZIONS project in order to share our findings and better understand current perceptions of the risks associated with wildlife farming, particularly in light of potential links to the COVID-19 pandemic. With the OUCRU public engagement team, we will design surveys to initiate future discussions (extending beyond the scope of this proposal) that consider questions related to bans on wildlife farming and consumption at the policy level and their potential economic impacts, as well as perceived risks and approaches to protecting animal and human health at the farm level.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Research Performance Sites

OUCRU in Ho Chi Minh City (HCMC) was the primary site of the VIZIONS project, which ran from 2012-2016. This project involved two components: 1) hospital-based surveillance of pathogens causing selected human illnesses and 2) three cohorts (~300 humans/cohort) of individuals considered at high occupational risk of contracting zoonotic infections. These cohorts were sampled over three years, along with the animals with which they were in contact. The proposed project will focus on animal samples collected under component 2 of the VIZIONS project in Dak Lak Province. All samples needed for this work have been maintained in OUCRU HCMC laboratory freezers at -80°C from the time of collection and can be easily linked to human questionnaire, serological, and pathogen data collected from the human cohorts within OUCRU's in-house data management system (CliRes).

These unique samples and data are available only at OUCRU, which is committed to facilitating the proposed research. Leadership and several staff members within OUCRU's Molecular Epidemiology group (including Dr. Nguyen) were involved in the design and conduct of the VIZIONS project, and will facilitate access to samples and data, as well as assist in sample processing and analysis. Expertise in molecular biology, viral surveillance, phylogenetics, and molecular epidemiology within the research group will ensure that Dr. Nguyen has the support necessary to complete the proposed project.

OUCRU have established state-of-the-art clinical diagnostics, as well as basic and applied research laboratories that will facilitate successful completion of all aspects of the proposed project. Laboratory facilities include: clinical laboratories (ISO 15189:2012 certified), Biosafety level (BSL) 2 and BSL3 laboratories, and a bio-archiving facility. The laboratories are equipped with safety cabinets (fume hoods, biosafety category II and III), shaking & stationary incubators, refrigerated centrifuges, thermocyclers, real-time quantitative PCR machines, a gel imaging platform (chemiluminescence, ultraviolet, and visible light), gel boxes, water baths, mixing devices, capillary DNA sequencers, Illumina MiSeq sequencers, Oxford Nanopore MinION sequencers, an ultra-centrifuge, a Luminex Flexmap 3D, -80°C freezers, -20°C freezers, refrigerators, liquid nitrogen tanks, ice machines, and autoclaves.

Molecular epidemiology research at OUCRU is conducted in facilities across the laboratories, including a specimen processing facility, molecular diagnostic facility, genomics facility, and an immune-biology facility with serology and cell culture capabilities. High-risk laboratory processes are conducted in the BSL3 laboratory. OUCRU maintains a bio-archiving facility (-20°C, -86°C, liquid nitrogen storage facility) containing 2.5 million samples with continuous temperature monitoring and sample tracking (Lab guard system, Freezerworks system, and biometric access control). Dr. Nguyen will have access to all of the infrastructure and support associated with these facilities to complete the proposed project.

All OUCRU employees have around-the-clock access to computer servers, a virtual private network (VPN), encryption software, information technology (IT) support, and all necessary software including: Git and Github (hosted software revision/audit service), Oracle Virtualbox virtual machines, Google Apps (hosted email and collaboration web-based software), Python, NodeJS, and R programming languages, Meteor (Javascript framework), Jenkins (Continuous Integration server), Microsoft Office, and Adobe CS6. OUCRU also has a dedicated 150+ core Linux server with 8 terabyte (TB) hard drives, and the Molecular Epidemiology group has two dedicated 16-core Mac Pro Servers with 4TB hard drives. Either server individually or in combination may be used for intensive sequence analysis, computational modeling and/or database processing by Dr. Nguyen to ensure successful completion of the project.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

CREID Research Center Collaboration

The goals and objectives of the proposed research project, *“Mixed-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam”*, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Viet Nam, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and its OUCRU partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the OUCRU research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between Dr. Nguyen and our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Dr. Nguyen’s professional development and strengthen research capacity in the region. Dr. Cathla Firth, Senior Scientist at EID-SEARCH and the project Mentor, has an established relationship with both Dr. Nguyen and his supervisor, Dr. Maia Rabaa, and will act as the liaison between EID-SEARCH and the OUCRU research team. An expected outcome of this research project will be pilot data to support a joint funding application in the future, led by Dr. Nguyen.

Furthermore, we expect this research to not only improve scientific understanding of zoonotic disease emergence, but also to raise risk awareness among government and local stakeholders and help inform local policies. EID-SEARCH has a team with a strong policy and social science background and extensive experience working with communities and engaging local governments. The EID-SEARCH team will support this project by helping the OUCRU team to develop locally-relevant evidence-based messages, and will strengthen multi-sectoral collaboration in developing practical risk-mitigation strategies. Dr. Nguyen has nearly ten years of experience engaging with local officials and farming communities to develop locally-acceptable research and One Health interventions on the ground in Viet Nam. These relationships Dr. Nguyen has cultivated during his time at OUCRU will facilitate the establishment of a sustainable scientific platform for ongoing research in emerging infectious diseases in Southeast Asia, as well as provide a direct pathway for policy impacts under the EID-SEARCH program.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Mentoring Plan

Although I am scheduled to complete my PhD on March 15, 2021 (viva date), I have been actively involved in research as a veterinarian and Program Coordinator at OUCRU since 2011. As a result, I have a broad understanding of the challenges involved in developing and implementing a research project, and a clear idea of how I would like to progress my career. My overall research goal is to improve the health of people in Viet Nam using a One Health approach that will allow me to maximize the impacts of both my veterinary and academic training. However, my aspirations are not just limited to the creation of scientific knowledge; instead, I wish to actively use this knowledge to address social issues in Viet Nam, as demonstrated by the focus of my PhD research on antimicrobial stewardship on poultry farms.

My previous community engagement experiences have focused primarily on highlighting the need for data-driven policy, and I have had only limited experience working with political agencies to translate scientific evidence into laws and regulations. Through the public engagement aim of the proposed project, I will be able to strengthen my relationships with government and local stakeholders, grow my network across Viet Nam, and enable my long-term success using data-driven, community-led research to generate real-world impacts. By working closely with members of EHA, who have a strong background in community engagement and policy development, and the recently formed Policy Engagement group at OUCRU, I feel that this project will provide the perfect opportunity for me to develop my career vision as an independent scientist.

Throughout my career, I have had experience and training in veterinary medicine, laboratory-based science, program coordination, and epidemiology. However, it is clear that genomics (and metagenomics) is now an increasingly common aspect of emerging infectious disease research. There is a pressing need for increased capacity in this field in Viet Nam, as well as in many other lower- and middle-income countries, to ensure that we have access to the best methods and analytical tools available to support a thriving science industry. I believe that, given the opportunity to further strengthen my analytical skills to include metagenomic data analysis, I will be in possession of a comprehensive skillset that will allow me to transition from a junior scientist to an independent science leader in Viet Nam, capable of initiating and delivering hypothesis-driven research to solve locally relevant problems.

With more than 15 years' experience working on emerging infectious diseases, Dr. Firth (my Mentor) has built a research program with a strong multi-disciplinary focus that is only enhanced by her recent appointment as Senior Scientist with EHA. Her expertise includes nearly 10 years' experience in the generation and analysis of metagenomic sequence data, which she has used in both clinically relevant and veterinary contexts, as well as to address a range of ecological and evolutionary questions [25,46–50]. Dr. Firth also has significant experience with field and laboratory science and has led or participated in projects in multiple countries, including Malaysia, Viet Nam, Australia, Brazil, The United States, and Canada. As a result, she has a broad scientific network that involves global leaders in infectious disease research, including those within Southeast Asia (e.g., Prof. Linfa Wang, Director, Emerging Infectious Diseases Program at Duke-NUS Medical School, Singapore; Prof. David Perera, Director, Institute of Health & Community Medicine, UNIMAS). Dr. Firth will actively create opportunities for me to interact with Prof. Wang and other leading scientists through the proposed research project, which will greatly increase my research network. A two-week visit to Prof. Wang's laboratory has been budgeted as part of the proposed project and will provide me with the opportunity to learn cutting-edge laboratory techniques, as well as interact directly with members of his lab. Dr. Firth has also committed to creating opportunities for me to discuss my metagenomic data directly with Prof. Edward Holmes (a world leader in virus discovery and metagenomics), who is highly supportive of the proposed project.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

In addition to her scientific skills and network, Dr. Firth has previous experiences training and mentoring scientists in lower- and middle-income countries. This should increase the effectiveness of her mentorship since I am also a junior scientist from one of these countries in Southeast Asia. Dr. Firth also has a close personal relationship with my in-country project supervisor and long-term collaborator, Dr. Maia Rabaa, who is co-lead of OUCRU’s Molecular Epidemiology research group. Drs. Firth and Rabaa completed their PhD degrees together and have maintained a strong relationship focused on peer mentorship since that time. As a result of their joint commitment to both this research project and my professional development, I will have access to an extremely high level of support and mentorship both locally and internationally. The combined mentoring, experience, and expertise I will gain through the CREID Pilot Research Program will assist me in my progression toward scientific independence by providing opportunities to develop my grant writing, budgeting, study management, and networking skills, in addition to the new scientific skills I will gain. The data generated as a result of the proposed project will also provide critical pilot data for future grant applications that will form the foundation of a long-term collaborative relationship with EHA.

Through the process of writing the application for the CREID Pilot Research Program, Dr. Firth and I have already established the foundation for an effective communication plan that will continue throughout the project. We have created a WhatsApp group that also includes Dr. Rabaa, which we use to communicate in an informal setting and in real-time. This has been invaluable for sharing ideas, asking questions, and facilitating the development of a good personal relationship that is a pre-requisite for effective mentorship. We have also agreed to a regularly scheduled Zoom meeting that will occur every two weeks, be agenda-driven, and focused on a topic or issue of direct relevance to the research project. Both Dr. Firth and I will be responsible for setting the agenda and following up on action items. I will also attend weekly academic meetings at OUCRU and EHA (over Zoom), which will expose me to the breadth of research at these institutions, and which I have found to be extremely useful for me in the past. Dr. Firth and I have also agreed to extend my visit to the United States to attend the annual CREID meeting to include a visit to EHA in New York City. The timing of this visit will allow me to bring some metagenomic data from the project with me and work through data analysis with Dr. Firth and other EHA scientists. Finally, Dr. Firth, Dr. Rabaa, and I will travel to Dak Lak province in Viet Nam at the end of the project to present the study outputs to the community members that participated in the VIZIONS study, as part of the public engagement aim.

Vertebrate Animals Section Requirements

No new animal sampling will be conducted in the proposed research study. All samples and data to be used in the proposed research project were previously obtained as part of the VIZIONS project, which concluded in 2016. Samples were collected under a protocol approved by the Oxford Tropical Research Ethics Committee (OxTREC code 157-12), and were locally reviewed and approved by the ethical review board of the Hospital for Tropical Diseases in HCMC, with local review and acceptance at all sites. Viet Nam did not have an animal ethics review board at the time that the VIZIONS project was conducted.

Details on the VIZIONS project are available in a 2015 publication [19].

The principal aims of the VIZIONS project were:

1. To establish a model international collaborative consortium with an integrated approach to human and animal health research.
2. To estimate the burden of viral and zoonotic diseases in Viet Nam.
3. To investigate the disease epidemiology of specified clinical syndromes and infections in a cohort of high-risk individuals occupationally exposed to animals, with targeted sampling from domestic animals and wildlife associated with these individuals.
4. To elucidate the etiology of infectious diseases of unknown origin in the human population and provide a repository of putative pathogens for further study.
5. To characterize genetic diversity within virus populations on either side of the species barrier to understand cross-species transmission and disease emergence.
6. To identify socio-demographic, environmental, and behavioral drivers for disease emergence.
7. To create a platform and resource for further research on zoonotic disease agents.

Key in-country partners on the VIZIONS project included:

- Hospitals (The Hospital for Tropical Diseases, HCMC; Dong Thap General Hospital, Cao Lanh City, Dong Thap Province; Dak Lak General Hospital, Buon Ma Thuot City, Dak Lak Province; Khanh Hoa General Hospital, Nha Trang City, Khanh Hoa Province; Hue Central Hospital, Hue City, Thua Thien Hue Province; National Hospital for Tropical Diseases, Ha Noi; Ba Vi District Hospital, Ha Noi)
- Academic institutions (OUCRU, HCMC; OUCRU, Ha Noi; Hanoi Medical University)
- Regional Animal Health Offices (RAHO5, Buon Ma Thuot City, Dak Lak Province)
- Sub-departments of Animal Health (sDAH) (Dak Lak sDAH, Buon Ma Thuot City, Dak Lak Province; Dong Thap sDAH, Cao Lanh City, Dong Thap Province)
- Preventive Medicine Centers (PMCs) (Dak Lak PMC, Buon Ma Thuot City, Dak Lak Province; Dong Thap PMC, Cao Lanh City, Dong Thap Province; Ba Vi District PMC, Ha Noi)
- Ba Vi District Veterinary Station

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Human Subjects Research

No human subjects, samples, or data will be involved in this research.

1. Are Human Subjects Involved?			No

Budget Justification

In total, we request \$149,970.57 for Dr. Nguyen for this one-year project, starting 1 June 2021, including: \$50,878.00 for personnel, \$1,200.00 for regulatory fees, \$1,000 for equipment, \$76,473.76 for consumables, \$9,309.88 for travel, and \$11,108.93 for indirect costs. Detailed expenses are calculated as follows:

A. Personnel (\$50,878.00)

Dr. Nguyen, PI, will commit 12 months (1 FTE) per year to this project for study design, supervising the laboratory work, training in new analytical methods, and conducting the metagenomic and epidemiological analyses. Dr. Nguyen is a veterinary epidemiologist specializing in pathogen surveillance at the human-animal interface and will have just completed his PhD studies (15 March 2021). We request \$28,563.00 total salary for Dr. Nguyen for the period of 12 months.

We also request funding for a senior research assistant who will commit 12 months (1 FTE) per year to this project to perform laboratory work and assist in the development of community engagement activities and materials. The research assistant will have significant experience working with and performing virus surveillance/sequencing on samples collected under the VIZIONS project, and will have experience participating in public engagement projects in Viet Nam. We request \$22,315.00 total salary for this research assistant for the period of 12 months.

B. Regulatory fees (\$1,200.00)

An import license from the Ministry of Health will be required for importation of any consumables, equipment, reagents, and biological materials related to this project, at the cost of \$1,200.00.

C. Equipment (\$1,000.00)

No equipment will be purchased with the exception of one laptop computer for Dr. Nguyen. We request budget (\$1,000.00) for one laptop computer for use by Dr. Nguyen.

D. Consumables (\$76,437.76)

RNA Extractions (\$29,170.00). We request (\$29,170.00, \$14.59 per sample) for RNA extractions. This total covers the cost of all kits, reagents, and consumables (MagNA Pure 96 DNA and Viral NA SV Kits, MagNA Pure 96 Processing Cartridges, MagNA Pure 96 Filter Tips, MagNA Pure 96 System Fluid, MagNA Pure 96 Sealing Foil, MagNA Pure 96 Output Plates, Qubit™ RNA HS Assay Kits, Qubit™ Assay Tubes, and TURBO™ DNase) for 2000 extractions.

Metagenomics (\$32,500.00). We request (\$32,500.00, \$270.83 per 10-sample pool) for metagenomic sequencing. This total covers the cost of reagents and consumables for library prep (Illumina Stranded Total RNA Prep with Ribo-Zero Plus kit, Illumina Sequencing Adapters, Agilent AMPure Beads, RNA Clean XP) and sequencing on a HiSeq-4000 at Macrogen (South Korea), for 120 pools.

Follow-up PCRs (\$14,173.56). We request (\$14,173.56, \$11.81 per sample) for targeted RT-PCR following results of the metagenomic analysis. This total covers the cost of all kits, reagents, and consumables (LightCycler 480 Multiwell Plates, 96-Well Half Skirt PCR Plates, Bubble Strip Caps for PCR Strips, SuperScript III One-Step RT-PCR, Primers, Agarose, SYBR™ Safe DNA Gel Stain, DNA Clean & Concentrator-5, Amplicon Sequencing) to cover 1200 reactions.

Other reagents & consumables (\$630.21). We request (\$630.21) to cover miscellaneous consumables. This total covers the cost of tubes, tips, personal protective equipment, and other consumables (varied

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

Axygen™ Aerosol Filter Tips, Water - Molecular Biology Reagent, Absolute Ethanol, LoBind Eppendorf tubes, nitrile gloves) required to process samples in the laboratory.

E. Travel (\$9,309.88)

International Travel (\$8,229.00). We request: 1) \$4,335.00 for one trip to the United States for Dr. Nguyen to the CREID meeting in Rockville, Maryland. This total covers one round-trip flight (\$1,600.00), lodging and per diem for 4 days/nights (\$250 per day; total \$1,000), ground transportation costs (\$150.00), insurance and visas (\$185.00), and quarantine costs for 14 days on return to Viet Nam (\$100.00 per day; total \$1,400.00). Additional costs for travel to New York City, lodging, and subsistence during this trip will be covered by EHA. 2) We also request an additional \$3,894.00 for one trip to meet and train with EID-SEARCH partners in Singapore. This total covers one round-trip flight (\$400.00), lodging and per diem for 14 days/nights (\$140.00 per day; total \$1,960.00), ground transportation costs (\$100.00), insurance (\$34.00), and quarantine costs for 14 days on return to Viet Nam (\$100.00 per day; total \$1,400.00).

Inter-province Travel (\$1080.88). We request \$1080.88 for Dr. Nguyen and two OUCRU staff members (one from the Molecular Epidemiology group and one from the Public Engagement team) to travel to Buon Ma Thuot city, Dak Lak Province for discussions with stakeholders and engagement planning activities. This total covers three round-trip flights (\$200.00 per person; total \$600.00), lodging and per diem for 3 people for 3 days (\$43.43 per person per day; total \$390.88), and ground transportation costs (\$30.00). Additional costs for engagement activities will be covered by internal OUCRU funding for Public Engagement activities.

Additional travel

EID-SEARCH (EcoHealth Alliance) will provide additional funding for international travel costs related to additional face-to-face meetings and collaborative work periods for Dr. Nguyen and Dr. Firth.

F. Indirect costs (\$11,108.93)

We are requesting 8% indirect costs on all direct costs (total \$11,108.93).

BIOGRAPHICAL SKETCH

A. Personal Statement

I have strong motivation to lead a research project characterizing viral diversity across multiple animal species, particularly in wildlife/domestic mixed species farms. I was involved in the implementation within the VIZIONS project from 2012-2016, acting as a research assistant and field coordinator. My research interests are focused on community-based studies investigating high potential zoonotic diseases and antimicrobial resistance at the animal-human interface. My primary research work during the VIZIONS study was coordinating the collection of high-quality data and samples, as well as establishing critical community partnerships in both the human and animal health sectors. Beyond my field coordinator role, I also processed and tested for the presence of known viruses in animal samples from the VIZIONS project. These studies collected and have reported on varied sources of data (i.e. epidemiological, clinical, laboratory, genomic, and behavioral data) to better understand the epidemiology and emergence of viral zoonoses. I currently coordinate an intervention project (ViParc: Vietnamese Platform for Antimicrobial Reduction in Chicken production) that aims to reduce antimicrobial usage in chicken production in southern Viet Nam. I now have nearly completed my PhD work characterizing antimicrobial usage in chicken production. I have delivered a number of high impact publications focused on key issues in veterinary epidemiology. I am also committed to providing training for local veterinary students on statistics and epidemiology, veterinary public health, and animal welfare (visiting university lecturer).

B. Positions and Honors

YEAR(S)	POSITION
2011-2013	Research Assistant, Oxford University Clinical Research Unit (OUCRU), Viet Nam
2014-2016	Senior Research Assistant, VIZIONS Field Coordinator, OUCRU, Viet Nam
2017-2021	PhD candidate, ViPARC project coordinator, OUCRU, Viet Nam
2020-present	Visiting University Lecturer at the Applied Science Institute, Ho Chi Minh University of Technology (HUTECH), Viet Nam

C. Contributions to Science

1. Zoonotic transmission at the human-animal interface

I played a crucial role in implementing a community-based study of zoonotic infections in Viet Nam under the VIZIONS project. By coordinating high quality data and sample collection, I contributed to the success and unique study design of many VIZIONS-related studies, driving a number of sub-studies investigating pathogen evolution and epidemiology. These studies provided insight into viral, bacterial, and parasitological zoonotic infections presenting in communities in Viet Nam. I played multiple roles on the project, including field work and sampling, laboratory-based screening, and complex epidemiological investigations of pathogen diversity in domestic and wild animal farms, as well as in wild animal populations (capturing bats in the jungle and rats in rice fields).

2. Usage and drivers of antimicrobial resistance in animal production

Antimicrobial resistance (AMR) is a global threat to the health and wealth of nations. The AMR crisis has been attributed to the overuse and misuse of antimicrobials. Excessive use of antimicrobials in animal production is one of the contributing factors to this global threat. In my PhD work, I characterized antimicrobial usage (AMU) in small-scale chicken farms in the Mekong Delta region of Viet Nam. This includes consumption of antimicrobials mixed with water by the farmer as well those included in commercial feeds as antimicrobial growth promoters (AGPs). The epidemiological data that I gathered in

this project was used to investigate the relationship between AMU and disease. Results from this thesis suggest that efforts to promote responsible use of antimicrobials and limit excessive AMU are effective in reducing AMU in animal production, and thus should focus on: 1) educating farmers on good farming practices and simple veterinary diagnostics, and 2) strengthening veterinary systems, including farm audits and provision of effective advice from animal health experts. These studies have also shown that the probability of effective treatment is often very low. My research concluded that the message 'prophylactic AMU does not reduce the probability of disease in flocks' should be further disseminated to poultry farming communities to reduce unnecessary AMU on farms.

3. Understanding AMR in commensal and pathogenic microorganisms in animal production

A better understanding of AMR in both commensal and pathogenic microorganisms in animal production is vital to improve treatment and control, particularly in the context of preventing those bacterial infections in animals as well as the transfer of their genes into human pathogenic bacteria. Epidemiological data from my studies have shown that high levels of AMU resulted in high levels of AMR in both commensal and pathogenic bacteria. These data have resulted in improved treatment and diagnostic policies for animal production across Viet Nam.

Columbia University, New York, NY	Postdoctoral	12/2012	Infectious Diseases & Public Health

A. Personal Statement

I am a molecular and evolutionary biologist who has been working on emerging infectious diseases for almost 15 years. In my current research, I explore the ecological and evolutionary dynamics of emerging zoonoses at the human-animal interface, with a focus on rapidly changing environments. I have more than seven years' experience leading independent research projects in this field, including collaborations with industry and local government. Over time, I have been responsible for the successful completion of every aspect of these studies, including project design, funding acquisition, implementation, and reporting/publishing. In 2015 I initiated a research program to investigate the response of zoonotic pathogens to urbanization in Malaysian Borneo using metagenomics, landscape ecology, and population genomics. This research has a strong multi-disciplinary component that includes evolutionary biology, molecular ecology, virology, pathogen genetics and genomics, field biology, and public health, and has required me to become adept at combining and analyzing multiple types of data, including environmental, ecological, and genomic data. As such, my experience, skills, and training are ideally suited to the proposed research project, which builds naturally on my previous work. I also have a strong track record in the generation and use of genetic and genomic data to explore the transmission dynamics and evolution of emerging viruses, with more than 20 publications in this field, seven of which have been cited more than 100 times since 2010. The mastery of phylogenetic and phylodynamic methods I have developed throughout my career are directly applicable to the proposed research. Further, I am strongly committed to supporting diversity and equity both within the scientific community and in the communities we serve, and have led several projects and initiatives aimed at improving science education and health service delivery for underserved communities in tropical northern Australia. I am also committed to providing training and mentorship for low- and middle-income country scientists and scholars, and in my previous role worked to develop protocols and bioinformatics pipelines to enable portable metagenomic sequencing in rural and remote regions in Australia and the Pacific. I am currently supervising three PhD students and three postdoctoral researchers (James Cook University, AUS).

B. Positions and Honors**Positions and Employment**

2001-2006	Research Assistant, Department of Zoology, The University of Guelph, Guelph, CAN
2006-2010	PhD Scholar, The Pennsylvania State University, State College, PA
2010-2012	Postdoctoral Fellow, Center for Infection and Immunity, Columbia University, New York, NY
2013	Associate Research Scientist, Center for Infection and Immunity, Columbia University, New York, NY

2013-2017	Research Scientist/ Australian Research Council (ARC) Discovery Early Career Research Fellow, Health and Biosecurity, The Commonwealth Scientific and Industrial Research Organization, Geelong, AUS
2017-2018	Australian Research Council (ARC) Discovery Early Career Research Fellow, School of BioSciences, The University of Melbourne, Parkville, AUS
2018-2020	HOT North Career Development Fellow, Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, AUS
2021-	Senior Research Scientist and Program Coordinator, EcoHealth Alliance, New York, NY
Honors	
2003-2005	Ontario Graduate Scholarship, The Province of Ontario (Canada)
2006-2009	Postgraduate Scholarship, Natural Science and Engineering Research Council of Canada
2015-2018	Discovery Early Career Researcher Award, The Australian Research Council
2019-2021	HOT North Career Development Fellowship, Northern Australia Tropical Disease Collaborative Research Programme, National Health and Medical Research Council (AUS)

C. Contributions to Science

Throughout my career, my research has focused on many aspects of infectious disease emergence and has encompassed evolutionary biology, molecular ecology, virology, pathogen genetics and genomics, field biology, and public/veterinary health. My most significant contributions include:

1. The use of genomic and metagenomic sequencing techniques to discover new pathogens, study their evolution, and explore microbial diversity.

I have successfully developed and used cutting-edge metagenomic techniques and bespoke bioinformatics pipelines for: (i) pathogen discovery, including a case of acute encephalitis in an immune-suppressed patient, (ii) studies of viral diversity, including coronaviruses and flaviviruses in bats; and (iii) genomics, including the epizootology of bluetongue virus, the evolution of rhabdoviruses, and the characterization of Australian bunyaviruses. I have also co-authored two perspectives on the utility of next-generation sequencing for pathogen discovery in people and animals. These included an invited submission that described an updated framework for proof of causation in the genomics era and discussed the emerging integration of on-the-ground metagenomics-based diagnostics with molecular epidemiology.

In 2013, I initiated a study that used metagenomics to characterize the viruses and bacteria carried by New York City rats across a range of habitats, with a focus on the built environment. At the time, little was known about the range of potential pathogens carried by urban rodents or the risk factors associated with zoonotic transmission in a city environment. To begin to address this, I designed the first comprehensive molecular survey of rodent-borne microbes in a U.S. city, and demonstrated that urban rats frequently carry a range of zoonotic pathogens. We also found evidence of substantial heterogeneity in pathogen distribution within and between cities, suggesting that the associated risks of human disease may be similarly heterogeneous.

2. I have helped develop the emerging field of urban zoonotic disease ecology.

In 2015, I pioneered an ongoing research program to investigate the response of zoonotic pathogens to urbanization using metagenomic sequencing, landscape ecology, and population genomics. Using a multi-disciplinary approach, this research explores how changes in the environment (e.g., land-use changes, microclimates, etc.), and host community and population structure (e.g., biodiversity, connectivity, density), influence pathogen community composition and zoonotic potential. Initial results of this work indicate that while mammalian diversity decreases with increasing urbanization, connectivity between populations increases, as does microbial species richness and the prevalence of known zoonotic pathogens. This suggests that some features of the built environment may inadvertently support pathogen persistence and spread, and as a result, some zoonotic pathogens may be more likely to emerge with intensifying urbanization. My reputation as an emerging researcher in this field has led to multiple invitations to present as a plenary or symposium speaker at national and international meetings, including the Ecological Society of Australia's Annual Conference (2019) and the Annual Meeting of the American Society of Mammalogists (2019), and the Joint Conference of the Asian Society of Conservation Medicine and the Wildlife Disease Association Australasia (2018).

3. I challenged established beliefs about the ecological and evolutionary processes linked to viral disease emergence, and the timescale over which they occur.

During my PhD, I was able to make significant contributions to this field by questioning the idea that viruses evolve either by cross-species transmission (spillover) or by co-evolution with their hosts, but rarely both. My work demonstrated that viruses with many genomic structures are capable of jumping species barriers, and that evolution through both co-divergence and cross-species transmission may be a

general trend of many virus systems. This has since been supported by numerous subsequent studies that have highlighted the complex evolutionary dynamics of both RNA and DNA viruses.

- a. Pagan I, **Firth C**, Holmes EC. 2010. Phylogenetic analysis reveals rapid evolutionary dynamics in the plant RNA virus genus tobamovirus. *Journal of Molecular Evolution* 71: 298-307. PMID: [20838783](#)

* Name changed from Ramsden to Firth in 2009

4. I was among the first to apply novel phylodynamic approaches to reconstruct the spatiotemporal processes behind disease emergence events.

Phylodynamic methods enable the synthesis of epidemiological, geographic, and phylogenetic data to reconstruct the processes behind infectious disease emergence and spread through time and space. These methods are of particular use for investigating the emergence and spread of viruses, as they have a rapid evolutionary rate that closely matches the timescale of virus transmission. I began to explore these approaches during my PhD and have now successfully used them to: (i) explore the genetics underpinning the rapid emergence and spread of human enterovirus 68; (ii) examine the patterns and processes that influence the diversity and geographic distribution of New World hantaviruses; (iii) explore the epizootology of porcine circovirus 2; iv) understand the evolutionary and ecological drivers behind the distribution of bluetongue virus in Australia; and (v) assess the likely origins of hepatitis C virus.

<https://www.ncbi.nlm.nih.gov/myncbi/1pcDCsap4HMk2/bibliography/public/>

Role: Co-Investigator. My role was to sequence the genomes of SARS-CoV-2 from patients and perform relevant analyses.

Goal: To predict clinical outcomes from SARS-CoV-2 infection using a combination of immunological and pathogen data collected from nasopharyngeal swabs, blood, and urine samples.

Tropical Australian Academic Health Centre Research Assistance Brown J (PI) 2020

Title: Building Research Support for Cairns Hospital.

Role: Co-Investigator. My role was to collaborate with and support clinicians engaging in infectious disease research, and help build a culture that fosters scientific research.

Goal: Cairns Hospital is a regional facility serving as a referral hospital for remote communities across Far North Queensland, yet does not have a strong culture of scientific research. This grant supported collaborations between academics and clinicians working in emerging infectious diseases in this region to improve research output for rural/remote Australia.

HOT North Pilot Project Grant Firth C (PI) 2019-2020

Title: Portable genome sequencing as a point-of-care diagnostic test in remote tropical Australia

Role: Principal Investigator. My role was to design the patient and sampling strategies, design a laboratory workflow suitable for uptake in a clinical diagnostic lab, assist in the development of novel bioinformatics pipelines for clinical metagenomics, and validate the approach.

Goal: To develop a clinical metagenomics ID diagnostic platform suitable for use in rural and remote hospitals and health services in tropical Northern Australia.

Australian Research Council Discovery Early Career Researcher Firth C (PI) 2015-2018

Title: Characterizing the impact of urbanization on viral diversity, ecology and disease emergence

Role: Principal Investigator. My role was project design and management, fieldwork and sample collection, metagenomic sequencing, data analysis and interpretation.

Goal: This project examined the viral response to changes in reservoir host and vector population structure and dynamics that occur as a result of urbanization, and identified viral characteristics associated with survival in an urban environment in Southeast Asia.

NIEHS Center for Environmental Health Pilot Project Grant Firth C (PI) 2013

Title: Identification of rodent-borne human pathogens in an urban environment and the features that influence their presence and prevalence

Role: Principal Investigator. My role was project design and management, fieldwork and sample collection, metagenomic sequencing, data analysis, and interpretation.

Goal: To characterize the zoonotic pathogens present in rats and their ectoparasites in New York City.

A. Personal Statement

I have the experience, expertise, training, and motivation needed to successfully support the proposed research project to analyze viral diversity and cross-species transmission on mixed-species farms in Viet Nam. I am a molecular epidemiologist at OUCRU Viet Nam. I have 8 years of experience in the design and implementation of research in human and animal health in Viet Nam, with a focus on emerging infections, viral zoonoses and antimicrobial resistance. I currently lead the Molecular Epidemiology group at OUCRU: a group of 28 staff (including one postdoctoral scientist, PhD students, clinicians, research assistants and technicians, nurses, and experienced project coordinators).

My primary research interests are laboratory, community, and hospital-based studies investigating the epidemiology, ecology, and evolution of pathogens in human populations and at the animal-human interface. My postdoctoral work focused on the development and implementation of a countrywide study of virus epidemiology and viral zoonoses, called VIZIONS, in which I designed and implemented scientific research and assisted in the management of collaborations across 7 Vietnamese hospitals and 3 local and regional animal health offices. I am now the PI on laboratory work and analyses of samples collected within the VIZIONS study, including identification of pathogens in farmed and wild animal populations. These studies use genomics, epidemiology, clinical, laboratory, and field science to test hypotheses on the emergence of viral zoonoses. Project coordinators currently on my team also worked on the VIZIONS study and maintain valuable links to collaborating institutions focused on human and animal health across the country. My team's previous experience and our nationwide network of collaborators will facilitate a scientifically rigorous study with important buy-in from local communities and health authorities. I have managed various institutional grants and delivered a number of significant and highly visible publications focused on a portfolio of varied pathogens and public health issues.

Further, I am committed to providing training and mentorship for low- and middle-income country researchers. In addition to junior research staff, I have supervised 3 PhD students to completion (University of Oxford [UK], Open University [UK]), and am currently supervising 2 PhD students (University of Oxford [UK]) and 1 postdoctoral scientist.

2007-2008	Research Associate at the Fogarty International Center, U.S. National Institutes of Health, Maryland, USA
2008-2009	Campbell Distinguished Graduate Fellowship, The Pennsylvania State University, USA
2009-2012	Graduate Research Fellowship, National Science Foundation, USA
2012-2015	Postdoctoral Research Fellow at the University of Edinburgh, Edinburgh, UK
2012-2020	Lead Molecular Epidemiologist at OUCRU, Ho Chi Minh City, VN
2015-2020	Research Fellow at the Nuffield Department of Medicine, University of Oxford, UK
2020-present	Molecular Epidemiology Research Group Head at OUCRU, Ho Chi Minh City, VN
2020-present	University Research Lecturer at the Nuffield Department of Medicine, University of Oxford, UK

C. Contributions to Science

1. Pathogen diversity and exchange at the human-animal interface

With Southeast Asia considered a hub of zoonotic transfer, I, with colleagues at OUCRU, the University of Edinburgh, and the Sanger Institute, sought to track the frequency and risks for pathogen transfer at the human-animal interface. I played a pivotal role in designing and implementing a national hospital- and community-based study of zoonotic infections in Viet Nam, driving a number of substudies and conducting analyses investigating pathogen evolution and epidemiology. These studies have uncovered frequent zoonotic infections presenting in clinical settings, and I am now the PI for several continuing analyses using archived samples and data to perform virological and serological investigations of zoonotic infections, as well as investigations of pathogen diversity in farmed and wild animal populations, including bats.

2. Evolution and epidemiology of flaviviruses

In my PhD and postdoctoral work, I performed detailed phylogenetic and epidemiological analyses of flavivirus populations to identify the determinants of novel flavivirus emergence in endemic and epidemic settings. This research showed the utility of connecting epidemiological and genomic data in understanding the spread of vector-borne disease, identifying risk factors (population connectivity, immunity, and climate) for flavivirus emergence at various spatial scales. Genomic studies of viruses sampled during phase III dengue vaccine trials showed that dengue virus genetics play a limited role in determining vaccine efficacy and identified genomic regions of the virus that may be under selection for vaccine escape. In these studies, I designed sampling strategies and conducted analyses of sequence data, clinical and epidemiological surveillance data, and geographical, climatological, and census data.

3. Mechanisms and determinants of antimicrobial resistance (AMR) emergence

Continual emergence of antimicrobial resistance is among the greatest threats to public health. As lead molecular epidemiologist at OUCRU, I have led various investigations of the genetics of AMR and its global spread. Working with collaborators across Asia, I drive both computational and lab-based experimental evolution studies to determine the drivers of the emergence and maintenance of AMR in human and animal populations. These studies have shown that plasmid transfer from healthy human gut microbiota can drive the emergence of resistance in pathogenic *Shigella*, and that inappropriate antimicrobial usage may enhance the frequency of plasmid transfer. Our studies also identify South and Southeast Asia, where inappropriate antimicrobial usage is rampant, as important hotspots of AMR emergence.

4. Typhoid epidemiology, genomics, and the role of carriage in transmission

A better understanding of the role of genetics in typhoid epidemiology is needed to improve diagnostics, treatment, and control, particularly in the context of introduction of typhoid conjugate vaccine in endemic regions. I have recently led and collaborated on studies that have utilized bacterial genomics to investigate the relationships between treatment failure, AMR, and vaccination, as well as to identify the selective pressures induced by gallbladder carriage and to better characterize the potential roles of typhoid carriers in typhoid transmission following large-scale vaccination. Our studies have shown that novel emerging clades of AMR *Salmonella* Typhi can rapidly undermine accepted treatment regimens; these data have resulted in improved treatment and diagnostic policies across Nepal. Novel studies of gallbladder carriage are expected to inform typhoid surveillance, including the identification and treatment of typhoid carriers, thus aiding elimination efforts.

BIOGRAPHICAL SKETCH

NAME: Rabaa, Maia Anita

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: University Research Lecturer in Medicine, Molecular Epidemiology Group Head

D. Additional Information: Research Support and/or Scholastic Performance

Pending Research Support

NIAID/NIH (Grant 13220428) Daszak (PI) 07/2021 – 06/2026

Title: Analyzing the potential for future bat coronavirus emergence in Southeast Asia

Goal: The overall goal of this study is to build a platform to pinpoint the risk of future coronavirus emergence in a region where COVID-19 likely originated, inform strategies to intervene and prevent future pandemics, and provide critical reagents, therapeutic interventions, and recombinant viruses for public health preparedness against future SARS- and COVID-like events.

Role: Co-Investigator (country PI)

Pfizer (Investigator Sponsored Research: Pre-clinical/Clinical) Pham (PI) 03/2021 – 03/2023

Title: The bacterial etiology and antimicrobial susceptibility patterns of lower respiratory and intra-abdominal infections in Viet Nam

Goal: The goal of this study is to characterize and compare the microbiology, antimicrobial resistance patterns, and clinical outcomes of lower respiratory tract and intra-abdominal infections in 6 metropolitan hospitals in Viet Nam between 2019 and 2020.

Role: Co-Investigator

Current Research Support

COVID-19 Research Response Fund, University of Oxford Baird (PI) 05/2020 – 03/2021

Title: Validating GeneXpert platform for SARS-CoV-2 diagnosis for remote sites in Eastern Indonesia

Goal: The goal is to validate the GeneXpert platform using various sample types and to estimate the prevalence of SARS-CoV-2 infection among patients seeking treatment for febrile illness in Sumba, Indonesia.

Role: Co-Investigator

Research grant, Oxford University Clinical Research Unit Rabaa (PI) 02/2020 – 12/2021

Title: Molecular epidemiology of *K. pneumoniae* in bloodstream infections

Goal: The goal is to investigate the epidemiology and evolution of *K. pneumoniae* causing bloodstream infections in southern Viet Nam from 2010-2019.

Role: PI

Research grant, Oxford University Clinical Research Unit Rabaa (PI) 02/2020 – 12/2021

Title: A novel molecular assay for simultaneous detection of pathogen and AMR genes

Goal: The goal is to develop a rapid, inexpensive assay that will allow for rapid screening and pathogen/AMR diagnostics for bloodstream infections in resource-poor hospitals.

Role: PI

Facilities, Existing Equipment, and Other Resources

Laboratory:

OUCRU, in partnership with the Hospital for Tropical Diseases, have established state-of-the-art clinical diagnostic, basic, and applied research laboratories. The laboratory facilities include: clinical laboratories (ISO 15189:2012 certified), BSL2 research laboratories (GLP and GCLP compliance), BSL3 laboratories (MoH, Viet Nam certified), and a bio-archiving facility (Biosecurity compliance). OUCRU laboratories in HCMC and Hanoi are collectively equipped with 29 safety cabinets (fume hoods, biosafety category II and III), 21 shaking and stationary incubators, 36 centrifuges including refrigerated centrifuges that accommodate swinging bucket and fixed angle rotors, six refrigerated microfuges, 12 thermocyclers, five real-time PCR machines, four UV/Visible microplate readers, a gel imaging platform (chemiluminescence, UV, and visible light), gel boxes, water baths, and mixing devices, 11 water-jacketed CO₂ incubators, five inverted microscopes, three fluorescence-activated flow cytometers (one with cell sorting capability), three capillary DNA sequencers, two Illumina MiSeq sequencers, Oxford Nanopore MinION sequencers, two HPLC systems, one GenXpert machine, one ultra-centrifuge, two Chef Mapper XA Systems, one Luminex Flexmap 3D, one Bio-Plex Suspension Array System, 26 -80°C freezers, 77 -20°C freezers, 33 refrigerators, eight liquid nitrogen tanks, a liquid nitrogen shipper, ice machines, autoclaves, and film developers. Molecular Epidemiology research is conducted in several facilities across the laboratories including a specimen processing facility, a molecular diagnostic facility (GeneXpert and RT-PCR based diagnosis), a genomics facility (NGS facility using Illumina MiSeq and Oxford Nanopore MinION systems), and an immune-biology facility (ELISA, Luminex, FACS Lyrics system, Fluoresce microscopy, and cell culture facility). High-risk laboratory processes are conducted in the BSL3 laboratory. OUCRU maintains a bio-archiving facility (-20°C, -80°C, and liquid nitrogen storage facility) containing 2.5 million samples with continuous temperature monitoring and sample tracking system (Lab guard system, Freezerworks system and biometric access control system).

Computer:

OUCRU employees have around-the-clock access to servers, VPN, encryption software, IT support, and all necessary software including: Git and Github (Hosted software revision/audit service), BBEdit text editors, Oracle Virtualbox virtual machines, Google Apps (Hosted email and collaboration web based software), Python, NodeJS, and R programming languages, Meteor (Javascript framework), Bash shell scripts, Jenkins (Continuous Integration server), Microsoft Office and Adobe CS6 running on Apple Mac OS X, Ubuntu Linux, and Windows Operating Systems. OUCRU has a dedicated 150+ core Linux server with 8TB hard drives, and the Molecular Epidemiology group has two dedicated 16-core Mac Pro Servers with 4TB hard drives. Either server individually or in combination may be used for intensive sequence analysis, computational modeling and/or database processing by Dr. Nguyen. Access to supercomputing services is maintained by a dedicated staff member from the IT team.

Office:

The applicant will have a dedicated desk in the office of the Molecular Epidemiology Group under the supervision of Drs. Maia Rabaa and Duy Pham Thanh, with expertise in both wet and dry laboratory research.

Letter of Organizational Support

28th February 2021

Dear CREID pilot research program funding committee,

Proposal from Nguyen Van Cuong

As Director of the Oxford University Clinical Research Unit (OUCRU) in Vietnam I would like to confirm my strongest possible support for the application from Nguyen Van Cuong.

Cuong has worked at OUCRU in Ho Chi Minh City since 2011, first as a Research Assistant and Project Coordinator for the Wellcome Trust funded Vietnam Initiative on Zoonotic infections (VIZIONS) project, and since 2017 as a PhD student and Project Coordinator for the ViPARC project (a Veterinary Intervention to Reduce Antimicrobial Usage in Animal Production). He has submitted an excellent PhD thesis (Open University, UK) and is scheduled to defend it on 15 March, 2021. In Cuong's tenure at OUCRU, he has developed strong skills in veterinary epidemiology, project coordination, and biostatistical analysis, along with varied wet laboratory skills. He will make an excellent post-doctoral researcher.

As Cuong moves into his postdoctoral career, the CREID pilot research program presents an excellent opportunity for him to grow in his independence as a scientist while gaining new scientific and program management skills as principal investigator of the proposed project. The proposed project will allow Cuong to develop additional expertise in study design, metagenomic sequencing, and bioinformatics. Additionally, the built-in mentorship program and regional and global networks that will be established through this collaboration with EcoHealth Alliance and the EID-SEARCH team will aid Cuong in designing and developing future impactful research on emerging infectious diseases at the human-animal interface, a topic that is in line with both Cuong's personal scientific agenda and the mission of OUCRU.

If funding is obtained for Cuong's proposal from the CREID pilot research program, OUCRU is committed to providing sufficient support to complete the project. Under this scheme, Cuong will have 100% protected time to complete the laboratory and analytical work to achieve the aims of this 1-year study, while working as a postdoctoral researcher within the OUCRU Molecular Epidemiology group, jointly led by Drs. Maia Rabaa and Duy Pham Thanh.

Cuong will have access to a remarkable collection of archived samples and data from the VIZIONS project for screening and downstream laboratory work, dedicated laboratory and office space within the OUCRU Molecular Epidemiology group, and access to shared laboratory spaces, computational resources, and equipment needed to complete the project. His research will be aided by existing laboratory and analytical expertise in the Molecular Epidemiology group, and a research assistant with experience in viral screening and sequencing will be employed to assist in sample processing and data management. As a member of the Molecular Epidemiology group, Cuong will participate in biweekly lab meetings, with regular opportunities to present and receive feedback on his work. He will also benefit from participation in extensive unit-wide academic and training programs.

I believe that the CREID pilot program will provide Cuong with a unique platform from which to develop veterinary epidemiology research within Viet Nam and across Southeast Asia. He would utilize the

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

knowledge and experience gained under this program to encourage and mentor future cohorts of scientists, veterinarians, and animal health officials in the pursuit of emerging infectious disease and OneHealth research and interventions to improve human and animal health in Viet Nam. He has my complete support.

Yours Faithfully,

(b) (6)

Professor Guy Thwaites FRCP FRCPATH FMedSci
Director, Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam;
Professor of Infectious Diseases, University of Oxford

Letter of Collaboration from CREID Research Center PI

Dr. Nguyen Van Cuong
Project Coordinator
Oxford University Clinical Research Unit
Ho Chi Minh City, Viet Nam

Dear Dr. Nguyen,

The Emerging Infectious Disease – South East Asia Research Collaboration Hub (EID-SEARCH) at EcoHealth Alliance is extremely interested in working with you and your collaborators at the Oxford University Clinical Research Unit (OUCRU) in Viet Nam on the proposed research: *“Multi-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam”*.

This collaboration will significantly contribute to the goal of the CREID Network and EID-SEARCH to develop in-country research capacity and build the research network for emerging infectious diseases in Southeast Asia. It will also form the foundation for new partnerships among EID-SEARCH, OUCRU and other in-country stakeholders in Viet Nam, which will strengthen international and multi-sectoral cooperation for emerging infectious disease research in Southeast Asia. Further, the networking, training, and mentorship opportunities embedded within the Pilot Research Program will develop your own skills in mentorship, project management, and supervision within a supportive framework, and grow your network both within and outside of Viet Nam.

Beyond capacity and network building, the proposed research strongly aligns with the core of EID-SEARCH’s scientific goals by exploring links between wildlife farming and several determinants of spillover risk, including farming practices and wildlife species diversity. By using an unbiased approach to virus surveillance and targeting a high-risk human-animal interface (wildlife farming), the proposed work has the potential to make a significant contribution to our understanding of the drivers behind cross-species transmission and infectious disease emergence. I am confident that this work will lead to at least one high-quality publication on the highly relevant topic of wildlife and emerging infectious diseases, particularly given the links between hunting, farming, and trading wildlife and the emergence of new zoonotic diseases, as highlighted by the ongoing COVID-19 pandemic.

I have high expectations for this collaborative research project and expect that this will only be the beginning of our work together. Members of EID-SEARCH (including myself and Dr Kevin Olival as PI and CI of EID-SEARCH, respectively) are committed to working closely with you to develop the research project and support the efforts needed for the success of this application and project implementation. Our Senior Research Scientist, Dr. Cadhla Firth, has enthusiastically joined the project as your Mentor to advise on study design, data collection, and analysis throughout the project. Dr Firth is committed to providing relevant and timely career advice to assist in your professional development, and brings a well-established network across Southeast Asia, Australia, and North America, which includes world leaders in the ecology and evolution of emerging infectious diseases. You will be invited to join all trainings conducted by EID-SEARCH and EcoHealth Alliance on emerging infectious disease field surveillance and statistical analysis to build your skillset, and Dr Firth will work closely with you to develop your skills in pathogen genetics and genomics. EID-SEARCH will also commit funding and arrange exchange opportunities for you to visit our partners in Singapore to expand your skill set in

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

sequencing and serology. You will be supported to present the results of this research at international conferences, as well as meetings with CREID Network and external partners, and to produce high-quality publications from this research.

I am confident that the proposed research collaboration represents a genuine opportunity for your professional development, particularly as you will have successfully defended your PhD on March 15 2021, and are ready to transition to a role with more scientific independence. I am particularly impressed with your extensive work history at the human-animal interface of emerging infectious disease, including as a Program Coordinator with the VIZIONS project, and am confident that you have already begun to emerge as a future leader in this field in Viet Nam.

This letter conveys my strong interest and commitment to making this application a success, and I look forward to working with you on this research project.

Sincerely,

(b) (6)

Peter Daszak
Principal Investigator, EID-SEARCH
President, EcoHealth Alliance

Letter from Mentor

Dr. Nguyen Van Cuong
Project Coordinator
Oxford University Clinical Research Unit
Ho Chi Minh City, Viet Nam

Dear Dr. Nguyen,

This letter is to express my support as your Mentor for your application to the CREID Pilot Research Program, entitled "*Mixed-species farming, viral diversity, and risks of cross-species transmission in the Central Highlands of Viet Nam.*"

I am extremely excited that you have chosen me to be your Mentor for the proposed project. The research question is timely and important, and your work has the potential to have a strong impact on our understanding of potential disease risks associated with wildlife farming. Given what we understand to be the likely origins of SARS-CoV-2, there has never been a more pressing need to examine the links between our interactions with wildlife and emerging zoonotic diseases.

I would be hard-pressed to think of a more appropriate applicant to lead this project, given your background in veterinary medicine, epidemiology, and project management. The skills you have acquired during your previous work on the VIZIONS project and throughout your PhD will be enhanced by the Mentorship plan we have developed together. It has become clear to me as we have worked on the Pilot Project application that you are ready to make the transition from a junior scientist to an independent researcher capable of driving your own research projects, and I look forward to the opportunity to support you in this process. Towards this aim, I commit to supporting your professional development in the following ways:

- I will actively work to maintain the healthy, open, and informal dialogue we have established while drafting the project proposal, and I will seek feedback from you on a regular basis to ensure that our communication plan continues to meet your needs as the project progresses.
- I will engage with your current and future in-country collaborators in a supportive and inclusive manner.
- I will create opportunities for you to interact with scientists across my network through your research project to widen your exposure to people with a range of expertise.
- I will give you timely feedback on all material in the manner that works best for you.
- I will provide you with opportunities to present your work to my colleagues at EcoHealth Alliance during our academic meetings and include you in any relevant trainings.
- I will share my scientific and technical expertise with you to help ensure the success of the project. When skills outside my area are required, I will assist you in accessing this expertise from scientists within my network.
- I will assist you in career planning, providing advice and support as required to maximize your opportunity to succeed.

Applicant Name (Last, first, middle): Nguyen, Cuong, Van

One of the likely outcomes from the proposed research project will be the generation of pilot data that can form the basis for additional funding applications. The President of EcoHealth Alliance, Peter Daszak, has already expressed his support for a joint funding application that will follow on from the proposed project, with you as the lead PI. This will present the perfect opportunity for you to complete the transition to an independent scientist, and I am committed to assisting you through the process of writing your first funding applications as lead investigator.

There is significant overlap between your research interests and skills, the overall goals of OUCRU, and those of EcoHealth Alliance and the EID-SEARCH team. This pilot project presents a real opportunity for you to become a liaison between these organizations, and to help drive forward future collaborative research projects in Viet Nam. I am thrilled to be able to support you at this critical stage in your career and am genuinely convinced that you have the potential to become a science leader in Southeast Asia in the very near future.

Sincerely,

(b) (6)

Cadhla Firth, PhD
Senior Scientist and Program Coordinator
EcoHealth Alliance

Total Budget	<i>Repeat this table if there are two Co-PIs</i>
Direct Costs	\$136,737.00
Indirect Costs	\$10,938.96
Proposed Start Date	01/05/2022
Proposed End Date	30/04/2023

Project Abstract (250 words)
<p>The ability to quickly assess risk of emerging infectious diseases at points of high exposure or contact is paramount for early warning systems and preventative actions. In addition, maintenance of surveillance systems in individual animals is costly and time consuming and prevents widespread coverage. One way to address this issue is to incorporate environmental sampling into surveillance programs to cast a wider net at high-risk interfaces and on a longitudinal basis. To this end, we have begun to incorporate environmental sampling at high-risk human-animal interfaces, including live animal markets, slaughterhouses, and domestic/wild animal interfaces. However, these samples have only been tested for specific pathogens of interest by conventional or real-time PCR, limiting their utility. The ability to use these samples for metagenomic surveillance and pathogen discovery would not only increase surveillance capacity, but also contribute to our understanding of new or emerging pathogens at these high-risk interfaces. Therefore, in the proposed project, we will: (1) utilize existing environmental samples from longitudinal pathogen surveillance to build metagenomic sequencing and bioinformatics capacities and capabilities; (2) assess the suitability of environmental metagenomics as an early warning system for endemic and emerging infectious diseases at high-risk interfaces in Cambodia; and, (3) potentially discover new, emerging, or zoonotic pathogens of concern in high-risk interfaces in Cambodia. Overall, the results from this study will potentially help to improve surveillance systems through rapid and broad pathogen detection, reduced cost, lowered occupational risk, and diminished animal and environmental impact.</p>

Study Personnel

Jurre SIEGERS, Ph.D., (Postdoctoral Researcher) is a postdoctoral researcher in the Virology Unit at IPC in charge for planning and conducting research on zoonotic viral diseases, including avian influenza and coronaviruses. Dr. Siegers currently oversees all avian influenza virus surveillance efforts of IPC. Dr. Siegers has been vital in implementing COVID-19 sequencing at Institut Pasteur du Cambodge. Dr. Siegers will plan, oversee and conduct sample processing, data collection, and analysis for this proposal. He will also be instrumental in preparing data and publications stemming from this work. He will meet with the mentors and technical personnel on a twice-weekly basis to discuss results, issues and future work. Dr. Siegers's commitment to this project constitutes 25% of his total professional effort for the year (3 calendar months).

Vireak HEANG, MS.c., is a research engineer at sequencing platform at IPC in charge of providing sequencing service to other scientists across the unit at IPC. Mr. Heang has an extensive experience over 15 years on molecular biology technique including PCR, Sanger sequencing and NGS. Prior to move to IPC Mr. Heang was working at US Naval Medical Research Unit. 2 (NAMRU-2), the place where he went through various training programs, on-the-job experiences and finally developed a deep understanding of molecular techniques and how it can be used in detection, characterization, and epidemiological modelling of pathogens. When he moved to IPC July last year, Mr. Heang managed to pull all the resources together to make the Illumina Miseq system functioning and he made this happen through his effort and the result was several runs of COVID-19 and Malaria specimens successfully sequenced. Mr. Heang will handle logistic, laboratory work and data analysis of this project. He will meet with the mentors and technical personnel on a twice-weekly basis to discuss results, issues and future work. Mr. Heang will be allocated 25% of his work to this proposed project.

Erik KARLSSON, Ph.D., is a Senior Research Scientist (Assistant Professor equivalent) and acts as the Deputy Head of the Virology Unit at Institut Pasteur du Cambodge. He is an expert on Respiratory Viruses, including SARS-CoV-2, and will act as the Primary Scientific Mentor for Dr. Siegers and Mr. Heang. He is the Director of the National Influenza Center in Cambodia, Director of the WHO Regional H5 Reference Laboratory, and Coordinator of the WHO Global COVID-19 Reference Laboratory housed in the Virology Unit. He is also Co-PI of the Sequencing Mini-Platform formed at IPC in 2021. He will meet regularly with the co-PIs to review experimental progress, troubleshoot issues, interpret data, and participate in preparation of publications resulting from this research.

Cadhla FIRTH, Ph.D., is part of the CREID EID-SEARCH Research Center and will act as the Research Mentor for Dr. Siegers and Mr. Heang. Dr. Firth is Senior Research Scientist and Program Coordinator at EcoHealth Alliance and holds a position as an Adjunct Senior Research Fellow at James Cook University in Australia. Dr. Firth has more than 15 years' experience conducting research on emerging infectious diseases, with a focus on the ecology and evolution of zoonotic pathogens at human-animal interfaces. Dr. Firth's expertise in molecular biology, metagenomic sequencing, and the analysis of genomic and metagenomic data match well the goals of the proposed project. Dr. Firth will provide methodological and analytical guidance, mentoring and career advice, and networking opportunities that support the co-PIs progression toward independence, as well as assisting in the preparation of publications or future funding applications that may arise from this work.

Research Aims & Objectives

The ability to quickly assess zoonotic disease risk at potential points of high exposure or contact is of paramount importance for effective early warning systems and the initiation of preventative actions. Therefore, **this pilot project aims to answer the question: “Can metagenomic pathogen discovery on environmental samples improve the speed, comprehensiveness, and cost of existing pathogen surveillance programs?”**

In Cambodia, current pathogen surveillance systems rely primarily on sampling and testing individual animals – a practice that is both costly and time consuming, and prevents widespread coverage of all high-risk areas. **One way to address this issue is the incorporation of environmental sampling (ES) into surveillance programs.** ES includes samples or swabs taken from soil, water sources (drinking, carcass wash, lakes and ponds), feeding sources, feathers, air, and surfaces such as cages, chopping boards, and defeathering machines. As such, **environmental pathogen surveillance casts a wide net at high-risk interfaces, potentially improving surveillance coverage and supporting expanded sampling on a longitudinal basis.** After collection, samples are currently tested using a series of molecular diagnostics targeting a range of pathogens, another cost- and time-limiting factor. We hypothesize that utilizing metagenomic pathogen discovery with ES can: **(i)** improve, expand and simplify existing methods of pathogen surveillance; **(ii)** reduce the cost of pathogen surveillance programs; **(iii)** reduce direct contact between people and large numbers of animals, thereby improving biosafety, animal welfare, and reducing occupational exposure risks; and **(iv)** set a precedent for lower-middle income countries (LMICs) to conduct broad pathogen surveillance cost-effectively.

To test these hypotheses, we will utilize a **large and unique biobank** from Cambodia that includes previously collected **paired samples** from individual animals and ES. These samples originate from ongoing longitudinal surveillance studies for: **(i)** avian influenza viruses in live bird markets (LBMs); **(ii)** swine influenza and Nipah virus in swine abattoirs **(iii)** bat-borne viruses from caves, roosts, and guano farms.

The proposed project has *three aims*:

AIM 1: To assess the suitability of environmental metagenomics as an early warning system for endemic and emerging infectious diseases at high-risk interfaces in Cambodia.

AIM 2: To utilize biobank environmental samples from longitudinal pathogen surveillance programs in Cambodia to build metagenomic sequencing and bioinformatics capacities and capabilities in Cambodia.

AIM 3: To discover new, emerging, or zoonotic pathogens of concern at high-risk interfaces in Cambodia.

The proposed project has *four objectives*:

Objective 1: Characterize and compare the viral diversity present in samples from individual animals (poultry, swine, bat guano/urine) and environmental samples (wash water, air samples, cage swabs), using a combination of metagenomics and polymerase chain reaction (PCR)-based screening methods. **Endpoint:** Comparison of 129 animal samples with 207 ES across 3 species for 3000+ viral targets

Objective 2: Assess whether a surveillance system that incorporates both environmental sampling and virus detection through metagenomics is sensitive and specific enough to replace or support conventional virus surveillance programs. **Endpoint:** Comparative sensitivity (detecting the same virus) in metagenomic versus previously detected pathogens by RT-PCR.

Objective 3: Discover previously undetected, (re)-emerging, and/or zoonotic pathogens of concern at high-risk interfaces in Cambodia. **Endpoint:** Sequencing 2M reads/sample to ensure coverage and maintain cost-effectiveness.

Objective 4: Build capacity and capability in metagenomic sequencing and bioinformatics at Institute Pasteur du Cambodge. **Endpoint:** Successful implementation of a user-friendly metagenomic sequencing and analysis platform.

Study Rationale/Research Gap/Impact

Emerging infectious diseases are a major and ongoing threat to global health and the economy as illustrated by the ongoing SARS-CoV-2 pandemic and a record-breaking avian influenza outbreak across Asia, Europe, the Middle East, and North America. Asia, especially Southeast Asia, is a hotspot of endemic and emerging infectious diseases, including avian influenza viruses (AIVs), and bat-borne viruses such as coronaviruses and henipaviruses with pandemic potential¹⁻⁴.

Cambodia is a resource poor, lower-middle income country in tropical Southeast Asia with a large socio-economic dependence on agriculture⁵. Since 2011, Institut Pasteur du Cambodge (IPC) has maintained active longitudinal pathogen surveillance programs at key live bird markets (LBMs), farms/slaughterhouses/storage facilities (poultry and pigs), and at locations where a diverse range of Cambodian bat species roost. These locations represent high-risk human-animal interfaces, where known zoonotic pathogens circulate and novel disease emergence events are likely to occur^{6,7}. Sentinel and research pathogen surveillance systems are conducted by IPC for the early detection/warning of known emerging infectious disease to support and inform Cambodian public health systems and the global virus community. Currently, these surveillance programs use PCR-based pathogen detection, which relies on specific or pan-virus primers to amplify conserved genomic targets from an individual virus family. While this approach has led to the successful identification of novel viruses in the past, reliance on conserved genomic targets limits detection of sufficiently divergent pathogens, including those that arise through recombination or reassortment^{8,9}. These surveillance efforts are also labor intensive, expensive, limited to known hotspots, and highly species-specific (both animal and viral family). To this end, we have begun to supplement our traditional surveillance methods, which depend on sampling directly from animals, with ES at high-risk human-animal interfaces. These samples include water, swabs, and air samples, which are collected alongside samples taken from individual animals, enabling a direct comparison of pathogens identified from environmental samples with those collected from individuals.

Despite the clear risks associated with Cambodian LBMs, pig farms/slaughterhouses, bat guano farms and caves, there is very limited understanding of virus diversity at these sites. However, the hunt for the origin of SARS-CoV-2 has led to a renewed interest in the viruses present at live animal markets and across the wildlife supply chain, as well as in viruses carried by bats. Hence, improved surveillance of poultry, pigs, bats and other wildlife (as putative reservoirs and intermediate hosts of zoonotic viruses) will be key for the development of early and effective disease prevention and intervention measures by identifying viruses with known or predicted zoonotic potential at high-risk interfaces, where pathogen spillover is most likely to occur. The ability to use environmental samples for metagenomic pathogen surveillance and discovery would not only increase surveillance capacity, but also contribute to our understanding of new or emerging pathogens at these high-risk interfaces. Environmental sampling has several benefits compared to individual animal sampling: 1) **Biosafety benefits**. Handling animals for sampling is risky, both for the animal (discomfort and distress) and the handler (increased exposure to zoonotic infections, trauma from bites/scratches, etc.); 2) **Economic benefits**. Sampling individual animals requires increased sample numbers, trained personnel, more personal protective equipment, increased number of molecular tests, and time which are costly. Short-term and long-term storage of individual samples requires additional space in -80 freezers and/or liquid nitrogen. 3) **Increased comprehensiveness**. Environmental sampling expands the source of sampling to include animal excretions from multiple animals and/or species (urine, feces, saliva), contact material, and aerosolized particles. As many zoonotic diseases are effectively transmitted through the environment (i.e., respiratory viruses, enteric viruses), sampling from these sources may more directly represent human disease risk at key interfaces.

Significance and Approach

Backyard livestock farms, LBMs, and wildlife farms often have limited biosafety measures in place despite representing potentially risky human-livestock-wildlife interfaces, and as a result, have repeatedly been associated with the (re-)emergence of zoonotic diseases¹⁻⁴. Therefore, developing early warning systems at these high-risk locations will be critical for monitoring and preventing zoonotic diseases from generating the next pandemic. Previous pathogen surveillance and virus diversity studies at human-livestock-wildlife interfaces in Cambodia have relied heavily on consensus PCR-based virus detection, and/or focused on only a single animal species¹⁰. These methods are time consuming and costly and may result in delayed disease detection and reporting. Every second counts between first detection and response. Indeed, the total cost of an outbreak grows exponentially as time from detection increases, making identification critical at emergence or early stages of spread¹¹. It is critical to get “left of sneeze.”

To this end, the proposed project will use and evaluate cutting-edge metagenomic approaches for multiple viral pathogens on broad coverage samples as a modern alternative to pathogen surveillance at high-risk interfaces. Comparison to standard methods will be conducted under a hypothesis-driven framework to reveal the diversity, abundance, and zoonotic potential of viruses circulating in high-risk locations for emergence. To our knowledge, this is the first data-driven project with the goal of providing a foundation for the role of metagenomic ES in monitoring virus prevalence and emergence in Cambodia.

Like much of South/Southeast Asia, Cambodia is a hotspot of endemic and emerging infectious diseases. However, despite active, longitudinal surveillance efforts, outbreaks still frequently occur and data on virus diversity at high-risk human-animal interfaces are still lacking¹²⁻¹⁴. Additionally, as a Least Developed Country, the economic impacts of endemic agricultural and human seasonal pathogens are high, making surveillance for novel emerging pathogens at the animal-human interface a costly lower priority. Furthermore, it is increasingly difficult to obtain samples and/or data from some countries in the region, increasing the importance of Cambodia as a critical location for monitoring zoonotic disease emergence. The unique biobank of samples we have collected as part of active, longitudinal surveillance programs represents a remarkable opportunity to compare standard pathogen surveillance using individual animals and PCR with metagenomic ES to determine viral diversity and viral abundance.

Outcomes from this pilot study will provide invaluable data on improved and cost-effective surveillance practices within a “One Health” perspective. This is critical, as viruses will likely jump to new hosts from the water they drink, the surfaces they touch, and the air they breathe - less likely because they are kissing a chicken. **Environmental sampling reduces occupational risk, improves animal welfare, and can have non-invasive or reduced impact on market trade and wildlife habitats.** Improving our ability to monitor multiple pathogens in the environment will increase our capacity to develop and communicate key biosecurity practices and guidelines to reduce risk, and influence policy. Environmental sampling with multiple pathogen detection will also reduce the overall cost of surveillance systems, which is a key consideration in resource-limited settings. Expanded pathogen detection with reduced sampling means being able to conduct surveillance over a broader area and/or more frequently, greatly enhancing the ability to detect a potentially pandemic-level pathogen at a high-risk interface. Indeed, rough estimations from the budget of this pilot project alone predict surveillance could double in length or breadth for a single pathogen itself, let alone the 3000+ targets included in each enhanced metagenomic run.

Thus, in line with the goals of the CREID network and the EID-SEARCH team (to improve the detection and surveillance of important emerging viruses), we will use previously collected samples from high-risk human-animal interfaces in Cambodia to systematically characterize and compare viral diversity within and between environmental and animal samples from the same locations. We will evaluate the benefits of incorporating ES into existing surveillance programs as a means to broaden pathogen

Bat Surveillance – 56 samples (35 animal ES individual/21 air ES individual)

Bat sampling sites for this proposal were chosen based on previous research efforts by IPC in Phnom Penh, Kampong Cham, Stung Treng, Kampot, Kandal, and Battambang provinces (**Figure 2**)^{10,16,17}. Our standard pathogen surveillance protocol for bats focuses on the collection of urine and guano; here, these will be referred to as animal samples, although it is worth bearing in mind that they may be representative of multiple animals in some cases. Sample collection for this project is performed under the FAO-USAID and includes air, guano, and urine samples collected in and around seven locations of bat caves, roosting sites, and/or guano farms. Air samplers (N = 21) are deployed at cave entrances, roosting trees, and bat guano farms where large groups of individual bats congregate, maximizing the capacity to sample many individuals collectively. In parallel, air samplers were fitted with a sterile plastic cover (2m x 2m) to collect urine and feces (N = 35) to compare the viruses identified in air samples with those from bat excretions.

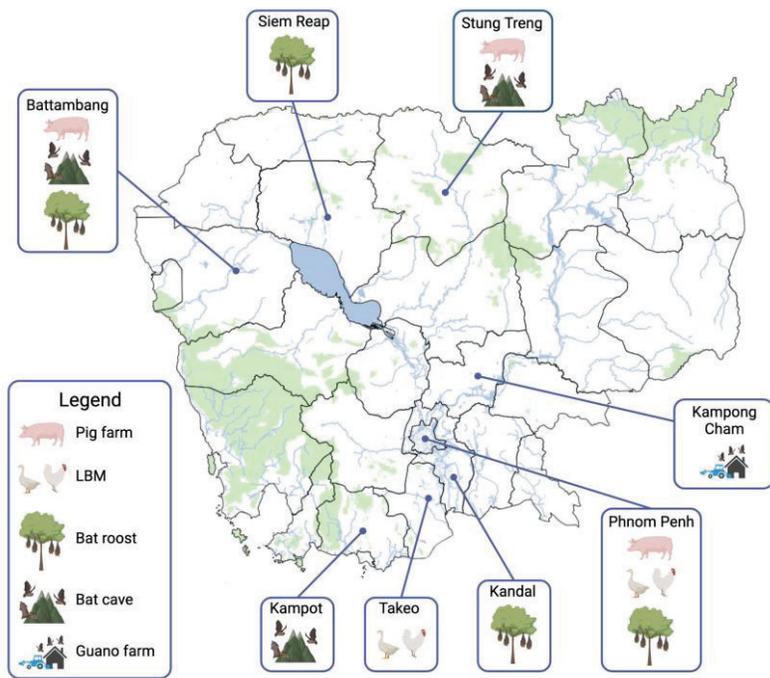

Figure 2. Location and type of sample previously collected in Cambodia and readily available for the proposed study.

Metagenomic Sequencing. While the advent of metagenomic sequencing was a significant step forward as a tool for pathogen detection and discovery, it remains relatively expensive and lacks the analytical sensitivity required for a true pathogen surveillance platform. Target enrichment panels were developed in response to this issue, but, until recently, were unable to facilitate the detection of highly divergent strains or novel viruses^{10,18}. In this project, we will use a cutting-edge hybridization-based target enrichment approach - The Twist Comprehensive Viral Research Panel (CVRP) – that was designed to explicitly address this need¹⁹. The CVRP contains more than a million probes covering the

genomes of 15,488 strains from 3,153 unique viruses (including animal viruses), and is tolerant to mismatches between virus and probe, supporting the detection of novel zoonoses. These include ssRNA, dsRNA, ssDNA, and dsDNA viruses belonging to every virus family capable of infecting people. Thus, target enriched metagenomics represents an ideal balance between the promise of unbiased virus detection and the feasibility of the standard tool of public health surveillance programs everywhere – quantitative PCR.

Prior to preparation for metagenomic sequencing, individual animal samples will be pooled by sampling session: 10 samples will be pooled for chickens and ducks per market (2 markets) per visit (10 selected visits), respectively; five samples will be pooled from pigs. Bat guano/urine will be run individually (**Table 1**). Wash water samples will be pooled by sampling session (N=2/session), as will cage swabs (N=5/session), while all air samples will be processed individually. Wash water samples will be pelleted and concentrated using ultrafilters²⁰ prior to RNA extraction.

In this project, we will follow the manufacturer’s recommended protocol for the generation of hybridization-enriched sequencing libraries, under the guidance of Prof. Linfa Wang at Duke-NUS, who

has been involved in the development and implementation of target enriched metagenomic sequencing for several years (see attached letter of support). Briefly, high quality total RNA will be extracted from

Table 1. Sample types and numbers (pools) from paired sampling locations selected for target enriched metagenomic sequencing.

System	Animal sample type	Animal number	sample	Environmental sample type	Environmental sample number
Poultry	Cloacal swab	Chicken: 600 (60)		Wash water	120 (60)
	Cloacal swab	Duck: 600 (60)		Cage swabs	55 (11)
				Air samples	33
Pigs	Nose/snout swab	45 (9)		Wash water	18 (9)
				Cage swabs	45 (9)
				Air samples	27
Bats	Urine/Guano	35		Air samples	21

each (pooled) environmental and animal sample using the RNeasy PowerMicrobiome Kit (Qiagen). RNA will be quantified and converted to cDNA using ProtoScript II First Strand cDNA Synthesis kit and random primers (New England Biolabs). The NEB Next Ultra II Non-Directional RNA second Strand Synthesis kit (New England Biolabs) will be subsequently used to convert single-stranded cDNA to dsDNA, and Illumina TruSeq-compatible libraries will be generated using the Twist Library Preparation Enzymatic Fragmentation kit (Twist Bioscience). These libraries will be hybridized for 16 hours with the set of 120 base pair biotinylated probes contained within the CVRP (Twist Bioscience) and sequenced with 2x75 bp paired-end reads on an Illumina MiSeq platform housed at IPC. Twelve target enriched libraries will be sequenced per run to achieve approximately 2 million reads/sample.

Metagenomic data analysis. For target enriched metagenomics to have utility as a public health surveillance tool, data analysis must be user-friendly and understandable to a non-expert in bioinformatics. Towards this aim, we will assess the performance and user-experience of two leading cloud-based metagenomics platforms for virus detection and compare the results to those generated by our bespoke bioinformatics pipeline²¹. Analysis of data generated by the CVRP is supported by One Codex software, a cloud-based platform for microbial genomics that will be used for preliminary data analysis and visualization²². One Codex uses a rapid, highly sensitive k-mer classification algorithm that maps sequencing reads to their custom database, which consists of more than 115k microbial genomes. The raw classification results are filtered through several statistical post-processing steps designed to eliminate false positive results caused by contamination or sequencing artifacts. We will analyze the same data using Genome Detective, a web-based platform that sorts sequence reads into bins prior to *de novo* assembly and compares the assembled contigs to the NCBI RefSeq and Swissprot UniRef90 databases, respectively, for virus identification²³. Each of these platforms is contained within a point-and-click, web-based interface and reports results using easy-to-understand visualizations, with click-through options for additional details should the user wish to perform analyses beyond pathogen detection. Finally, we will analyze these same data with our bespoke bioinformatics pipeline (representing the gold standard approach), which uses Trinity RNA-Seq for *de novo* assembly²¹, followed by comparisons with the complete non redundant nucleotide and protein databases available through GenBank using E-value cutoffs of 1E-10 and 1E-4, respectively, and the program Diamond²⁴. Additional full genome assembly will be attempted for all known or potentially zoonotic viruses identified by any of the three analysis approaches using either metaSPAdes (for *de novo assembly* of highly divergent viruses), or BWA MEM for reference mapping of known viruses^{25,26}. Sequences representing viral genomes will be further

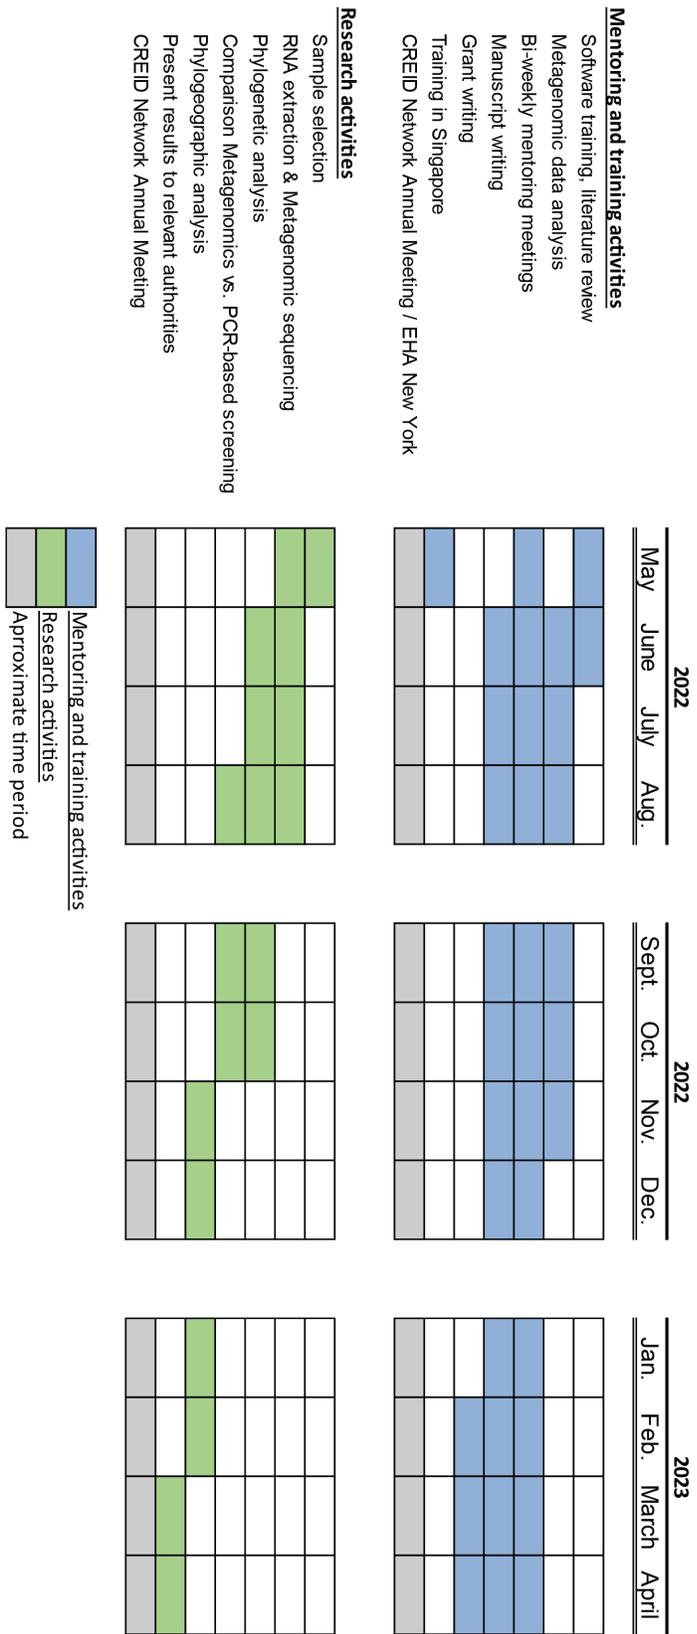

characterized using phylogenetic analysis targeting conserved domains (e.g, the RNA polymerase) that will include related viruses from GenBank to estimate evolutionary relationships and infer potential zoonotic disease risk. Phylogenies will be estimated using the maximum likelihood method implemented in IQ-Tree 2, employing the best-fit amino acid substitution models for each virus family²⁷. The resultant phylogenies will be used along with the Virus-Host DB²⁸ to identify putative host species for viruses found in environmental samples, where genetic material from multiple host species may be present.

Assessing the utility of target-enriched environmental metagenomics for pathogen surveillance. First, we will interrogate the utility of ES as a tool for pathogen surveillance by comparing metagenomic data from environmental samples with metagenomic data from animal samples collected at the same time and location. From each sequencing library, we will calculate the following metrics: number (and identity) of virus families identified, number (and identity) of unique viruses identified, and percent genome coverage for each virus. These will be combined by sample type and sampling session (as replicates) to provide a snapshot of circulating viral diversity at each time/place. The metrics associated with each environmental sample type will be compared to those from the corresponding animal samples from the same time and location. This will allow us to assess what proportion of virus diversity in a host population is detectable from the environment, as well as to identify any taxon-specific biases in environmental sampling, if present. We will also compare viral community structure across sample types using standard measures from community ecology, including species richness, alpha diversity, and beta diversity, which will be calculated using a range of R packages²⁹. Permutational multivariate analysis of variance tests (permanova) will be used to assess differences in virome composition between sample types.

Next, we will examine the utility of target enriched metagenomics as an alternative to traditional molecular diagnostics (qRT-PCR and consensus PCR). As part of our routine pathogen surveillance efforts, individual animal samples from these same sampling sessions have previously been tested for the following pathogens: **Poultry** – AIV and Newcastle disease virus; **Pigs** – influenza, African swine fever virus, classical swine fever virus, Nipah virus, and porcine reproductive and respiratory syndrome virus; **Bats** – coronaviruses, Nipah virus, orthomyxoviruses. The results of these tests will be compared to the metagenomic results from environmental and animal samples to evaluate how well this approach recapitulates the results from standard pathogen surveillance efforts.

Potential Pitfalls and Alternative Plans: Overall, this is a straight forward study using novel and readily accessible samples. Any resultant data will be extremely useful in understanding the benefits of ES over animal sampling for pathogen surveillance. No issues are foreseen with utilizing retrospective samples for metagenomic sequencing; however, storage and collection issues can affect sample quality. If insufficient samples are available, IPC plans to continue surveillance activities throughout the period of this project and fresh samples can be collected for analysis. In addition, given the need to maintain cost-effectiveness, only 2M reads will be collected per sample using CVRP. A series of spike-in experiments will be conducted to ensure sequencing reads and dept is adequate for known viruses before conducting sequencing on precious samples to ensure detectability (not funded through this project). At the current time, no internationally recognized guidelines exist on the use of environmental sampling (ES) and data management. It is hopeful these studies will contribute to future guidelines surrounding the use of ES in surveillance sampling.

Project Timeline

Research Performance Sites (1-page limit)

The Institut Pasteur in Cambodia, established in 1953, is a non-profit research institution operating under the auspice of the Cambodian Ministry of Health (MoH) and the Institut Pasteur in Paris, France. IPC missions are: **(i)** to conduct innovative life science and health research on infectious and emerging disease in Cambodia; **(ii)** to provide public health services; **(iii)** to contribute to training and capacity building in the field of biomedical and life science.

IPC constitutes a strong team and a state-of-the-art facility with modern, secured and standardized laboratories appropriate for experiment with hazardous pathogens. These laboratories include biosafety level (BSL) 2 and 3. The BSL3 facility comprises four modules dedicated to different and separate activities including a safety cabinet with gloves box allowing BSL3+ safety conditions. The proposed project will take place within The Virology Unit at IPC, which serves as the reference laboratory for COVID-19, Influenza, Arboviruses, and Rabies for Cambodia, and conducts surveillance and research on endemic, emerging, and zoonotic pathogens. To respond to the COVID-19 pandemic, the Virology Unit at IPC has recently increased its sequencing capacity to include both Oxford Nanopore (GridION and MinION) and Illumina MiSeq technologies.

The Virology Unit works closely with the Epidemiology/Public Health, Entomology, Bacteriology, and Malaria Units at IPC, as well as national and international partners, to conduct One Health-focused surveillance and studies in Cambodian people, domestic animals, and wildlife. As such, IPC is continually searching for new and innovative ways to expand and improve surveillance activities. IPC also serves as a model for state-of-the-art research in a Least Developed Country/Low-Middle Income Country and successful studies at IPC can inform future work in the region.

All samples needed for this work have been maintained in IPC laboratory freezers at -80°C from the time of collection and can be easily linked to collection and pathogen metadata. These unique samples and data are available only at IPC, which is committed to facilitating the proposed research. Please see “12.10 - Facilities and Resources” for a more detailed description of infrastructure and equipment available at IPC to ensure the success of this project.

CREID Research Center Collaboration (1-page limit)

The goals and objectives of the proposed research project, “In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on improving, expanding and simplifying existing surveillance efforts to cast a wider net for pathogen surveillance and monitor virus diversity at key human-animal interfaces and on a longitudinal basis we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, uses archival samples, and includes a robust individual development and capacity building component that together corresponds to the overall research strategy of CREID and EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of applying metagenomics to pathogen surveillance and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on robust surveillance networks to timely identifying emerging zoonotic threat at key human-animal interfaces the proposed research is both timely and likely to yield highly-cited, impactful publications and policy recommendations for EID-SEARCH and its IPC partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic, genomic, and bioinformatics analyses, who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the IPC research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between Dr. Jurre Siegers and Vireak Heang and our partners in Southeast Asia (based in Singapore, Australia and the US) that will facilitate Dr. Jurre Siegers and Vireak Heang professional development and strengthen research capacity in the region. Dr. Cadhla Firth, Senior Scientist at EID-SEARCH and the project Mentor, has an established relationship with both Dr. Jurre Siegers and his supervisor, Dr. Erik Karlsson, and will act as the liaison between EID-SEARCH and the IPC research team. An expected outcome of this research project will be pilot data to support a joint funding application in the future, led by Dr. Jurre Siegers.

Mentoring Plan

The co-PIs, Vireak Heang and Jurre Siegers, are at different stages of their respective careers with discrete professional development goals. This Mentoring Plan allows the co-PIs to pursue independent professional goals while working as a team to achieve the learning and development objectives associated with the proposed project.

1. Developing Leadership and Independence

Vireak Heang: My long-term goal is to train the next generation of Cambodian scientists. I can pass on my knowledge in my native language, Khmer, providing greater educational opportunity to all Cambodians. The opportunity for future scientists to learn in their native language is a critical step towards rebuilding the scientific infrastructure of my country. Prior to joining IPC, much of my work was technical, with limited experience in project management. However, at IPC, my Scientific Mentor, Dr. Karlsson, took an immediate interest in my professional development and is actively involving me in the entire scientific process – from conception, to study design, implementation, and analysis. As a result, we have developed a strong mentoring relationship built on trust and mutual respect that will continue across this project to improve my scientific career. My Research Center Mentor, Dr. Firth, has a broad scientific network, and regularly interacts with scientists across Southeast Asia in her role as a Project Coordinator for EID-SEARCH. To strengthen my ability to communicate complex scientific topics, both Mentors will actively provide opportunities for me to interact with and present my research to other scientists across Southeast Asia and through their respective global networks of research partners.

Jurre Siegers: My overall research goal is to improve the health of people, animals, and ecosystems using a “One Health” approach that will allow me to maximize my academic training, and scientific and personal interests. I wish to develop my skills in novel diagnostic tools, such as metagenomics, to contribute to improved surveillance and research capacity in the field of emerging viruses at human-animal interfaces. However, my aspirations are not just limited to the generation of scientific knowledge, methods, and policies. Instead, I wish to actively use my knowledge in virology (Ph.D. training) and emerging infectious diseases (Postdoctoral) to train the next generation of Cambodian scientists that will one day be local leaders in the field of emerging infectious diseases. As my Scientific Mentor, Dr. Karlsson has already demonstrated his commitment to my scientific progress by providing me with opportunities to develop project management skills and improve my scientific writing. Both Mentors will continue to mentor me in this capacity. Both Mentors have also been actively guiding me in grant writing (including with this proposal) and will continue to provide hands-on instruction. Both Mentors will support my attendance and participation at (inter)national conferences on emerging zoonotic diseases and provide opportunities to present my work to scientists at IPC, EcoHealth Alliance (EHA), and across EID-SEARCH/CREID. Both Mentors will also provide me with networking opportunities from across their respective networks as they support my development to become a more independent leader in the field of emerging infectious disease research.

2. Building Expertise in Metagenomics

Vireak Heang: My extensive experience and training in laboratory-based sciences has developed a deep understanding of molecular techniques and how they can be used in the detection, characterization, and epidemiological modeling of pathogens. While my work has primarily dealt with shotgun and amplicon-based sequencing, metagenomics is a critical tool for pathogen detection and discovery. In Cambodia, this

capacity is very limited; however, we recently set up the IPC Sequencing Mini-Platform (Illumina MiSeq and ONT technologies) and are exploring the full potential of this system. Given the opportunity to strengthen my hands-on and analytical skills to include metagenomics, will broaden my skillset, and further transition me to scientific independence in Cambodia, capable of using cutting-edge genomics techniques to solve locally relevant problems. Dr. Firth has more than 15 years' experience in the generation and analysis of genomic and metagenomic data in the context of zoonotic disease detection, discovery, and characterization (including BSL3), and is experienced in training and mentoring scientists from LMICs in Southeast Asia. She is therefore an ideal mentor in this area and will work closely with me to develop laboratory SOPs and workflows for metagenomics that are fit-for-purpose at IPC. In addition, Dr. Firth has arranged for me and Dr. Siegers to visit Prof Linfa Wang's laboratory at Duke-NUS Medical School in Singapore for training in cutting-edge molecular techniques, as well as to interact directly with members of his lab.

Jurre Siegers: In Cambodia and other LMICs, there is a pressing need for increased capacity in the field of (meta)genomics, which is becoming increasingly common in emerging infectious disease surveillance and research. Given the opportunity to further strengthen my analytical skills to include genomic and metagenomic data analysis, I will be in possession of a skillset that will allow me to make significant career steps as a junior scientist, capable of initiating and delivering hypothesis-driven research at the forefront of virology and emerging diseases. I will also actively work to disseminate this knowledge to local scientists and staff to ensure that these methods and tools are available to Cambodian scientists, and to support national and international surveillance efforts. Dr. Firth has a wealth of experience in viral sequence analysis, phylogenetics, and phylodynamics, and a broad network of experts in this field. She will work closely with me to develop my technical skills in this area and will facilitate interactions across her network as needed to achieve the analytical goals of the project and build my expertise in this area.

3. Communication Plan

Through the process of writing the application for the CREID Pilot Research Program, the four of us have established the foundation for an effective communication plan that will continue throughout the project. We have already created a WhatsApp group used to communicate in a real-time, informal setting. This has been invaluable for sharing ideas, asking questions, and facilitating development of good interpersonal relationships - the foundations of effective mentorship. We have also agreed to regularly scheduled Zoom meetings (every two weeks) that are agenda-driven, and focused on a topic or issue of direct relevance to the research project. Both the Co-PIs and the Mentors will set the agenda and follow-up on action items. Co-PIs will meet weekly in-person with Dr. Karlsson to discuss project developments, troubleshoot, and develop skills in project and budget management. In addition, the Co-PIs will attend weekly academic meetings at IPC in person and at EHA (remote), which will expose them to the breadth of research and broaden their knowledge base.

Finally, we have scheduled two in-person visits between Dr. Firth and the Co-PIs. The first will coincide with the CREID annual meeting and will include a visit to EHA's headquarters in New York City. This visit will focus on learning relevant analytical techniques, performing preliminary data analysis, and networking with EHA's scientists and staff. Towards the end of the project, Dr. Firth will join us in Cambodia to assist in preparing and analyzing our data for publication and will discuss future directions and plans for future funding following on from this project.

Vertebrate Animals Section Requirements

Projects involving animal samples were collected (2019-2021) under a protocol approved by National Ethics Committee for Health Research under the Ministry of Health, Cambodia (NECHR143, NECHR149, and NECHR320); however, Cambodia did not have a specific animal ethics review board at the time the collections were conducted. Continuing ethics approvals (NECHR013) for projects involving further animal sample collections in 2022 are in revision and projected to be approved in February 2022.

Human Subjects Research

This proposal will not involve experimental procedures with or on human subjects and is therefore not applicable.

A. Personal Statement

I first began conducting research in 2006 when I was hired by the US Naval Medical Research Unit No. 2 (NAMRU-2) in Phnom Penh Cambodia and I am now working at Institute Pasteur of Cambodia as a Research Engineer for the sequencing platform. My first position at NAMRU-2 was as a Molecular Biology Laboratory Technician. In this role, I was introduced to the exciting world of infectious disease surveillance in one of the global hotspots of these diseases. Over the next 15 years, I rose to become the Head of Molecular Diagnostics where I oversaw a diverse team of 10 people that conducted molecular detection and characterization of pathogens. Utilizing technologies such as RT-PCR, Sanger sequencing, and Next Generation Sequencing (NGS), we collected and analyzed data on infectious pathogens that was critical not only for the US Department of Defense, but also for the Cambodian Ministry of Health, and the Cambodian Armed Forces. Through various training programs and on-the-job experiences, I have developed a deep understanding of molecular techniques and how they can be used in the detection, characterization and epidemiological modeling of pathogens. In 2017, the NAMRU-2 laboratory was chosen by the Global Emerging Infectious Surveillance and Response System (GEIS) to be one of the NGS and Bioinformatics (BI) Consortiums. The goal was to rapidly detect and characterize known, emerging, and novel infectious agents through the establishment of a harmonized Department of Defense laboratory capability that uses data from NGS and BI to inform armed forces health protection decision making. As part of the consortium, each laboratory was sent a set of blinded specimens and we were to run, analyze, and send the report back to the consortium. My role was to set up and manage the plan for running and analyzing those blinded specimens using our in-house techniques, and we correctly identified 85% of the pathogens that the consortium sent us. I have since managed to sequence a variety of specimens - from bacteria isolates to clinical specimens - using Illumina Miseq, including Escherichia coli, Salmonella spp., Shigella spp., influenza virus, Chikungunya virus, and Dengue virus. In my current role, I am a designated expert on Illumina sequencing and assist scientists from across all different units at IPC, regardless of discipline. Recently, I managed to successfully sequence 96 respiratory specimens for SARS-CoV-2 using the Illumina Miseq ARTIC protocol.

My work has encompassed all aspects of infectious diseases from human-specific diseases to analyzing zoonotic transmission at the animal-human interface. From these experiences, I have come to understand the “whole” of health as it applies to animal and environmental reservoirs and the dynamics of transmission. I also have experience across multiple levels of research – from hands-on work at the bench, to team lead, to leading an entire department executing multiple projects. Through these varied responsibilities, I have developed a keen knowledge of how to manage both projects and teams, excellent communication skills, and programmatic expertise. My personal goals are to continue to expand my knowledge and abilities in molecular science. I am keenly interested in the dynamic relationship that microorganisms, especially pathogens, have with their hosts, including natural reservoirs and spillover hosts. By understanding these interactions, I feel we can develop better protections against disease, whether those be through enhanced detection, novel prophylactics, or targeted therapeutics.

B. Positions, Scientific Appointments and Honors

2020-Present	Research Engineer, Institute Pasteur of Cambodia.
2013-2020	Molecular Biology Project Manager, US Naval Medical Research Unit.2
2010-2013	Laboratory Technician, US Naval Medical Research Unit.2
2006-2008	Laboratory Technician, US Naval Medical Research Unit.2, Contractor
2001-2006	Laboratory/X-ray Technician, International SOS clinic.

C. Contributions to Science

1. My early publications focused on the reemergence of Zika virus in Cambodia. My work first began by detecting and describing a case report of Zika infection in a Cambodian citizen in 2010. The identification of this index case signaled that ZIKV was still circulating in Cambodia. Continuing the investigation, we sequenced the Cambodian isolate with four other isolates from across the globe, expanding the number of characterized isolates in Cambodia from two to seven. Our results demonstrated that there appeared to be two distinct lineages of ZIKV circulating, one originating in Africa and one from Asia.

2. A second focus of my work has been the detection and characterization of drug resistance in bacterial pathogens circulating in Cambodia. Cambodia lacks regulation in the use of antibiotics and thusly the use of incorrect antibiotics and/or improper dosing is common. This has led to a rise in multi-drug resistant strains of bacteria across the country. My worked has helped detect the presence of antibiotic resistance in Cambodia and characterize the mechanisms of resistance using molecular techniques.

PMID: 32824772; PMCID: PMC7460656.
3. Finally, I have also contributed to broad topics including drug resistance in malaria and observational studies into the causes of sepsis. Cambodia has experienced malaria treatment failures to multiple frontline drugs, creating great concern should these resistant strains continue to proliferate. My work helped to evaluate the efficacy of new combinations of drugs in the treatment of malaria. Sepsis continues to be a significant cause of morbidity and mortality, especially in areas with a rudimentary health care system such as Cambodia. I contributed to the seminal description of the causes of sepsis in Cambodia through the use of next generation sequencing techniques for pathogen detection and characterization.

Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Jurre Ynze Siegers

eRA COMMONS USER NAME (credential, e.g., agency login): N/A

POSITION TITLE: Postdoctoral Scientist

EDUCATION/TRAINING *(Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)*

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
University of Applied Sciences van Hall Larenstein, Leeuwarden the Netherlands	BASc	08/2011	Biotechnology
Erasmus University Rotterdam, the Netherlands	MSc	08/2013	Infection & Immunity
Erasmus University Rotterdam, the Netherlands	PhD	03/2022	Virology
Institute Pasteur du Cambodia, Phnom Penh, Cambodia	Postdoctoral		Virology, Global Health

A. Personal Statement

I am virologist who has been working in the field of emerging infectious diseases since 2013. During my PhD training in the Department of Viroscience at the Erasmus Medical Center in Rotterdam, the Netherlands, I studied the extra-respiratory tract complications of (zoonotic) influenza A virus infection using a wide range of disciplines that included virology, immunology, molecular biology and pathology. Following completion of my Ph.D., I began to pursue a research career focused on emerging respiratory viruses at the human-animal interface in Cambodia that incorporates surveillance, viral evolution, host-pathogen interactions, and pathogenesis. As a postdoctoral scientist at Institut Pasteur du Cambodge (IPC) in Phnom Penh, Cambodia, I coordinate and oversee all daily activities related to seasonal human and avian influenza viruses. These include molecular surveillance for influenza-like illness (ILI-surveillance), avian influenza surveillance in Cambodian live bird markets and wild birds, phylogenetics, cell culture work at BSL-2 and BSL-3 level for virus isolation, and serology. Furthermore, I am in charge of implementing novel virus characterization methods at the BSL-2 and BSL-3 lab facilities. Of particular relevance to the proposed project, I also oversee all management, development, and training related to routine sequencing at IPC Virology Unit using Oxford Nanopore technologies.

My research portfolio has a strong multi-disciplinary component that includes virology, immunology, pathology, pathogen genetics and genomics, field work, and public health, and has required me to become adept at combining and analyzing multiple types of data, including experimental, environmental, and genomic data. I also have a strong track record in the discovery/identification and characterization of emerging viruses, with 6 publications in this field, four of which have been cited more than 10 times since 2013 (total citation: 161). Adding pathogen metagenomics to my portfolio would advance my career significantly by becoming an expert in the field of emerging viruses, capable of performing initial pathogen discovery as well as primary virus characterization. As such, my experience, skills, and training are ideally suited to the proposed research project, which builds naturally on my previous work. Further, I am strongly committed to supporting diversity and equity both within the scientific community and in the communities we serve by improving science education and good/safe farming practices for underserved communities in rural Cambodia. I am also committed to providing training and mentorship for low- and middle-income country scientists and scholars.

B. Positions and Honors

Positions and Employment

2020-	Postdoctoral Scientist, Institut Pasteur du Cambodge, Phnom Penh, Cambodia
2015-2020	PhD Candidate, Erasmus Medican Center, Rotterdam, the Netherlands
2015	Volunteer. Clinical Laboratory Technician (Ebola Virus Diagnostics). Koidu, Sierra Leone
2014	Research Asissant, Murdoch Children's Research Institute, Melbourne, Australia

Other Experience, Commissions of Trust and Professional Memberships

2018-	Membership. American Society for Virology
2014-	Ad Hoc Reviewer. Peer reviewer for different journals including Neuron, the Lancet, Journal of Virology.

Honors

2021	Young Scientist Fund, The eight ESWI conference, Virtual
2020	Young Scientist Fund, The seventh ESWI conference, Virtual
2019	Travel grant award. CADDE Genomic Epidemiology Workshop, Sao Paulo, Brazil
2018	Travel grant award. Visiting Scientist, University of Queensland, Australia
2017	Young Scientist Fund, The sixth ESWI conference, Riga, Latvia
2017	Travel grant award, European Seminar in Virology, Bertinoro, Italy
2016	Travel grant award, Options XI for the control of Influenza, Chicago, US
2015	Best poster award, Young Predigone (Predemix/Antigone), Rotterdam, the Netherlands
2015	Best abstract award, 7th Orthomyxovirus Research Conference, Toulouse, France
2015	Travel grant award, 7th Orthomyxovirus Research Conference, Toulouse, France
2013	Travel grant award, 100th American Association for Immunologist (AAI), Hawaii, US

C. Contributions to Science

I have authored 18 publications (published or in press) in the fields of influenza, respiratory viruses, infectious disease, and immunology, nine of which (50%) are first author publications. The primary theme of my work is understanding the emergence, prevalence, transmission, and pathogenesis of viruses at the human-animal interface. *As of this dossier, Google Scholar: **Total citations:** 374, **h-index:** 10, **i10-index:** 11

1. **Immunologic consequences of chronic diseases in humans.** The start of my scientific career began during my bachelor's degree internship at the Murdoch Children's Research Institute in Melbourne Australia where I started a new line of research within the Cell & Gene Therapy group. This research shed light on the mechanism that underlies the increased susceptibility to bacterial infections observed in patients suffering from the genetic blood disorder beta-thalassemia. I identified that neutrophils of beta-thalassemia patients are functionally abnormal due to a block in neutrophil maturation. My interest in the field of immunology and infectious disease grew during this internship and led me to pursue a MSc degree in infection & immunity. During one of my MSc internships at the department of Hematology, Erasmus Medical Center Rotterdam, the Netherlands, I examined the role of the cytokine IL-22 and the IL-22 receptor in rheumatoid arthritis and identified IL-22 as an important enhancer of the germinal center reaction, which are essential for the production of autoantibody-secreting plasma cells.
 - V. Reduced PU.1 expression underlies aberrant neutrophil maturation and function in β -thalassemia mice and patients. Siwaponanan P, **Siegers JY**, Ghazali R, Ng T, McColl B, Ng GZ, Sutton P, Wang N, Ooi I, Thientavor C, Fucharoen S, Chaichompoo P, Svasti S, Wijburg O, Vadolas J. **Blood**. 2017 Jun 8;129(23):3087-3099. doi: 10.1182/blood-2016-07-730135. Epub 2017 Mar 21.
 - VI. Loss of IL-22 inhibits autoantibody formation in collagen-induced arthritis in mice. Epub 2016 May 12.
2. **Characterization of emerging (respiratory) viruses.** After exploring immunology, it was time to pursue my biggest interest, the world of emerging viruses. I was able to contribute scientific knowledge and advancements related to the novel avian-origin H7N9 virus, where I first reported on the attachment pattern of this potentially pandemic virus to the respiratory tract of five different animal models frequently used in influenza virus research. In addition, I showed that in humans, H7N9 viruses attach to cells in both the upper and lower respiratory tract, something never before observed for an avian-origin influenza virus. In terms of virus discovery, I described the first identification and genetic characterization of a dolphin rhabdovirus and during the Zika virus outbreak, a re-emerging virus, I contributed by describing fundamental intrinsic *in vitro* differences between the African and Asian lineage Zika viruses in neuronal cells. Finally, I contributed to the identification of zinc-embedded polyamide fabrics as a suitable "passive" inactivation of SARS-CoV-2 virus that could be used in personal protective equipment.

3. **Pathogenesis of seasonal, pandemic, and zoonotic influenza A virus associated extra-respiratory complications.** My PhD project focused on the extra-respiratory complications of influenza virus infection where I made significant contributions to our understanding of the pathogenesis of extra-respiratory disease. First, I described the pathogenesis and extra-respiratory complications of pandemic 1918 H1N1 virus in a ferret animal model and provided new insights into the significant pathogenicity of this virus. Second, I provided new insights into the impact of chronic metabolic diseases (excess weight/obesity) on the

development of influenza virus-associated extra-respiratory disease. Third, I described the intrinsic differences - viral and host factors - in the ability of seasonal, pandemic, and zoonotic influenza A viruses to replicate in cells of the central nervous system, and proposed a potential mechanism. Finally, I evaluated the efficacy of vaccination and pre-exposure prophylaxis antivirals in the development of extra-respiratory tract disease associated with highly pathogenic avian influenza H5N1 virus infection in ferrets.

Print 2019 Jun 1.
4. **Emerging respiratory viruses at human-animal interface.** My current postdoctoral training is focused on emerging (respiratory) viruses at the human-animal interface in Cambodia and includes - but is not limited to - influenza, coronaviruses, and paramyxoviruses. Using a “One Health” approach I contribute to understanding the dynamics of avian influenza at Cambodian live bird markets and in wild birds, the epidemiology of seasonal influenza, and the emergence of zoonotic viruses in humans. Thus far, I have identified the first human A/H9N2 infection in Cambodia and performed genetic and antigenic characterization of an influenza A(H3N2) outbreak in Cambodia during the COVID-19 pandemic.

INSTITUTION AND LOCATION	DEGREE	Completion Date	FIELD OF STUDY
University of Guelph, Guelph, CAN	BS	06/2003	Zoology
University of Guelph, Guelph, CAN	MS	06/2005	Evolutionary Ecology
The Pennsylvania State University, State College, PA	PHD	05/2010	Biology
Columbia University, New York, NY	Postdoctoral	12/2012	Infectious Diseases & Public Health

A. Personal Statement

I am a molecular and evolutionary biologist who has been working on emerging infectious diseases for 15 years. In my current research, I explore the ecological and evolutionary dynamics of emerging zoonoses at the human-animal interface, with a focus on rapidly changing environments in Southeast Asia. I have more than eight years' experience leading independent research projects in this field, including collaborations with industry and local government. Over time, I have been responsible for the successful completion of every aspect of these studies, including project design, funding acquisition, implementation, and reporting/publishing. In 2015 I initiated a research program to investigate the response of zoonotic pathogens to urbanization in Malaysian Borneo using metagenomics, landscape ecology, and population genomics. This research has a strong multi-disciplinary component that includes evolutionary biology, molecular ecology, virology, pathogen genetics and genomics, field biology, and public health, and has required me to become adept at combining and analyzing multiple types of data, including environmental, ecological, and genomic data. This work has already resulted in three last-author publications, with a fourth currently in revisions at *Proceedings of the National Academy of Sciences of the USA*. As such, my experience, skills, and training are ideally suited to the proposed research project, which builds naturally on my previous work. I also have a strong track record in the generation and use of genetic and genomic data to explore the transmission dynamics and evolution of emerging viruses, with more than 20 publications in this field, nine of which have been cited more than 100 times since 2010. The mastery of genomic, phylogenetic, and phylodynamic methods I have developed throughout my career are directly applicable to the proposed research. Further, I am strongly committed to supporting diversity and equity both within the scientific community and in the communities we serve and have led several projects and initiatives aimed at improving science education and health service delivery for underserved communities in tropical northern Australia. I am also committed to providing training and mentorship for low- and middle-income country scientists and scholars, and in my previous role worked to develop protocols and bioinformatics pipelines to enable portable metagenomic sequencing in rural and remote regions in Australia and the Pacific. I am currently supervising two PhD students (James Cook University, AUS) and formally mentor a postdoctoral scientist, Dr. Nguyen Van Cuong, at the Oxford University Clinical Research Unit (OUCRU) in Viet Nam as part of my activities within the Centres for Research in Emerging Infectious Diseases (CREID) network.

B. Positions, Scientific Appointments, and Honors

Positions and Employment

2006-2008	Braddock Graduate Fellowship, The Pennsylvania State University
2003-2005	Ontario Graduate Scholarship, The Province of Ontario (Canada)
1999	Undergraduate Entrance Scholarship, The University of Guelph

C. Contributions to Science

Throughout my career, my research has focused on many aspects of infectious disease emergence and has encompassed evolutionary biology, molecular ecology, virology, pathogen genetics and genomics, field biology, and public/veterinary health. My most significant contributions include:

- 1. The use of genomic and metagenomic sequencing techniques to discover new pathogens, study their evolution, and explore microbial diversity.** I have successfully developed and used cutting-edge metagenomic techniques and bespoke bioinformatics pipelines for: (i) pathogen discovery, including a case of acute encephalitis in an immune-suppressed patient, (ii) studies of viral diversity, including coronaviruses and flaviviruses in bats; and (iii) genomics, including the epizootology of bluetongue virus, the evolution of rhabdoviruses, and the characterization of Australian bunyaviruses. I have also co-authored two perspectives on the utility of next-generation sequencing for pathogen discovery in people and animals. These included an invited submission that described an updated framework for proof of causation in the genomics era and discussed the emerging integration of on-the-ground metagenomics-based diagnostics with molecular epidemiology. In 2013, I initiated a study that used metagenomics to characterize the viruses and bacteria carried by New York City rats across a range of habitats, with a focus on the built environment. At the time, little was known about the range of potential pathogens carried by urban rodents or the risk factors associated with zoonotic transmission in a city environment. To begin to address this, I designed the first comprehensive molecular survey of rodent-borne microbes in a U.S. city, and demonstrated that urban rats frequently carry a range of zoonotic pathogens. We also found evidence of substantial heterogeneity in pathogen distribution within and between cities, suggesting that the associated risks of human disease may be similarly heterogeneous.

Phylodynamic modelling of bacterial outbreaks using nanopore sequencing. **Molecular Biology and Evolution**. *In Press*.

Related Pre-print available: <https://doi.org/10.1101/2021.04.30.442218>

2. **I have helped develop the emerging field of urban zoonotic disease ecology.** In 2015 I pioneered an ongoing research program to investigate the response of zoonotic pathogens to urbanization using metagenomic sequencing, landscape ecology, and population genomics. Using a multi-disciplinary approach, this research explores how changes in the environment (e.g., land-use changes, microclimates, etc.), and host community and population structure (e.g., biodiversity, connectivity, density), influence pathogen community composition and zoonotic potential. Initial results of this work indicate that while mammalian diversity decreases with increasing urbanization, connectivity between populations increases, as does microbial species richness and the prevalence of known zoonotic pathogens. This suggests that some features of the built environment may inadvertently support pathogen persistence and spread, and as a result, some zoonotic pathogens may be more likely to emerge with intensifying urbanization. My reputation as an emerging researcher in this field has led to multiple invitations to present as a plenary or symposium speaker at national and international meetings, including the Ecological Society of Australia's Annual Conference (2019) and the Annual Meeting of the American Society of Mammalogists (2019), and the Joint Conference of the Asian Society of Conservation Medicine and the Wildlife Disease Association Australasia (2018).

3. **I challenged established beliefs about the ecological and evolutionary processes linked to viral disease emergence, and the timescale over which they occur.** During my PhD, I was able to make significant contributions to this field by questioning the idea that viruses evolve either by cross-species transmission (spillover) or by co-evolution with their hosts, but rarely both. My work demonstrated that viruses with many genomic structures are capable of jumping species barriers, and that evolution through both co-divergence and cross-species transmission may be general trend of many virus systems. This has since been supported by numerous subsequent studies that have highlighted the complex evolutionary dynamics of both RNA and DNA viruses.

4. **I was among the first to apply novel phylodynamic approaches to reconstruct the spatiotemporal processes behind disease emergence events.** Phylodynamic methods enable the synthesis of epidemiological, geographic, and phylogenetic data to reconstruct the processes behind infectious disease emergence and spread through time and space. These methods are of particular use for investigating the emergence and spread of viruses, as they have a rapid evolutionary rate that closely matches the timescale of virus transmission. I began to explore these approaches during my PhD and have now successfully used them to: (i) explore the genetics underpinning the rapid emergence and spread of human enterovirus 68; (ii) examine the patterns and processes that influence the diversity and geographic distribution of New World hantaviruses; (iii) explore the epizootology of porcine circovirus 2; iv) understand the evolutionary and ecological drivers behind the distribution of bluetongue virus in Australia; (v) assess the likely origins of hepatitis C virus; and (vi) understand the global emergence of community-associated MRSA and MSSA.

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Erik Albert KARLSSON

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Deputy Head of Unit, Director of National Influenza Center of Cambodia, Director of WHO Regional H5 Reference Laboratory, Coordinator of WHO Global COVID-19 Reference Laboratory, Virology Unit, Institut Pasteur du Cambodge

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
University of North Carolina, Chapel Hill	B.S.	05/2005	Biochemistry
University of North Carolina, Chapel Hill	Ph.D.	05/2010	Nutrition
St. Jude Children's Research Hospital	Postdoctoral	06/2016	Virology

A. Personal Statement

During my doctoral work in the Department of Nutrition at the Gilling's School of Global Public Health, University of North Carolina at Chapel Hill, I studied the effect of nutrition, especially diet-induced obesity, on immune responses to viral pathogens. Following completion of my Ph.D., I began to pursue a research career focused on understanding surveillance, viral evolution, host-pathogen interactions, and immune responses. I began working as a Postdoctoral Research Associate with Dr. Stacey Schultz-Cherry and collaborators at St Jude Children's Research Hospital to expand my knowledge of virology, viral pathogenesis, co-infection, immunology (primary and vaccine-induced), and infectious disease surveillance. I became a Staff Scientist in Dr. Schultz-Cherry's laboratory, focusing further on the interaction of nutrition and infectious disease as well as helping to oversee influenza surveillance at the animal-human interface worldwide. I currently serve as a Senior Researcher (Assistant Professor equivalent) at Institut Pasteur du Cambodge (IPC) in Phnom Penh, Cambodia. I am the Deputy Head of the Virology Unit and in charge of all ongoing activities related to respiratory viruses, including human seasonal and zoonotic viruses, and am the Director of the National Influenza Center and the Regional WHO H5 Reference lab. I am integral in the COVID-19 response in Cambodia and worldwide and serve as the Coordinator for the WHO Global COVID-19 Reference Laboratory in the Virology Unit. I also serve as the Co-PI of the newly developed Sequencing Platform at IPC. My work at IPC focuses on surveillance of endemic and emerging viruses in Cambodia, including developing Early Warning systems against the next pandemic. I also frequently consult for UN organizations (FAO and WHO) and am the founder of a research think-tank named: "CANARIES: Consortium of Animal market Networks to Assess Risks of emerging Infectious diseases through Enhanced Surveillance."

B. Positions and Honors**Positions and Employment**

2016-2017 Staff Scientist, Department of Infectious Diseases, St. Jude Children's Research Hospital, Memphis, TN

2017-2020 Senior Researcher, Virology Unit, Institut Pasteur du Cambodge, Phnom Penh, Cambodia

2020- Deputy Head, Virology Unit, Institut Pasteur du Cambodge, Phnom Penh, Cambodia

Other Experience, Commissions of Trust, and Professional Memberships (since 2011)

2011-	American Society for Virology
2011-	Ad Hoc Reviewer. Peer reviewer for 60+ journals Full review record available on Publons: https://publons.com/author/737520/erik-albert-karlsson#profile
2012-2013	Secretary. Nutritional Immunology RIS. American Society for Nutrition
2013-2015	Chair Elect. Nutritional Immunology RIS. American Society for Nutrition.
2015-2016	Chair. Nutritional Immunology and Inflammation RIS. American Society for Nutrition
2015-	Editorial Board Member. Journal of Nutritional Biochemistry
2017-	Editorial Board Member. Virus Genes
2019-	Founder. Consortium of Animal market Networks to Assess Risks of emerging Infectious diseases through Enhanced Surveillance (CANARIES; http://www.canarieshmhp.org).
2020-	Consultant, Laboratory Technical Advisor, Emergency Centre for Transboundary Animal Diseases, Food and Agriculture Organization of the United Nations, Regional Office for Asia and the Pacific.
2020-2021	Consultant, Scientific Expert. World Health Organization. Global Influenza Surveillance and Response System.
2021-	Consultant, Technical Expert – Genomic Surveillance. World Health Organization, European Region, Turkey.

Honors Since 2011

2011	ASV 2011 Postdoctoral Fellow Travel Award. American Society for Virology General Meeting 2011, Minneapolis, MN
2011	Travel Award. ISIRV-AVG Conference: Influenza Antivirals: Efficacy and Resistance. Rio de Janeiro, Brazil. November, 2011
2012	Travel Award. Nutritional Immunology Research Interest Section. American Society for Nutrition. Experimental Biology 2012, San Diego, CA
2012	Young Investigator Travel Award. Palm Beach Infectious Disease Research Institute. PBIDI Symposium 2012, Palm Beach, FL
2012	Travel Award. 6 th Orthomyxovirus Research Conference. Bromont, Quebec, Canada. September, 2012
2012	Travel Award. Obesity Research Interest Section. American Society for Nutrition. Experimental Biology 2012, San Diego, CA
2013	Promising Young Investigator Scholarship. Options for the Control of Influenza VII. Cape Town, South Africa. September 2013.
2015	Young Investigator Travel Award. 3 rd ISIRV International Symposium on Neglected Influenza Viruses. Athens, Georgia, USA. April, 2015.
2015	Merck Junior Investigator Award - Best Speaker. 3 rd ISIRV International Symposium on Neglected Influenza Viruses. Athens, Georgia, USA. April, 2015.
2018	Francis Crick Institute Best Poster Award. ISIRV Symposium – Influenza 2018: Centenary of the 1918 Pandemic. London, UK. June, 2018.

C. Contributions to Science

As of this submission, I have authored 70+ publications (published or in press) in the fields of nutrition, influenza, respiratory viruses, and infectious disease: 28 (40%) first author publications and 7 (10%) senior author publications. Full list available at: <https://scholar.google.com/citations?user=lq1f7K0AAAAJ&hl=en>

*As of this dossier: **Total citations:** 3,395, **h-index:** 31, **i10-index:** 53

1. **Global avian influenza virus surveillance and response in domestic poultry and wild birds.** Avian influenza virus is a major concern worldwide. Aside from seasonal epidemics and occasional pandemics, avian influenza viruses continue to cause human infections. I have been involved in influenza virus surveillance in wild and domestic poultry in Africa, South America, and Southeast Asia. These studies have defined new hotspots of influenza, determined seasonal patterns, and even helped to define policy recommendations. Selected References:

d)

4. **Defining the risk of emerging viruses and the bottlenecks overcome to cross species barriers.** A major concern with zoonotic viruses, especially avian influenza virus, is the risk of zoonotic transmission. These studies seek to define factors (host-related, bacteriological, and virological) which can help to predict risk of zoonotic transmission and severity of viruses and emerging diseases. Selected References:

Other Support – Project/Proposal

ACTIVE

*Title: Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of South East Asia

Major Goals: This project aims to identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife, identify key risk pathways for zoonotic transmission, and identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts focusing in Thailand and Malaysia.

*Status of Support: Active

Project Number: 1U01AI15179

Name of PD/PI: Daszak, Peter

*Source of Support: NIH/NIAID

*Primary Place of Performance: EcoHealth Alliance, New York

Project/Proposal Start and End Date: (MM/YYYY) (if available): 06/2020 – 05/2025

* Total Award Amount (including Indirect Costs): \$7,573,721

* Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)
1. [2022]	3.0 calendar
2. [2023]	3.0 calendar
3. [2024]	3.0 calendar
4. [2025]	3.0 calendar
5. [2026]	3.0 calendar

*Title: Understanding the establishment and persistence of community associated methicillin-resistant Staphylococcus aureus (CA-MRSA) in resource-limited, high-burden settings: How can we reduce the burden of disease?

Major Goals: To determine the clinical impact of MRSA-related acute hematogenous osteomyelitis (AHO) in the PNG highlands and identify interventions to reduce the burden and impact of this infection. We will evaluate the feasibility of point-of-care diagnosis of MRSA, determine the persistence and transmission pathways of CA-MRSA, and determine the diversity and phylodynamics of MRSA strains circulating in PNG highland communities and their association with AHO cases.

*Status of Support: Active

PENDING

*Title: Revealing the Determinants of Virus Diversity and Cross-Species Transmission on Wildlife Farms in Southeast Asia

Major Goals: This project will characterize viral diversity, assess the rate of cross-species transmission, and evaluate zoonotic disease risk. Using innovative mathematical models, this project will estimate key epidemiological parameters for cross-species transmission within farms, simulate the impact of different farming practices, and assess the associated profit-risk trade-offs.

Commons ID: (b) (6)

Other Support – Project/Proposal

ACTIVE

*Title: Avian and human influenza surveillance activities in Cambodia and genetic analysis using novel sequencing techniques

Major Goals: The major goals of this project are continued longitudinal surveillance of avian influenza virus at the poultry-human interface in Cambodia and integration of new sequencing technologies.

*Status of Support: Active

Project Number: LOA/RAP/2021/22

Name of PD/PI: Karlsson, Erik

*Source of Support: FAO-USAID

*Primary Place of Performance: Institut Pasteur du Cambodge

Project/Proposal Start and End Date: (MM/YYYY) (if available): 06/2021 – 05/2022

* Total Award Amount (including Indirect Costs): \$199,970

* Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)
1. [2022]	1.8 calendar

*Title: NIAID Centres of Excellence for Influenza Research and Response – UPenn CEIRR - Influenza Surveillance, Risk Assessment, and Response Project 1: Swine Influenza Surveillance and Risk Assessment: Cambodia

Major Goals: The major goals of this project are longitudinal influenza virus surveillance in swine and humans to detect, characterize, and analyze the evolution, disease dynamics, and risk profile of IAVs at the human-swine interface in Cambodia. We will monitor the evolutionary trajectories of swine IAVs currently circulating in backyard and commercial swine holdings in key border regions of Cambodia

*Status of Support: Active

Project Number:

Name of PD/PI: Karlsson, Erik (Country PI), Hensley, Scott (Center PI)

*Source of Support: NIH/NIAID

*Primary Place of Performance: Institut Pasteur du Cambodge

Project/Proposal Start and End Date: (MM/YYYY) (if available): 06/2021 – 03/2028

* Total Award Amount (including Indirect Costs): \$1,503,684

Applicant Name (Karlsson, Erik):

* Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)
1. [2022]	3.6 calendar
2. [2023]	3.6 calendar
3. [2024]	3.6 calendar
4. [2025]	3.6 calendar

6. [2027]	3.6 calendar
7. [2028]	1.8 calendar

*Title: Into the Wild: Prevalence of AIV in Wild Birds in the Kingdom of Cambodia

Major Goals: The major goals of this project are to obtain preliminary information on avian influenza virus prevalence in wild birds in Cambodia, develop preliminary data for building an Early Warning System (including the use of novel techniques) and to provide capacity building to Cambodian Veterinary Epidemiologists

*Status of Support: Active

Project Number: STEP TD04-001

Name of PD/PI: Karlsson, Erik

*Source of Support: DTRA

*Primary Place of Performance: Institut Pasteur du Cambodge

Project/Proposal Start and End Date: (MM/YYYY) (if available): 10/2021 – 05/2022

* Total Award Amount (including Indirect Costs): \$282,154

* Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)
1. [2022]	1.8 calendar

*Title: CREID COVID Supplement: Support for COVID Sequencing in Cambodia. PICREID.

Major Goals: The major goals of this project are to further support sequencing and analysis of SARS-CoV-2 genomes in Cambodia as part of the national response to COVID-19.

*Status of Support: Active

Project Number:

Name of PD/PI: Karlsson, Erik

*Source of Support: NIH/NIAID

*Primary Place of Performance: Institut Pasteur du Cambodge

Project/Proposal Start and End Date: (MM/YYYY) (if available): 11/2021 – 05/2022

* Total Award Amount (including Indirect Costs): \$107,266

* Person Months (Calendar/Academic/Summer) per budget period.

Applicant Name (Karlsson, Erik):

Year (YYYY)	Person Months (##.##)
1. [2022]	0.5 calendar

PENDING

*Title: Novel detection and sampling techniques for surveillance of bat-borne zoonoses in Cambodia

Major Goals: This project will utilize novel field technologies (RT-PCR, sequencing) in conjunction with novel sampling strategies (air, environment) to develop better ways to sample bats across Cambodia.

*Status of Support: Pending LoA

Project Number:

Name of PD/PI: Karlsson, Erik

*Source of Support: FAO-USAID

*Primary Place of Performance: Institut Pasteur du Cambodge

Project/Proposal Start and End Date: (MM/YYYY) (if available): 01/2022 – 11/2022

* Total Award Amount (including Indirect Costs): \$77,000

* Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months (##.##)
1. [2022]	1.8 calendar

*Title: One Health understanding of small-holder swine value chain in Cambodia

Major Goals: This study aims to enhance the health and livelihood of small-holder swine value chain stakeholders through cost-effective intervention measures following a One-Health approach. We believe that small-holder pig producers play a key role in the spread of several important zoonotic diseases, including food borne diseases. Applying cost-effective interventions and risk-based surveillance along the value chain will reduce risk and enhance the livelihood of the stakeholders. The project will tackle gender-related inequalities in the roles assigned along the pig-value chain in risk awareness, mitigation and exposure, and identify solutions to empower women in this system.

*Status of Support: Pending

Date: January 30, 2022

Co-PI Plan (only needed if applying as Co-PIs):

As stated in the Mentoring Plan, the co-PIs, Vireak Heang and Jurre Siegers, are at different stages of their respective careers and have discrete professional development goals. This Co-PI Plan was developed to maximize the strengths of each PI, provide opportunities to learn from each other, and create a supportive environment where they can pursue their independent professional goals while working as a team to achieve the project objectives.

Overall, the proposed research project will be jointly and equally managed by Dr. Siegers and Mr. Heang. Dr. Siegers will plan, oversee, and conduct sample management and processing. He will also lead the data analysis aspects of the work. Mr. Heang will be responsible for the technical aspects of metagenomic sequencing, including logistics and protocol development, laboratory work, and initial data curation and quality control. He will work closely with the Research Center Mentor, Dr. Cadhla Firth, to develop these aspects of the project. As the project progresses, Dr. Siegers will be exposed to the technical aspect of metagenomics, including how to prepare and load samples onto the sequencing platform, by learning from Mr. Heang. Likewise, Mr. Heang will develop skills in upstream sample preparation and handling and will have the opportunity to participate in downstream data analysis, as he learns from Dr. Siegers. This collaboration will ensure that both individuals gain technical skills in areas where they have less experience, and each will become a more well-rounded scientist as a result of their joint efforts. While Mr. Heang will be more involved with the technical aspects of sequencing and data generation, Dr. Siegers will take the lead to work with EcoHealth Alliance's modeling experts to explore the virological data and the meaning for potential surveillance efforts.

Both PIs will jointly manage data curation, analysis, and dissemination for this proposal. In addition, the Co-PIs will jointly manage the project budget with oversight from their Scientific Mentor, Dr. Erik Karlsson. The PIs will receive a budget code in the IPC system on which they can charge reagents and supplies, as well as manage spending, and purchases will be co-signed by Dr. Karlsson. In terms of specific reagents, Mr. Heang will oversee the ordering of supplies needed for sequencing, and Dr. Siegers will be responsible charges related to sample preparation. Both PIs will jointly book and conduct travel. While Mr. Heang will be more involved in generating metagenomic sequencing data in the lab, Dr. Siegers will lead the initial drafting of reports and publications that will result from this research. However, both authors will contribute to the writing and publication of any manuscripts and will jointly share authorship. The Co-PIs will work closely with both Mentors on all aspects of the project and will regularly attend IPC and EcoHealth Alliance scientific meetings to present work and progress.

WHO: World Health Organization

Facilities and Resources

Laboratory:

The Institut Pasteur in Cambodia (IPC) is an institution of public utility engaged with the Royal Government of Cambodia by a convention and under the patronage of the Ministry of Health to meet the challenges of the future in the areas of scientific research, public health and education. It is a member of the Institut Pasteur International Network with which it develops ongoing collaborations, with 33 member institutes spread across the globe, which facilitates collaboration and scientific exchanges. Visiting scientists from Institut Pasteur Paris can provide expertise to setup specific assays and collaborations with Institut Pasteur Paris enable access state-of-the-art equipment if needed for the proposed research.

The Virology Unit at the Institut Pasteur du Cambodge (IPC) has been instrumental in public health responses in Cambodia, especially against respiratory viruses such as avian influenza. As such, IPC has served as the National Influenza Centre (NIC) for Cambodia since 2006 and was designated as a WHO H5 Reference Laboratory in October 2014 (H5RL), as part of the WHO Global Influenza Surveillance and Response System (GISRS). In addition, IPC serves as a reference laboratory for a number of other pathogens. Programs and procedures are also in place to identify, diagnose, and sequence numerous other emerging and zoonotic pathogens, such as Coronavirus (CoV). The IPC Virology Unit was designated by the Cambodian Ministry of Health as first line laboratory for diagnosis of COVID-19 and currently acts as the National Reference Laboratory for COVID-19. In April 2020, IPC Virology Unit was recently named a WHO Global Reference Laboratory for COVID-19.

The virology laboratory space covered by the Virology Unit contains all equipment needed for virology research. Biological Level 1 and 2 space (200 m²) is dedicated for sample acquisition, processing and storage, serology, extraction, post-amplification procedures, molecular biology and PCR. Separate BSL2 spaces are also dedicated to human samples (23 m²), animal samples (24 m²), cell maintenance (12 m²) and cell culture work (35 m²). In response to A/H5N1 circulation in Cambodia the Virology Unit was upgraded in 2008 to include a BSL3 facility (142 m²). The BSL3 facility comprises four modules dedicated to different and separate activities: arboviruses, emerging viruses (including a safety cabinet with gloves box allowing BSL3+ safety conditions) and mycobacterium (activity handled by the IPC clinical laboratory). The last module includes isolators for animal experiments.

Equipment includes: CO₂ incubators (n=3 dedicated to cell maintenance and cell culture work in a dedicated BSL2 spaces and n=2 dedicated to cell culture work in BSL3), automated extraction (n=4), real time qRT-PCR machines (n=7 BioRad CFX96), conventional PCR machines (n=8 BioRad T100), a Sanger sequencing (ABI 3500xL Genetic analyzer), 2x MinION next generation sequencer (Oxford Nanopore), 1x GridION next generation sequencer (Oxford Nanopore), 1x MiSeq next generation sequencer (Illumina), a gel imaging system (BioRad ChemiDoc WRS+), a capillary electrophoresis device (Qiagen QIAxcel advanced system), light microscopes (n=2 direct light; n=4 inverted light), a fluorescent microscope, bench top centrifuges, three ELISA washers (BioRad), two ELISA readers (BioRad and ThermoFisher Scientific) and Qubit fluorometer.

Applicant Name (Last, first, middle): Siegers, Jurre, Ynze and Heang, Vireak

The sequencing mini-platform at IPC is a newly established platform intended to provide the sequencing services to all scientists within the institute regardless of their discipline. The sequencing mini-platform is situated in the Regional Research Platform-ASIA (PRR) building and contains all the equipment needed to perform sequencing. We have 20m² dedicated for library preparation and another 20m² for the instruments. Equipment includes: 1 Illumina Miseq, 1 TapeStation 4150, 1 Qubit 4.0, 1 Thermocycler.

Clinical:

The medical analysis laboratory of IPC has received ISO NF 15189 accreditation for all its applications for the analysis of clinical biology, biochemistry, hematology, and microbiology in 2018.

Animal:

A conventional mouse facility and dedicated BSL2 and BSL3 level space for animal experiments are available at IPC; however, they will not be utilized in this proposal.

Computer:

Information technology access: Since the Institute is located in a low-income country, we are eligible for the Hinari Access to Research for Health Programme of the world health organization (WHO), providing us online access to all major journals in biomedical research. Both the laboratories and PI's office are equipped with Macintosh and PC computers and printers. Computers are protected by enterprise antivirus software. Email solution is Microsoft Exchange 2010 server. Local network is managed with Cisco catalyst switches, linked with fiber optics or network cables, with redundant paths. VLANs are used to segregate research units, enabling more confidentiality. Two telco links provide access to the internet: primary/nominal with fiber optics Online operator, with 8 Mbit/s bandwidth and 24/7 support. IPC has a reliable internet connection with 35Mbs download and 35Mbs upload speeds. Backup link is operated by OpenNet with 4 Mbit/s bandwidth.

The computational resources for generating, analyzing, storing and managing sequencing data are available locally. IPC acquired two Ubuntu server compute nodes (each equipped with 64 cores, 128GB of RAM, and a high-end NVIDIA GPU) connected over 10Gbs switches to 222 TB of shared networked storage.

Applicant Name (Last, first, middle): Siegers, Jurre, Ynze and Heang, Vireak

Office:

Office space is separated from the laboratory space with dedicated offices for postdoctoral researchers, students, PI's and technicians.

Other:

Biological sample storage and access: All samples will be stored in -80°C freezers and liquid nitrogen tanks housed within the IPC biobanking system. The IPC biobank is a multisite biological resource center (BRC), which collects, transforms, analyses, stores and provides resources according to specific pre-requirements and manages associated data. All the activities of preparation, analysis and biological resource (BR) processing are realized according to stringent quality requirements. For long-term security and confidentiality, Biobank Management Software has been implemented and established and used to manage the BR and associated data from different laboratories and research units at IPC. Only the PI and relevant key personnel has access to the samples. The biobank includes human, animal and pathogenic samples.

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Dr. Jurre SIEGERS and Mr. Vireak HEANG
Project Title:	<i>In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.</i>
Institution:	Institut Pasteur du Cambodge
Foreign Research Site:	Phnom Penh, Cambodia
Point of Contact for Research Site:	Dr. Jurre SIEGERS Virology Unit, Institut Pasteur du Cambodge 5 Monivong Blvd, PO Box #983 Phnom Penh, Cambodia email: jsiegers@pasteur-kh.org

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goals of this project are: (1) to assess the suitability of environmental metagenomics as an early warning system for endemic and emerging infectious diseases at high-risk interfaces in Cambodia; (2) to utilize biobank environmental samples from longitudinal pathogen surveillance programs in Cambodia to build metagenomic sequencing and bioinformatics capacities and capabilities in Cambodia; and, (3) To discover new, emerging, or zoonotic pathogens of concern at high-risk interfaces in Cambodia.

To achieve these goals, investigators and primary Scientific Mentor on site will collaborate with EcoHealth Alliance and their CREID partners as part of the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH). The EID-SEARCH team will support this project by helping the Institut Pasteur du Cambodge (IPC) team conduct and analyze metagenomic sequencing on Cambodian samples.

\$147,675.96 of grant funds will be sent to IPC for these studies.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will coordinate and/or perform all laboratory work and data analyses necessary for the proposed project (including metagenomic sequencing).

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - IRB approval number for parent study: **Not Applicable**
 - IRB approval date:
 - Human Subject Assurance Number:
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - **No**
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - **No**
 - How many subjects provided the existing samples to be used? **Not Applicable**

- Will human subjects be recruited (Yes or No)
 - No
 - Number of human subjects that will be recruited: **Not Applicable**
- Population parameters: **Not Applicable**
 - Gender:
 - Age Group:
 - Race/Ethnicity:
- Sample collection will include: **Not Applicable**
 - Blood:
 - Urine:
 - Tissues:
 - Other samples (describe):
- Sample collection will be completed in how many visits: **Not Applicable**
- Will samples be de-identified (Yes or No)? If No, describe how they will be protected.
 - **Not Applicable**
- Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.
 - **Not Applicable**
- Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.
 - **Not Applicable**
- Will samples be brought back to the US (Yes or No)?
 - **Not Applicable**
- Will data be brought back to the US (Yes or No)?
 - **Not Applicable**

Animal Subjects (1 word or 1 sentence per bullet):

- Parent study IACUC approval
 - IACUC approval number for parent study: ○ Projects involving animal samples were collected (2019-2021) under a protocol approved by National Ethics Committee for Health Research under the Ministry of Health, Cambodia (NECHR143, NECHR149, and NECHR320); however, Cambodia did not have a specific animal ethics review board at the time the collections were conducted. Continuing ethics approvals (NECHR013) for projects involving further animal sample collections in 2022 are in revision and projected to be approved in February 2022.
 - IACUC approval date: **Not Applicable**
Animal Welfare Assurance Number: **Not Applicable**
- Does this study require a modification to the IACUC approval of a parent study (Yes or No)?
 - **No**
- Will existing samples from animal subjects will be used: (Yes or No)?
 - **Yes**
 - How many animal subjects provided the existing samples to be used? **2445**
- Will vertebrate animals be collected (Yes or No)?
 - **No**

- **Species of animals (e.g. rats, mice, rabbits, monkeys):** **Not Applicable**
- **Animal parameters:**
 - **Total number of animals:**
 - **Gender:**
 - **Age range:**
 - **Lab strain (e.g. Sprague-Dawley rats, Balb/C mice):**
 - **Wild animals procured in country (e.g. Rhesus monkeys from a reserve):**
- **What will be done to them or with them and how often?**
 - **Not Applicable**
- **What are the follow-ups?**
 - **Not Applicable**
- **What will be their fate at the end of the experiments – will they be euthanized?**
 - **Not Applicable**
- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - **Not Applicable**
- **Will samples be brought back to the US (Yes or No)?**
 - **No**
- **Will data be brought back to the US (Yes or No)?**
 - **Yes, some of the data will be shared with EcoHealth Alliance/EID-SEARCH for relevant analysis.**

Phnom Penh, January 31, 2022

O/Ref.: N°034/IPC/DIR/2022

Dr. Jurre Siegers & Mr. Vireak Heang
Institut Pasteur du Cambodge
Phnom Pehn, Cambodia

Object: Institutional Support for your application to the CREID Pilot Research Program, entitled “In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.”

Dear Dr. Siegers & Mr. Heang,

The Institut Pasteur du Cambodge (IPC) is pleased to support your application to the **CREID Pilot Research Program**, entitled “In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.” We are fully committed in executing the statement of work utilizing next-generation metagenomics techniques for emerging zoonoses and potentially developing novel methods of expanding our surveillance in Cambodia.

The work proposed in this project will be given the highest priority and complements nicely to all of the other endemic and emerging virus research being conducted at IPC. In addition, it serves very nicely to bring together our long-standing Virology Unit with the newly created Sequencing Mini-Platform to build capacity and capability not only in our institution, but also for the next generation of Cambodian scientists.

As such, IPC asserts that all necessary time, facilities, and resources required for the project will be made fully available to you to successfully complete the work proposed in this project.

Sincerely,

Prof. André SPIEGEL
Director

EID-SEARCH

Emerging Infectious Diseases
South East Asia Research Collaboration Hub

Dr. Jurre Siegers, Mr. Vireak Heang
Institut Pasteur du Cambodge
No. 5 Monivong Boulevard
P.O Box. 983
Phnom Penh, Cambodia

Dear Jurre and Vireak,

The Emerging Infectious Disease-Southeast Asia Research Collaboration Hub (EID-SEARCH) at EcoHealth Alliance is highly interested in working with you and your collaborators at the Institut Pasteur du Cambodge in Cambodia on the proposed project titled: *“In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.”*

This project will significantly contribute to the goals of the CREID Network and EID-SEARCH to build in-country research capacity and an international research network for emerging infectious diseases in Southeast Asia. It will develop a foundation for new collaborations among EID-SEARCH, Institut Pasteur du Cambodge, and other in-country stakeholders, strengthening the multi-sectoral cooperation for emerging infectious diseases in Cambodia. Furthermore, the process to develop and implement this project will help develop your skills in project management, provide training and networking opportunities with scientists from EID-SEARCH and the CREID Network, and most importantly, expand your skills in metagenomics, to prepare you to be independent researchers leading emerging infectious disease research both within and outside of Cambodia.

Beyond capacity and network building, the proposed project strongly aligns with the EID-SEARCH’s scientific objectives and research strategies by conducting surveillance among humans and animals to identify emerging pathogens with zoonotic potential at the high-risk human-animal interfaces and develop an early-warning system for zoonotic disease emergence. The research sites of this project - live animal markets, bat caves, slaughterhouses, animal farms – represent scenarios where zoonotic spillover are mostly concerned that require further in-depth investigation to reveal the spillover pathways. In addition, the innovative approach to conduct surveillance among environmental samples will not only expand our knowledge in viral discovery from the environment but also promote the One Health surveillance by establishing a validated sampling and analysis method that will significantly contribute to the disease surveillance and prevention strategies in Cambodia through collaborative and coordinative cooperation among a variety of stakeholders.

I am optimistic that this collaborative research project will bring valuable insights to advance disease surveillance and early warning systems for endemic and emerging infectious diseases in Cambodia. Members of EID-SEARCH are committed to working closely with you to develop the research project and support the efforts necessary for the success of this project. Our Senior Research Scientist, Dr. Cadhla Firth, has enthusiastically joined the project as your Mentor to advise on the study design, data collection, and analysis throughout the project. Dr. Firth will work closely with Dr. Erik Karlsson, a mentor from your IPC Virology Unit, to provide pertinent and timely career advice to assist in your professional development and brings a well-established network with leaders and experts in the ecology and evolution of infectious diseases across Southeast Asia, North America, and Australia. You will be invited to join all training conducted by EID-SEARCH and EcoHealth Alliance regarding emerging infectious disease fields, surveillance, and statistical analysis to build your skillset. In addition, Dr. Linfa

EID-SEARCH

Emerging Infectious Diseases
South East Asia Research Collaboration Hub

Wang, Co-Investigator from the EID-SEARCH, will support you on the metagenomics analysis by advising on the project and providing training or exchange opportunities at the Duke-NUS Medical School. You will be supported to present the findings of this research at international conferences, CREID Network meetings, and external partners and produce high-quality publications from this research.

I am confident that this proposed project will bring genuine opportunities for your professional development. The interdisciplinary expertise, a hallmark of “One Health”, in virology, genomics, public health, extensive experience working with sequencing platforms from Dr. Siegers and Mr. Heang, and the improved environmental metagenomics methods and skills through this research will make this a successful and purposeful project to bring public health impacts in a broad region with the similar social and cultural context.

This letter conveys my strong interest and commitment to making this application a success. I look forward to collaborating with you and your team on all phases of this proposed project. I wish you success in the CREID Pilot Research Program application.

Sincerely,

Peter Daszak
Principal Investigator, EID-SEARCH
President, EcoHealth Alliance

Jurre Siegers, Vireak Heang
Institut Pasteur du Cambodge
No. 5 Monivong Boulevard
P.O Box. 983
Phnom Penh Cambodia

Dear Jurre and Vireak,

I am writing this letter in support of your CREID Network Pilot Research Program application “In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance” conducted at the Institut Pasteur du Cambodge.

I and my group at Duke-NUS Medical School have long experience working on the emerging infectious diseases associated with bats and other animals. Your current proposal complements and expands this scope to identify the at-risk groups and the risk factors of viral spillover from wildlife to human populations.

I also work with the Emerging Infectious Diseases - South East Asia Research Collaboration Hub (EID-SEARCH) to develop serological tests and conduct virus characterization. I am very much looking forward to participating in this research to contribute my expertise, advise and provide relevant laboratory training.

This letter conveys my strong interest and commitment to making this application a success. I am excited to be part of the research to build scientific evidence to better predict zoonotic disease emergence, and I look forward to working with you on this research.

Yours sincerely,

(b) (6)

Linfa (Lin-Fa) WANG, PhD FTSE
Professor in Programme in Emerging Infectious Diseases

30th January, 2022

Dr. Jurre Siegers & Mr. Vireak Heang
Institut Pasteur du Cambodge
Phnom Pehn, Cambodia

Dear Dr. Siegers & Mr. Heang,

This letter is to express my support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled “*In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.*”

I am extremely excited that you have chosen me to be one of your Mentors for the proposed project. The research question is timely and important, and your work has the potential to have a strong impact on our approach to pathogen surveillance at high-risk human-animal interfaces. Given what we understand to be the likely origins of SARS-CoV-2, there has never been a more pressing need to improve the efficiency, sensitivity, and cost-effectiveness of zoonotic disease surveillance in emerging infectious disease hotspots.

I would be hard-pressed to think of two more appropriate applicants to co-lead this project, given your combined expertise in pathogen surveillance, molecular diagnostics, next-generation sequencing, and emerging respiratory viruses. Although you each have unique longer-term personal and professional goals, you also have a shared vision of using your scientific knowledge and expertise to train the next generation of Cambodian scientists, while building intellectual and scientific capacity around emerging infectious diseases in the country. I believe that increased access to the CREID Network, and to the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), in particular, will greatly help facilitate these goals by increasing your access to other scientists working on similar research questions across Southeast Asia. Many Southeast Asian countries face similar challenges in preventing and mitigating the impacts of emerging zoonotic diseases, and stronger regional partnerships have the potential to really drive forward innovations in this area. These include the implementation of novel, cost-effective approaches to pathogen surveillance, as proposed in your pilot project application.

The well-established relationship you each have with your chosen Primary Scientific Mentor for this project, Dr. Erik Karlsson, will provide an excellent foundation for the proposed work that will be enhanced by the joint Mentorship Plan we have developed together. I believe that Dr. Karlsson and I have distinct but complementary scientific skills, expertise, and networks that will maximize your professional and scientific development throughout the duration of the project, and I look forward to working more closely with all of you. I can see multiple opportunities for this new collaboration between the four of us to develop into a fruitful, long-term scientific partnership. Towards that aim, I am committed to supporting your professional development in the following ways:

- I will actively work to maintain the healthy, open, and informal dialogue we have established while drafting the project proposal, and I will seek feedback from you on a regular basis to ensure that our communication plan continues to meet your needs as the project progresses.

EcoHealth Alliance

- I will engage with your current and future in-country collaborators in a supportive and inclusive manner.
- I will create opportunities for you to interact with scientists across my network through your research project to widen your exposure to people with a range of expertise.
- I will give you timely feedback on all material in the manner that works best for you.
- I will provide you with opportunities to present your work to my colleagues at EcoHealth Alliance and across EID-SEARCH during our academic meetings and will include you in any relevant training or networking opportunities.
- I will share my scientific and technical expertise with you to help ensure the success of the project. When skills outside my area are required, I will assist you in accessing this expertise from scientists within my network.
- I will assist you in career planning, providing advice and support as required to maximize your opportunity to succeed.

Finally, I believe that the data you will collect about the potential zoonotic pathogens circulating in live bird markets, swine abattoirs, and bat roosts and guano farms in Cambodia will lead to a wealth of new research questions and hypotheses that could form the basis for additional research projects. This will present the perfect opportunity for you to continue the transition towards scientific independence, and I am committed to assisting you through the process of conceptualizing and writing your first funding applications as lead investigators.

There is significant overlap between your research interests and skills, the overall goals of the Institut Pasteur du Cambodge, and those of EcoHealth Alliance and the EID-SEARCH team. This pilot project presents a real opportunity for you to increase collaboration between these organizations, and to help drive forward future research projects on emerging zoonoses at high-risk interfaces in Cambodia. I am thrilled to be able to support you at these stages in your careers and am genuinely convinced that you both have the potential to become scientific leaders in Southeast Asia in the very near future.

Sincerely,

(b) (6)

Cadhla Firth, PhD
Senior Scientist and Program Coordinator
EcoHealth Alliance

30th January, 2022

Dr. Jurre Siegers & Mr. Vireak Heang
Institut Pasteur du Cambodge
Phnom Penh, Cambodia

Object: Support as Primary Scientific Mentor for your application to the CREID Pilot Research Program, entitled *“In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.”*

Dear Dr. Siegers & Mr. Heang,

This letter is to express my support as Primary Scientific Mentor for your application to the CREID Pilot Research Program, entitled *“In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance.”*

I am proud to be able to continue to mentor both of you as one of your Mentors for the proposed project. I serve as both your mentor in the Institut Pasteur du Cambodge (IPC) Virology Unit (Dr. Siegers) and in the IPC Sequencing Mini-Platform (Mr. Heang). You are both in the top 1% of individuals I have ever had the pleasure to mentor/supervise. I have observed you both as extremely organized, productive, proactive, and responsive. You have never failed in any challenge placed in front of you and always deliver extra in your work. You are always willing to learn and adapt to new situations, and you both have extremely good leadership qualities, which will make your excellent PIs in the future.

As you well know, IPC serves as a major institution in the Institut Pasteur International Network and has been involved in research and diagnosis of human and animal infectious diseases in the Kingdom of Cambodia since 1953. IPC serves as a research institute, non-profit foundation for vaccination, diagnosis, and treatment, and is part of the Cambodian Ministry of Health (MoH). The Virology Unit at IPC was opened in 1996 and serves as the reference laboratory for Influenza, Arboviruses, and Rabies for Cambodia, as well as conducting surveillance and research on endemic, emerging, and zoonotic pathogens. The unit opened the first, and only, BSL3+ laboratory in the country in 2008. The Virology Unit works in close collaboration with the Epidemiology/Public Health, Entomology, Bacteriology, and Malaria Units at IPC as well as national and international partners to conduct One Health-focused surveillance and studies in Cambodian humans, domestic animals, and wildlife. In 2021, we opened the IPC Sequencing Mini-Platform to further increase these studies through advances in next generation sequencing equipment and support.

The research question proposed in this pilot program is both timely and important, and the work has great potential for increasing capacity and capability at IPC and in Cambodia as a whole. Indeed, the research proposed has significant potential to impact our approach to pathogen surveillance at high-risk human-animal interfaces. Indeed, the project will also serve to further link the Virology Unit and the Sequencing Mini-Platform at IPC with scientists in the CREID Network, specifically the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), which will allow future work across Southeast Asia and positively influence your networking and future careers. There is significant overlap between this proposal, the overall mission of the Institut Pasteur du Cambodge, and the goals of EcoHealth Alliance and the EID-SEARCH team. Therefore, this pilot project presents a real opportunity for you to increase

Télécopie : +855 23 725 606

collaboration, and to spearhead future research projects on emerging zoonoses at high-risk interfaces in Cambodia. In addition, I am completely supportive of your vision to utilize the knowledge you gain from this proposal to train the next generation of Cambodian scientists, a critical part of our mission at IPC.

I fully support your choice of Research Center Mentor for this project, Dr. Cadhla Firth. Dr. Firth and I feel that our distinct but complementary scientific skills, expertise, and networks will maximize your professional and scientific development throughout the duration of the project. In the future, I see multiple opportunities for this new collaboration to develop into long-term scientific partnership. Indeed, I believe the data collected in this proposal regarding new ways to survey potential zoonotic pathogens circulating in Cambodia will lead to scientific independence and further lead investigator applications for you on novel research questions and hypotheses.

Therefore, I am committed to supporting your professional development in the following ways:

- I will continue to actively maintain the healthy, open, and informal mentoring relationship we have established as your mentor at IPC
- I will continue to meet with you on scheduled and *ad hoc* basis to support whatever needs you might have regarding this project, other ongoing projects, and future projects
- I will continue to provide (and ensure the institution provides) the time and resources needed to complete all research activities proposed in this pilot project
- I will continue to engage with our current and future in-country collaborators in a supportive and inclusive manner and promote your engagement with them
- I will continue to give you timely feedback on all material in the manner that works best for you
- I will continue to support and promote opportunities to interact with other scientists through your research project to widen your exposure to people with a range of expertise.
- I will continue to share my scientific and technical expertise with you to help ensure the success of the project. When skills outside my area are required, I will continue to assist (and encourage) you in accessing this expertise from scientists within my network.
- I continue to assist you in career planning, providing advice, and any other support as needed to maximize your opportunity to succeed.

Overall, I am thrilled you have chosen me as Primary Scientific Mentor on this project and I look forward to working with you on this project and throughout your careers.

Pilot Program Application Submission Checklist – Final Application Submission

Title of Application: In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance

Submitted by: Siegers, Jurre, Ynze and Heang, Vireak

Submission Date: 1/31/2022

Full Application Submission Requirements

- Proposal Cover Sheet
- Title and Table of Contents
- Study Personnel (*1-page limit*)
- Main Application Body Section Requirements (*7-page limit*):
 - Research Aims & Objectives
 - Study Rationale/Research Gap/Impact
 - Significance and Approach
 - Research Methods
- Project Timeline (*1-page limit*)
- Research Performance Sites (*1-page limit*)
- CREID Research Center Collaboration (*1-page limit*)
- Mentoring Plan (*2-page limit*)
- Vertebrate Animals Section Requirements (*3-page limit*):
 - Description of Procedures
 - Justifications
 - Minimization of Pain and Distress
 - Method of Euthanasia (Cover Page Supplement / PHS Fellowship Supplemental Form)
- Human Subjects Research (*3-page limit*):
 - Summary of the parent study and IRB approval information for the study
 - Risks to the subjects
 - Adequacy of protection against these risks
 - Potential benefits of the research to the subjects and others
 - Importance of the knowledge gained or to be gained
 - Country / institution-specific ethics / IRB regulations addressed
- Research, Related Project Information, and Budget/Budget Justification
 - R&R Other Project Information Form
 - Full budget, with total costs of no more than \$150,000
 - Budget justification which describes the labor and other direct costs
 - If your institution does not have adequate funds for a cost-reimbursement award and requires pre-payment of funds during the award year, please note this in your budget justification and outline a payment schedule that will function for your project.
- Supporting Documentation
 - Biographical Sketch and Other Support. All applications must include:
 - Applicant PI Biographical Sketch (*4-page limit*)
 - Applicant PI Previous/Current/Pending Support (Include funding amounts, *no page limit*)
 - Mentor Biographical Sketch (*4-page limit*)
 - Mentor Current/Pending Support (*no page limit*)
 - Key Personnel Biographical Sketches (*4-page limit each*)
 - Key Personnel Current/Pending Support (*no page limit*)

Thank you, Bow!

Kio and Spencer,

Attached are the two successful applications for 2021 and 2022 for your reference.

And can you please quickly write up one paragraph of your proposed idea (like the abstract) **before Monday next week?** We have received eight requests to collaborate this year, so Kevin, Peter, and I need to review all of them together on Monday to decide which three to support, and it would be great if you can send something written-down.

Best,
Hongying

CREID Annual Meeting Welcome

Dear Meeting Attendees,

We are pleased to welcome you to the 2022 CREID Network Annual Meeting. With a focus on the science, the 2022 Annual Meeting will showcase the diverse ongoing research by members of the CREID Network.

The CREID Network was established in 2020 with overarching goals of improved rapid and coordinated outbreak research response and capacity building. CREID is a coordinated network operating in regions around the globe where emerging and re-emerging infectious disease outbreaks are likely to occur. Multidisciplinary teams of investigators are conducting pathogen/host surveillance, studying pathogen transmission, pathogenesis, and immunologic responses in the host, and developing reagents and diagnostic assays for improved detection of important emerging pathogens and their vectors.

This is the first Annual Meeting to include in-person attendees and we eagerly anticipate the collaboration and relationship building that will bring. Those of you joining virtually have an equally valuable contribution to make. We look forward to your engaged participation around this meeting and moving forward as CREID continues to develop its global network.

We look forward to a successful meeting,

Sincerely,
DMID and CREID Coordinating Center Teams

2022 Pilot Awardee ePosters

(see Between Session slides)

-
- Investigation of ecological drivers of sarbecoviruses spillover in Myanmar and Nepal | Ohnmar Aung (EEIDI)
 - Vector surveillance in context of urban transmission and spread of Crimean-Congo hemorrhagic fever virus (CCHFV), Karachi Pakistan | Najia Ghanchi (UWARN)
 - In the Air Tonight: Metagenomic Pathogen Discovery as Tools in Pathogen Surveillance | Jurre Siegers and Vireak Heang (EID-SEARCH)
 - Pathogenic Mammarenaviruses and Orthohantaviruses in Argentina | María Martín and Carina Sen (WAC-EID)
 - Surveillance for known and novel viruses with zoonotic potential at the interface between humans and livestock in Kenya | Stephanie Seifert and Isaac Ngere (CREID-ECA)
 - Characterization of the mosquito microbiome and its role in arbovirus emergence and maintenance in Senegal | Laura Dickson and Alioune Gaye (WAC-EID)
-

Lightning Talk Concurrent Session Details

Day 3 | Friday, September 23 | 13:00-14:30

Concurrent Session A: Ecology, Entomology and Field Methods

Location: Fitzgerald B/C & Zoom

Session Chair: Peter Dascal (EID-SEARCH)

Session Co-Chair: Tierra Smiley (EEIDI)

- Building capacity for ecological surveillance and molecular diagnostics of mosquito-borne viruses in Sierra Leone | Robert Cross on behalf of Aiah Lebbie (WAC-EID)
- Active surveillance to detect low-level Rift Valley Fever Virus transmission in humans in East and Central Africa | Jeanette Dawa (CREID-ECA)
- [The use of satellite imagery to create robust geospatial sampling designs and examine landscape dynamics across an urban to rural gradient in Managua, Nicaragua](#) |  Kathryn Hacker (A2CARES)
- Higher infestation indices of the vector *Aedes aegypti* in rural areas than in urban areas in Managua, Nicaragua | Jose Victor Zambrana (A2CARES)
- [Rainfall and the prevalence of *Aedes aegypti* in northern coastal Ecuador](#) |  Jessica Uruchima (A2CARES)
- Setting the standard for field biosafety at the human-animal interface | Marc Valitutto (EID-SEARCH)
- [Effective Recruitment Strategies during an Infectious Disease Surveillance Study at Rural Health Facilities in Liberia; WARN-ID Liberia Team Experience](#) |  Bode Shobayo (WARN-ID)
- Environmental surveillance of informal sewage systems reveals community SARS-CoV-2 transmission dynamics | Joshua Levy (WARN-ID)
- Mosquito ecology and risk of arboviral infectious disease spillover in southwestern Uganda | Jalika Joyner (EEIDI)
- Report of arbovirology surveillance prospective cohort as model of early detection of viral circulation | Mauricio Nogueira (CREATE-NEO)
- Towards the laboratory maintenance of *Haemagogus janthinomys*, the major neotropical vector of sylvatic yellow fever | Adam Hendy (CREATE-NEO)

Lightning Talk Concurrent Session Details, continued

Concurrent Session B: One Health and Zoonotic Surveillance

Location: Fitzgerald A North & Zoom

Session Chair: Christine Johnson (EEIDI)

Session Co-Chair: Isaac Ngere (2022 Pilot Awardee, CREID-ECA)

- One Health Pathogen Surveillance in the Bwindi Impenetrable Forest Region of Uganda | [John Kayiwa \(EEIDI\)](#)
- [Use of molecular epidemiological, serological and experimental approaches to study COVID-19 transmission in Hong Kong](#) | [Leo Poon \(CREID-ESP\)](#)
- Evidence of Bourbon virus in ticks and humans in St. Louis Missouri, USA | Ishmael D. Aziati (CREID-ESP)
- Potential reservoirs hosts zoonotic pathogens in Senegal including emerging viruses such arboviruses, Lassa, Ebola, coronaviruses and henipaviruses | Mawlouth Diallo (WAC-EID)
- [A One Health investigation framework for zoonotic and vector-borne disease outbreaks](#) | [Soledad Colombe \(CREID-ECA\)](#)
- Coronavirus Circulation in Peridomestic Rodent Populations in Sierra Leone | Allison Smither (WAC-EID)
- One Health surveillance of Lassa fever in rodents and human close contacts in North Central Nigeria | Nathan Shehu on behalf of Pam Luka (WAC-EID)
- Plasmodium vivax infection in two non-human primates in the Amazon | Marcus Lacerda (CREATE-NEO)
- YF-neutralizing antibodies in pied tamarins (Saguinus bicolor) captured in Amazon Rainforest fragments in the urban area of Manaus, Brazil | Marcus Lacerda (CREATE-NEO)
- CREATE-NEO arboviral surveillance in mosquitoes, febrile humans and non-human primates in transition zones in Panama and Darien | Sandra Lopez-Verges (CREATE-NEO)
- Late Breaker: Predicting the zoonotic capacity of mammals to transmit SARS-CoV-2 | Barbara Han (CREATE-NEO)
- [Late Breaker: Coronavirus surveillance among farmed collared peccaries \(Dicotyles tajacu\) and caretakers in the Peruvian Amazon](#) | [Carlos Calvo-Mac \(EEIDI\)](#)
- Late Breaker: SARS-CoV-2 Genomic Variant Surveillance in Human and Non-Human Primates in Peru | Mariana Leguía (EEIDI)

Concurrent Session C: Clinical and Laboratory Science

Location: Fitzgerald A South & Zoom

Session Chair: Rob Brieman (CREID-ECA)

Session Co-Chair: Bronwyn Gunn (2021 Pilot Awardee, CREID-ECA)

- [Acute Neurologic Syndromes associated with Chikungunya virus infections in Salvador, Brazil](#) | [Lorena Martins on behalf of Mateus Santana do Rosário \(UWARN\)](#)
- Predictors of severity in dengue-suspected pediatric patients during 2019 dengue epidemic in Brazil | Mauricio Nogueira (CREATE-NEO)
- Influence of previous Zika virus exposure on Brazilian dengue outbreak in 2019 | Cassia Fernanda Estofolete (CREATE-NEO)
- Immune escape mutations in the Spike protein of an endemic SARS-CoV-2 variant in Panama | Sandra Lopez-Verges (CREATE-NEO)
- The highly conserved stem-loop II motif is important for the lifecycle of astroviruses but dispensable for SARS-CoV-2 | David Wang (CREID-ESP)
- Antibody fucosylation predicts disease severity in secondary dengue infection | Tineke Cantaert (PICREID)
- Unexpected Acute Viral Fever Mimicking Dengue-Like Illness in Major City of Pakistan | Najeeha Talat Iqbal (UWARN)
- [Comparison of the Immunogenicity of five COVID-19 vaccines in Sri Lanka](#) | [Chandima Jeewandara \(A2CARES\)](#)
- SARS-CoV-2 Variant Detection and Surveillance with an Economical and Scalable Molecular Protocol | Jesse Waggoner (A2CARES)
- [Multiplexed detection of respiratory viruses and SARS-CoV-2 variants with mCARMEN](#) | [Nicole Welch \(WARN-ID\)](#)
- Developing Rapid Antigen Diagnostics for Emerging Viruses using Antibodies Cloned from Sorted Single Memory B-cells | Lee Gehrke (CREATE-NEO)

- A simplified Cas13-based assay for the identification of SARS-CoV-2 and its variants | Jon Artizti Sanz (WARN-ID)
- Late Breaker: Dynamics of infectious virus neutralization from convalescent and vaccine cohorts across global SARS-CoV-2 variant lineages reveals boost protection and novel monoclonal antibody efficacy against Omicron strains | Michael Gale (UWARN)

Concurrent Session D: Epidemiology and Surveillance Across the Americas

Location: Warfields & Zoom

Session Chair: Wes Van Voorhis (UWARN)

Session Co-Chair: Daniel Aguiar, 2021 Pilot Awardee (CREATE-NEO)

- [A Dengue outbreak in Panama, 2022](#) | [Luis Felipe Rivera \(CREATE-NEO\)](#)
- [Seroprevalence of Zika, Dengue, and Chikungunya viruses in a rural area in Brazil](#) | [Marcos Vinicius Lima de Oliveira Francisco \(UWARN\)](#)
- Zika virus infection surveillance in Manaus, Amazonas state | Marcus Lacerda (CREATE-NEO)
- Real-time genomic surveillance of DENV-1 and DENV-2 in Brazil: improving public health outbreaks response | Luiz Alcantara (UWARN)
- [Surveillance and evolutionary analysis of Dengue viruses to understand the epidemiological dynamics of dengue outbreaks, São José do Rio Preto, São Paulo, Brazil](#) | [Livia Sacchetto \(CREATE-NEO\)](#)
- Monitoring the genetic diversity of reemerging chikungunya virus in Brazil | Luiz Alcantara (CREATE-NEO)
- Genomic and epidemiological monitoring of YFV reemergence in Brazil: unveiling the corridor of spread and the geographic hot spots for predicting and preventing other possible spillover events | Marta Giovanetti (UWARN)
- Genomic surveillance of SARS-CoV-2 in symptomatic vaccinated and unvaccinated asymptomatic patients in Brazil | Luiz Alcantara (UWARN)
- [SARS-CoV-2 genomic surveillance and the impact of different lineages circulation in the epidemiological landscape of São José do Rio Preto, São Paulo, Brazil](#) | [Cecília Artico Banho \(CREATE-NEO\)](#)
- Genomic epidemiology reveals the impact of national and international restrictions on the SARS-CoV-2 epidemic in Brazil | Marta Giovanetti (UWARN)
- Occurrence of SARS-CoV-2 reinfections at regular intervals in Ecuador | Paul Cardenas (A2CARES)
- [Genomic characterization of SARS-CoV-2 during the COVID-19 pandemic in Nicaragua](#) | [Cristhiam Cerpas \(A2CARES\)](#)

Concurrent Session E: Epidemiology and Surveillance Across Africa and Asia

Location: Grason & Zoom

Session Chair: Anavaj Sakuntabhai (PICREID)

Session Co-Chair: Robert Langat, 2021 Pilot Awardee (CREID-ECA)

- Flaviviruses and Lassa fever in febrile patients in North Central Nigeria: A cross-sectional study | Nathan Shehu (WAC-EID)
- [Double Stigma and discrimination: A qualitative study of Lassa fever and hearing loss in Northern Nigeria](#) | [Kachollom Best \(WAC-EID\)](#)
- A brief chronicle of SARS-CoV-2 genomic surveillance in Cambodia | PICREID Representative on behalf of Erik Karlsson (PICREID)
- [Identification of Genetic Variations of SARS-CoV-2 Omicron Strain and their Clinical Significance in Karachi, Pakistan](#) | [Aqsa Khalid \(UWARN\)](#)
- Genetic characterization of Norovirus strains from an unusual diarrheal outbreak in the community in Thailand | Krongkan Srimuang (EID-SEARCH)
- Factors associated with changing Dengue case numbers during the COVID-19 pandemic in Sri Lanka | Dinuka Ariyaratne (A2CARES)
- SARS-CoV-2 genomic epidemiology in Sierra Leone | John Demby Sandi (WARN-ID)
- Yellow Fever outbreak in eastern Senegal, 2020–2021 | Moussa Diagne (WAC-EID)
- [The evolving SARS-CoV-2 epidemic in Africa: Insights from rapidly expanding genomic surveillance](#) | [Houriiyah Tegally \(UWARN\)](#)

- Detection and Characterization of Variants of Concern: Insights from the South African Epidemic | James Emmanuel San (UWARN)
- Emergence of novel combinations of SARS-CoV-2 spike receptor binding domain variants in Senegal | Amroise Ahoudi (UWARN)
- [COVID-19 laboratory surveillance at IRESSEF in Senegal](#) | [Cheikh Ibrahim Lo](#) (UWARN)
- [Dynamics of Variants of Concern \(VOC\) during the different waves of COVID-19 in Senegal](#) | [Abdou Padane](#) (UWARN)

– AGENDA: TABLETOP EXERCISE, APPLIED SESSIONS A and B –

DAY 1 | WEDNESDAY, SEPTEMBER 21

The *Tabletop Exercise Situation Report* will be introduced during the *Collaboration for Outbreak Research Response & Tabletop Introduction* session during the Scientific Meeting (Time: UMT -4, 14:15-15:15)

[TTX Zoom Link](#)

DAY 2 | THURSDAY, SEPTEMBER 22

Time (UMT -4)	Session	Location	Participants
08:30-10:40	Tabletop Exercise: Applied Session A		Network Members, DMID, EAC, NIAID
	Breakout Rooms		
	Combined Biorepository and Data Capture & Harmonization (hybrid session)	Fitzgerald A South & Zoom	
	Facilitators: Tony Moody (CREID CC), Nikos Vasilakis (CREATE-NEO), Nathan Vandergrift (CREID CC), Cecilia Sanchez (EID-SEARCH)		
	Reporters: Hilary Bouton-Verville, Nefer Batsuli (CREID CC)		
	Laboratory Assays (hybrid session)	Fitzgerald A North & Zoom	
	Facilitators: Greg Sempowski (CREID CC), Bob Garry (WARN-ID)		
	Reporters: Thad Gurley, Eric Earley (CREID CC)		
10:40-11:00	Outbreak Research Response A (in-person session only)	Warfields	
	Facilitators: Peter Rabinowitz (UWARN), Jay Hemingway-Foday (CREID CC)		
	Reporter: Megan Averill (CREID CC)		
11:00-17:00	Outbreak Research Response B (in-person session only)	Fitzgerald B/C	
	Facilitators: Richard Reithinger (CREID CC), Christine Johnson (EIDI)		
	Reporter: Hongying Li (EID-SEARCH)		
11:00-17:00	Outbreak Research Response C (virtual session)	Grason & Zoom	
	Facilitators: Rob Breiman (CREID-ECA), Souleymane Mboup (UWARN), Kathy Hanley (CREATE-NEO)		
	Reporters: Danielle Wagner, Aaron Macoubray (CREID CC)

Outbreak Research Response Tabletop Exercise Applied Sessions

Annual Meeting, Days 2 and 3
All Network Members

Research Response

Outbreak *simulation* to stress test Network capacity to launch rapid & effective research for future outbreaks.

Network-wide interactive outbreak simulation activity in support of the Network Vision to build capacity and outbreak research response readiness.

An outbreak *Situation Report* will be presented on Day 1 in the General Scientific Session.

Exercise Goals:

- Work as multidisciplinary teams to respond to a *Pathogen X* outbreak
- Build collaborative connections with Network colleagues
- Pressure test existing Network Tools/Inventories to launch coordinated research response
- Identify critical gaps/pinch points for effective research response
- Develop an After-Action Report to guide Network capacity building and outbreak research readiness

Mentimeter Tool

Using your smartphone, laptop, or other mobile device, please go to [mentimeter.com](https://www.mentimeter.com) to participate in interactive polls, quizzes, and post questions.

Applied Session Schedule: Day 2, 8:30-10:40am EDT | Day 3, 8:30-10:40am EDT

Additional Information:

See detailed agendas

Email: info@creid-network.org

TTX Activities at Annual Meeting (Day 1 and 2)

15
min

Facilitator presents scripted, cross-cutting scenario (**Sit Rep 1**) and briefs participants on objectives, procedures, & expectations. Research Centers with communication/ coordination with in-country partners in preparation for applied sessions.

10
min

Facilitator reminds participants of outbreak scenario, reviews expectations and WG-specific objectives for session, and orients participants to the Mentimeter facilitation tool.

100
min

Facilitator uses scripted questions in the Facilitator Guide and Mentimeter facilitation tool to generate discussion about how participants would respond to the outbreak scenario presented in Sit Rep 1. Participants discuss, make decisions, and take action in real-time (e.g., test Network tools).

20
min

Facilitator (or reporter) summarizes key take-aways from Session 1 and presents Sit Rep 2, which will be used in Applied Session 2 ("Outbreak evolves")

Presentation of Sit Rep 1 and plan for applied session

1. Presentation of WG-specific module

APPLIED SESSION A: OUTBREAK IDENTIFIED

2. Guided Discussion with interspersed polling through menti.com

3. Wrap-up and Late Breaking news

2022 Annual Meeting Scientific Session (Day 1)

The Coordinating Center presents Situation Report (Sit Rep) #1, which describes the scenario to be discussed on Day 2 in the applied session.

2022 Annual Meeting Concurrent Working Group Sessions (Day 2 from 8:30-10:40 am ET)

Participants meet in WG-specific break-out groups to discuss response to Sit Rep 1.

1. Biorepository Collaboration & Quality/ Data Capture & Harmonization (combined group)
2. Laboratory Assay Oversight and Quality
3. Outbreak Research Response (split into 3 concurrent sessions)

Note: As a cross-cutting activity, capacity building considerations will be integrated into other WG discussions rather than convening a stand-alone session. Capacity Building WG members will have the opportunity to join the other WG session of their choice.

TTX Activities at Annual Meeting (Day 3)

10
min

Facilitator (or reporter) provides a summary of key take-aways from Session 1 and a reminder of Sit Rep 2.

50
min

Facilitator uses Facilitator's Guide and Mentimeter facilitation tool to guide participants through scripted questions and to generate discussion about how participants would respond to the new information presented in Sit Rep 2. Participants discuss, make decisions, and take action in real-time.

10
min

Facilitator (or reporter) summarizes key take-aways from Session 2.

60
min

Reporter from each WG session briefs Network on key discussion and take-aways from Applied Sessions 1 and 2.

APPLIED SESSION B: OUTBREAK EVOLVES

1. Summary of Session 1 and reminder of Sit Rep 2

2. Guided Discussion with interspersed polling using menti.com

3. Wrap-up

Report on Key Take-Aways

2022 Annual Meeting Concurrent Working Group Sessions (Day 3 from 8:30-9:40 am ET)

Participants re-convene in their WG-specific breakout groups from Day 2 to discuss Sit Rep #2.

1. Biorepository Collaboration & Quality/ Data Capture & Harmonization (combined group)
2. Laboratory Assay Oversight and Quality
3. Outbreak Research Response (split into 3 concurrent sessions)

2022 Annual Meeting General Session (Day 3 from 9:40-10:40 am ET)

Pathogen X-Like Outbreak of Suspected Animal Origin

Situation Report 01

01 September 2022 (Epi Week 36)

1. Situation at a Glance

8 Affected Countries

Cases
56

Deaths
4

CFR
7.1%

- Since 05 August 2022, a total of 56 suspected cases have been identified in 8 countries, with geographic clusters in West Africa (Sierra Leone, Guinea) and Central Africa (DRC, Uganda). Isolated cases have also been identified in Brazil, China, France, and Senegal.
- Four deaths have been reported to date. One death has been linked to an immunocompromised patient. No further information is available about the other deaths.
- Many cases (n=31) report a history of animal exposure, including rodents, bats, monkeys (species unknown), wild pig, domesticated dogs, and livestock (poultry, pigs).
- All cases report fever and malaise. Other common symptoms include rash, swollen lymph nodes, cough, anorexia, myalgia, nausea, and skin lesions.
- Separate and distinct epidemiological linkages have been established among cases in West African cases (Sierra Leone and Guinea) and Central Africa (DRC and Uganda).
- Epidemiological investigation and laboratory analyses are ongoing.

2. Epidemiological Summary

Since 05 August 2022, WHO has received reports of a pathogen X-like illness in Brazil, China, Democratic Republic of Congo (DRC), France, Guinea, Senegal, Sierra Leone, and Uganda (Table 1). Clustering of cases has occurred in West Africa, along the Sierra Leone-Guinea border, as well as Central Africa, along the DRC-Uganda border. Among cases reported in West and Central Africa, 29 have a recent history of animal exposure, most commonly rodents. Cases also report exposure through livestock (poultry, pigs), domesticated dogs, or preparation or consumption of bushmeat (bats, monkeys, “bush rats”, wild pigs).

Table 1. Suspected Cases, Deaths, and Samples for Pathogen X-like Illness (05 to 31 August 2022)

Country	Cases	Deaths	Samples Collected
Sierra Leone	21	1	18
DRC	16	2	16
Guinea	6	0	6
Uganda	7	1	7
Senegal	2	0	2
China	2	0	2
Brazil	1	0	1
France	1	0	1
Total	56	4	53

Epidemiological investigation suggests two separate and distinct transmission chains, with the index cases located in Sierra Leone and DRC. The index cases and transmission dynamics are further described in **Section 3 (Description of Cases)**. There is no known evidence of epidemiological linkages between the cases in West Africa and Central Africa.

Isolated cases have also been identified in Brazil, China, France, and Senegal; Among these cases, five have reported recent travel to West or Central Africa and two have reported animal exposure.

Clinical presentation. All cases presented with fever and malaise. Other common symptoms include rash, swollen lymph nodes, cough, anorexia, myalgia, nausea, and skin lesions. A total of four deaths have been reported (2 in DRC; 1 in Uganda; 1 in Sierra Leone). One death has been linked to an immunocompromised patient. No further information is available about the other deaths.

Diagnostic Activities. Blood samples have been collected from a total of 53 cases (see Table 1) and sent to the National Reference Laboratory in each affected country for diagnosis and viral identification by real-time PCR. Diagnostic testing results are not yet available. All samples collected in Sierra Leone, Guinea, and Senegal were sent to the Institut Pasteur de Dakar (Dakar, Senegal) for additional diagnostic and confirmatory testing.

3. Description of Cases

Suspected Clusters in Sierra Leone and Guinea. On 05 August 2022, the National IHR Focal Point in Sierra Leone notified WHO of a cluster of cases of a Pathogen X-like illness in the Kailahun District. All cases presented with fever and malaise; Other symptoms included rash, swollen lymph nodes, skin lesions, and respiratory symptoms. Epidemiological investigation indicates that the index case was a 21-year-old male with a history of animal exposure, including household exposure to rodents and domestic animals or livestock (dogs, poultry, pig) and consumption of bushmeat (bat, “bush rat”). The majority of cases (8) were identified in Yenga, a village located in a remote forest area that sits at the main international border crossing with Guinea. On 15 August 2022, health authorities in Guinea reported a household cluster of three cases presented with symptoms similar to the Sierra Leone cases. The household cluster is located in Nongoa, within the Guéckédou prefecture, and approximately 9 miles from the Sierra Leone border. Epidemiological investigations are ongoing; preliminary information indicates that one of the Guinea cases has an established travel link to affected areas in Sierra Leone and all three Guinea cases have a history of animal exposure, including rodents, bats, monkeys (unknown species), and domesticated animals or livestock. The proximity of the affected areas to international borders, cross-border movement between the Sierra Leone and Guinea, and the potential transmission of the unknown pathogen between animal vectors and humans poses an increased risk for cross-border spread. These factors also suggest a high risk at the national and regional level, given that the Kailahun District is well connected to the Guéckédou prefecture in Guinea and Lofa County in Liberia.

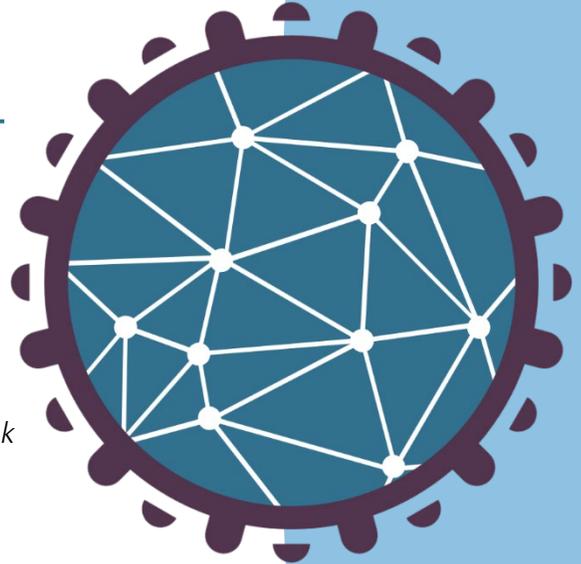

Suspected Clusters in DRC and Uganda. On 25 August 2022, the Minister of Health in DRC reported 16 cases of Pathogen X-like illness in the North Kivu Province. Epidemiological investigation indicates that the suspected index case and majority of suspected cases reside in the Beni Health zone, located on the border with Uganda. This report of the cluster in Beni directly follows the 22 August 2022 announcement by the DRC Minister of Health of a newly identified Ebola virus disease (EVD) outbreak in the same health zone. The suspected index case is a 5-year-old male who presented to a public health facility with a 10-day history of fever, malaise, swollen lymph nodes, and appearance of rashes on his skin. Three household contacts presented with similar symptoms, although the time of symptom onset was less than seven days. Before presenting to the health facility, the child and his family sought care from a traditional health practitioner who provided local herbs for the fever and rash. The suspected index case and his household contacts report a history of animal exposure, including rodents, monkeys of unknown species, and livestock (poultry, goats) within two weeks of symptom onset. The mother of the suspected index case also reports frequent trips to neighboring villages, including several villages in the Kasese District of Uganda to sell bush meat.

Suspected Cases in Senegal, China, Brazil, and France. Isolated cases of Pathogen X-like disease have also been reported in Senegal, China, Brazil, and France, five cases reported recent travel to West or Central Africa (2 from China and 1 each from Senegal, Brazil, and France). Among these five patients, only those from Senegal and France reported travel to an area with an identified cluster. Two suspected cases (1 from China and 1 from Senegal) also report a recent animal exposure.

CREID Preparedness Session 1b: Now open for YOUR input via XLEAP!

Activity Goals

- *Collectively identify evidence gaps and critical research questions that can be addressed by the Network during inter-outbreak periods*
- *Promote knowledge-sharing and relationship-building across CREID Research Centers and Sites*
- *Define mechanisms for rapid and effective research coordination, collaboration, and execution when an outbreak occurs*

Overview and Activity Methodology

Outbreak Research Preparedness Session 1b is a follow-up to the Zoom-based Session 1 on Lassa Fever (LASV) and Chikungunya Fever (CHIKV), which was held in July 2022.

For this asynchronous crowd-sourcing activity (Session 1b), the CC is employing a virtual facilitation tool called **XLeap**. Please visit the CREID Private Portal to access:

- Brief instructions on how to use and navigate within XLeap
- An informational demo of this activity in XLeap
- <https://creid-network.org/login>

XLeap is a secure, password protected site. Please use the login details below to access the XLeap platform and provide your responses to the four questions posed regarding CHKV and LASV within the XLeap platform **by September 26th, 2022**. Your responses will be reviewed and prioritized by a CREID Steering Committee-assigned panel of Subject Matter Experts in early October.

PLAZA LEVEL

SECOND LEVEL

**2022 CREID Network Annual Meeting
COVID-19 Guidance
Updated: 09/19/2022**

To In-Person CREID Annual Meeting Participants:

Included here is information about the COVID-19 Community Level in Baltimore County, Maryland, the site of the Annual Meeting, and the mitigation efforts the meeting organizers are putting in place. All information and mitigation efforts are based on guidance from the U.S. Centers for Disease Control and Prevention (CDC).

Current (as of September 19, 2022) transmission in Baltimore County: **Low**

We will update the COVID-19 information shared with meeting attendees and if the COVID-19 Community Level changes, our guidance to meeting participants will change accordingly. If you have any questions, please contact info@creid-network.org.

Annual Meeting COVID-19 logistics (for low transmission of COVID-19)

Based on updated NIH policy (as of August 24, 2022) meeting attendees are no longer required to provide vaccination attestations or a negative COVID test.

Onsite COVID-19 Mitigation

- Meeting organizers will provide masks and hand sanitizer onsite at the hotel.
- We ask all attendees to conduct a self-assessment utilizing the *CDC Coronavirus Self Checker* before attending the meeting and we ask that anyone exhibiting COVID-19 symptoms to participate in the meeting virtually: Symptoms of COVID-19: <https://www.cdc.gov/coronavirus/2019-ncov/symptoms-testing/symptoms.html>

Baltimore County COVID-19 Information

According to the CDC COVID-19 County Check for **Baltimore County, Maryland** on **September 19, 2022**, where the Sheraton Baltimore North Hotel is located, the COVID-19 Community Level is **Low**, which is determined by “hospital beds being used, hospital admissions, and the total number of new COVID-19 cases in an area.” *Source:* <https://www.cdc.gov/coronavirus/2019-ncov/your-health/covid-by-county.html>

CDC Low Community Level guidance is:

- Stay up to date with COVID-19 vaccines (<https://www.cdc.gov/coronavirus/2019-ncov/vaccines/stay-up-to-date.html>)
- Get tested if you have symptoms (<https://www.cdc.gov/coronavirus/2019-ncov/symptoms-testing/testing.html>)
- People may choose to mask at any time. People with symptoms, a positive test, or exposure to someone with COVID-19 should wear a mask.

Additional information from the CDC COVID Data Tracker: County View https://covid.cdc.gov/covid-data-tracker/#county-view?list_select_state=Maryland&data-type=CommunityLevels&list_select_county=24005)

[Venue_Map_v3.pdf](#)
[COVIDguidance_09192022.pdf](#)

Dear CREID Network Members,

We are looking forward to seeing you – in person or virtually – on Wednesday as our CREID Network Annual Meeting gets underway.

Please find final materials attached for your reference:

1. Welcome Packet
2. Final Scientific Agenda (Zoom links included)
3. Tabletop Agenda and Materials (Zoom links included)
4. Preparedness Session 1b flyer
5. Venue Map
6. COVID guidance

For those attending in person:

- A registration table will be set up (see venue map) for you to pick up your badges and a hard copy of meeting materials starting Tuesday afternoon (for about an hour at 4pm EDT) or in the mornings before the sessions start.
- Good news! COVID transmission in Baltimore County is now low; updated COVID information is attached.
- We hope you take advantage of the no-host social hours – Tuesday, Wednesday, and Thursday evenings – to get to know one another better. See the Welcome Packet for location details.
- Look for the CREID CC team members with the yellow ribbons on their name badges if you have questions or concerns during your stay.

If you have any questions, please email info@creid-network.org.

For those who are traveling, safe travels!

Abstract: Bats are hosts for a variety of viruses, some with potential to cause human disease. *Pteropus medius* are fruit bats that live in close association with humans in Bangladesh and are a known source of Nipah virus and other viruses of unknown pathogenic risk. Here we report on dynamics of seroprevalence against multiple viruses in a population of *P. medius* in Bangladesh over five years. We found evidence of regular circulation of Nipah virus, a rubulavirus, and a filovirus. Nipah virus circulated primarily among adult bats, with no seasonal patterns. The rubulavirus exhibited annual cycles in juveniles and near universal seroprevalence in adults. The filovirus exhibited annual cycles and antibody waning in juveniles and little circulation but lower seroprevalence amongst adults. We found no evidence for spatial differences in Nipah virus dynamics, but weak evidence for differences with other viruses. Host-viral interactions result in very different viral circulation patterns in the same individual bats and environments.

Keywords: bats; Nipah virus; filovirus; Rubulavirus; *Pteropus medius*; Bangladesh; serology; disease dynamics; generalized additive models

Introduction

Bats have been associated with a large diversity of viruses, several of which have been linked to human epidemics¹⁻³. The discovery of Severe Acute Respiratory Syndrome (SARS)-related coronaviruses (CoVs) in Chinese horseshoe bats (*Rhinolophus spp.*) in 2004 and subsequent discoveries of related viruses^{4,5} including close relatives of SARS-CoV-2⁶, along with studies of other high consequence pathogens such as Ebola virus, Marburg virus, Nipah virus, Hendra virus have led to questions about whether and why bats were disproportionately represented among mammals as reservoirs for zoonotic viruses^{1,2,7}.

Bat species can carry diverse viruses which circulate simultaneously within single populations⁸⁻¹¹. *Rousettus aegyptiacus* is a natural reservoir of Marburg virus, and IgG antibodies against Ebola Zaire virus have also been detected in this bat in Central Africa, suggesting that it may play a role in the circulation of multiple filoviruses^{12,13}. In addition to these filoviruses, a novel zoonotic and pathogenic paramyxovirus, Sosuga virus, was also found in Ugandan *R. aegyptiacus* populations¹⁴.

Commented [NRI]: Please check that your affiliation is as it should be!

46 *Eidolon helvum*, another pteropodid bat with a broad geographic range in Africa, has been found to
47 carry a lyssavirus, a henipavirus, and several other viruses of unknown pathogenicity¹⁵. Various
48 surveillance efforts have found diverse viruses from with the same viral family in various bat
49 species^{5,16,17}, and other studies have used metagenomic approaches to look broadly at viral diversity
50 within individual bat species^{9,11,18-21}.

51 Studies of viral diversity in a single taxonomic host group can inform evolutionary history of
52 viruses and their relationships to specific hosts^{6,22} and inform public health strategies²³. However,
53 detection of a zoonotic virus in an animal host is insufficient to determine whether the associated
54 host species is a natural reservoir for the virus, or to characterize the demographic, physiological, or
55 abiotic factors that may influence the timing of viral shedding and therefore risk of spillover to other
56 species, including domestic animals and humans²⁴. For these, more detailed demographic and
57 longitudinal studies are required, especially in cases of multiple viruses, as direct or indirect
58 interactions between multiple pathogens may affect disease presence, prevalence, and dynamics²⁵⁻²⁷.
59 Some longitudinal studies of zoonotic viruses in bats have provided insight into the timing of viral
60 infection and shedding, generally of single viruses. Nipah virus in *Pteropus lylei* in Thailand has been
61 observed to have annual shedding patterns²⁸, whereas Hendra virus, which is closely related to
62 Nipah virus and is carried by multiple pteropodid bat species in Australia, has asynchronous and non-
63 periodic cycles which appear to be influenced by localized factors such as specific bat species
64 abundance and climatic factors²⁹. Bi-annual pulses of Marburg virus shedding were observed in
65 Uganda, coinciding with synchronous birth pulses in *R. aegyptiacus*³⁰. Serological data is often
66 valuable in understanding disease dynamics and transmission³¹⁻³³, especially in cases where direct
67 detection and incidence rates of viruses are low³⁴.

68 *Pteropus sp.* are reservoirs of henipaviruses, a group of mostly zoonotic, lethal neurotropic
69 viruses that include Nipah, Hendra, Cedar, Ghana and Mojiang virus³⁵⁻³⁷. In Bangladesh and India,
70 *P. medius* is a reservoir of Nipah virus, which has spilled over to human populations repeatedly³⁸.
71 Viruses from eight other viral families have been detected in *P. medius* in Bangladesh⁹. The
72 epidemiology of these other viruses is far less characterized, and little is known about their
73 interactions or zoonotic potential.

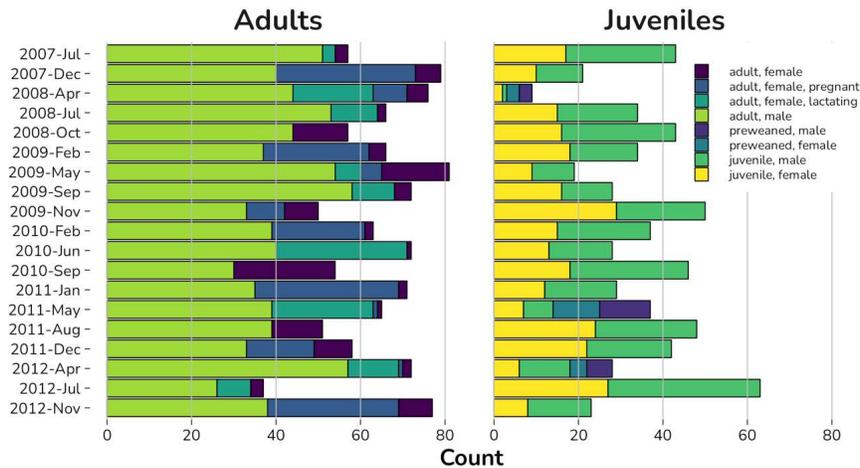

74 Here, we report on the dynamics of seroprevalence against three types of viruses - Nipah virus,
75 a filovirus, and a rubulavirus - circulating simultaneously in *P. medius* populations in three sites in
76 Bangladesh. We conducted a longitudinal study over a period of five years, and two shorter, one-
77 year studies for comparative seasonal data. These studies enable us to develop a detailed picture of
78 the seasonal and demographic serological patterns, and infer the extent and periodicity of viral
79 circulation. We find that Nipah virus circulates primarily among adults without distinct seasonality,
80 while the rubulavirus exhibits strong annual dynamics characteristic of juvenile epidemics driven by
81 waning maternal antibodies. The filovirus, the first detected in *P. medius* in Bangladesh, also
82 circulated in juveniles but exhibited distinct patterns antibody waning and limited maternal
83 inheritance.

84 2. Results

85 *Bat dynamics and demographics*

86 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly from a roost
87 complex in the vicinity of Faridpur, Bangladesh, and also two parallel one-year studies sampling bats
88 monthly from roosts in Chakhoria and Ramnagar, Bangladesh. In the five-year study, we sampled
89 and tested serology of 1,886 bats: 1,224 adults, 623 free-flying juveniles, and 39 weaning juveniles
90 (captured attached to adult females) over 19 sampling events (Figure 1). During the one-year studies,
91 919 bats were sampled: 435 in Chakhoria (251 adults, 144 free-flying juveniles and 40 weaning
92 juveniles) and 484 in Ramnagar (277 adults, 164 free-flying juveniles and 43 weaning juveniles (Figure
93 S1). Nearly all juveniles (as determined by examination of maturation of sex organs) were 14 months
94 old or less and could be assigned to a birth cohort based on size. Pregnant and juvenile bats were
95 captured more frequently during the late spring and summer months. Mother-pup pairs were all

96 captured during April and May in the five-year study whilst in the one-year-studies a small number
 97 were also captured in June and July. Pregnant females were captured between November and
 98 April/May. Lactating females were found between April and July.
 99

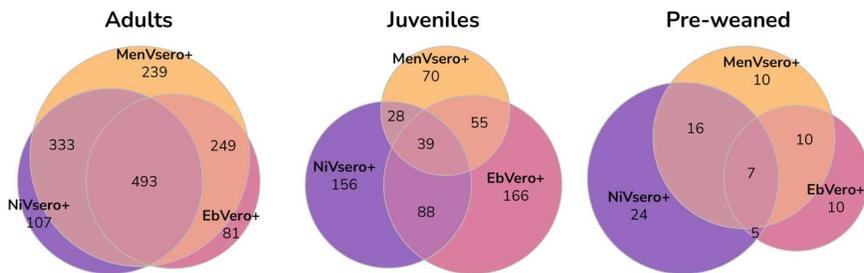

100 **Figure 1.** Demographics of bats captured in longitudinal sampling. Pregnant females were captured
 101 in months from November to June, lactating females were captured in months from April to July.
 102 Females with pre-weaning juveniles attached were found from April to May.

103 *Patterns of Immunity and Co-immunity*

104 We found bats were seropositive for antibodies against the Nipah virus (NiVsero+), a filovirus
 105 (EbVsero+), and a rubulavirus (MenVsero+). Among adult bats, antibodies against the rubulavirus
 106 were common; 1,314 of 1752 adult bats were MeNsero+. Antibodies against Nipah virus or filovirus
 107 were less common – 1,031 were NiVsero+ and 921 were EbVsero+. Among the 921 juveniles, 192 were
 108 MenVsero+, 311 were NiVsero+ and 348 were EbVsero+. Of the 122 pre-weaned juveniles, 43 were
 109 MenVsero+, 52 were NiVsero+, and 32 were EbVsero+.

110 Co-exposure to multiple viruses was common (Figure 2). Over half (1,173) of the 1752 adults had
 111 antibodies against more than one of the three viruses, and 493 had antibodies against all three.
 112 Among the 921 juveniles, 210 had antibodies against more than one, and 39 had antibodies all three.
 113 38 of 122 pre-weaned juveniles had more than one of the three antibodies, with seven having all three.

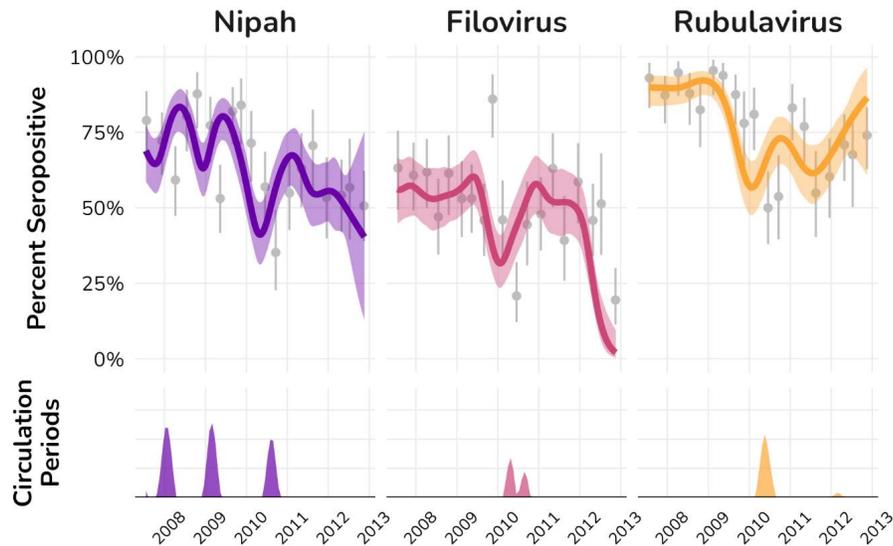

114 We found correlations [between](#) serostatus between all three pairs of viruses in a model
 115 accounting for bat age, sex, and study location, with all viruses tending to co-occur with each other
 116 more than would be expected than if they were distributed independently among bats. Nipah virus
 117 and filovirus antibodies had a standardized covariance of 0.13 (95% posterior interval 0.08-0.20).
 118 Nipah virus and rubulavirus antibodies were also more likely to occur together, with a covariance of
 119 0.15 (0.09-0.21). Filovirus and rubulavirus antibodies had a covariance of 0.23 (0.17-0.29).

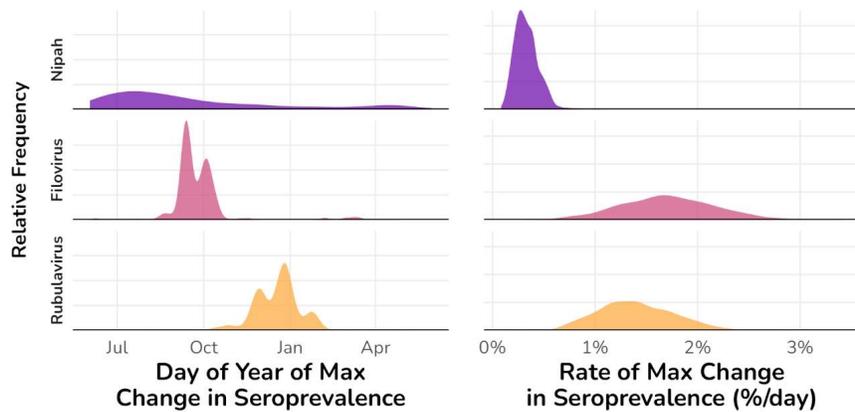

120 **Figure 2. Detection of IgG antibodies against multiple viruses in individual *Pteropus medius*:** Venn
 121 diagrams for adult, juvenile, and pre-weaned bats testing positive for antibodies against Nipah virus,
 122 filovirus, and Rubulavirus. Numbers under labels are counts of bats with only those viruses, numbers
 123 in overlapping areas represent number of bats detected with multiple viruses.

124 *Serodynamics*

125 Dynamics of population seroprevalence were different across the viral types. In adults,
 126 population seroprevalence against Nipah virus decreased over the study period from 78% (66%-88%)
 127 to 50% (40-62%) (Figure 3). Three periods of distinct increase in seroprevalence stood out in the inter-
 128 annual signal: early 2008, early 2009, and the second half of 2010. Nipah seroprevalence showed very
 129 weak seasonal patterns (Figure 4). (Nipah dynamics were previously reported in [Epstein, et al. 34](#)).
 130

131 **Figure 3. Inter-annual serodynamics in adult bats.** Top: Measured and modeled population
 132 seroprevalence in adults over the term of the study. X-axis ticks mark the first day of the year. Grey
 133 points and bars represent measured population seroprevalence from individual sampling events on
 134 and 95% exact binomial confidence intervals. Thick lines and shaded areas represent the inter-annual
 135 (non-seasonal) spline component of a generalized additive mixed model (GAMM) of serodynamics
 136 and 95% confidence intervals for the mean pattern over time. Bottom: Circulation periods, when
 137 modeled slopes of the [GAMM splines](#) are positive for >95% of 1000 draws from the model posterior.
 138

139

140

141

142

143

Figure 4. Timing and strength of seasonality of viral circulation in adults. Plots show posterior densities of the date for which increase in seroprevalence is greatest (left), and the rate of increase (right), for adult bats, drawn from GMM models of seasonality. Densities are of these quantities derived from 1000 samples of model posteriors.

144

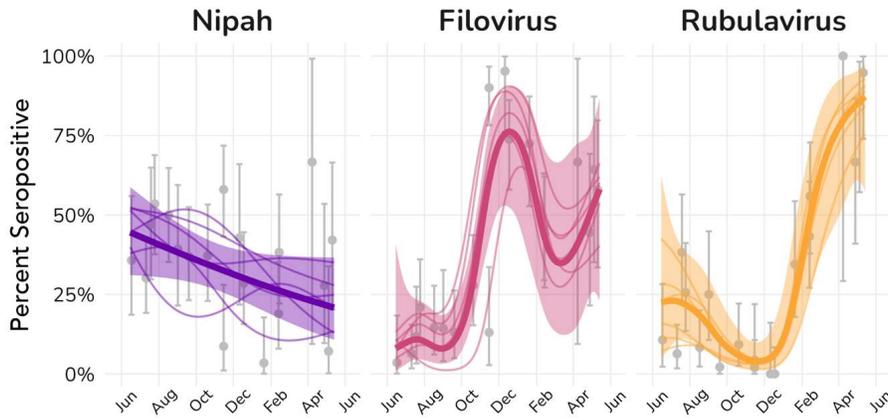

145

146

147

148

Among juveniles, we examined the dynamics of each cohort over their first year. For Nipah virus, the average cohort had 44% (32%-58%) seroprevalence in June, which consistently decreased over the course of the year to 20% (10%-36%) (Fig. 5). Year-to-year dynamics varied little, with overall declining seroprevalence in all years. No part of the year exhibited regular increases in seroprevalence for juveniles; the maximum rate of increase was indistinguishable from zero (Fig. 6).

149

150

151

154

155

156

157

Figure 5. Serodynamics in juvenile bats in five-year study. Measured and modeled population seroprevalence in juvenile bats caught over their first year of life. Sampling events from multiple years are transposed onto a single year starting June (the earliest month free-flying young-of-the-year juveniles were captured). X-axis ticks mark the first day of each month. Grey points and bars represent measured population seroprevalence from individual sampling events on and 95% exact binomial confidence intervals. Thick lines and shaded areas represent GMM-modeled average serodynamics across all years and 95% confidence intervals for the mean effect. Thin lines represent individual-year deviations from the average year pattern.

158

159 **Figure 6. Timing and strength of seasonality of viral circulation in juveniles over the five-year**
 160 **study.** Plots show posterior densities of the date for which increase in seroprevalence is greatest (left),
 161 and the rate of increase (right), for juvenile bats. Densities are of these quantities derived from 1000
 162 samples of model posteriors.

163 Filovirus seroprevalence exhibited different patterns. Among adults, seroprevalence against
 164 filovirus was lower than for Nipah virus or Rubulavirus. As with Nipah virus, filovirus
 165 seroprevalence decreased over the study period, from 64% (50%-76%) to 20% (12%-30%), and had
 166 periods of distinct increases in spring/summer 2010 (concurrently with a circulation period for Nipah
 167 virus) (Fig. 3). filovirus seroprevalence did not exhibit cyclic annual patterns in adults (Fig. 4).

168 Among juveniles within the average year, filovirus seroprevalence started very low in June at
 169 8% (2%-40%), but increased to a peak of 44% (32%-58%) in juveniles approximately six months of age
 170 before declining. (Fig 5). This pattern was consistent across years; though the peak varied in size, it
 171 consistently occurred in December or January. The average date with the greatest rate of
 172 seroprevalence increase was Oct 31 (Jul 14-Nov 25), and the maximum rate of increase was 7.1%/day
 173 (4.5%/day-9.9%/day).

174 Rubulavirus seroprevalence had a distinct dynamic pattern. Among adults, rubulavirus
 175 seroprevalence was high at 92% (82%-98%), and remained high through the end of the period at 74%
 176 (62%-84%), though there were some temporary periods of decline. There were distinct periods of
 177 increasing circulation in early 2010 and early 2012. Only for the rubulavirus did adult seroprevalence
 178 exhibit patterns of seasonality. Periods of increasing seroprevalence in adults exhibited strong
 179 seasonality of 1.6%/day (1.0%/day-2.4%/day) increase on peak days, with the mean peak date
 180 occurring on Dec 15 (Oct 15-Feb 1)

181 In juveniles, seroprevalence against the rubulavirus in the average year was 22% (4%-62%) in
 182 the youngest bats in June, though in individual years this could range from 7%-43%. In all years
 183 juvenile seroprevalence declined to a low of 1.7% (0.6%, 8.3%) that occurred between Oct 9 and Dec
 184 11, then increased starting in winter, reaching high values in yearling juveniles of 88% (56%-99%)
 185 The peak rate of increase for juvenile rubulavirus seroprevalence was 6.4%/day (4.2%-8.8%) and occurred
 186 Jan 9 (Dec 21-Mar 16).

187 *Spatial Comparisons*

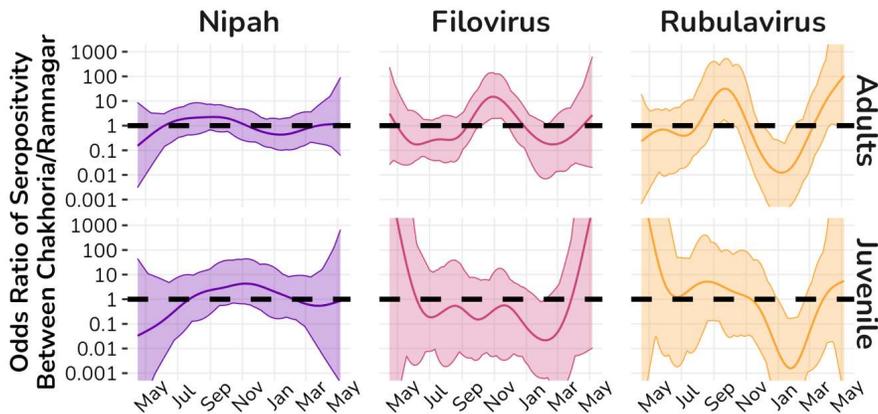

188 Seroprevalence trends in both adult and juvenile bats within the one-year studies in Chakhoria
 189 and Ramnagar broadly mirrored those in the five-year study in Faridpur (Supplementary Figure 2).
 190 In adults, Nipah virus seroprevalence increased in both Ramnagar and Chakhoria over the course of
 191 April 2010-May 2011, consistent with the period of increased seroprevalence observed in late 2010 in

192 the Faridpur. In Ramnagar, the seroprevalence in adults was 41% (24%-61%) in April 2010, rising to
 193 60% (36%-81%) in May 2011 whilst in Chakhoria it rose from 26% (10%-48%) to 60% (36%-81%) over
 194 the same period. The trend in juveniles was as described for the five-year study.

195 For the filovirus, the seroprevalence in the one-year studies was higher than the reported
 196 average in the five-year study, with seroprevalence ranging between 41% (21%-64%) and 75% (51%-
 197 91%) in Ramnagar and between 48% (26%-70%) and 100% (83%-100%) in Chakhoria. A period of
 198 distinct increase in spring/summer 2010 was described in the five-year study which overlaps the
 199 timing of the one-year studies and may explain this difference in seroprevalence. In Ramnagar the
 200 serodynamics in both adults and juveniles were as described for the five-year study. In Chakhoria,
 201 there were two periods of increasing seroprevalence in adults over the course of the year. The first of
 202 these occurred in late 2010 when the adult seroprevalence increased from 48% (28%-69%) in August
 203 2010 to 100% (83%-100%) in October 2010. The second period of increase occurred at the end of the
 204 study period in Spring 2011 with seroprevalence rising from 48% (26%-70%) to 75% (51%-91%)
 205 between early March 2011 to late April 2011.

206 Rubulavirus seroprevalence was high in adults throughout the one-year studies, ranging from
 207 50% (27%-73%) to 95% (76%-100%) in Ramnagar and 29% (11%-52%) to 100% (83%-100%) in
 208 Chakhoria, with the lowest values observed in September 2010 in Ramnagar and December
 209 2010/January 2011 in Chakhoria. These decreases were followed by rapid increases back to high
 210 seroprevalence, coincident with increasing levels in juveniles. The pattern in juveniles was as
 211 described in the five-year study, with seroprevalence estimates in yearlings in April 2011 of 80%
 212 (28%-99%) in both locations.

213 Comparison of the seroprevalence trends within each age group and virus between the two one-
 214 year study locations did not support spatial differences in the timing of changes in seroprevalence
 215 (Figure 7). Only for the filovirus in adults was there some evidence of a difference in trend between
 216 locations coinciding with the period of increased seroprevalence observed in adults in Chakhoria at
 217 the end of 2010.

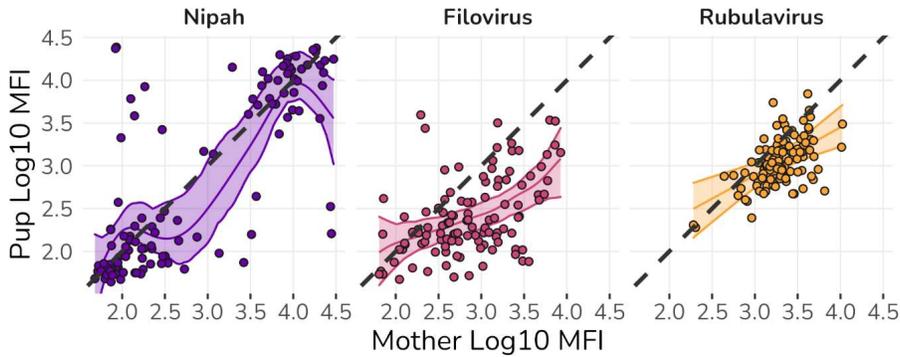

218
 219 **Figure 7. Comparison of splines for seroprevalence trends between locations in adults and**
 220 **juveniles over one-year study.** Thick lines and shaded errors represent the estimated difference
 221 in trends and their associated 95% confidence intervals. The horizontal dashed line is set at zero.
 222 Where the confidence interval excludes zero, there is evidence for a significant difference in the
 223 serodynamics between the Ramnagar and Chakhoria populations over that period.

224 *Maternal Inheritance of antibodies*

225 We examined the relationship between mother and pup antibody titers, as measured by our
 226 Luminex assays (see Methods). This relationship varied between viruses (Figure 7). For Nipah virus,

227 the relationship was nonlinear due to clustering at high and low values, but largely followed a 1:1
228 relationship between mother and pup antibody titers. For the rubulavirus the relationship was near-
229 linear and near 1:1. For the filovirus, though, the relationship between MFI values measured in
230 mothers and their pups fell well below the 1:1 line, indicating pups having low inheritance of
231 antibodies against the filovirus relative to the other two viruses.

232
233 **Figure 8. Maternal inheritance of antibodies.** In each plot, points are measured log-MFI values for
234 adults and juveniles in mother-pup pairs for each of the three antibody tests. Lines represent the
235 predicted mean relationship between the two and their associated 95% confidence intervals.

236 3. Discussion

237 We found serological evidence for regular circulation of multiple viruses in *P. medius*
238 populations in Bangladesh. These included Nipah virus, which spills over from bat populations to
239 humans in the region, as well as a filovirus and a Rubulavirus. It was common for bats to have
240 antibodies against multiple viruses, and more common in adults than juveniles. Co-immunity
241 patterns among pre-weaned juveniles mirrored those in adults, reflecting maternal inheritance
242 patterns. Patterns of co-immunity were not random, with antibodies against all three virus types
243 being positively correlated within bats.

244 The dynamic patterns in population seroprevalence were distinct for the three viral groups. The
245 rubulavirus exhibited the most regular and consistent patterns. Some juveniles in these populations
246 inherit maternal antibodies against the Rubulavirus, which wane over the first six months of their
247 life, after which a regular annual epidemic occurs in the juvenile population, causing a steep rise in
248 juvenile seroprevalence by the end of their first year. High adult seroprevalence is likely the
249 consequence of most bats being exposed to the disease as juveniles. When adult seroprevalence
250 drops, as it did in 2009 to 2011, it rapidly rebounds during the same season as juveniles, indicating
251 the same regular epidemics affect both adults and juveniles. We expect circulation and shedding of
252 the rubulavirus to be strongest in the late winter and early spring months in these populations.
253 Mortlock et al.³⁹ found irregular patterns of rubulavirus shedding in *Rousettus* bats over one year (via
254 PCR detection in pooled urine samples), including a peak during a period of presumed antibody
255 waning, though only within a one-year study.

256 An outstanding question is how the rubulavirus is maintained in the population despite high
257 seroprevalence in inter-epidemic periods. Recrudescence is one possibility. Evidence for latent
258 infections and recrudescence has been found for Nipah virus in *Pteropus vampyrus*⁴⁰, Hendra virus in
259 *P. Medius*⁴¹, and Lagos bat lyssavirus and African henipavirus in *Eidolon helvum*⁴². Another possibility
260 is re-importation. In concurrent work with this study, we found that bat home ranges overlapped

261 with nearby colonies so as to form a meta-population³⁴, allowing occasional infection from outside
262 bats, as has been shown to maintain Hendra virus in *Pteropus* populations^{43,44}.

263 The identity of the rubulavirus in this population is unclear. Our test was designed for Menangle
264 virus, which has been found in *P. medius* in Australia^{45,46}. At least 11 distinct Paramyxoviruses have
265 been found in *P. medius* in Bangladesh alone: Nipah virus and ten uncharacterized species, including
266 six Rubulaviruses closely related to Menangle virus and the Tioman virus^{9,47}. It is possible that the
267 serological patterns observed represent antibodies against a complex of multiple Rubulaviruses,
268 though the regular interannual patterns in seroprevalence would indicate that they are operating
269 similarly.

270 Nipah virus serodynamics exhibited a different pattern. We found serodynamics consistent with
271 little to no circulation amongst juveniles. Instead, each cohort of juveniles appeared to inherit some
272 maternal antibodies - maternal inheritance was most consistent for Nipah virus in our mother-pup
273 comparisons - and population seroprevalence declined over their first year for all cohorts. Adults
274 experienced several outbreaks, but Nipah virus serodynamics did not exhibit any seasonal patterns,
275 rather, circulation events occurred in irregular intervals one to two years apart. In Thailand, Nipah
276 virus shedding in *Pteropus lylei* was found to vary in time over two years and this pattern varied by
277 strain; Bangladesh-strain Nipah virus shedding clustered in spring months, but only over two years²⁸.
278 Human Nipah virus outbreaks in Bangladesh, on the other hand, exhibit seasonality associated with
279 the palm-sap consumption, the most likely spillover mechanism⁴⁸.

280 We had repeated positive detections of filovirus antibodies, using a test designed for Ebola-Zaire
281 virus. This is the first detection of filovirus antibodies in *P. medius* in Bangladesh, though they have
282 been found in *R. leschenaultii* in the country⁴⁹. This could be one of several known filoviruses or an
283 unknown species. There have been several recent findings of new Ebola-like filoviruses in bats
284 extending across Africa and Asia. These include Bombali virus in Sierra Leone⁵⁰, and Měnglà virus
285 in *Rousettus* bats in China⁵¹. Ebola-Reston virus was found in multiple bat species (*M. australis*, *C.*
286 *brachyotis* and *Ch. plicata*) in the Philippines⁵². Marburg virus and Ebola-Zaire virus may have been
287 detected in Sierra Leone and Liberia (unpublished,^{53,54}). Serological evidence of filoviruses in bats has
288 been found in multiple bat species in Central^{12,55} and Western⁵⁶ African countries, Singapore⁵⁷,
289 China⁵⁸, as well as Trinidad⁵⁹. Our finding here adds to the evidence of broad host and geographic
290 host ranges for filoviruses.

291 Several components of the serological patterns of filovirus antibodies are of interest. Young
292 juveniles were almost all seronegative, and seroprevalence rose over the course of the first six months
293 all years, then declined in the latter half of the year. Adult seroprevalence remained steady despite
294 these regular juvenile outbreaks near 50% over the course of the five-year study. Adult
295 seroprevalence against the filovirus also did not exhibit regular annual cycles, though the one period
296 of detectable increase, in mid-2010, coincided with one of the regular seasonal periods of increase
297 among juveniles. One possible hypothesis explaining this pattern is that the filovirus may exhibit low
298 transmissibility in this system, only circulating when seroprevalence is near zero in young juveniles.
299 It is also possible that bats may exhibit weak or waning filovirus antibody response but remain
300 immune. In *R. aegyptiacus*, infected with the Marburg virus, antibody waning post-infection was
301 found to be rapid, but bats retained protective immunity even with very low antibody titers^{60,61}. If a
302 similar mechanism occurs in this population, this could explain low seroprevalence in adults despite
303 regular apparent periods of circulation in juveniles. The regular drop of seroprevalence in juveniles
304 following the peak is consistent with this explanation.

305 However, if adults remain immune to the filovirus despite low antibody titers, this immunity
306 does not appear to transfer to juveniles, as seroprevalence is near-zero among newborns and
307 circulation in juveniles begins soon after birth. The relationship of pup/dam MFI found for the
308 filovirus antibodies suggests that there may be differential inheritance of antibodies and possibly
309 differential maternally derived immunity. If pups derive weaker immunity from dams than for other
310 viruses, this may provide another mechanism for maintenance of the virus. It possible that patterns
311 in filovirus antibody detection are an artifact of our test, specific to Ebola-Zaire virus, and that
312 temporal trends are in part reflective of differential cross-reaction with viruses in this bat population.

313 However, while this may modify estimates of overall seroprevalence, the differential pup/dam MFI
314 relationship, and consistent rise in seroprevalence among young juveniles, would require the test to
315 exhibit differential sensitivity by age.

316 Serodynamics in our two one-year studies were broadly similar to those found in the five-year
317 study. We found weak evidence for differences in serodynamics between sites for the filovirus in
318 adults, and the rubulavirus for adults and juveniles. However, limited sample numbers and the
319 shorter study period limit our ability to generalize about seasonal patterns. In a concurrent study³⁴,
320 we found that flying foxes home ranges in Bangladesh extended an average of 50 km from their
321 roosts. The roosts at Chakoria and Ramnagar, the sites of the one-year studies, are approximately 225
322 km apart. Thus, we would not expect the dynamics of these sites to be strongly coupled. It is plausible
323 that inter- and even intra-annual dynamics of these viruses could be similar if weak coupling and/or
324 environmental factors drive some of the dynamics. More detailed and longer-term studies at multiple
325 sites in parallel are needed to better understand spatiotemporal variation in viral circulation.

326 Regular co-circulation of these viruses indicates the potential for viral interactions to affect host-
327 viral dynamics. Viral interactions in hosts – whether direct during co-infection or indirect from
328 infection in different periods – can enhance or suppress pathogen mortality, fecundity, or
329 transmission, via competition for host nutritional or cellular resources, or via immune-mediation
330 involving cross-immunity or antibody-dependent enhancement, and these interactions structure
331 viral communities²⁶. These interactions can have complex, even opposite effects when scaled to the
332 population²⁷. Here, we found positive correlations between serostatus against different viruses.
333 External factors may also affect these relationships. For instance, all three viruses appear to have
334 circulated in adults in mid-2010. It is possible that common factors like population density and/or
335 nutrition availability³² affected transmission of multiple viruses.

336 While rich observational serological data reveal these patterns, greater study is required to
337 characterize these viruses and their effects on the host population and potential for spillover, as well
338 as the degree and mechanisms of interactions. Our inferred periods of viral circulation point to
339 optimal sub-populations and times to sample this population to detect viral shedding and isolate
340 these viruses, and potentially capture co-infected hosts.

341 Extended longitudinal sampling also sheds light on viral dynamics not found in short-term
342 studies. One- to two-year studies can identify temporal patterns in serology or viral prevalence and
343 shedding, but establishing patterns or variation in seasonality requires extended, multi-year
344 sampling. In our case, while Nipah virus outbreaks occurred in the same season in two years, it was
345 apparent from the longer time series that there was no distinct seasonal pattern in dynamics. The
346 consistency of the filovirus and rubulavirus patterns required repeated years of sampling to establish.
347 Similarly, we were able to understand these patterns far better by separating juvenile and adult
348 patterns, which we would be unable to distinguish in pooled samples.

349 While such extended individual-capture longitudinal studies are resource-intensive,
350 understanding the joint circulation of multiple viruses can be accomplished via multiplex
351 immunoassays such as those used here. The continuous measures from these assays also have the
352 potential to identify key patterns such as the differential inheritance of filovirus antibodies we
353 identified here. Interpretation of these values is challenging and the relationship between immune
354 status, antibody titer, and measured fluorescence is complex³², but they have much potential to shed
355 light on mechanistic drivers of disease circulation.

356 **Methods**

357 *Field collection*

358 We conducted a five-year longitudinal study sampling *P. medius* bats quarterly and two one-
359 year studies in different locations, sampling monthly. All capture and sampling methods were
360 approved by Tufts University IACUC protocol #G929-07 and icddr,b animal ethical review (protocol
361 2006-012). For the five-year study, we sampled from a roost complex near Faridpur, Bangladesh, as
362 previously described in Epstein, et al. ³⁴ The area of the roost complex consists of patchy forest

363 interspersed with agrarian human settlements and large rice paddies. Sampling occurred from July
364 2007 to November 2012 approximately every three months. The bat colony regularly shifted amongst
365 roosts within the 80km² roost complex over the period of the study. Sampling occurred at the largest
366 occupied roost found each quarterly sampling trip, sampling at different roosts within the complex
367 across consecutive sampling nights if required to capture a sufficient number of individuals.

368 Approximately 100 bats were captured at each sampling event, which lasted 7-10 days. We
369 captured bats with a 10x15m mist net between 11pm and 5am each night as bats returned from
370 foraging until the count of 100 was reached.

371 In the one-year longitudinal studies, sampling was undertaken in two roost complexes in
372 Ramnagar and Chakhoria, Bangladesh between April 2010 and May 2011. Monthly sampling of
373 approximately 40 bats in each location was performed to obtain data at a finer temporal scale. Details
374 of collection are otherwise as described for the five-year study.

375 For each study, we recorded each bat's age class, reproductive status, weight, size, and body
376 condition. We collected up to 3.0 mL of blood from each bat's brachial vein into serum tubes with
377 serum clot activator (Vacutainer, USA). Blood tubes were stored vertically on ice packs in a cold box
378 and serum was allowed to separate overnight. Serum was drawn from the tube after 24 hours and
379 placed in a screw-top cryovial (Corning, USA) and stored in a liquid nitrogen dewar (Princeton
380 Cryogenics, NJ, USA).

381 As part of a larger study to detect viral RNA, we also collected urine, rectal, and oropharyngeal
382 swabs and pooled urine samples from under colonies. Further details can be found in [Epstein, et al.](#)
383 [34](#)

384 *Serological Assays*

385 Sera from the longitudinal studies were sent to the Australian Animal Health Laboratory and
386 gamma irradiated upon receipt. We used a bead-based microsphere assay that specifically detects
387 antibodies to the soluble attachment glycoproteins^{57,63,64} for a panel of viruses. Beads coated with each
388 protein were mixed with sera at a dilution of 1:100. Biotinylated Protein A/G and Streptavidin-PE
389 were then used to detect bound antibody. Beads were interrogated by lasers in a BioRad BioPlex
390 machine and the results recorded as the Median Fluorescent Intensity (MFI) of 100 beads. We report
391 here results for Nipah, Ebola-Zaire, and Menangle, the only three for which we established regular
392 positive results.

393 While the Nipah virus has been detected in this population⁶⁵ and the specificity of the Nipah test
394 is well-established⁶⁶, the Ebola-Zaire and Menangle virus tests are cross-reactive with other Ebola
395 and rubulavirus species^{67,68}. Thus we refer to these as tests for filovirus and Rubulavirus.

396 *Data Analysis*

397 We determined individual bat serostatus using Bayesian mixture models⁶⁹ fit on pooled data
398 across all three longitudinal studies, calculating a cutoff of log-MFI as the point of equal probability
399 between the smallest and second-smallest cluster of equal distributions for each assay.

400 To determine correlations of serostatus in bats across the three viruses, we fit a Bayesian
401 multivariate probit model^{70,71} which allows estimation of the joint outcomes (serostatus against each
402 virus) and the correlation between the outcomes. We included age and sex variables to account for
403 these effects on serostatus.

404 To examine time-varying changes in population seroprevalence, we fit binomial generalized
405 additive mixed models (GAMMs)^{72,73} to the time-series of serostatus measurements. For the five-year
406 study, we fit separate models for adults and juveniles and for each immunoassay. For adults, we fit
407 a model for seroprevalence dynamics over the course of the whole study. This treats the adult
408 population as a single unit, though individuals within the population may turn over via migration,
409 death and recruitment. We included both long-term and annual cyclic components for the multi-year
410 time series of measurements. For juveniles, we treated each year's cohort of new recruits as separate
411 populations with commonalities in overall first-year dynamics. The dynamics of each year's juvenile
412 cohort were modeled as random-effect splines, deviating from an overall mean splines for juveniles

413 over their first year. To estimate periods of peak viral circulation within the population, we calculated
414 the derivatives of model-derived seroprevalence over time. We sampled these from GAMM posterior
415 distributions and classified periods with >95% of samples with positive derivatives - that is,
416 increasing population seroprevalence - as periods of viral circulation. We also calculated strength
417 and timing seasonality for each virus as the maximum rate of seroprevalence increase and the date
418 at which this maximum occurred, again sampling these values from the model posterior, and
419 calculating mean and high-density posterior interval (HDPI) values.

420 For the one-year studies, we fit models primarily to detect differences in time-varying changes
421 between sites. We fit binomial generalized additive models (GAMs) to the monthly serostatus
422 measurements with separate models for each immunoassay. We included a separate, fixed-term
423 spline in each model for age (adult or juvenile) and location (Chakhoria or Ramnagar). The trends in
424 serodynamics for each virus in each age group were compared between locations to test for spatial
425 differences⁷⁴. Juveniles identified as being from the previous year's cohort were excluded from the
426 analysis.

427 To examine patterns of maternal inheritance, we used GAMs to fit a relationship of log-MFI
428 between adult lactating females and their attached pups for each viral assay. We limited these to data
429 from the five-year longitudinal study.

430 **Data Availability:** Raw data from this study and reproducible code used to perform analyses is available at the
431 Zenodo Scientific Archive [Zenodo DOI to be generated] and also on GitHub at

Chris let us know that you should be on the attached paper as you developed some of the proteins used in the panel run in our previous Bangladesh study. Glad to have you on, as this way we'll have another joint reference for the grant.

We're doing final revisions on it now before sending to preprint before the end of the month. If you have any feedback, maybe we touch on it when we meet next week?

Best,
Noam

Colleagues,

I hope you're all doing well. I'm excited to share a draft manuscript, led by Noam, that details the serodynamics of henipaviruses, filoviruses and rubulaviruses in a population of *Pteropus medius*. We plan to submit this to *Nature Communications* in September. Please send Noam and I your comments by **September 10th**.

Cheers,
Jon

EcoHealth Alliance develops science-based solutions to prevent pandemics and promote conservation

SPECIFIC AIMS

We propose to develop robust analytical approaches for using quantitative serological data to better target novel disease discovery and surveillance in both human and wildlife populations. Multiplex and quantitative serological assays are increasingly used in disease surveillance to identify spillover, but are underutilized because they produce large datasets without a standardized analytical framework. The confounding effects of cross-reactivity, and a lack of true controls in wildlife species or for yet-uncharacterized viruses stymies use of rich quantitative data that they produce. Using PCR and other direct viral detection methods is costly because of the rarity of positive detection. **Our approach will allow more cost effective and statistically powerful serological assays to be used for identifying high risk populations for pathogen spillover.**

We will test and validate our methods using paired serological and viral detection data from extensive surveillance studies of wildlife and human populations collected and curated by our team. Our team has unique experience applying multiplex serological assays in regions of pathogen emergence in parallel with PCR-based viral detection, allowing us to use paired samples to validate our approach. This includes work on SARS-related bat coronavirus spillover in Southeast and East Asia, and filovirus and henipavirus exposure in Africa and Asia. This strategy leverages access to extensive, comparable, field data and also prior investments by NIH and other federal agencies (DTRA, USAID) in zoonotic disease emergence.

Our statistical approaches are applicable to a broad range of serological technologies that can quantify immune response including Luminex, epitope serochips, and quantitative LFIA and ELISA. **They will be published as open-source software packages to enable their rapid adoption and validation.**

Our specific aims are to:

- 1. Develop an approach for identifying and characterize novel viruses from multiplex panels of quantitative serological assays.** We will develop detailed reaction/cross reaction profiles of a broad panel of Luminex serological tests and incorporate these into statistical models with explicit representations of sampling and measurement processes. With these, we will determine whether serological “profiles” are more likely to represent antibodies of known viruses, mixtures of multiple known antiviruses, or previously uncharacterized viruses. We extend techniques of antigenic mapping, using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential
- 2. Create a robust bioinformatics pipeline for multiplex detection platforms.** "Serochips" consist of hundreds of thousands of synthetic epitopes drawn from libraries of viral genetic sequences. While promising platforms for broad surveillance, they suffer from multiple testing dilemmas combined with problems cross-reaction and within-sequence correlation. We will build mechanistic, hierarchical Bayesian models to translate the large data generated by these platforms into usable measures of immune response. Using simulation experiments, we will test reduced-form, simple models against fully structured models so as to develop statistically robust procedures to interpret these data without high-performance computation.
- 3. Use spatio-temporal quantitative serological data to identify populations with distinct profiles indicative of novel pathogens.** We will develop spatio-temporal models that capture population-level immunological patterns from spatially extensive quantitative multiplex serological assays. Using ordination techniques drawn from community ecology, we will scale up the approach to individual-scale serological profiles to populations. We will work directly with an active NIAID-funded CREID research center in Southeast Asia (EID-SEARCH), along with a global consortium of research groups using similar datasets to develop our models. These analyses will allow us to characterize groups and regions with distinct exposure profiles, characterize spatial variation, and identify populations that have unique mixtures of immune assay responses that indicate exposures to novel pathogens or distinct combinations of pathogens – targets for intensive surveillance, viral detection and characterization.

Hi Eric,

Hi! I hope you are well. I had a call with Spencer yesterday about this grant as I know you've been away for family reasons. (CC'ing him to chat with you about this when he has the chance). We discussed things that we could write into the grant on your side, notably validation/calibration testing using the Filovirus standard coming out of Oxford, and also running tests on the sera from experimental infections that are at BSL-4 labs at RMN, UTMB, and maybe South Africa. These could be used to model how we expect real responses to look in related virus and host species.

Here are my follow-up items:

- *I'd like to have a conversation with you about nuts and bolts and budgeting.* I'm headed out for vacation Friday afternoon through Labor day. *If you want to chat tomorrow or Friday pick a time* at this link, if not I will write when I return: <https://calendly.com/noamross/60-minute-chat-extended-hours>

- *I'll get you a draft* with a bulleted section on this stuff that you and Spencer can make sound like a virologist who knows what they are talking about. I expect this *around September 12.*

- I think it would be good for me to *come down to USU for a day or two in early-mid September* for us to work through some of this stuff if you agree and have the time. If so, let's schedule that.

Best,
Noam

Hi Eric,

After many false starts, I really am planning to submit an R01 on bioinformatics and statistical methods for Luminex serology in the next cycle (due Oct 6). Everyone came back from the BatID conference really jazzed about this. I still think it works best with you and I as co-PIs. If you are still game, want to have a call about it? I'd still like to come down to USU for a day in the next month, too, if you'd like to spend a day working on it and other related issues.

Schedule a call on my calendar here: <https://calendly.com/noamross/60-min-chat>

Last draft of specific aims attached.

Best,

Noam

Section 1. Executive Summary

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary center focused on analyzing zoonotic disease risk in a key EID hotspot region. Our aims are to 1) characterize diverse coronaviruses (CoVs), paramyxoviruses (PMVs), filoviruses (FVs), and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in Thailand, Malaysia, and Singapore. Highlights of research and significant findings during the reporting period (October 2021 – August 2022) include:

To be updated with bullet points by Peter and Kevin...

- Developed and optimized multiplex serological assays including pan-sarbecovirus and Henipavirus multiplex surrogate virus neutralization test (sVNT); and transferred these technologies to labs in Thailand and Malaysia.
- Conducted extensive sampling of bat, rodent and non-human primate populations; discovered 8 putative novel CoVs and 8 novel PMVs – including full genome of a bat SARS2-related CoV.
- Began human community surveillance in Thailand at sites with high human-wildlife contact.
- Obtained preliminary evidence of filovirus and henipavirus zoonotic spillover in humans.
- Supported viral diarrhea outbreak investigation in Chanthaburi province, Thailand.
- Strengthened outbreak preparedness for Monkeypox virus with Ministry of Public Health and helped detect first cases in Thailand (July 2022).
- Conducted experimental research on Swine Acute Diarrhea Syndrome coronavirus (SADS-CoV) and pangolin coronavirus to identify essential factor for infection, potential for spillover, and efficacy of existing CoV therapeutics and vaccines.
- Published 9 peer-reviewed papers; 4 others in revision, and 3 more in prep.
- Drafted extensive Field Biosafety Manual (presented at the CREID Scientific Meeting), to be peer-reviewed, revised and shared broadly with CREID Network in Fall 2022.
- Strengthened cross-Research Center communication via information sharing for outbreak research response and sharing protocol and diagnostic assays.

Commented [K01]: Agree w Eric, great if we could reference some pre-prints or in review titles of papers. Also prob could cut this section a little more (Peter).

Section 2: Research Center Overview

A. Specific Aims

The overarching goal of the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is to characterize the diversity of key viral pathogens in wildlife, assess the frequency and causes of their spillover, and identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in people. The research goals of the EID-SEARCH follow three specific aims designed to advance our understanding of spillover and outbreak risk for novel viruses in a globally important EID hotspot, strengthen in-country research capacity, and enhance international collaboration:

- Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.
- Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.
- Specific Aim 3: Identify and characterize the viral etiology of ‘cryptic’ outbreaks in clinical cohorts.

B. Partners and Staffing

EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions (EcoHealth Alliance PI Peter Daszak; University of North Carolina Co-I Ralph Baric; Uniformed Service University Co-Is Christopher Broder and Eric Laing), and in Thailand (Chulalongkorn University Co-Is Supaporn Wacharapluesadee and Opass Putcharoen), Singapore (Duke-NUS Medical School Co-I Linfa Wang), and the three major Malaysian administrative regions (Conservation Medicine Co-I Tom Hughes). These organizations represent the 'hub' of the center, with an additional, more informal collaborative network of research partners across almost all Southeast Asian countries. By enhancing and focusing research within the three hub countries, and coordinating communication among the network, EID-SEARCH is acting as an early warning system for outbreaks; a way to exchange information, reagents, samples, and technology; and a collaborative powerhouse for translational research. EID-SEARCH is supported by a multidisciplinary team of researchers at our partner institutions, with skills in epidemiology, clinical management, molecular biology, virology, wildlife biology, and advanced data and statistical analyses. The long collaborative history between the key personnel and partner institutions has facilitated our outbreak research response in the region.

C. Research Sites

The three core (hub) countries for the EID-SEARCH are Thailand, Malaysia, and Singapore, *expanded to Viet Nam (in 2021) and Cambodia (in 2022) through the CREID Pilot Research Program*. Our geography covers one of the most significant foci of EID risk globally. Additionally, we have assembled a greater network of EID-SEARCH partners that includes >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries – stretching from Nepal to the Philippines. Our targeted field research includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak, Sabah, Viet Nam, and Cambodia. Our field sites in mainland Southeast Asia allows us to sample representative wildlife species that occur across the greater biogeographic region, including India, Bangladesh, Myanmar, Southwest China, Laos, Cambodia, Philippines, and Indonesia, and thus characterize zoonotic disease risk more broadly outside our study area.

Section 3: Research Center Progress and Accomplishments

Progress and Accomplishments

- Organized by Aim
- Focus on key accomplishments
- Address outbreak research response if applicable
- Address how the 2021 EAC recommendations have been incorporated (*see Appendix A for 2021 EAC report*)

A. Projects and Studies

- Have you reverted to your original (pre-pandemic) CREID research agenda in the last year? If not, how has your research agenda changed in the last year due to the ongoing impact of SARS-CoV-2?
- What additional changes to your CREID research agenda have taken place in the last year?

Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife

- **Field surveillance among wild bats, rodents, and non-human primates.** To date, we have collected 18,033 specimens from 2,660 animals of 31 bat species, one non-human primate (NHP) species, and five rodent species from 9 sites at high-risk human-wildlife interfaces in Malaysia and Thailand (Table 1).

Commented [LH2]: This is from the original proposal. Tom suggested removing this because we don't actually work in Sarawak.

Commented [K03]: Should we put in a short update about Cecilia's paper published last week? Or was this fully covered last time? I guess the revisions proposed by reviewers and slightly new estimated numbers would be new? OR THE VIRAL CURVE stuff?

Commented [LH4R3]: We have highlighted the paper last year

Table 1. EID-SEARCH summary of sampling and virus surveillance in wildlife in Thailand and Malaysia.

	Thailand	Malaysia
No. of collected specimens ¹	3,862	14,171
No. of individuals	454 bats, 106 rodents, 100 NHPs	2,000 bats
No. of species	6 (bats), 5 (rodents) 1 (NHP)	24 (bats)
No. of sites	5	4
No. of tested individuals	506	1,332
No. of PCR tests for CoVs, PMVs, FLVs, influenza viruses	5,063	9,228
Detected divergent viral PCR sequences (RdRp) ²	3 novel CoVs from 11 bats ³ (in 1 species)	5 novel CoVs from 112 bats (in 3 species)
	3 known PMVs from 4 rodents (in 2 species)	4 novel PMVs from 10 bats (in 2 species)
	4 novel PMVs from 11 bats (in 1 species)	2 known PMVs from 2 bats (in 1 species)
No. of specimens for multiplex immunoassay for FLVs, CoV and Henipavirus	100 (macaques) 92 (rodents)	720 (bats)

*Abbreviations: CoV – Coronavirus; PMV – Paramyxovirus; FLV – Filovirus

- **Discovery of novel bat SARS-related coronavirus in Thailand.** Whole genomes of novel sarbecoviruses from *Rhinolophus pusillus* revealed a 91.72% nucleotide similarity to SARS-CoV-2. Phylogenetic analysis suggested that this virus is closer to pangolin CoV-GD-1 than to SARS-CoV-2; however, the receptor binding domain (RBD) is most closely related to bat-CoV RaTG13. Experimental assays suggest that this new virus binds to human ACE2 receptors and is able to mediate cell entry. Whole-genome sequencing of additional novel CoVs from Thailand and Malaysia is ongoing.
- **Genome-wide CRISPR knockout screen identifies essential factor for HKU2/SADS-CoV infection.** Using a genome-wide CRISPR knockout screen, we identified placenta-associated 8 protein (PLAC8) as an essential host factor for Swine Acute Diarrhea Syndrome coronavirus (SADS-CoV) infection of human cells. Infection is prevented in PLAC8 knockouts and can be restored by transiently transfecting PLAC8 from multiple species, including human, pig, mouse, and bat. Trypsin treatment of SADS-CoV bypasses the PLAC8-dependent pathway and partially rescues SADS-CoV infection. PLAC8 is involved in both early entry and later dissemination of SADS-CoV infection and PLAC8 KO cells have: 1) delayed and reduced viral subgenomic RNA expression and 2) diminished cell-to-cell viral spreading of infected cells. *These results suggest that PLAC8 is a promising target for antiviral development for the potential pandemic SADS-CoV virus.*
- **Host range, transmissibility, and antigenicity of a pangolin coronavirus.** Using a synthetically derived infectious cDNA clone, we recovered the wildtype pangolin (Pg) CoV-GD and derivatives encoding indicator genes. Like SARS-CoV-2, PgCoV-GD virus efficiently uses human and many other orthologous mammalian ACE2 receptors for entry, shares a similarly broad host range *in vitro*, and displays altered sensitivity to host proteases. PgCoV-GD replicates to slightly higher to lower titers in primary human cells derived from the proximal to distal lung, respectively, and with reduced fitness

¹ Collected specimens include oral swabs, rectal swabs, urogenital swabs, and whole blood, types of specimens may vary among individual animals.

² Further studies are needed to understand the characteristics and classification of these divergent viral sequences, as partial-gene phylogenetic trees suggest that these are potentially “novel viruses”.

³ Complete whole genome sequences were obtained from 3 samples and partial whole genome sequences obtained from (8 samples), further viral characterization studies are undergoing.

Commented [MOU5]: Footnote about what “specimens” includes, how were 14,000 specimens obtained from 2,000 bats. 1 bat -> blood sample, oral swab, rectal swab, body swab, ectoparasite removed, wing puncture, etc...

Commented [LH6R5]: Added footnote

Commented [SN9]: Based on complete whole genome sequences (3 samples) and partial whole genome sequences (8 samples)

Commented [LH10R9]: Added to the footnote

Commented [MOU11]: Same species? Details.

Commented [LH12R11]: Added no. of species, not sure if we need to detail the species, no much space

Commented [MOU7]: I’m not a mol. evol. geneticist but the way this is laid out in the table gives equal weight to a full genome, *Thailand 1 new CoV*, and distinct RdRp NT sequences that are used to create phylogenetic trees. I don’t think I’ll ever understand how the virology field uses small NT reads to discover new viruses. I suggest adding another row for “full virus genome sequenced” and a footnote about the methods used to determine how a new virus has been genetically identified.

Commented [LH8R7]: Added footnote

Commented [KO13]: Agree w Eric, great if we could reference some pre-prints or in review titles of papers. Also prob could cut this section a little more (Peter).

compared to SARS-CoV-2. PgCoV-GD also replicates efficiently in hamsters and could transmit via the aerosol route, but at a lower frequency than SARS-CoV2. Efficient PgCoV-GD replication in primary nasal airway epithelial cells and transmission in the hamster highlights the high emergence potential of this virus. However, PgCoV-GD is efficiently neutralized by COVID-19 patient sera and many commercially available SARS-CoV-2 therapeutic antibodies, but not by human antibodies targeting the spike N-terminal domain. Furthermore, a pan-sarbecovirus antibody, ADG-2, and a SARS-CoV-2 prefusion stabilized spike protein (S2P) recombinant protein vaccine protected mice in a PgCoV-GD replication model. Lastly, we showed that cross-neutralizing antibodies in pre-immune SARS-CoV-2 humans and the benefit of current COVID-19 countermeasures should impede its ability to emerge and spread globally in humans. *This research helps demonstrate the efficacy of FDA-approved therapeutic antibodies against a range of CoVs with emergence potential, allowing for the creation on-the-shelf therapeutics to target future emerging coronaviruses. As all FDA approved or emergency authorized vaccines express the prefusion stabilized spike this work further shows that FDA-approved SARS-CoV-2 vaccines also protect animals from PgCoV-GD when challenged in vivo.*

Aims 2 & 3: Identify evidence and analyze risk factors for viral spillover in high-risk communities and clinical cohorts, and characterize viral etiology of ‘cryptic’ outbreaks

- Incorporation our bat-CoV spike proteins into the multi-family multiplex-based immunoassay (MMIA).** Specific bat-CoV spike proteins including bat SARSr-CoVs RaT13, bat SARSr-CoV ZXC21, bat MERSr-CoV PDF2180, and HKU9 were designed as pre-fusion stabilized spike glycoprotein ectodomain trimers (S-2P). These spike protein antigens were incorporated into our 17-plex henipavirus/filovirus-focused serology assay expanding the representation of virus targets to include priority coronaviruses such as SARS-CoV-2 and bat SARSr-CoVs/bat MERSr-CoV. SOPs were revised and updated to reflect best practices that were optimized during Year 1.
- Community serology surveillance.** We initiated human surveillance work in Thailand, with 56 participants enrolled at one community surveillance site with high levels of bat-human contact, and 2 individuals from a clinic site, with a total of 58 participants enrolled. Serology testing using multi-family MMIA showed evidence of previous infection by Asiatic FLVs, PMVs, and CoV (Fig. 1). Preliminary data suggest several interesting findings. First, a single human serum sample was reactive with envelope glycoproteins (GP) from Ebola virus, Bundibugyo virus, Bombali virus, Sudan virus, and Lloviu virus, consistent with a serologic pattern of cross-reactivity due to exposure to a phylogenetically-related, likely novel, Asiatic ebolavirus (Figure 1A). Follow-up testing will explore whether broad cross-reactions with FLVs antigens is driven by glycosylated epitopes that may be more conserved across the ebolaviruses than protein sequence similarity would imply. Second, Henipavirus serology showed one individual reactive with Hendra and Cedar virus, and several individuals with evidence of exposure to Mojang or Mojang-related viruses. Lastly, CoV serology was complicated by prior COVID-19 vaccination of participants. At the low testing titer, cross-reactions with phylogenetically related bat sarbecoviruses were expectedly observed (Figure 1C) – patterns we are currently exploring in more detail. Interestingly, two participants had sera IgG that bound to the bat MERSr-CoV PDF2180, which does not utilize the orthologous human DPP4/CD20 receptor for cellular entry, and it quite distinct from the sarbecoviruses.

Fig. 1 Serology testing results for FLVs (A), HNVs (B), and CoVs (C) among community participants in (n=56).

Commented [MOU14]: ? not sure what this means. Were there lower viral loads in the respiratory tract? Is aerosol route correct, or should it be respiratory secretions? There is a lot of data in this section, is there a reference to a pre-print or article?

Commented [GLE15R14]: The transmission studies showed occasional, but less, transmission to exposed hamsters than was seen with SARS2 infected animals. No preprint at this time.

Commented [MOU16]: List these?

Commented [GLE17R16]: B38, REGN10933, REGN10987, LY-COV016

Commented [MOU18]: This is pretty nuanced. Do the commercially available mAbs that neutralized PgCoV-GD target the RBD or Q neutralizing epitopes in the S glycoprotein and not the NTD?

Commented [GLE19R18]: All of the early SARS2 mAbs targeted RBD so those are the most broadly available for testing. We tested 3 SARS2 NTD binding antibodies and none neutralized pangolin. 13 of 15 RBD targeting antibodies had efficient neutralization of pangolin.

Commented [MOU20]: Is this an FDA EUA or authorized treatment?

Commented [GLE21R20]: In trials, published in Science as having pan-coronavirus efficacy

Commented [MOU22]: This is something not FDA EUA? Will stakeholders understand what S-2P etc means? This is what NovaVax is making.

Commented [GLE23R22]: Removing S2P to be less jargony makes sense here.

Commented [MOU24]: Replication, not infection or disease model? What did these mAb and vaccine prot... [1]

Commented [GLE25R24]: Mice show no weight loss after pangolin infection but have high virus titer at day... [2]

Commented [MOU26]: What does this mean, sera from humans with memory to seasonal beta-human... [3]

Commented [GLE27R26]: We are not sure what Ralph means here.

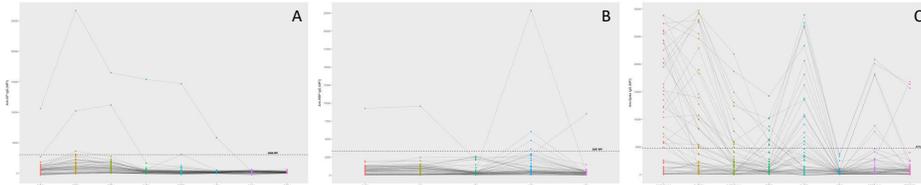

Commented [MOU28]: I didn't see any mention of FDA-approved antibody therapies or vaccine countermeas... [4]

Commented [KO29]: Think it's okay to make a little longer than one sentence as this is interesting stuff. I... [5]

Commented [LH30]: Peter and Kevin - please shorten this if possible, we don't have space, and may not wan... [6]

Commented [MOU31]: Needs a proper legend.

Commented [KO32]: Unless we get a much simpler figure, I would suggest we ditch the figures and just de... [7]

- **Design and application of pan-sarbecovirus multiplex surrogate virus neutralization test (sVNT)**
The assay covers SARS-CoV-2 variants of concern (Alpha, Beta, Gamma, Delta, Mu, Lambda, Omicron BA.1 and BA.2), clade-2 sarbecoviruses (BANAL-52, BANAL-263, GD-1, RaTG13, GX-P5L), clade-1 sarbecoviruses (Rs2018B, LYRa11, WIV-1, RsSHC014, Rs4231), SARS-CoV-1, and *the newly discovered bat SARS-CoV we recently sequenced from Thailand*. This assay allows for the discrimination of past SARS-CoV-2 infection from that of other sarbecoviruses in human and animal samples, which will be critical for identifying cryptic spillover of sarbecoviruses in people and in identifying the progenitor of SARS-CoV-2 in animals.

We have also optimization and established a pan-henipavirus multiplex sVNT at Chulalongkorn University to screen human and animal samples for neutralizing antibodies via a virus-free/cell-culture free, bead-based serology assay.

Outbreak research response and preparedness in Thailand

- The Ministry of Public Health in Thailand requested support from EID-SEARCH for a viral diarrhea outbreak investigation in Chanthaburi province. We received samples from both Prapokklao Hospital (regional hospital) and Khlong Khut Health-Promoting hospital collected from 59 healthcare workers and students who had diarrhea during Dec. 2021-Feb. 2022. PCR tests were conducted for six gastrointestinal viruses causing gastrointestinal tract infections including adenovirus, astrovirus, norovirus GI, norovirus GII, rotavirus, and sapovirus. 32 samples (54.24%) were positive for norovirus GII, which appears to be the likely etiological agent.
- In preparedness for Monkeypox outbreaks, EID-SEARCH's lab partner in Thailand coordinated with the Department of Medical Science, MOPH, National lab to establish the Monkeypox PCR testing platform in April 2022 and detected the first Monkeypox case in Thailand in July 2022.

B. Dissemination of Results

- Summarize dissemination plan
- Include number of peer-reviewed publications; highlight those in high-impact journals
- Number and content of presentations on CREID research, including audience

EID-SEARCH members were invited to present the project work at government and inter-government briefings (> 10), conference and university lectures (>13), panels and webinars (>18), and public interviews (>6) in Thailand, Malaysia, the US, regionally and internationally on the trends in global disease emergence, zoonotic surveillance, pandemic control and prevention, and research results from this project research activities. Nine (9) peer-reviewed papers have been published or posted as preprints from EID-SEARCH research, four (4) manuscripts are currently under revision, and three (3) manuscripts are in preparation for submission, including papers on.. please highlight the high-impact ones. We organized a workshop with 55 scientists and government officials from Thailand, Malaysia,

Commented [SN33]: As mentioned earlier, I re-tested the two serum samples that were weakly positive for NiV and it turned out that both of them showed seronegative. So I'm not sure that should this part still be included.

Commented [KO34R33]: I edited it to be part of the assay establishment and optimization, no results.

Commented [KO35]: Hongying, are the preprints the same ones that are in revision? Can we add refs anywhere and list all these, then just give reference numbers here?

Commented [SN36]: 1. Our paper "Rapid and Simultaneous Detection of Omicron and Other Concerned SARS-CoV-2 Variants (Alpha, Beta, and Delta) in Clinical Specimens Using Multiplex PCR MassARRAY Technology" is under revision

2. "Homologous or Heterologous COVID-19 Booster Regimens Significantly Impact Sero-Neutralization of SARS-CoV-2 Virus and its Variants" has been accepted for publication in vaccines journal

Commented [LH37R36]: Counted!

Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, and Australia to present EID-SEARCH work, share knowledge, strengthen research capacity, and foster scientific collaborations in Southeast Asia.

C. Training and Capacity Building Activities

- Summarize capacity building plan
- Include number of training activities and number of participants for each training
- Address how capacity building activities were adapted due to COVID-19 and long-term changes as a result of the pandemic

EID-SEARCH is committed to in-country capacity building to strengthen outbreak response and research and develop next-generation EID researchers in Southeast Asia. Within our network, nine (9) training sessions were conducted by EID-SEARCH partners in Thailand, Malaysia, and Viet Nam for project members, local government partners, universities, research institutes, and NGOs within the reporting period, 89 participants were trained in lab biosafety (2 training 32 participants), research biosafety (1 training 3 participants in Malaysia), lab monitoring (1 training 3 participants), Bio-plex and multiplex immunoassay introduction (1 training, 2 participants), applying data sharing tools (1 training 10 participants), serology data analysis (1 training, 14 participants), field biosafety and animal sampling SOPs (2 training sessions with 25 participants, virtual and in-person), to strengthen in-country research capacity and improve information sharing. Regular virtual meetings were held for results analysis, hands-on lab and field training were conducted in Thailand and Viet Nam, all training was conducted to accommodate COVID conditions. As travel and COVID-19 restrictions have begun to be lifted, students, postdocs, and all EID-SEARCH research staff have been provided with professional development opportunities to travel to attend conferences, workshops, and other in-person training activities.

D. Challenges and Proposed Solutions

- Bottlenecks to CREID-related research that might be like those that you could face when pivoting research activities in direct response to an EID outbreak. What solutions could be or have you put in place in advance to solve those challenges? How is being part of the CREID Network mitigating those or not?

The significant challenges we encountered during the reporting period were travel restrictions to our field partner countries and within countries, as well as a large number of hospitalized patients in local hospitals in Thailand and Malaysia due to COVID-19 that delayed human participant enrollment at targeted community and hospital sites and the subsequent laboratory analysis we anticipated in Year 2. To address these issues, we worked closely with in-country partners and stakeholders to continue assessing the situations (i.e., safety and research priorities of study sites) to ensure a rapid start of enrollment and focused on the refinement of assays to be ready for human surveillance. Meanwhile, to prevent a possible supply shortage of PPE and swabs as happened in early Year 2, we have identified supply sources to ensure we can procure the necessary consumables without significant delays. With travel restrictions in Southeast Asian countries now beginning to be lifted, international travel of US-based staff to our field sites has begun (April 2022).

E. Examples of Network Collaboration

- How has the work/research of your RC been affected by or involved collaboration with other members of the CREID Network?
- Examples: highlight joint publications, joint activities, sharing materials and data, benefits of Working Groups, etc.

Commented [LH38]: These training were organized by Conservation Medicine. From the feedbacks on annual report, Tom was very upset that we lumped all these as overall EID-SEARCH efforts, just FYI, if you want to edit

Through the participation of different CREID Working Groups, EID-SEARCH members participated in the network's outbreak research responses, capacity building, and cross-center collaboration by sharing expertise, leveraging existing local partnerships, and sharing protocols and relevant resources.

- In outbreak response and research to Monkeypox, EID-SEARCH partner Uniformed Services University (Dr. Eric Laing) works with PICREID to co-lead the efforts in sharing protocols or approaches and planning for the development and optimization of a multiplex, species independent, Luminex-bead based serology assay for MPXV, collaborating with DMID. Meanwhile, EID-SEARCH has been actively participating in the network's response to Monkeypox by providing local partnerships and monitoring platforms in DRC and Thailand.
- For lab assay sharing, EID-SEARCH partner Uniformed Services University (Dr. Eric Laing) is working with WAC-EID PIs, Dr. Robert Cross and Dr. Scott Weaver, to establish an MTA with UTMB and regional partners in Liberia and Nigeria for the multi-family FLV/HNV MMIA for anti-EBOV serology testing. Enquiries has been made with Dr. Mark Page and the National Institute for Biological Standards and Control (NIBSC) regarding additional MARV and NiV serology standards.
- We have been communicating with multiple Research Centers regarding the Field Biosafety Manual presented at the CREID Scientific Meeting by EID-SEARCH senior field veterinarian (Dr. Marc Valitutto). The Manual and corresponding training resources will be made available to all CREID members once the peer review process is completed in Fall 2022.
- EID-SEARCH has provided scientific expertise on CCHF, Henipavirus, RVF related research by connecting CREID members with our research partners via the Outbreak Research Response working group or other *ad hoc* requests.

Commented [K039]: Correct date?

Section 4: Future Directions

- Plan for the next reporting period.
- How is your Research Center adapting to the April 2022 NIAID Program Priorities and how does this change (or not) your planned activities in the next year? *See Appendix B for NIAID Program Priorities.*
- Moving forward, what is the greatest opportunity your RC has to advance the knowledge base for emerging infectious diseases? What are the significant knowledge gaps that the RC can advance research on?

In the next reporting period, we will continue to follow the research plan laid out in our original proposal which aligns with the CREID network overall research priorities, as follows:

Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.

- Wildlife (bats, rodents, and non-human primates) sampling at selected sites, with plans to increase sampling of rodents and non-human primates and potential longitudinal sampling at selected sites to analyze patterns of viral shedding and spillover risk.
- Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 3-5 of the project. Refine models to analyze cost-efficacy of viral discovery.
- Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses, filoviruses, and paramyxoviruses.
- Perform serology testing on the wildlife samples for coronaviruses, filoviruses, and henipaviruses.

- Continue developing a more comprehensive multiplex CoV RBD-based sVNT covering newly identified sarbecoviruses and additional merbecoviruses to allow the evaluation of neutralizing activity in serum samples against a much broader and more comprehensive range of RBDs.
- Conduct in-country whole-genome and spike glycoprotein sequencing for newly identified viruses.
- Continue research to further characterize a subset of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies, including pangolin GD strain, BANAL-52, and other significant viruses identified in Y1-3.

Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays

- Increase the number of sites and enrolled participants for community surveillance among at-risk populations for biological and behavioral data collection in Thailand, Peninsular Malaysia, and Sabah Malaysia. Identify community sites concurrent with animal surveillance sites (Specific Aim 1).
- Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and paramyxoviruses. Test pre-COVID-19 archived human sera using sarbecovirus multiplex serology panel.
- Conduct epidemiological analyses of biological and behavioral data

Commented [KO40]: We didn't mention the CDC collaboration in Thailand, but probably as the details are not yet worked out – so maybe best.

Specific Aim 3: Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts

- Start enrolling participants at selected hospital/clinic sites for syndromic surveillance at two sites in Thailand, and identified sites in Sabah, Malaysia and Peninsular Malaysia, Malaysia
- Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.
- Start serological and molecular testing on collected human samples.
- Start viral characterization work if any novel viruses are identified.

Through the work under Specific Aims 2&3, we are engaging multiple disciplines of social science, anthropology, health policy, and behavioral science towards EID risk mitigation strategies on key human-animal interfaces, we will share relevant research methods (e.g., behavioral questionnaires) and best practices with the CREID Network members.

Training and capacity-building activities among in-country team members, especially young EIDs researchers, to strengthen domestic, regional, and international capacity and readiness to efficiently undertake the research required in response to emerging or re-emerging threats. Available training materials or resources will be made available to the CREID Network.

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures and discussion as well as hands-on guidance.
- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing.
- Conduct training in traditional viral whole-genome sequencing using primer walking for paramyxoviruses.
- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training.
- Trial the use of the portable Oxford Nanopore MinION platform as an in-house sequencing solution in Malaysia.
- Continue training on multiplex microsphere immunoassay (MMIA) data analysis and interpretation.
- Conduct refresh training on human research regarding survey design, interview skills, and data analysis.

Commented [SN41]: Would it be possible to propose training on RBD and/or spike glycoprotein design and coupling?

- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer-review, publication, and broad distribution.
- Continue sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government in a timely manner.
- Organize meetings and workshop with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region (November 2022).
- Initiate exchange training for young researchers among EID-SEARCH partners for NGS and other laboratory technology transfers.
- Support in-country outbreak research and response as requested.

Appendix A: 2021 EAC Report

Centers for Research in Emerging Infectious Diseases (CREID) CREID External Advisory Committee (EAC) Summary In follow up to the CREID Network Annual Meeting November 3-5, 2021 (virtual meeting)

Prepared by Mark Feinberg, MD, PhD on behalf of the CREID EAC

Overview of EAC Perspectives and Recommendations

The EAC members were unanimous in their assessment that the CREID Network team made very impressive and positive progress in their first year of this very important and timely new NIAID/DMID initiative. While the amount of progress realized in starting up a new global collaborative research network would be highly laudable overall in any circumstance, the EAC members were even further impressed by the fact that the initiation of the CREID Network coincided with the emergence of the COVID-19 pandemic (with all of its attendant challenges). This coincidence provided a clear initial focus for many of the CREID efforts on SARS-CoV-2-related topics, but it also provided very strong validation for the original rationale for establishment of the CREID Network by the NIAID/DMID leadership as a means of fostering global networks for research collaboration on emerging infectious disease threats. While the EAC members identified a number of areas where additional attention and effort will be beneficial to maximize the impact of the CREID Network, and key to fostering the sustainability of its efforts, our expectations for what the Network has the potential to accomplish were raised by the strong foundation that the CREID PIs and collaborators have already put in place in their first year. We were also very impressed with the clear commitment, thoughtfulness and inclusive approach of the CC leadership, and with the expertise, passion, and experience of the broader CREID Network community of scientists. At the heart of the CREID is a commitment to new models of collaborative science that links investigators from around the world to understand, prepare for, and respond to emerging infectious disease threats. As such, the extent to which CREID utilizes current best practices for collaborative research and pioneers new ones; embraces the essential role played by investigators working in countries at risk for disease emergence (including resource-limited settings); partners in new and more effective and mutually trusting ways with governments, normative agencies and other emerging infectious disease-focused research organizations; exemplifies and communicates the value of scientific research in providing solutions to emerging infectious disease threats to governments and the public; and delivers on its commitment to genuine research capacity strengthening and sustainability will be critical measures for evaluating the future success of the CREID. The EAC recognizes that this is a very ambitious agenda filled with often challenging objectives, and that the inherent nature of time-limited NIH funding mechanisms presents additional challenges to their potential realization. In considering these issues, the EAC felt that significant progress has been made in the first year of the CREID Network, but that additional opportunities exist for the PIs and CREID investigators to be even more intentional and strategic about their collaborative research efforts. The CREID Network has the opportunity to establish a number of positive precedents in models of effective global collaborative science where the “whole is truly greater than the sum of its parts”; by demonstrating new approaches for the “decolonization” of international research; and by delivering on a strong commitment to diversity and inclusion in all of its endeavors. In many ways, achieving these goals will require innovation in collaborative research models within a large global network, and not just in delivering innovative, high quality scientific research results. The EAC members recognize the challenge of finding the right balance between investigator- and RC-initiated science with broader strategies and shared goals of a large collaborative network, but also note that doing so will require an overarching strategy, effective

communication tools and ongoing performance monitoring and adjustment. The EAC members also recognize that the important Network goals of research capacity strengthening and sustainability are not trivial undertakings and that they are very promising, but also rather novel objectives, within the context of NIH-supported research programs. These are additional important areas where the CREID CC and RC leadership can further articulate a respectful, inclusive, realistic, achievable and measurable strategy.

In all of these areas, the EAC recommends that the CREID investigators further develop and implement (a) a clear, well-defined and shared set of Network priorities (that links the work across RCs) and key performance indicators (KPIs) to measure performance toward realizing them, (b) a shared strategic vision and plan that connects the research efforts being prioritized and conducted across the Network centers, (c) a mechanism to share best practices across the Coordinating Center (CC) and Research Centers and (d) a proactive approach to identify collaborative research opportunities, fill gaps, avoid duplication and pursue synergies both within the CREID Network and, importantly, with the large and growing number of other organization working on preparing for and responding to emerging infectious disease outbreaks. Clarity and specificity in these efforts will be beneficial, as well as adopting an appropriate sense of realism about what can be accomplished by the CREID Network itself and where the new partnerships it implements with other organizations working in the emerging infectious disease arena will be essential. In this regard, given the complexity of the emerging infectious disease landscape, the CREID Network's ability to have the most significant impact will likely depend on the connections it establishes with other stakeholders and the innovation it drives in conceptualizing and delivering on effective new collaborative endeavors it develops with other capable partners. Towards this end, the Network would benefit from developing a thorough understanding of the ecosystem of potential partners and a defined approach to engage with the most relevant and promising ones. In addition, while the CREID Network includes collaborators from many centers and countries, its true global scope is limited by gaps in its geographic coverage (eg, countries in Asia, the Middle East, Northern Africa, Australia, etc...including those where risk of pathogen emergence are significant). Understanding if the CREID Network will be limited by its current geographic reach or plans to work to build additional connections (perhaps via strategic partnerships) in other regions will be beneficial from both practical and strategic levels.

Given that the readiness of the CREID Network for future outbreak response (and to be able to perform research in the midst of an outbreak when many challenges prevail) and for pandemic preparedness is a priority for NIAID/DMID, it will be important for the Network to clearly define how they best proactively plan to be able to promptly implement critical research programs when a new pathogen emerges or a previously known one reemerges. It will also be beneficial for the CREID CC and RCs to develop a clear plan (including protocols for coordination, implementation, data sharing and communication) to enable the Network to be able to respond expeditiously to an emerging infectious disease threat. Towards this end, tabletop exercises (or similar) to "pressure test" Network approaches and identify gaps/opportunities for improvement are worth considering.

The EAC is excited about what the CREID CC and RCs, and all of the collaborating CREID investigators, have accomplished in their first year of work and look forward to seeing the innovations and insights the Network will deliver in the future. The EAC recognizes that the CREID Network cannot realistically be "all things for all people", and should not strive to be. WE therefore also look forward to seeing how your Network priorities are further articulated, implemented and measured moving forward.

Additional EAC Impressions

The EAC felt that the Executive Summary of the CREID Network Annual Meeting provided an accurate overview of the meeting proceedings and of the EAC feedback provided at the end of the meeting proceedings. Some specific additional impressions/requests shared by EAC members include:

- Gaining a better understanding of how CREID investigators are interfacing with local governments and ministries, public health authorities (eg, WHO, US CDC, Africa CDC, etc), normative agencies will be helpful, and how learnings of effective approaches should be shared across the Network. In addition, optimization of engagements with other research organizations, enabling disciplines (eg, social science, health economics, health policy, ethics), as well as the medical countermeasures community, will be helpful
- Gaining a better understanding of the experience to date in data sharing efforts and how these can be optimized
- Gaining a better understanding of how bilateral sharing of research materials and specimens can be optimized (given the role of host institutions and government policies) and how these might operate during an outbreak/pandemic
- How the CREID investigators view and are approaching their educational efforts with governments, political leaders and the public, and sharing of best practices for engagement and trust-building
- How the CREID Network is engaging with industry partners that both supply enabling tools and technologies and who may also assist in the development and commercialization of CREID-advanced innovations (eg, diagnostics)
- Opportunities exist to demonstrate the CREID commitment to decolonization of global health (with increased attention to having the voices from LMIC-based investigators better balanced with those of US-based investigators)
- Opportunities exist to better model the Network's and the NIH's commitment to DEI objectives (with increased attention to full representation in all aspects of the work...including presentations, leadership groups, pilot research awards)
- Opportunities for enhancing epidemiology, bioinformatics, digital tools and modeling capacity
- Gaining a better understanding of the role of social and cultural aspects of the outbreak response and communication, and exploring innovative approaches to address them
- Understanding how engagement with governments and other local stakeholders is being pursued to advance capacity strengthening and sustainability goals
- Further articulation of rapid response collaboration frameworks
- Gaining a better understanding of how local priorities influence the prioritization decisions of the CC and RCs
- Gaining a better understanding/"needs assessment" of capacity gaps (eg, BSL-3 training and labs) and how these are being addressed via strategic connections or focused investment
- How "parachute or safari research" is avoided, and how local researchers are engaged as full partners/leaders
- Definition of opportunities to maximize speed and efficiency in research implementation efforts (eg, US permits and in-country regulations, IRB delays, key relationship gaps) needed for prompt outbreak responses
- Value of developing a clear vision and plan for sustainability that maximizes the connection with and contributions of other partners and local governments
- South-South collaboration should be applauded and fostered
- Shared EAC interest in seeing the CREID Network's progress in ongoing database and biorepository workstreams

Appendix B: NIAID CREID Network Program Priorities (April 2022)

(4 main priorities all carry equal weight and are intended to cover research and activities to prepare for and respond to emerging and re-emerging threats.)

- **Conduct innovative research to expand our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats**
 - Research Priorities:
 - Pathogen discovery & characterization
 - Pathogen/host surveillance
 - Pathogen transmission
 - Pathogenesis & immunologic responses in the host
 - Natural history & contemporary clinical disease
 - Develop reagents & diagnostic/detection assays
 - Engage in coordinated, Network wide outbreak/pandemic research readiness, differentiated from standard public health responses
- **Establish a collaborative, strategic, and preemptive research Network to ensure coordination of efforts across the Network**
 - Centralize communication
 - Conduct Network wide capacity inventory
 - Establish effective data harmonization and platforms for sharing
 - Harmonize sample collection, biorepositories, and network sharing/agreements
 - Share laboratory assay best practices and protocols
 - Share reagents, diagnostic/detection assays, and other resources
- **Develop and expand flexible domestic and international capacity and readiness to efficiently undertake research required in response to emerging or re-emerging threats**
 - Prioritize and engage with key stakeholders that will enhance network capabilities and integrate into the global health landscape
 - Strengthen and enhance research collaboration and partnerships globally
 - Pivot programmatic priorities and resources when needed for a timely response to emerging or re-emerging pathogen threats
 - Develop protocols for coordination, implementation, data sharing, and communication.
 - Execute tabletop exercises to test, refine, and maintain Network readiness
 - Formulate novel strategies to detect, control, and prevent outbreaks
 - Translate findings to downstream partners to facilitate development of medical countermeasures or preventive interventions
 - Develop adaptable risk assessment tools for evaluating a pathogen threat's potential for significant emergence and impact
- **Contribute to the development of the next generation of emerging/re-emerging infectious disease scientists and leaders**
 - Develop and maintain a pilot research program
 - Foster a diverse and inclusive research environment and program

Page 6: [1] Commented [MOU24] Microsoft Office User 8/2/2022 8:39:00 AM

Replication, not infection or disease model? What did these mAb and vaccine protect from, infection?

Page 6: [2] Commented [GLE25R24] Gralinski, Lisa E 8/16/2022 2:11:00 PM

Mice show no weight loss after pangolin infection but have high virus titer at days 2 and 4 post-infection so mice are a good virus replication model. We can block virus replication in mice with ADG2 antibody treatment or vaccination for SARS2.

Page 6: [3] Commented [MOU26] Microsoft Office User 8/2/2022 8:41:00 AM

What does this mean, sera from humans with memory to seasonal beta-human coronaviruses can cross-neutralize PgCoV-GD, by binding recognition to the S2 fusion domains?

Page 6: [4] Commented [MOU28] Microsoft Office User 8/2/2022 8:43:00 AM

I didn't see any mention of FDA-approved antibody therapies or vaccine countermeasures being tested in the sentences before.

Tighten this up with explicit details.

Page 6: [5] Commented [KO29] Kevin Olival 8/15/2022 8:29:00 PM

Think it's okay to make a little longer than one sentence as this is interesting stuff. I shortened a bit tho.

Page 6: [6] Commented [LH30] Li, Hongying 8/15/2022 12:02:00 PM

Peter and Kevin - please shorten this if possible, we don't have space, and may not want to include these details.

Page 6: [7] Commented [KO32] Kevin Olival 8/15/2022 8:36:00 PM

Unless we get a much simpler figure, I would suggest we ditch the figures and just describe the results as we do. OR, maybe we just include the FV and Henipa figures and not the CoVs as it's complicated.

Section 1. Executive Summary

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary center focused on analyzing zoonotic disease risk in a key EID hotspot region. Our aims are to 1) characterize diverse coronaviruses (CoVs), paramyxoviruses (PMVs), filoviruses (FVs), and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in Thailand, Malaysia, and Singapore. Highlights of research and significant findings during the reporting period (October 2021 – August 2022) include:

- Developed and optimized multiplex serological assays including pan-sarbecovirus and Henipavirus multiplex surrogate virus neutralization test (sVNT); transferred these technologies to labs in Thailand and Malaysia; shared protocols with other CREID Network centers.
- Conducted extensive sampling of bat, rodent and non-human primate populations; discovered 8 putative novel CoVs and 8 novel paramyxoviruses
- Sequenced full genome of a SARS-CoV-2-related CoV from bat samples in Thailand associated with bat guano collectors. New CoV has higher RBD sequence identity to SARS-CoV-2 than BANAL group, is most closely related to RaTG13 (RBD), but binds to human ACE2.
- Began human community surveillance in Thailand at sites with high human-wildlife contact.
- Obtained serological evidence of filovirus and paramyxovirus (Mojiang-related) spillover in humans.
- Supported viral diarrhea outbreak investigation in Chanthaburi province, Thailand.
- Strengthened outbreak preparedness for Monkeypox virus with Ministry of Public Health and detected first cases in Thailand (July 2022).
- Tested whether Swine Acute Diarrhea Syndrome coronavirus (SADS-CoV) and pangolin CoV can infect human cells, and efficacy of existing CoV therapeutics and vaccines against them.
- Published 9 peer-reviewed papers; 4 others in revision, and 3 more in prep.
- Drafted first ever comprehensive Field Biosafety Manual. Currently being peer-reviewed, revised and will be shared broadly with CREID Network in Fall 2022, then publicly.
- Strengthened cross-Research Center communication via information sharing for outbreak research response and sharing protocol and diagnostic assays.

Section 2: Research Center Overview

A. Specific Aims

The overarching goal of the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is to characterize the diversity of key viral pathogens in wildlife, assess the frequency and causes of their spillover, and identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in people. The research goals of the EID-SEARCH follow three specific aims designed to advance our understanding of spillover and outbreak risk for novel viruses in a globally important EID hotspot, strengthen in-country research capacity, and enhance international collaboration:

1. Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.
2. Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.
3. Identify and characterize the viral etiology of ‘cryptic’ outbreaks in clinical cohorts.

B. Partners and Staffing

EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions (EcoHealth Alliance PI Peter Daszak; University of North Carolina Co-I Ralph Baric; Uniformed Service University Co-Is Christopher Broder and Eric Laing), and in Thailand (Chulalongkorn University Co-Is Supaporn Wacharapluesadee and Opass Pucharoen), Singapore (Duke-NUS Medical School Co-I Linfa Wang), and

the three major Malaysian administrative regions (Conservation Medicine Co-I Tom Hughes). These organizations represent the ‘hub’ of the center, with an additional, more informal collaborative network of research partners across almost all Southeast Asian countries. By enhancing and focusing research within the three hub countries, and coordinating communication among the network, EID-SEARCH acts as an early warning system for outbreaks; a way to exchange information, reagents, samples, and technology; and a collaborative powerhouse for translational research. EID-SEARCH is supported by a multidisciplinary team of researchers at our partner institutions, with skills in epidemiology, clinical management, molecular biology, virology, wildlife biology, and advanced data and statistical analyses. The long collaborative history between the key personnel and partner institutions has facilitated our outbreak research response in the region.

C. Research Sites

The three core (hub) countries for the EID-SEARCH are Thailand, Malaysia, and Singapore, *expanded to include Viet Nam (in 2021) and Cambodia (in 2022) through the CREID Pilot Research Program*. Our geography covers one of the most significant foci of EID risk globally. We have also assembled an informal network of EID-SEARCH partners that includes >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries – stretching from Nepal to the Philippines. These provide updates on outbreaks and research in their countries. Our work includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sabah, Viet Nam, and Cambodia. Our field sites in mainland Southeast Asia allows us to sample representative wildlife species that occur across the greater biogeographic region, including India, Bangladesh, Myanmar, Southwest China, Laos, Cambodia, Philippines, and Indonesia, and thus characterize zoonotic disease risk more broadly outside our study area.

Section 3: Research Center Progress and Accomplishments

A. Projects and Studies

Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife

- **Field surveillance among wild bats, rodents, and non-human primates.** To date, we have collected 18,033 specimens from 2,660 animals of 31 bat species, one non-human primate (NHP) species, and five rodent species from 9 sites at high-risk human-wildlife interfaces (Table 1).

Table 1. EID-SEARCH summary of sampling and virus surveillance in wildlife in Thailand and Malaysia.

	Thailand	Malaysia
# samples ¹	3,862	14,171
# individuals	454 bats, 106 rodents, 100 NHPs	2,000 bats
# species	6 (bats), 5 (rodents) 1 (NHP)	24 (bats)
# sites	5	4
# individuals tested	506	1,332
# PCR tests for CoVs, PMVs, FLVs, influenza viruses	5,063	9,228
Divergent viral PCR sequences (RdRp) detected ²	3 novel CoVs from 11 bats ³ (in 1 species) 3 known PMVs from 4 rodents (in 2 species) 4 novel PMVs from 11 bats (in 1 species)	5 novel CoVs from 112 bats (in 3 species) 4 novel PMVs from 10 bats (in 2 species) 2 known PMVs from 2 bats (in 1 species)
# specimens for multiplex immunoassay for FLVs, CoV, Henipaviruses	100 (macaques) 92 (rodents)	720 (bats)

¹ Specimens include oral swabs, rectal swabs, urogenital swabs, and whole blood, types of specimens may vary among individual animals.

² Further studies are underway to classify and characterize these divergent viral sequences. Partial-gene phylogenetic trees suggest that these are potentially “novel viruses”.

³ Complete whole genome sequences were obtained from 3 samples and partial whole genome sequences obtained from (8 samples), further viral characterization studies underway.

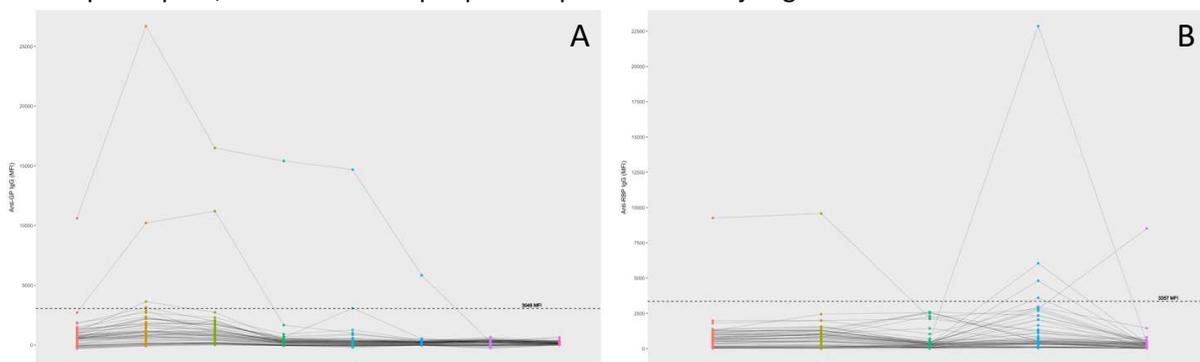

- **Discovery of novel bat SARS-related coronavirus in Thailand.** Whole genomes of novel sarbecoviruses from *Rhinolophus pusillus* revealed a 91.72% nucleotide similarity to SARS-CoV-2. Phylogenetic analysis suggested that this virus is closer to pangolin CoV-GD-1 than to SARS-CoV-2; however, the receptor binding domain (RBD) is most closely related to bat-CoV RaTG13. Experimental assays suggest that this new virus binds to human ACE2 receptors and is able to mediate cell entry. Whole-genome sequencing of additional novel CoVs from Thailand and Malaysia is ongoing, plans to look for furin cleavage sites using NGS are underway.
- **Genome-wide CRISPR knockout screen identifies essential factor for HKU2/SADS-CoV infection.** Using a genome-wide CRISPR knockout screen, we identified placenta-associated 8 protein (PLAC8) as an essential host factor for Swine Acute Diarrhea Syndrome coronavirus (SADS-CoV) infection of human cells. Infection is prevented in PLAC8 knockouts and can be restored by transiently transfecting PLAC8 from multiple species, including human, pig, mouse, and bat. Trypsin treatment of SADS-CoV bypasses the PLAC8-dependent pathway and partially rescues SADS-CoV infection. PLAC8 is involved in both early entry and later dissemination of SADS-CoV infection and PLAC8 KO cells have: 1) delayed and reduced viral subgenomic RNA expression and 2) diminished cell-to-cell viral spreading of infected cells. *These results suggest that PLAC8 is a promising target for antiviral development for the potential pandemic SADS-CoV virus.*
- **Host range, transmissibility, and antigenicity of a pangolin coronavirus.** Using a synthetically derived infectious cDNA clone, we recovered the Guangdong wildtype pangolin (Pg) CoV-GD and derivatives encoding indicator genes. Like SARS-CoV-2, PgCoV-GD virus efficiently uses human and many other orthologous mammalian ACE2 receptors for entry, shares a similarly broad host range *in vitro*, and displays altered sensitivity to host proteases. PgCoV-GD replicates to slightly higher to lower titers in primary human cells derived from the proximal to distal lung, respectively, and with reduced fitness compared to SARS-CoV-2. PgCoV-GD also replicates efficiently in hamsters and could transmit via the aerosol route, but at a lower frequency than SARS-CoV2. Efficient PgCoV-GD replication in primary nasal airway epithelial cells and transmission in the hamster highlights the high emergence potential of this virus. However, PgCoV-GD is efficiently neutralized by COVID-19 patient sera and many commercially available SARS-CoV-2 therapeutic antibodies, but not by human antibodies targeting the spike N-terminal domain. A pan-sarbecovirus antibody, ADG-2, and a SARS-CoV-2 prefusion stabilized spike protein recombinant protein vaccine protected mice in a PgCoV-GD replication model. We showed that cross-neutralizing antibodies in pre-immune SARS-CoV-2 humans and the benefit of current COVID-19 countermeasures should impede its ability to emerge and spread globally in humans. *This research helps demonstrate the efficacy of FDA-approved therapeutic antibodies against a range of CoVs with emergence potential, allowing for the creation on-the-shelf therapeutics to target future emerging coronaviruses. As all FDA approved or emergency authorized vaccines express the prefusion stabilized spike this work further shows that FDA-approved SARS-CoV-2 vaccines also protect animals from PgCoV-GD when challenged in vivo.*

Aims 2 & 3: Identify evidence and analyze risk factors for viral spillover in high-risk communities and clinical cohorts, and characterize viral etiology of ‘cryptic’ outbreaks

- **Incorporation our bat-CoV spike proteins into the multi-family multiplex-based immunoassay (MMIA).** Specific bat-CoV spike proteins including bat SARSr-CoVs RaT13, bat SARSr-CoV ZXC21, bat MERSr-CoV PDF2180, and HKU9 were designed as pre-fusion stabilized spike glycoprotein ectodomain trimers (S-2P). These spike protein antigens were incorporated into our 17-plex henipavirus/filovirus-focused serology assay expanding the representation of virus targets to include priority coronaviruses such as SARS-CoV-2 and bat SARSr-CoVs/bat MERSr-CoV. SOPs were revised and updated to reflect best practices that were optimized during Year 1.

- Community serology surveillance.** We initiated human surveillance work in Thailand, with 56 participants enrolled at one community surveillance site with high levels of bat-human contact, and 2 individuals from a clinic site, with a total of 58 participants enrolled. Serology testing using multi-family MMIA showed evidence of previous infection by Asiatic FLVs, PMVs, and CoV (Fig. 1). Preliminary data suggest several interesting findings: **First**, a single human serum sample was reactive with envelope glycoproteins (GP) from Ebola virus, Bundibugyo virus, Bombali virus, Sudan virus, and Lloviu virus, consistent with a serologic pattern of cross-reactivity due to exposure to a phylogenetically-related, likely novel, Asiatic ebolavirus. Follow-up testing will explore whether broad cross-reactions with FLVs antigens is driven by glycosylated epitopes that may be more conserved across the ebolaviruses than protein sequence similarity would imply. **Second**, Henipavirus serology showed one individual reactive with Hendra and Cedar virus, and several individuals with evidence of exposure to Mòjiāng virus or Mòjiāng virus-related viruses. **Third**, CoV serology was complicated by prior COVID-19 vaccination of participants. At the low testing titer, cross-reactions with phylogenetically related bat sarbecoviruses were expectedly observed – patterns we are currently exploring in more detail. Interestingly, two participants had sera IgG that bound to the bat MERSr-CoV PDF2180, which does not utilize the orthologous human DPP4/CD20 receptor for cellular entry, and it quite distinct from the sarbecoviruses.

Fig. 1 Multiplex serology testing results for filoviruses (A), paramyxoviruses (B) among high-wildlife contact community participants (n=56). Note the presence of antibodies against an unidentified filovirus in one participant, and a cluster of people seropositive for Mòjiāng-related virus.

- Design and application of pan-sarbecovirus multiplex surrogate virus neutralization test (sVNT)**
The assay covers SARS-CoV-2 variants of concern (Alpha, Beta, Gamma, Delta, Mu, Lambda, Omicron BA.1 and BA.2), clade-2 sarbecoviruses (BANAL-52, BANAL-263, GD-1, RaTG13, GX-P5L), clade-1 sarbecoviruses (Rs2018B, LYRa11, WIV-1, RsSHC014, Rs4231), SARS-CoV-1, and *the newly discovered bat SARSr-CoV we recently sequenced from Thailand*. This assay allows for the discrimination of past SARS-CoV-2 infection from that of other sarbecoviruses in human and animal samples, which will be critical for identifying cryptic spillover in people and progenitors of SARS-CoV-2 in animals.
We also have optimization and established a pan-henipavirus multiplex sVNT at Chulalongkorn University to screen human and animal samples for neutralizing antibodies via a virus-free/cell-culture free, bead-based serology assay.

Outbreak research response and preparedness in Thailand

- The Ministry of Public Health in Thailand requested support from EID-SEARCH for a viral diarrhea outbreak investigation in Chanthaburi province. We received samples from both Prapokklao Hospital (regional hospital) and Khlong Khut Health-Promoting hospital collected from 59 healthcare workers and students who had diarrhea during Dec. 2021-Feb. 2022. PCR tests were conducted for

six gastrointestinal viruses causing gastrointestinal tract infections including adenovirus, astrovirus, norovirus GI, norovirus GII, rotavirus, and sapovirus. 32 samples (**54.24%**) were positive for norovirus GII, which appears to be the likely etiological agent.

- In preparedness for Monkeypox outbreaks, EID-SEARCH's lab partner in Thailand coordinated with the Department of Medical Science, MOPH, National lab to establish the Monkeypox PCR testing platform in April 2022 and detected the first Monkeypox case in Thailand in July 2022.

B. Dissemination of Results

EID-SEARCH members were invited to present the project work at government and inter-government briefings (> 10), conference and university lectures (>13), panels and webinars (>18), and public interviews (>6) in Thailand, Malaysia, the US, regionally and internationally on the trends in global disease emergence, zoonotic surveillance, pandemic control and prevention, and research results from this project research activities. Nine (9) peer-reviewed papers have been published or posted as preprints from EID-SEARCH research, four (4) manuscripts are currently under revision, and three (3) manuscripts are in preparation for submission, including a risk assessment of HKU-2 viruses in the region, details of a novel SARS-CoV-2-like virus in Thailand, and serological results from high wildlife-exposure cohorts. We organized a workshop with 55 scientists and government officials from Thailand, Malaysia, Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, and Australia to present EID-SEARCH work, share knowledge, strengthen research capacity, and foster scientific collaborations in Southeast Asia.

C. Training and Capacity Building Activities

EID-SEARCH is committed to in-country capacity building to strengthen outbreak response and research and develop next-generation EID researchers in Southeast Asia. Within our network, nine (9) training sessions were conducted by EID-SEARCH partners in Thailand, Malaysia, and Viet Nam for project members, local government partners, universities, research institutes, and NGOs within the reporting period, 89 participants were trained in lab biosafety (2 training 32 participants), research biosafety (1 training 3 participants in Malaysia), lab monitoring (1 training 3 participants), Bio-plex and multiplex immunoassay introduction (1 training, 2 participants), applying data sharing tools (1 training 10 participants), serology data analysis (1 training, 14 participants), field biosafety and animal sampling SOPs (2 training sessions with 25 participants, virtual and in-person), to strengthen in-country research capacity and improve information sharing. Regular virtual meetings were held for results analysis, and hands-on lab and field training was conducted in Thailand and Viet Nam, all training was conducted to accommodate COVID conditions. As travel and COVID-19 restrictions have begun to be lifted, students, postdocs, and all EID-SEARCH research staff have been provided with professional development opportunities to travel to attend conferences, workshops, and other in-person training activities.

D. Challenges and Proposed Solutions

The only challenges we encountered during the reporting period were travel restrictions in our field partner countries, as well as a large number of hospitalized patients in local hospitals in Thailand and Malaysia due to COVID-19. The patient influx delayed human participant enrollment at targeted community and hospital sites and the subsequent laboratory analysis we anticipated in Year 2. To address these issues, we worked closely with in-country partners and stakeholders to continue assessing the situations (i.e., safety and research priorities of study sites) to ensure a rapid start of enrollment and focused on the refinement of assays to be ready for human surveillance. Meanwhile, to prevent a possible supply shortage of PPE and swabs as happened in early Year 2, we have identified supply sources to ensure we can procure the necessary consumables without significant delays. With travel

restrictions in Southeast Asian countries now beginning to be lifted, international travel of US-based staff to our field sites has begun (April 2022).

E. Examples of Network Collaboration

Through the participation of different CREID Working Groups, EID-SEARCH members participated in the network's outbreak research responses, capacity building, and cross-center collaboration by sharing expertise, leveraging existing local partnerships, and sharing protocols and relevant resources.

- In outbreak response and research to Monkeypox, EID-SEARCH partner Uniformed Services University (Dr. Eric Laing) works with PICREID to co-lead the efforts in sharing protocols or approaches and planning for the development and optimization of a multiplex, species independent, Luminex-bead based serology assay for MPXV, collaborating with DMID. Meanwhile, EID-SEARCH has been actively participating in the network's response to Monkeypox by providing local partnerships and monitoring platforms in DRC and Thailand.
- For lab assay sharing, EID-SEARCH partner Uniformed Services University (Dr. Eric Laing) is working with WAC-EID PIs, Dr. Robert Cross and Dr. Scott Weaver, to establish an MTA with UTMB and regional partners in Liberia and Nigeria for the multi-family FLV/HNV MMIA for anti-EBOV serology testing. Enquiries has been made with Dr. Mark Page and the National Institute for Biological Standards and Control (NIBSC) regarding additional MARV and NiV serology standards.
- We have been communicating with multiple Research Centers regarding the Field Biosafety Manual presented at the CREID Scientific Meeting by EID-SEARCH senior field veterinarian (Dr. Marc Valitutto). The Manual and corresponding training resources will be made available to all CREID members once the peer review process is completed in Fall 2022.
- EID-SEARCH has provided scientific expertise on CCHF, Henipavirus, RVF related research by connecting CREID members with our research partners via the Outbreak Research Response working group or other *ad hoc* requests.

Section 4: Future Directions

In the next reporting period, we will continue to follow the research plan laid out in our original proposal which aligns with the CREID network's overall research priorities, engage multiple disciplines of social science, anthropology, health policy, and behavioral science toward EID risk mitigation strategies on key human-animal interfaces, and share relevant research methods (e.g., behavioral questionnaires) and best practices with the CREID Network members:

Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.

- Wildlife (bats, rodents, and non-human primates) sampling at selected sites, with plans to increase sampling of rodents and non-human primates and potential longitudinal sampling at selected sites to analyze patterns of viral shedding and spillover risk.
- Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 3-5 of the project. Refine models to analyze cost-efficacy of viral discovery.
- Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses, filoviruses, and paramyxoviruses.
- Perform serology testing on the wildlife samples for coronaviruses, filoviruses, and henipaviruses.
- Continue developing a more comprehensive multiplex CoV RBD-based sVNT covering newly identified sarboviruses and additional merbecoviruses to allow the evaluation of neutralizing activity in serum samples against a much broader and more comprehensive range of RBDs.

- Conduct in-country whole-genome and spike glycoprotein sequencing for newly identified viruses.
- Continue research to further characterize a subset of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies, including pangolin GD strain, BANAL-52, and other significant viruses identified in Y1-3.

Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays

- Increase the number of sites and enrolled participants for community surveillance among at-risk populations for biological and behavioral data collection in Thailand, Peninsular Malaysia, and Sabah Malaysia. Identify community sites concurrent with animal surveillance sites (Specific Aim 1).
- Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and paramyxoviruses. Test pre-COVID-19 archived human sera using sarbecovirus multiplex serology panel.
- Conduct epidemiological analyses of biological and behavioral data
- Work with US CDC and Thailand MoH to test human samples for range of antibodies to high-risk viral agents

Specific Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts

- Start enrolling participants at selected hospital/clinic sites for syndromic surveillance at two sites in Thailand, and identified sites in Sabah, Malaysia and Peninsular Malaysia, Malaysia
- Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.
- Start serological and molecular testing on collected human samples.
- Start viral characterization work if any novel viruses are identified.

Training and capacity-building activities among in-country team members, especially young EIDs researchers, to strengthen domestic, regional, and international capacity and readiness to efficiently undertake the research required in response to emerging or re-emerging threats. Available training materials or resources will be made available to the CREID Network.

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures and discussion as well as hands-on guidance.
- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing.
- Conduct training in traditional viral whole-genome sequencing using primer walking for paramyxoviruses.
- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training.
- Trial the use of the portable Oxford Nanopore MinION platform as an in-house sequencing solution in Malaysia.
- Continue training on multiplex microsphere immunoassay (MMIA) data analysis and interpretation.
- Conduct refresh training on human research regarding survey design, interview skills, and data analysis.
- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer-review, publication, and broad distribution.
- Continue sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government in a timely manner.
- Organize meetings and workshop with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region (November 2022).
- Initiate exchange training for young researchers among EID-SEARCH partners for NGS and other laboratory technology transfers.
- Support in-country outbreak research and response as requested.

Appendix A: 2021 EAC Report

Centers for Research in Emerging Infectious Diseases (CREID)

CREID External Advisory Committee (EAC) Summary

In follow up to the CREID Network Annual Meeting

November 3-5, 2021 (virtual meeting)

Prepared by Mark Feinberg, MD, PhD on behalf of the CREID EAC

Overview of EAC Perspectives and Recommendations

The EAC members were unanimous in their assessment that the CREID Network team made very impressive and positive progress in their first year of this very important and timely new NIAID/DMID initiative. While the amount of progress realized in starting up a new global collaborative research network would be highly laudable overall in any circumstance, the EAC members were even further impressed by the fact that the initiation of the CREID Network coincided with the emergence of the COVID-19 pandemic (with all of its attendant challenges). This coincidence provided a clear initial focus of many of the CREID efforts on SARS-CoV-2-related topics, but it also provided very strong validation for the original rationale for establishment of the CREID Network by the NIAID/DMID leadership as a means of fostering global networks for research collaboration on emerging infectious disease threats.

While the EAC members identified a number of areas where additional attention and effort will be beneficial to maximize the impact of the CREID Network, and key to fostering the sustainability of its efforts, our expectations for what the Network has the potential to accomplish were raised by the strong foundation that the CREID PIs and collaborators have already put in place in their first year. We were also very impressed with the clear commitment, thoughtfulness and inclusive approach of the CC leadership, and with the expertise, passion, and experience of the broader CREID Network community of scientists. At the heart of the CREID is a commitment to new models of collaborative science that links investigators from around the world to understand, prepare for, and respond to emerging infectious disease threats. As such, the extent to which CREID utilizes current best practices for collaborative research and pioneers new ones; embraces the essential role played by investigators working in countries at risk for disease emergence (including resource-limited settings); partners in new and more effective and mutually trusting ways with governments, normative agencies and other emerging infectious disease-focused research organizations; exemplifies and communicates the value of scientific research in providing solutions to emerging infectious disease threats to governments and the public; and delivers on its commitment to genuine research capacity strengthening and sustainability will be critical measures for evaluating the future success of the CREID. The EAC recognizes that this is a very ambitious agenda filled with often challenging objectives, and that the inherent nature of time-limited NIH funding mechanisms presents additional challenges to their potential realization.

In considering these issues, the EAC felt that significant progress has been made in the first year of the CREID Network, but that additional opportunities exist for the PIs and CREID investigators to be even more intentional and strategic about their collaborative research efforts. The CREID Network has the opportunity to establish a number of positive precedents in models of effective global collaborative science where the “whole is truly greater than the sum of its parts”; by demonstrating new approaches for the “decolonization” of international research; and by delivering on a strong commitment to diversity and inclusion in all of its endeavors. In many ways, achieving these goals will require innovation in collaborative research models within a large global network, and not just in delivering innovative, high quality scientific research results. The EAC members recognize the challenge of finding the right balance between investigator- and RC-initiated science with broader strategies and shared goals of a large collaborative network, but also note that doing so will require an overarching strategy, effective

communication tools and ongoing performance monitoring and adjustment. The EAC members also recognize that the important Network goals of research capacity strengthening and sustainability are not trivial undertakings and that they are very promising, but also rather novel objectives, within the context of NIH-supported research programs. These are additional important areas where the CREID CC and RC leadership can further articulate a respectful, inclusive, realistic, achievable and measurable strategy.

In all of these areas, the EAC recommends that the CREID investigators further develop and implement (a) a clear, well-defined and shared set of Network priorities (that links the work across RCs) and key performance indicators (KPIs) to measure performance toward realizing them, (b) a shared strategic vision and plan that connects the research efforts being prioritized and conducted across the Network centers, (c) a mechanism to share best practices across the Coordinating Center (CC) and Research Centers and (d) a proactive approach to identify collaborative research opportunities, fill gaps, avoid duplication and pursue synergies both within the CREID Network and, importantly, with the large and growing number of other organization working on preparing for and responding to emerging infectious disease outbreaks. Clarity and specificity in these efforts will be beneficial, as well as adopting an appropriate sense of realism about what can be accomplished by the CREID Network itself and where the new partnerships it implements with other organizations working in the emerging infectious disease arena will be essential. In this regard, given the complexity of the emerging infectious disease landscape, the CREID Network's ability to have the most significant impact will likely depend on the connections it establishes with other stakeholders and the innovation it drives in conceptualizing and delivering on effective new collaborative endeavors it develops with other capable partners. Towards this end, the Network would benefit from developing a thorough understanding of the ecosystem of potential partners and a defined approach to engage with the most relevant and promising ones. In addition, while the CREID Network includes collaborators from many centers and countries, its true global scope is limited by gaps in its geographic coverage (eg, countries in Asia, the Middle East, Northern Africa, Australia, etc...including those where risk of pathogen emergence are significant). Understanding if the CREID Network will be limited by its current geographic reach or plans to work to build additional connections (perhaps via strategic partnerships) in other regions will be beneficial from both practical and strategic levels.

Given that the readiness of the CREID Network for future outbreak response (and to be able to perform research in the midst of an outbreak when many challenges prevail) and for pandemic preparedness is a priority for NIAID/DMID, it will be important for the Network to clearly define how they best proactively plan to be able to promptly implement critical research programs when a new pathogen emerges or a previously known one reemerges. It will also be beneficial for the CREID CC and RCs to develop a clear plan (including protocols for coordination, implementation, data sharing and communication) to enable the Network to be able to respond expeditiously to an emerging infectious disease threat. Towards this end, tabletop exercises (or similar) to "pressure test" Network approaches and identify gaps/opportunities for improvement are worth considering.

The EAC is excited about what the CREID CC and RCs, and all of the collaborating CREID investigators, have accomplished in their first year of work and look forward to seeing the innovations and insights the Network will deliver in the future. The EAC recognizes that the CREID Network cannot realistically be "all things for all people", and should not strive to be. WE therefore also look forward to seeing how your Network priorities are further articulated, implemented and measured moving forward.

Additional EAC Impressions

The EAC felt that the Executive Summary of the CREID Network Annual Meeting provided an accurate overview of the meeting proceedings and of the EAC feedback provided at the end of the meeting proceedings. Some specific additional impressions/requests shared by EAC members include:

- Gaining a better understanding of how CREID investigators are interfacing with local governments and ministries, public health authorities (eg, WHO, US CDC, Africa CDC, etc), normative agencies will be helpful, and how learnings of effective approaches should be shared across the Network. In addition, optimization of engagements with other research organizations, enabling disciplines (eg, social science, health economics, health policy, ethics), as well as the medical countermeasures community, will be helpful
- Gaining a better understanding of the experience to date in data sharing efforts and how these can be optimized
- Gaining a better understanding of how bilateral sharing of research materials and specimens can be optimized (given the role of host institutions and government policies) and how these might operate during an outbreak/pandemic
- How the CREID investigators view and are approaching their educational efforts with governments, political leaders and the public, and sharing of best practices for engagement and trust-building
- How the CREID Network is engaging with industry partners that both supply enabling tools and technologies and who may also assist in the development and commercialization of CREID-advanced innovations (eg, diagnostics)
- Opportunities exist to demonstrate the CREID commitment to decolonization of global health (with increased attention to having the voices from LMIC-based investigators better balanced with those of US-based investigators)
- Opportunities exist to better model the Network's and the NIH's commitment to DEI objectives (with increased attention to full representation in all aspects of the work...including presentations, leadership groups, pilot research awards)
- Opportunities for enhancing epidemiology, bioinformatics, digital tools and modeling capacity
- Gaining a better understanding of the role of social and cultural aspects of the outbreak response and communication, and exploring innovative approaches to address them
- Understanding how engagement with governments and other local stakeholders is being pursued to advance capacity strengthening and sustainability goals
- Further articulation of rapid response collaboration frameworks
- Gaining a better understanding of how local priorities influence the prioritization decisions of the CC and RCs
- Gaining a better understanding/"needs assessment" of capacity gaps (eg, BSL-3 training and labs) and how these are being addressed via strategic connections or focused investment
- How "parachute or safari research" is avoided, and how local researchers are engaged as full partners/leaders
- Definition of opportunities to maximize speed and efficiency in research implementation efforts (eg, US permits and in-country regulations, IRB delays, key relationship gaps) needed for prompt outbreak responses
- Value of developing a clear vision and plan for sustainability that maximizes the connection with and contributions of other partners and local governments
- South-South collaboration should be applauded and fostered
- Shared EAC interest in seeing the CREID Network's progress in ongoing database and biorepository workstreams

Appendix B: NIAID CREID Network Program Priorities (April 2022)

(4 main priorities all carry equal weight and are intended to cover research and activities to prepare for and respond to emerging and re-emerging threats.)

- **Conduct innovative research to expand our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats**
 - Research Priorities:
 - Pathogen discovery & characterization
 - Pathogen/host surveillance
 - Pathogen transmission
 - Pathogenesis & immunologic responses in the host
 - Natural history & contemporary clinical disease
 - Develop reagents & diagnostic/detection assays
 - Engage in coordinated, Network wide outbreak/pandemic research readiness, differentiated from standard public health responses
- **Establish a collaborative, strategic, and preemptive research Network to ensure coordination of efforts across the Network**
 - Centralize communication
 - Conduct Network wide capacity inventory
 - Establish effective data harmonization and platforms for sharing
 - Harmonize sample collection, biorepositories, and network sharing/agreements
 - Share laboratory assay best practices and protocols
 - Share reagents, diagnostic/detection assays, and other resources
- **Develop and expand flexible domestic and international capacity and readiness to efficiently undertake research required in response to emerging or re-emerging threats**
 - Prioritize and engage with key stakeholders that will enhance network capabilities and integrate into the global health landscape
 - Strengthen and enhance research collaboration and partnerships globally
 - Pivot programmatic priorities and resources when needed for a timely response to emerging or re-emerging pathogen threats
 - Develop protocols for coordination, implementation, data sharing, and communication.
 - Execute tabletop exercises to test, refine, and maintain Network readiness
 - Formulate novel strategies to detect, control, and prevent outbreaks
 - Translate findings to downstream partners to facilitate development of medical countermeasures or preventive interventions
 - Develop adaptable risk assessment tools for evaluating a pathogen threat's potential for significant emergence and impact
- **Contribute to the development of the next generation of emerging/re-emerging infectious disease scientists and leaders**
 - Develop and maintain a pilot research program
 - Foster a diverse and inclusive research environment and program

Section 1. Executive Summary

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary center focused on analyzing zoonotic disease risk in a key EID hotspot region. Our aims are to 1) characterize diverse coronaviruses, paramyxoviruses, filoviruses, and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in Thailand, Malaysia, and Singapore. Highlights of research and significant findings during the reporting period (October 2021 – August 2022) include:

To be updated with bullet points by Peter...

Section 2: Research Center Overview

A. Specific Aims

The overarching goal of the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is to characterize the diversity of key viral pathogens in wildlife, assess the frequency and causes of their spillover, and identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in people. The research goals of the EID-SEARCH follow three specific aims designed to advance our understanding of spillover and outbreak risk for novel viruses in a globally important EID hotspot, strengthen in-country research capacity, and enhance international collaboration:

- Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.
- Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.
- Specific Aim 3: Identify and characterize the viral etiology of ‘cryptic’ outbreaks in clinical cohorts.

B. Partners and Staffing

EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions (EcoHealth Alliance PI Peter Daszak; University of North Carolina Co-I Ralph Baric; Uniformed Service University Co-Is Christopher Broder and Eric Laing), and in Thailand (Chulalongkorn University Co-Is Supaporn Wacharapluesadee and Opass Putcharoen), Singapore (Duke-NUS Medical School Co-I Linfa Wang), and the three major Malaysian administrative regions (Conservation Medicine Co-I Tom Hughes). These organizations represent the ‘hub’ of the center, with an additional, more informal collaborative network spanning >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries. By enhancing and focusing research within the three hub countries, and coordinating communication among the network, we envision EID-SEARCH acting as an early warning system for outbreaks; a way to exchange information, reagents, samples, and technology; and a collaborative powerhouse for translational research. EID-SEARCH is supported by a multidisciplinary team of researchers at our partner institutions, with skills in epidemiology, clinical management, molecular biology, virology, wildlife biology, and advanced data and statistical analyses. The long collaborative history between the key personnel and partner institutions is a significant asset that can be deployed to support outbreak research response in the region.

C. Research Sites

The three core (hub) countries for the EID-SEARCH are Thailand, Malaysia, and Singapore, *expanded to Viet Nam and Cambodia through the CREID Pilot Research Program*. These stretch through one of the

most significant foci of EID risk globally. Additionally, we have assembled a greater network of EID-SEARCH partners that includes >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries – stretching from Nepal to the Philippines. Our targeted field research includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak, Sabah, Viet Nam, and Cambodia. The central location of our hub countries in mainland Southeast Asia allows us to sample representative wildlife species that occur in other countries across the greater biogeographic region, including India, Bangladesh, Myanmar, Southwest China, Laos, Cambodia, Philippines, and Indonesia.

Section 3: Research Center Progress and Accomplishments

Progress and Accomplishments

- Organized by Aim
- Focus on key accomplishments
- Address outbreak research response if applicable
- Address how the 2021 EAC recommendations have been incorporated (see Appendix A for 2021 EAC report)

A. Projects and Studies

- Have you reverted to your original (pre-pandemic) CREID research agenda in the last year? If not, how has your research agenda changed in the last year due to the ongoing impact of SARS-CoV-2?
- What additional changes to your CREID research agenda have taken place in the last year?

Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife

- Field surveillance among wild bats, rodents, and non-human primates.** We have collected 14,302 specimens from 2,055 animals of 31 bat species, one non-human primate (NHP) species, and five rodent species from six sites at high-risk human-wildlife interfaces in Malaysia and Thailand. (Table 1)

	Thailand	Malaysia
No. of collected specimens	3,862	14,171
No. of individuals	454 bats, 106 rodents	2,000 bats
No. of species	6 (bats), 5 (rodents)	24 (bats)
No. of sites	5	4
No. of tested individuals	407	1,332
No. PCR tests for coronaviruses (CoVs), paramyxoviruses (PMVs), filoviruses (FLVs), influenza viruses (IVs)	4,070	9,228
Identified viruses	1 new CoV from 3 bats 3 known PMVs from 4 rodents 4 new PMVs from 11 bats	5 new CoVs from 112 bats 4 new PMVs from 10 bats 2 known PMVs from 2 bats
No. of specimen for multiplex immunoassay for FLVs and Henipavirus	-	720 bats

Table 1. EID-SEARCH viral surveillance in wildlife in Malaysia and Thailand.

- Discovery of novel SARS-like beta-coronavirus in bats in Thailand.** The whole genomes revealed a 91.72% nucleotide similarity to SARS-CoV-2. Phylogenetic analysis suggested that this virus is closer to pangolin CoV-GD-1 than to SARS-CoV-2; however, the RBD is more similar to that of bat-CoV RaTG13, suggesting that this new virus may also bind to mammalian ACE2 receptors. Whole-genome sequencing of other new CoVs from Thailand and Malaysia is ongoing.
- Genome-wide CRISPR knockout screen identifies essential factor for HKU2/SADS-CoV infection.** Using a genome-wide CRISPR knockout screen, we identified placenta-associated 8 protein (PLAC8) as

Commented [MOU1]: Footnote about what “specimens” includes, how were 14,000 specimens obtained from 2,000 bats. 1 bat -> blood sample, oral swab, rectal swab, body swab, ectoparasite removed, wing puncture, etc...

Commented [MOU2]: I’m not a mol. evol. geneticist but the way this is laid out in the table gives equal weight to a full genome, Thailand 1 new CoV, and distinct RdRp NT sequences that are used to create phylogenetic trees. I don’t think I’ll ever understand how the virology field uses small NT reads to discover new viruses. I suggest adding another row for “full virus genome sequenced” and a footnote about the methods used to determine how a new virus has been genetically identified.

Commented [MOU3]: Same species? Details.

Commented [MOU4]: Check ICTV guideline, I thought it was established to use, e.g., bat SARS-related coronavirus (bat SARSr-CoV). The use of beta-coronavirus widens the focus away from sarbecoviruses.

Commented [MOU5]: The fusion data Chee Wah presented indicated that it does bind to and mediate cellular entry/fusion via the human ACE-2 orthologue.

an essential host factor for SADS-CoV infection of human cells. Infection is prevented in PLAC8 knockouts and can be restored by transiently transfecting PLAC8 from multiple species, including human, pig, mouse, and bat. Trypsin treatment of SADS-CoV bypasses the PLAC8-dependent pathway and partially rescues SADS-CoV infection. PLAC8 is involved in both early entry and later dissemination of SADS-CoV infection and PLAC8 KO cells have: 1) delayed and reduced viral subgenomic RNA expression and 2) diminished cell-to-cell viral spreading of infected cells. *These results suggest that PLAC8 is a promising target for antiviral development for the potential pandemic SADS-CoV virus.*

- **Host range, transmissibility, and antigenicity of a pangolin coronavirus.** Using a synthetically derived infectious cDNA clone, we recovered the wildtype pangolin (Pg) CoV-GD and derivatives encoding indicator genes. Like SARS-CoV-2, PgCoV-GD virus efficiently uses human and many other orthologous mammalian ACE2 receptors for entry, shares a similarly broad host range *in vitro*, and displays altered sensitivity to host proteases. PgCoV-GD replicates to slightly higher to lower titers in primary human cells derived from the proximal to distal lung, respectively, and with reduced fitness compared to SARS-CoV-2. PgCoV-GD also replicates efficiently in hamsters and could transmit via the aerosol route, but at a lower frequency than SARS-CoV2. Efficient PgCoV-GD replication in primary nasal airway epithelial cells and transmission in the hamster highlights the high emergence potential of this virus. However, PgCoV-GD is efficiently neutralized by COVID-19 patient sera and many commercially available SARS-CoV-2 therapeutic antibodies, but not by human antibodies targeting the spike N-terminal domain. Furthermore, a pan-sarbecovirus antibody, ADG-2, and a SARS-CoV-2 prefusion stabilized spike protein (S2P) recombinant protein vaccine protected mice in a PgCoV-GD replication model. Lastly, however, efficient PgCoV replication in primary nasal airway epithelial cells and transmission in the hamster highlights the high emergence potential of this virus. We showed that cross-neutralizing antibodies in pre-immune SARS-CoV-2 humans and the benefit of current COVID-19 countermeasures should impede its ability to emerge and spread globally in humans. *This research helps build FDA-approved therapeutic antibodies against a range of CoVs with emergence potential and shows that FDA-approved SARS-CoV-2 vaccines also protect animals from PgCoV-GD when challenged in vivo.*

Aims 2 & 3: Identify evidence and analyze risk factors for viral spillover in high-risk communities and clinical cohorts, and characterize viral etiology of ‘cryptic’ outbreaks

- **Incorporation our** Designed and secured the expression of bat-CoV spike proteins into the multi-family for incorporation into our multiplex-based immunoassay (MMIA) (multi-family) serological assay. Specific bat-borne-CoV spike proteins including bat SARSr-CoVs RaT13, bat SARSr-CoV ZXC21, bat MERsr-CoV PDF2180, and HKU9 were designed as pre-fusion stabilized spike glycoprotein ectodomain trimers (S-2P). These were spike protein antigens were incorporated into our 17-plex henipavirus/filovirus-focused serology assay expanding the representation of virus targets to include to include priority coronaviruses such as SARS-CoV-2 and bat SARSr-CoVs/bat MERsr-CoV and bat-borne CoV antigens. We also optimized an sVNT for Nipah virus and provided enough material to characterize Nipah virus IgG positive serum samples neutralizing antibodies. SOPs were revised and updated to reflect best practices that were optimized during Year 1.
- **Community serology surveillance.** We initiated the human surveillance work in Thailand, with 56 participants enrolled at one at-risk community site, and 2 individuals from a clinic site, with a total of 58 participants enrolled. Serology testing of samples from 56 participants from the community site showed positive for PMVs, henipaviruses (HNVs) (family Paramyxoviridae) Henipavirus, filoviruses

Commented [MOU6]: ? not sure what this means. Were there lower viral loads in the respiratory tract? Is aerosol route correct, or should it be respiratory secretions? There is a lot of data in this section, is there a reference to a pre-print or article?

Formatted: Highlight

Commented [MOU7]: List these?

Commented [MOU8]: This is pretty nuanced. Do the commercially available mAbs that neutralized PgCoV-GD target the RBD or Q neutralizing epitopes in the S glycoprotein and not the NTD?

Commented [MOU9]: Is this an FDA EUA or authorized treatment?

Commented [MOU10]: This is something not FDA EUA? Will stakeholders understand what S-2P etc means? This is what NovaVax is making.

Commented [MOU11]: Replication, not infection or disease model? What did these mAb and vaccine protect from, infection?

Commented [MOU12]: What does this mean, sera from humans with memory to seasonal beta-human coronaviruses can cross-neutralize PgCoV-GD, by binding recognition to the S2 fusion domains?

Commented [MOU13]: I didn't see any mention of FDA-approved antibody therapies or vaccine countermeasures being tested in the sentences before.

Tighten this up with explicit details.

Commented [MOU14]: What does this mean?

(FLVs), and CoVs (Fig. 1). Human sera were tested in the multi-family MMIA for serologic evidence of previous infection by Asiatic FLVs, HNVs, and CoV. We observed minimal reactivity and IgG binding with the NiV receptor-binding protein (RBP), implying that subclinical cryptic NiV infections had not occurred in these participants (Figure 1B). One human serum sample possessed IgG that was reactive with envelope glycoproteins (GP) from Ebola virus, Bundibugyo virus, Bombali virus, Sudan virus, and Lloviu virus, consistent with a serologic pattern of cross-reactivity among phylogenetically-related ebolaviruses (Figure 1A). A diversity of genetically and antigenically uncharacterized Asiatic filoviruses is likely to exist, and this serology results is consistent with other serology-focused projects in the region. The antigenic relationships and contribution of glycoepitopes to heterotypic cross-reactions among ebolaviruses and broadly within FLVs remains poorly understood, follow-up testing will explore whether broad cross-reactions with FLVs antigens is driven by glycosylated epitopes that may be more conserved across the ebolaviruses than protein sequence similarity/identify would imply. Lastly, human sera displayed maximum preferential reactivity with SARS-CoV-2 spike protein, consistent with COVID-19 vaccination status of participants. At the low testing titer, cross-reactions with phylogenetically-related bat sarbecoviruses was expectedly observed (Figure 1C). Interestingly, two participants had sera IgG that bound to the bat MERSr-CoV PDF2180, which does not utilize the orthologous human DPP4/CD20 receptor for cellular entry, and it quite distinct from the sarbecoviruses.

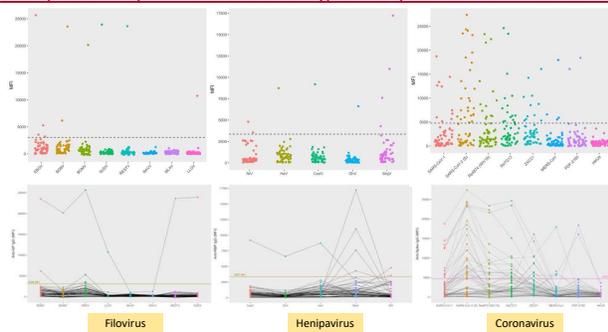

Fig. 1 Serology testing results for FLVs, HNVs, Henipavirus, and CoVs among community participants in Thailand (n=56).

Commented [MOU15]: Needs a proper legend.

Commented [MOU16]: These panels are showing the same thing, pick one format and make these bigger. I prefer the "connected" lines because it shows that it's the same individual.

- **Design and application of pan-sarbecovirus multiplex surrogate virus neutralization test (sVNT) platform** that covers SARS-CoV-2 and variants of concern (Alpha, Beta, Gamma, Delta, Mu, Lambda, Omicron BA.1 and BA.2), clade-2 sarbecoviruses (BANAL-52, BANAL-263, GD-1, RaTG13, GX-P5L), clade-1 sarbecoviruses (Rs2018B, LYRa11, WIV-1, RsSHC014, Rs4231), SARS-CoV-1, and the newly discovered bat SARSr-CoV we recently sequenced from Thailand. This assay allows for the discrimination of past SARS-CoV-2 infection from that of other sarbecoviruses in human and animal samples, which will be critical for identifying cryptic spillover of sarbecoviruses in people. It also has the potential to aid in identifying the progenitor of SARS-CoV-2 in animals.

- **Optimization and establishment of pan-henipavirus multiplex sVNT at Chulalongkorn University.** We also optimized an sVNT for Nipah virus and provided enough material to characterize Nipah virus IgG positive serum samples for neutralizing antibodies via a virus-free/cell-culture free bead-based serology assay.

- **Designed and secured the expression of bat-CoV spike proteins for incorporation into our multiplex (multi-family) serological assay.** Specific bat-borne CoV spike proteins include bat SARSr-

Formatted: Indent: Left: 0.25", No bullets or numbering

Formatted: Font: (Default) Calibri, Font color: Text 1

CoVs RaT13, ZXC21, bat MERSr-CoV PDF2180, and HKU9. These were incorporated into our 17-plex henipavirus/filovirus-focused serology assay to include SARS-CoV-2 and bat-borne CoV antigens. We also optimized an sVNT for Nipah virus and provided enough material to characterize Nipah virus IgG positive serum samples neutralizing antibodies. SOPs were revised and updated to reflect best practices that were optimized during Year 1.

Outbreak investigation and preparedness in Thailand

- The Ministry of Public Health in Thailand requested support from EID-SEARCH for a viral diarrhea outbreak investigation in Chanthaburi province. We received samples from both Prapokklao Hospital (regional hospital) and Khlong Khut Health-Promoting hospital collected from 59 healthcare workers and students who had diarrhea during Dec. 2021-Feb. 2022. PCR tests were conducted for six gastrointestinal viruses causing gastrointestinal tract infections including adenovirus, astrovirus, norovirus GI, norovirus GII, rotavirus, and sapovirus. 32 samples (54.24%) were positive for norovirus GII. Further genomic characterization of the detected norovirus GII will be performed, allowing for comparison with noroviruses found in other provinces in Thailand.
- In preparedness for Monkeypox outbreaks, EID-SEARCH's lab partner in Thailand coordinated with the Department of Medical Science, MOPH, National lab to establish the Monkeypox testing platform in April 2022 and detected the first Monkeypox case in Thailand in July 2022.

B. Dissemination of Results

- Summarize dissemination plan
- Include number of peer-reviewed publications; highlight those in high-impact journals
- Number and content of presentations on CREID research, including audience

EID-SEARCH members were invited to present the project work at government and inter-government briefings (> 10), conference and university lectures (>13), panels and webinars (>18), and public interviews (>6) in Thailand, Malaysia, the US, regionally and internationally on the trends in global disease emergence, zoonotic surveillance, pandemic control and prevention, and research results from this project research activities. Nine (9) peer-reviewed paper has been published or with preprint available from EID-SEARCH work, two (2) manuscripts are currently under revision, and three (3) manuscripts are in preparation for submission, including papers on.. please highlight the high-impact ones. We organized a workshop with 55 scientists and government officials from Thailand, Malaysia, Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, and Australia to present EID-SEARCH work, share knowledge, strengthen research capacity, and foster scientific collaborations in Southeast Asia.

Commented [MOU17]: If not including the PMID, I'd at least add the Surname, First Initial, et al. J. Infect Dis. 2022.

C. Training and Capacity Building Activities

- Summarize capacity building plan
- Include number of training activities and number of participants for each training
- Address how capacity building activities were adapted due to COVID-19 and long-term changes as a result of the pandemic

During this reporting period, XX training sessions with a total of XX participants were conducted by EID-SEARCH partners in Thailand, Malaysia, and Vietnam for project members, local government partners, universities, research institutes, and NGOs. These training focused on biosafety (x training x participants by x), applying new technologies (x training x participants by x), and field and laboratory SOPs (x training

x participants by x), to strengthen in-country research capacity and improve information sharing. Both in-person and online training was conducted to accommodate COVID conditions. As travel and COVID-19 restrictions have begun to be lifted, students, postdocs, and all EID-SEARCH research staff have been provided with professional development opportunities to travel to attend conferences, workshops, and other in-person training activities. **To be updated with numbers....**

D. Challenges and Proposed Solutions

- Bottlenecks to CREID-related research that might be like those that you could face when pivoting research activities in direct response to an EID outbreak. What solutions could be or have you put in place in advance to solve those challenges? How is being part of the CREID Network mitigating those or not?

The significant challenges we encountered during the reporting period were travel restrictions to our field partner countries and within countries, as well as a large number of hospitalized patients in local hospitals in Thailand and Malaysia due to COVID-19 that delayed human participant enrollment at targeted community and hospital sites and the subsequent laboratory analysis we anticipated in Year 2. To address these issues, we worked closely with in-country partners and stakeholders to continue assessing the situations (i.e., safety and research priorities of study sites) to ensure a rapid start of enrollment and focused on the refinement of assays to be ready for human surveillance. Meanwhile, to prevent a possible supply shortage of PPE and swabs as happened in early Year 2, we have identified supply sources to ensure we can procure the necessary consumables without significant delays. With travel restrictions in Southeast Asian countries now beginning to be lifted, international travel of US-based staff to our field sites has begun (April 2022).

E. Examples of Network Collaboration

- How has the work/research of your RC been affected by or involved collaboration with other members of the CREID Network?
- Examples: highlight joint publications, joint activities, sharing materials and data, benefits of Working Groups, etc.

Through the participation of different CREID Working Groups, EID-SEARCH members participated in the network's outbreak responses, capacity building, and cross-center collaboration by sharing existing local partnerships, techniques, and relevant resources.

- For outbreak responses, EID-SEARCH has been actively participating in the network's response to Monkeypox by providing local partnerships and monitoring platforms in DRC and Thailand.
- For lab assay sharing, EID-SEARCH partner Uniformed Services University is working with **UW** **AREN** **Pls, Dr. Robert Cross and Dr. Scott Weaver, to establish a MTA with UTMB and regional partners in Liberia and Nigeria for the multi-family FLV/HNV MMIA for anti-to share the multiplex microsphere immunoassay (MMIA) with the regional partners for EBOV serology testing. Enquiries ,has been made with and plan to work Dr. Mark Page and with the National Institute for Biological Standards and Control (NIBSC) regarding additional MARV and NiV serology standards. to... Eric, please feel free to edit to add more info**
- We are contacted by multiple Research Centers regarding the Field Biosafety Manual presented at the CREID Scientific Meeting by EID-SEARCH senior field veterinarian, the Manual and corresponding training resources will be made available to all CREID members once it's completed with peer review. **Marc, please feel to edit...**
- EID-SEARCH are also committed to providing our expertise on CCHF, Henipavirus, RVF related research by connecting CREID members with our research partners.

Section 4: Future Directions

- Plan for the next reporting period.
- How is your Research Center adapting to the April 2022 NIAID Program Priorities and how does this change (or not) your planned activities in the next year? *See Appendix B for NIAID Program Priorities.*
- Moving forward, what is the greatest opportunity your RC has to advance the knowledge base for emerging infectious diseases? What are the significant knowledge gaps that the RC can advance research on?

In the next reporting period, we will follow the research plans laid out in our proposal with the specific actions to **continue expanding our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats that align with the CREID network research priorities:**

Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.

- Wildlife (bats, rodents, and non-human primates) sampling at selected sites, with increased efforts for rodents and non-human primates and potential longitudinal sampling at a few selected sites to analyze patterns of viral shedding and spillover risk.
- Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 3-5 of the project.
- Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses, filoviruses, and paramyxoviruses.
- Perform serology testing on the wildlife samples for coronaviruses, filoviruses, and henipavirus.
- Continue developing a more comprehensive multiplex CoV RBD-based sVNT covering newly identified sarbecoviruses and additional merbecoviruses to allow the evaluation of neutralizing activity in serum samples against a much broader and more comprehensive range of RBDs.
- Conduct whole-genome and spike glycoprotein sequencing in countries with newly identified viruses.
- Continue research to further characterize a subset of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies, including pangolin GD strain, BANAL-52, and other significant viruses identified in Y1-2.
- Develop zoonotic risk analyses for relevant viruses, including the analysis of Spike and whole-genome sequences to predict host range using a variety of in silico approaches, model the host range, geographic distribution, extent of overlap with high-density human populations, etc. using existing apps/models to assess potential zoonotic disease risk

Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays

- Increase the number of sites and enrolled participants for community surveillance among at-risk populations for biological and behavioral data collection in Thailand, Peninsular Malaysia, and Sabah Malaysia
- Continue to identify community sites concurrent with animal surveillance sites (Specific Aim 1).
- Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and paramyxoviruses
- Begin epidemiological analyses of biological and behavioral data.

Specific Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts

- Start enrolling participants at selected hospital/clinic sites for syndromic surveillance at two sites in Thailand, and identified sites in Sabah, Malaysia and Peninsular Malaysia, Malaysia
- Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.
- Start serological and molecular testing on collected human samples.
- Start viral characterization work if any novel viruses are identified.

Through the work under Specific Aims 2&3, we are engaging multiple disciplines of social science, anthropology, health policy, and behavioral science towards EID risk mitigation strategies on key human-animal interfaces, we will share relevant research methods (e.g., behavioral questionnaires) and best practices with the CREID Network members.

Training and capacity-building activities among in-country team members, especially young EIDs researchers, to strengthen domestic, regional, and international capacity and readiness to efficiently undertake the research required in response to emerging or re-emerging threats. Available training materials or resources will be made available to the CREID Network.

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures and discussion as well as hands-on guidance.
- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing.
- Conduct training in traditional viral whole-genome sequencing using primer walking for paramyxoviruses.
- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training.
- Trial the use of the portable Oxford Nanopore MinION platform as an in-house sequencing solution in Malaysia.
- Continue training on multiplex microsphere immunoassay (MMIA) data analysis and interpretation.
- Conduct refresh training on human research regarding survey design, interview skills, and data analysis.
- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer-review, publication, and broad distribution.
- Continue sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government in a timely manner.
- Organize meetings and workshops with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region (November 2022).
- Initiate exchange training for young researchers among EID-SEARCH partners for NGS and other laboratory technology transfers.
- Support in-country outbreak research and response.

Appendix A: 2021 EAC Report

Centers for Research in Emerging Infectious Diseases (CREID) CREID External Advisory Committee (EAC) Summary In follow up to the CREID Network Annual Meeting November 3-5, 2021 (virtual meeting)

Prepared by Mark Feinberg, MD, PhD on behalf of the CREID EAC

Overview of EAC Perspectives and Recommendations

The EAC members were unanimous in their assessment that the CREID Network team made very impressive and positive progress in their first year of this very important and timely new NIAID/DMID initiative. While the amount of progress realized in starting up a new global collaborative research network would be highly laudable overall in any circumstance, the EAC members were even further impressed by the fact that the initiation of the CREID Network coincided with the emergence of the COVID-19 pandemic (with all of its attendant challenges). This coincidence provided a clear initial focus for many of the CREID efforts on SARS-CoV-2-related topics, but it also provided very strong validation for the original rationale for establishment of the CREID Network by the NIAID/DMID leadership as a means of fostering global networks for research collaboration on emerging infectious disease threats. While the EAC members identified a number of areas where additional attention and effort will be beneficial to maximize the impact of the CREID Network, and key to fostering the sustainability of its efforts, our expectations for what the Network has the potential to accomplish were raised by the strong foundation that the CREID PIs and collaborators have already put in place in their first year. We were also very impressed with the clear commitment, thoughtfulness and inclusive approach of the CC leadership, and with the expertise, passion, and experience of the broader CREID Network community of scientists. At the heart of the CREID is a commitment to new models of collaborative science that links investigators from around the world to understand, prepare for, and respond to emerging infectious disease threats. As such, the extent to which CREID utilizes current best practices for collaborative research and pioneers new ones; embraces the essential role played by investigators working in countries at risk for disease emergence (including resource-limited settings); partners in new and more effective and mutually trusting ways with governments, normative agencies and other emerging infectious disease-focused research organizations; exemplifies and communicates the value of scientific research in providing solutions to emerging infectious disease threats to governments and the public; and delivers on its commitment to genuine research capacity strengthening and sustainability will be critical measures for evaluating the future success of the CREID. The EAC recognizes that this is a very ambitious agenda filled with often challenging objectives, and that the inherent nature of time-limited NIH funding mechanisms presents additional challenges to their potential realization. In considering these issues, the EAC felt that significant progress has been made in the first year of the CREID Network, but that additional opportunities exist for the PIs and CREID investigators to be even more intentional and strategic about their collaborative research efforts. The CREID Network has the opportunity to establish a number of positive precedents in models of effective global collaborative science where the “whole is truly greater than the sum of its parts”; by demonstrating new approaches for the “decolonization” of international research; and by delivering on a strong commitment to diversity and inclusion in all of its endeavors. In many ways, achieving these goals will require innovation in collaborative research models within a large global network, and not just in delivering innovative, high quality scientific research results. The EAC members recognize the challenge of finding the right balance between investigator- and RC-initiated science with broader strategies and shared goals of a large collaborative network, but also note that doing so will require an overarching strategy, effective

communication tools and ongoing performance monitoring and adjustment. The EAC members also recognize that the important Network goals of research capacity strengthening and sustainability are not trivial undertakings and that they are very promising, but also rather novel objectives, within the context of NIH-supported research programs. These are additional important areas where the CREID CC and RC leadership can further articulate a respectful, inclusive, realistic, achievable and measurable strategy.

In all of these areas, the EAC recommends that the CREID investigators further develop and implement (a) a clear, well-defined and shared set of Network priorities (that links the work across RCs) and key performance indicators (KPIs) to measure performance toward realizing them, (b) a shared strategic vision and plan that connects the research efforts being prioritized and conducted across the Network centers, (c) a mechanism to share best practices across the Coordinating Center (CC) and Research Centers and (d) a proactive approach to identify collaborative research opportunities, fill gaps, avoid duplication and pursue synergies both within the CREID Network and, importantly, with the large and growing number of other organization working on preparing for and responding to emerging infectious disease outbreaks. Clarity and specificity in these efforts will be beneficial, as well as adopting an appropriate sense of realism about what can be accomplished by the CREID Network itself and where the new partnerships it implements with other organizations working in the emerging infectious disease arena will be essential. In this regard, given the complexity of the emerging infectious disease landscape, the CREID Network's ability to have the most significant impact will likely depend on the connections it establishes with other stakeholders and the innovation it drives in conceptualizing and delivering on effective new collaborative endeavors it develops with other capable partners. Towards this end, the Network would benefit from developing a thorough understanding of the ecosystem of potential partners and a defined approach to engage with the most relevant and promising ones. In addition, while the CREID Network includes collaborators from many centers and countries, its true global scope is limited by gaps in its geographic coverage (eg, countries in Asia, the Middle East, Northern Africa, Australia, etc...including those where risk of pathogen emergence are significant). Understanding if the CREID Network will be limited by its current geographic reach or plans to work to build additional connections (perhaps via strategic partnerships) in other regions will be beneficial from both practical and strategic levels.

Given that the readiness of the CREID Network for future outbreak response (and to be able to perform research in the midst of an outbreak when many challenges prevail) and for pandemic preparedness is a priority for NIAID/DMID, it will be important for the Network to clearly define how they best proactively plan to be able to promptly implement critical research programs when a new pathogen emerges or a previously known one reemerges. It will also be beneficial for the CREID CC and RCs to develop a clear plan (including protocols for coordination, implementation, data sharing and communication) to enable the Network to be able to respond expeditiously to an emerging infectious disease threat. Towards this end, tabletop exercises (or similar) to "pressure test" Network approaches and identify gaps/opportunities for improvement are worth considering.

The EAC is excited about what the CREID CC and RCs, and all of the collaborating CREID investigators, have accomplished in their first year of work and look forward to seeing the innovations and insights the Network will deliver in the future. The EAC recognizes that the CREID Network cannot realistically be "all things for all people", and should not strive to be. WE therefore also look forward to seeing how your Network priorities are further articulated, implemented and measured moving forward.

Additional EAC Impressions

The EAC felt that the Executive Summary of the CREID Network Annual Meeting provided an accurate overview of the meeting proceedings and of the EAC feedback provided at the end of the meeting proceedings. Some specific additional impressions/requests shared by EAC members include:

- Gaining a better understanding of how CREID investigators are interfacing with local governments and ministries, public health authorities (eg, WHO, US CDC, Africa CDC, etc), normative agencies will be helpful, and how learnings of effective approaches should be shared across the Network. In addition, optimization of engagements with other research organizations, enabling disciplines (eg, social science, health economics, health policy, ethics), as well as the medical countermeasures community, will be helpful
- Gaining a better understanding of the experience to date in data sharing efforts and how these can be optimized
- Gaining a better understanding of how bilateral sharing of research materials and specimens can be optimized (given the role of host institutions and government policies) and how these might operate during an outbreak/pandemic
- How the CREID investigators view and are approaching their educational efforts with governments, political leaders and the public, and sharing of best practices for engagement and trust-building
- How the CREID Network is engaging with industry partners that both supply enabling tools and technologies and who may also assist in the development and commercialization of CREID-advanced innovations (eg, diagnostics)
- Opportunities exist to demonstrate the CREID commitment to decolonization of global health (with increased attention to having the voices from LMIC-based investigators better balanced with those of US-based investigators)
- Opportunities exist to better model the Network's and the NIH's commitment to DEI objectives (with increased attention to full representation in all aspects of the work...including presentations, leadership groups, pilot research awards)
- Opportunities for enhancing epidemiology, bioinformatics, digital tools and modeling capacity
- Gaining a better understanding of the role of social and cultural aspects of the outbreak response and communication, and exploring innovative approaches to address them
- Understanding how engagement with governments and other local stakeholders is being pursued to advance capacity strengthening and sustainability goals
- Further articulation of rapid response collaboration frameworks
- Gaining a better understanding of how local priorities influence the prioritization decisions of the CC and RCs
- Gaining a better understanding/"needs assessment" of capacity gaps (eg, BSL-3 training and labs) and how these are being addressed via strategic connections or focused investment
- How "parachute or safari research" is avoided, and how local researchers are engaged as full partners/leaders
- Definition of opportunities to maximize speed and efficiency in research implementation efforts (eg, US permits and in-country regulations, IRB delays, key relationship gaps) needed for prompt outbreak responses
- Value of developing a clear vision and plan for sustainability that maximizes the connection with and contributions of other partners and local governments
- South-South collaboration should be applauded and fostered
- Shared EAC interest in seeing the CREID Network's progress in ongoing database and biorepository workstreams

Appendix B: NIAID CREID Network Program Priorities (April 2022)

(4 main priorities all carry equal weight and are intended to cover research and activities to prepare for and respond to emerging and re-emerging threats.)

- **Conduct innovative research to expand our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats**
 - Research Priorities:
 - Pathogen discovery & characterization
 - Pathogen/host surveillance
 - Pathogen transmission
 - Pathogenesis & immunologic responses in the host
 - Natural history & contemporary clinical disease
 - Develop reagents & diagnostic/detection assays
 - Engage in coordinated, Network wide outbreak/pandemic research readiness, differentiated from standard public health responses
- **Establish a collaborative, strategic, and preemptive research Network to ensure coordination of efforts across the Network**
 - Centralize communication
 - Conduct Network wide capacity inventory
 - Establish effective data harmonization and platforms for sharing
 - Harmonize sample collection, biorepositories, and network sharing/agreements
 - Share laboratory assay best practices and protocols
 - Share reagents, diagnostic/detection assays, and other resources
- **Develop and expand flexible domestic and international capacity and readiness to efficiently undertake research required in response to emerging or re-emerging threats**
 - Prioritize and engage with key stakeholders that will enhance network capabilities and integrate into the global health landscape
 - Strengthen and enhance research collaboration and partnerships globally
 - Pivot programmatic priorities and resources when needed for a timely response to emerging or re-emerging pathogen threats
 - Develop protocols for coordination, implementation, data sharing, and communication.
 - Execute tabletop exercises to test, refine, and maintain Network readiness
 - Formulate novel strategies to detect, control, and prevent outbreaks
 - Translate findings to downstream partners to facilitate development of medical countermeasures or preventive interventions
 - Develop adaptable risk assessment tools for evaluating a pathogen threat's potential for significant emergence and impact
- **Contribute to the development of the next generation of emerging/re-emerging infectious disease scientists and leaders**
 - Develop and maintain a pilot research program
 - Foster a diverse and inclusive research environment and program

**Centers for Research in Emerging Infectious
Diseases (CREID) Network**

Section 1. Executive Summary

The Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is a multidisciplinary center focused on analyzing zoonotic disease risk in a key EID hotspot region. Our aims are to 1) characterize diverse coronaviruses, paramyxoviruses, filoviruses, and other viral pathogens in wildlife; 2) assess the frequency and causes of their spillover; & 3) identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in Thailand, Malaysia, and Singapore. Highlights of research and significant findings during the reporting period (October 2021 – August 2022) include:

To be updated with bullet points by Peter...

Section 2: Research Center Overview

A. Specific Aims

The overarching goal of the Emerging Infectious Diseases – South East Asia Research Collaboration Hub (EID-SEARCH) is to characterize the diversity of key viral pathogens in wildlife, assess the frequency and causes of their spillover, and identify viral etiologies of undiagnosed ‘cryptic’ outbreaks in people. The research goals of the EID-SEARCH follow three specific aims designed to advance our understanding of spillover and outbreak risk for novel viruses in a globally important EID hotspot, strengthen in-country research capacity, and enhance international collaboration:

- Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.
- Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays.
- Specific Aim 3: Identify and characterize the viral etiology of ‘cryptic’ outbreaks in clinical cohorts.

B. Partners and Staffing

EID-SEARCH includes leaders in the field of emerging viral pathogens at key US institutions (EcoHealth Alliance PI Peter Daszak; University of North Carolina Co-I Ralph Baric; Uniformed Service University Co-Is Christopher Broder and Eric Laing), and in Thailand (Chulalongkorn University Co-Is Supaporn Wacharapluesadee and Opass Putcharoen), Singapore (Duke-NUS Medical School Co-I Linfa Wang), and the three major Malaysian administrative regions (Conservation Medicine Co-I Tom Hughes). These organizations represent the ‘hub’ of the center, with an additional, more informal collaborative network spanning >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries. By enhancing and focusing research within the three hub countries, and coordinating communication among the network, we envision EID-SEARCH acting as an early warning system for outbreaks; a way to exchange information, reagents, samples, and technology; and a collaborative powerhouse for translational research. EID-SEARCH is supported by a multidisciplinary team of researchers at our partner institutions, with skills in epidemiology, clinical management, molecular biology, virology, wildlife biology, and advanced data and statistical analyses. The long collaborative history between the key personnel and partner institutions is a significant asset that can be deployed to support outbreak research response in the region.

C. Research Sites

The three core (hub) countries for the EID-SEARCH are Thailand, Malaysia, and Singapore, *expanded to Viet Nam and Cambodia through the CREID Pilot Research Program*. These stretch through one of the

most significant foci of EID risk globally. Additionally, we have assembled a greater network of EID-SEARCH partners that includes >50 clinics, laboratories, and research institutes across almost all Southeast Asian countries – stretching from Nepal to the Philippines. Our targeted field research includes sampling wildlife and people in Thailand, Peninsular Malaysia, Sarawak, Sabah, Viet Nam, and Cambodia. The central location of our hub countries in mainland Southeast Asia allows us to sample representative wildlife species that occur in other countries across the greater biogeographic region, including India, Bangladesh, Myanmar, Southwest China, Laos, Cambodia, Philippines, and Indonesia.

Section 3: Research Center Progress and Accomplishments

Progress and Accomplishments

- Organized by Aim
- Focus on key accomplishments
- Address outbreak research response if applicable
- Address how the 2021 EAC recommendations have been incorporated (*see Appendix A for 2021 EAC report*)

A. Projects and Studies

- Have you reverted to your original (pre-pandemic) CREID research agenda in the last year? If not, how has your research agenda changed in the last year due to the ongoing impact of SARS-CoV-2?
- What additional changes to your CREID research agenda have taken place in the last year?

Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife

- **Field surveillance among wild bats, rodents, and non-human primates.** We have collected 14,302 specimens from 2,055 animals of 31 bat species, one non-human primate (NHP) species, and five rodent species from six sites at high-risk human-wildlife interfaces in Malaysia and Thailand. (Table 1)

	Thailand	Malaysia
No. of collected specimens	3,862	14,171
No. of individuals	454 bats, 106 rodents	2,000 bats
No. of species	6 (bats), 5 (rodents)	24 (bats)
No. of sites	5	4
No. of tested individuals	407	1,332
No. PCR tests for coronaviruses (CoVs), paramyxoviruses (PMVs), filoviruses (FLVs), influenza viruses (IVs)	4,070	9,228
Identified viruses	1 new CoV from 3 bats 3 known PMVs from 4 rodents 4 new PMVs from 11 bats	5 new CoVs from 112 bats 4 new PMVs from 10 bats 2 known PMVs from 2 bats
No. of specimen for multiplex immunoassay for FLVs and Henipavirus	-	720 bats

Table 1. EID-SEARCH viral surveillance in wildlife in Malaysia and Thailand.

- **Discovery of novel SARS-like beta-coronavirus in bats in Thailand.** The whole genomes revealed a 91.72% nucleotide similarity to SARS-CoV-2. Phylogenetic analysis suggested that this virus is closer to pangolin CoV-GD-1 than to SARS-CoV-2; however, the RBD is more similar to that of bat-CoV RaTG13, suggesting that this new virus may also bind to mammalian ACE2 receptors. Whole-genome sequencing of other new CoVs from Thailand and Malaysia is ongoing.
- **Genome-wide CRISPR knockout screen identifies essential factor for HKU2/SADS-CoV infection.** Using a genome-wide CRISPR knockout screen, we identified placenta-associated 8 protein (PLAC8) as

an essential host factor for SADS-CoV infection of human cells. Infection is prevented in PLAC8 knockouts and can be restored by transiently transfecting PLAC8 from multiple species, including human, pig, mouse, and bat. Trypsin treatment of SADS-CoV bypasses the PLAC8-dependent pathway and partially rescues SADS-CoV infection. PLAC8 is involved in both early entry and later dissemination of SADS-CoV infection and PLAC8 KO cells have: 1) delayed and reduced viral subgenomic RNA expression and 2) diminished cell-to-cell viral spreading of infected cells. *These results suggest that PLAC8 is a promising target for antiviral development for the potential pandemic SADS-CoV virus.*

- Host range, transmissibility, and antigenicity of a pangolin coronavirus.** Using a synthetically derived infectious cDNA clone, we recovered the wildtype pangolin (Pg) CoV-GD and derivatives encoding indicator genes. Like SARS-CoV-2, PgCoV-GD virus efficiently uses human and many other mammalian ACE2 receptors for entry, shares a similarly broad host range *in vitro*, and displays altered sensitivity to host proteases. PgCoV replicates to slightly higher to lower titers in primary human cells derived from the proximal to distal lung, respectively, and with reduced fitness compared to SARS-CoV-2. PgCoV also replicates efficiently in hamsters and could transmit via the aerosol route, but at a lower frequency than SARS-CoV2. PgCoV is efficiently neutralized by COVID-19 patient sera and many commercially available SARS-CoV-2 therapeutic antibodies, but not by human antibodies targeting the spike N-terminal domain. A pan-Sarbecovirus antibody ADG-2 and SARS-CoV-2 S2P recombinant protein vaccine protected mice in a PgCoV replication model; however, efficient PgCoV replication in primary nasal airway epithelial cells and transmission in the hamster highlights the high emergence potential of this virus. We showed that cross-neutralizing antibodies in pre-immune SARS-CoV-2 humans and the benefit of current COVID-19 countermeasures should impede its ability to emerge and spread globally in humans. *This research helps build FDA-approved therapeutic antibodies against a range of CoVs with emergence potential and shows that FDA-approved SARS-CoV-2 vaccines also protect animals from PgCoV when challenged in vivo.*

Aims 2 & 3: Identify evidence and analyze risk factors for viral spillover in high-risk communities and clinical cohorts, and characterize viral etiology of ‘cryptic’ outbreaks

- Community serology surveillance.** We initiated the human surveillance work in Thailand, with 56 participants enrolled at one at-risk community site, and 2 individuals from a clinic site, with a total of 58 participants enrolled. Serology testing of samples from 56 participants from the community site showed positive for PMVs, Henipavirus, and CoVs (Fig. 1)

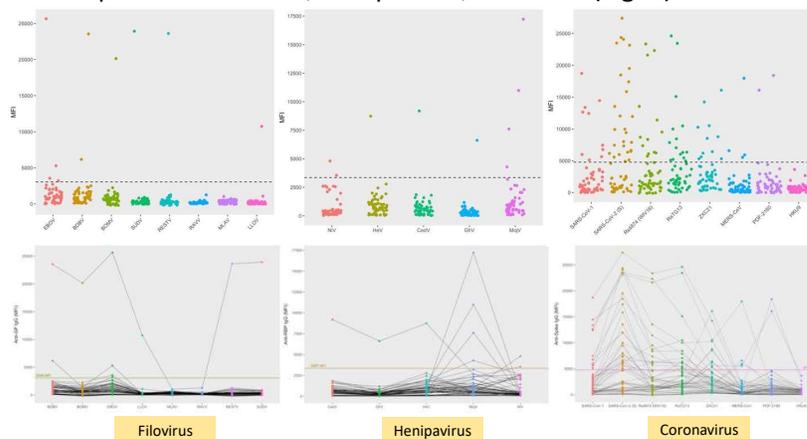

Fig. 1 Serology testing results for FLVs, Henipavirus, and CoVs among community participants in Thailand (n=56)

- Design and application of multiplex surrogate virus neutralization test (sVNT) platform** that covers SARS-CoV-2 and variants of concern (Alpha, Beta, Gamma, Delta, Mu, Lambda, Omicron BA.1 and

BA.2), clade-2 sarbecoviruses (BANAL-52, BANAL-263, GD-1, RaTG13, GX-P5L), clade-1 sarbecoviruses (Rs2018B, LYRa11, WIV-1, RsSHC014, Rs4231), SARS-CoV-1, and *the newly discovered bat CoV we recently sequenced from Thailand*. This assay allows for the discrimination of past SARS-CoV-2 infection from that of other sarbecoviruses in human and animal samples, which will be critical for identifying cryptic spillover of sarbecoviruses in people. It also has the potential to aid in identifying the progenitor of SARS-CoV-2 in animals.

- **Designed and secured the expression of bat-CoV spike proteins for incorporation into our multiplex (multi-family) serological assay.** Specific bat-borne CoV spike proteins include bat SARSr-CoVs RaT13, ZXC21, bat MERSr-CoV PDF2180, and HKU9. These were incorporated into our 17-plex henipavirus/filovirus-focused serology assay to include SARS-CoV-2 and bat-borne CoV antigens. We also optimized an sVNT for Nipah virus and provided enough material to characterize Nipah virus IgG positive serum samples neutralizing antibodies. SOPs were revised and updated to reflect best practices that were optimized during Year 1.

Outbreak investigation and preparedness in Thailand

- The Ministry of Public Health in Thailand requested support from EID-SEARCH for a viral diarrhea outbreak investigation in Chanthaburi province. We received samples from both Prapokklao Hospital (regional hospital) and Khlong Khut Health-Promoting hospital collected from 59 healthcare workers and students who had diarrhea during Dec. 2021-Feb. 2022. PCR tests were conducted for six gastrointestinal viruses causing gastrointestinal tract infections including adenovirus, astrovirus, norovirus GI, norovirus GII, rotavirus, and sapovirus. 32 samples (**54.24%**) were positive for norovirus GII. Further genomic characterization of the detected norovirus GII will be performed, allowing for comparison with noroviruses found in other provinces in Thailand.
- In preparedness for Monkeypox outbreaks, EID-SEARCH's lab partner in Thailand coordinated with the Department of Medical Science, MOPH, National lab to establish the Monkeypox testing platform in April 2022 and detected the first Monkeypox case in Thailand in July 2022.

B. Dissemination of Results

- Summarize dissemination plan
- Include number of peer-reviewed publications; highlight those in high-impact journals
- Number and content of presentations on CREID research, including audience

EID-SEARCH members were invited to present the project work at government and inter-government briefings (> 10), conference and university lectures (>13), panels and webinars (>18), and public interviews (>6) in Thailand, Malaysia, the US, regionally and internationally on the trends in global disease emergence, zoonotic surveillance, pandemic control and prevention, and research results from this project research activities. Nine (9) peer-reviewed paper has been published or with preprint available from EID-SEARCH work, two (2) manuscripts are currently under revision, and three (3) manuscripts are in preparation for submission, **including papers on.. please highlight the high-impact ones**. We organized a workshop with 55 scientists and government officials from Thailand, Malaysia, Singapore, Bangladesh, Cambodia, Indonesia, Lao PDR, Myanmar, Nepal, Vietnam, USA, and Australia to present EID-SEARCH work, share knowledge, strengthen research capacity, and foster scientific collaborations in Southeast Asia.

C. Training and Capacity Building Activities

- Summarize capacity building plan
- Include number of training activities and number of participants for each training
- Address how capacity building activities were adapted due to COVID-19 and long-term changes as a result of the pandemic

During this reporting period, XX training sessions with a total of XX participants were conducted by EID-SEARCH partners in Thailand, Malaysia, and Vietnam for project members, local government partners, universities, research institutes, and NGOs. These training focused on biosafety (x training x participants by x), applying new technologies (x training x participants by x), and field and laboratory SOPs (x training x participants by x), to strengthen in-country research capacity and improve information sharing. Both in-person and online training was conducted to accommodate COVID conditions. As travel and COVID-19 restrictions have begun to be lifted, students, postdocs, and all EID-SEARCH research staff have been provided with professional development opportunities to travel to attend conferences, workshops, and other in-person training activities. **To be updated with numbers....**

D. Challenges and Proposed Solutions

- Bottlenecks to CREID-related research that might be like those that you could face when pivoting research activities in direct response to an EID outbreak. What solutions could be or have you put in place in advance to solve those challenges? How is being part of the CREID Network mitigating those or not?

The significant challenges we encountered during the reporting period were travel restrictions to our field partner countries and within countries, as well as a large number of hospitalized patients in local hospitals in Thailand and Malaysia due to COVID-19 that delayed human participant enrollment at targeted community and hospital sites and the subsequent laboratory analysis we anticipated in Year 2. To address these issues, we worked closely with in-country partners and stakeholders to continue assessing the situations (i.e., safety and research priorities of study sites) to ensure a rapid start of enrollment and focused on the refinement of assays to be ready for human surveillance. Meanwhile, to prevent a possible supply shortage of PPE and swabs as happened in early Year 2, we have identified supply sources to ensure we can procure the necessary consumables without significant delays. With travel restrictions in Southeast Asian countries now beginning to be lifted, international travel of US-based staff to our field sites has begun (April 2022).

E. Examples of Network Collaboration

- How has the work/research of your RC been affected by or involved collaboration with other members of the CREID Network?
- Examples: highlight joint publications, joint activities, sharing materials and data, benefits of Working Groups, etc.

Through the participation of different CREID Working Groups, EID-SEARCH members participated in the network's outbreak responses, capacity building, and cross-center collaboration by sharing existing local partnerships, techniques, and relevant resources.

- For outbreak responses, EID-SEARCH has been actively participating in the network's response to Monkeypox by providing local partnerships and monitoring platforms in DRC and Thailand.
- For lab assay sharing, EID-SEARCH partner Uniformed Services University is working with UWAEN to share the multiplex microsphere immunoassay (MMIA) with the regional partners for EBOV serology testing, and plan to work with the National Institute for Biological Standards and Control (NIBSC) to... **Eric, please feel free to edit to add more info**

- We are contacted by multiple Research Centers regarding the Field Biosafety Manual presented at the CREID Scientific Meeting by EID-SEARCH senior field veterinarian, the Manual and corresponding training resources will be made available to all CREID members once it's completed with peer review. **Marc, please feel to edit...**
- EID-SEARCH are also committed to providing our expertise on CCHF, Henipavirus, RVF related research by connecting CREID members with our research partners.

Section 4: Future Directions

- Plan for the next reporting period.
- How is your Research Center adapting to the April 2022 NIAID Program Priorities and how does this change (or not) your planned activities in the next year? *See Appendix B for NIAID Program Priorities.*
- Moving forward, what is the greatest opportunity your RC has to advance the knowledge base for emerging infectious diseases? What are the significant knowledge gaps that the RC can advance research on?

In the next reporting period, we will follow the research plans laid out in our proposal with the specific actions to **continue expanding our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats that align with the CREID network research priorities:**

Specific Aim 1: Identify, characterize, and rank spillover risk of high zoonotic potential viruses from wildlife.

- Wildlife (bats, rodents, and non-human primates) sampling at selected sites, with increased efforts for rodents and non-human primates and potential longitudinal sampling at a few selected sites to analyze patterns of viral shedding and spillover risk.
- Continue to develop predictive host-range models and spatial risk models to prioritize sampling sites and species in Years 3-5 of the project.
- Conduct viral family-level molecular screening of collected wildlife samples for coronaviruses, filoviruses, and paramyxoviruses.
- Perform serology testing on the wildlife samples for coronaviruses, filoviruses, and henipavirus.
- Continue developing a more comprehensive multiplex CoV RBD-based sVNT covering newly identified sarbecoviruses and additional merbecoviruses to allow the evaluation of neutralizing activity in serum samples against a much broader and more comprehensive range of RBDs.
- Conduct whole-genome and spike glycoprotein sequencing in countries with newly identified viruses.
- Continue research to further characterize a subset of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies, including pangolin GD strain, BANAL-52, and other significant viruses identified in Y1-2.
- Develop zoonotic risk analyses for relevant viruses, including the analysis of Spike and whole-genome sequences to predict host range using a variety of in silico approaches, model the host range, geographic distribution, extent of overlap with high-density human populations, etc. using existing apps/models to assess potential zoonotic disease risk

Specific Aim 2: Identify evidence and analyze risk factors for viral spillover in high-risk communities using novel serological assays

- Increase the number of sites and enrolled participants for community surveillance among at-risk populations for biological and behavioral data collection in Thailand, Peninsular Malaysia, and Sabah Malaysia
- Continue to identify community sites concurrent with animal surveillance sites (Specific Aim 1).
- Perform serology testing of collected human samples with optimized multiplex assays for coronaviruses, filoviruses, and paramyxoviruses
- Begin epidemiological analyses of biological and behavioral data.

Specific Aim 3: Identify and characterize viral etiology of ‘cryptic’ outbreaks in clinical cohorts

- Start enrolling participants at selected hospital/clinic sites for syndromic surveillance at two sites in Thailand, and identified sites in Sabah, Malaysia and Peninsular Malaysia, Malaysia
- Continue to identify potential clinical cohorts and sites in the catchment of the community (Specific Aim 2) and animal surveillance (Specific Aim 1) sites.
- Start serological and molecular testing on collected human samples.
- Start viral characterization work if any novel viruses are identified.

Through the work under Specific Aims 2&3, we are engaging multiple disciplines of social science, anthropology, health policy, and behavioral science towards EID risk mitigation strategies on key human-animal interfaces, we will share relevant research methods (e.g., behavioral questionnaires) and best practices with the CREID Network members.

Training and capacity-building activities among in-country team members, especially young EIDs researchers, to strengthen domestic, regional, and international capacity and readiness to efficiently undertake the research required in response to emerging or re-emerging threats. Available training materials or resources will be made available to the CREID Network.

- Conduct annual field biosafety and animal surveillance training (bats, rodents, non-human primates) with lectures and discussion as well as hands-on guidance.
- Conduct training in enriched RNAseq protocols for coronavirus whole-genome sequencing.
- Conduct training in traditional viral whole-genome sequencing using primer walking for paramyxoviruses.
- Conduct virtual and in-person viral phylogenetic and metagenomics analysis training.
- Trial the use of the portable Oxford Nanopore MinION platform as an in-house sequencing solution in Malaysia.
- Continue training on multiplex microsphere immunoassay (MMIA) data analysis and interpretation.
- Conduct refresh training on human research regarding survey design, interview skills, and data analysis.
- Finalize the standard operating procedures (SOP) manual for emerging infectious disease research field biosafety for peer-review, publication, and broad distribution.
- Continue sharing research resources (protocols, SOPs, technologies) and results within the scientific community and local government in a timely manner.
- Organize meetings and workshops with scientists from Southeast Asia to identify common challenges and opportunities for emerging infectious disease research in the region (November 2022).
- Initiate exchange training for young researchers among EID-SEARCH partners for NGS and other laboratory technology transfers.
- Support in-country outbreak research and response.

Appendix A: 2021 EAC Report

Centers for Research in Emerging Infectious Diseases (CREID) CREID External Advisory Committee (EAC) Summary In follow up to the CREID Network Annual Meeting November 3-5, 2021 (virtual meeting)

Prepared by Mark Feinberg, MD, PhD on behalf of the CREID EAC

Overview of EAC Perspectives and Recommendations

The EAC members were unanimous in their assessment that the CREID Network team made very impressive and positive progress in their first year of this very important and timely new NIAID/DMID initiative. While the amount of progress realized in starting up a new global collaborative research network would be highly laudable overall in any circumstance, the EAC members were even further impressed by the fact that the initiation of the CREID Network coincided with the emergence of the COVID-19 pandemic (with all of its attendant challenges). This coincidence provided a clear initial focus of many of the CREID efforts on SARS-CoV-2-related topics, but it also provided very strong validation for the original rationale for establishment of the CREID Network by the NIAID/DMID leadership as a means of fostering global networks for research collaboration on emerging infectious disease threats.

While the EAC members identified a number of areas where additional attention and effort will be beneficial to maximize the impact of the CREID Network, and key to fostering the sustainability of its efforts, our expectations for what the Network has the potential to accomplish were raised by the strong foundation that the CREID PIs and collaborators have already put in place in their first year. We were also very impressed with the clear commitment, thoughtfulness and inclusive approach of the CC leadership, and with the expertise, passion, and experience of the broader CREID Network community of scientists. At the heart of the CREID is a commitment to new models of collaborative science that links investigators from around the world to understand, prepare for, and respond to emerging infectious disease threats. As such, the extent to which CREID utilizes current best practices for collaborative research and pioneers new ones; embraces the essential role played by investigators working in countries at risk for disease emergence (including resource-limited settings); partners in new and more effective and mutually trusting ways with governments, normative agencies and other emerging infectious disease-focused research organizations; exemplifies and communicates the value of scientific research in providing solutions to emerging infectious disease threats to governments and the public; and delivers on its commitment to genuine research capacity strengthening and sustainability will be critical measures for evaluating the future success of the CREID. The EAC recognizes that this is a very ambitious agenda filled with often challenging objectives, and that the inherent nature of time-limited NIH funding mechanisms presents additional challenges to their potential realization.

In considering these issues, the EAC felt that significant progress has been made in the first year of the CREID Network, but that additional opportunities exist for the PIs and CREID investigators to be even more intentional and strategic about their collaborative research efforts. The CREID Network has the opportunity to establish a number of positive precedents in models of effective global collaborative science where the “whole is truly greater than the sum of its parts”; by demonstrating new approaches for the “decolonization” of international research; and by delivering on a strong commitment to diversity and inclusion in all of its endeavors. In many ways, achieving these goals will require innovation in collaborative research models within a large global network, and not just in delivering innovative, high quality scientific research results. The EAC members recognize the challenge of finding the right balance between investigator- and RC-initiated science with broader strategies and shared goals of a large collaborative network, but also note that doing so will require an overarching strategy, effective

communication tools and ongoing performance monitoring and adjustment. The EAC members also recognize that the important Network goals of research capacity strengthening and sustainability are not trivial undertakings and that they are very promising, but also rather novel objectives, within the context of NIH-supported research programs. These are additional important areas where the CREID CC and RC leadership can further articulate a respectful, inclusive, realistic, achievable and measurable strategy.

In all of these areas, the EAC recommends that the CREID investigators further develop and implement (a) a clear, well-defined and shared set of Network priorities (that links the work across RCs) and key performance indicators (KPIs) to measure performance toward realizing them, (b) a shared strategic vision and plan that connects the research efforts being prioritized and conducted across the Network centers, (c) a mechanism to share best practices across the Coordinating Center (CC) and Research Centers and (d) a proactive approach to identify collaborative research opportunities, fill gaps, avoid duplication and pursue synergies both within the CREID Network and, importantly, with the large and growing number of other organization working on preparing for and responding to emerging infectious disease outbreaks. Clarity and specificity in these efforts will be beneficial, as well as adopting an appropriate sense of realism about what can be accomplished by the CREID Network itself and where the new partnerships it implements with other organizations working in the emerging infectious disease arena will be essential. In this regard, given the complexity of the emerging infectious disease landscape, the CREID Network's ability to have the most significant impact will likely depend on the connections it establishes with other stakeholders and the innovation it drives in conceptualizing and delivering on effective new collaborative endeavors it develops with other capable partners. Towards this end, the Network would benefit from developing a thorough understanding of the ecosystem of potential partners and a defined approach to engage with the most relevant and promising ones. In addition, while the CREID Network includes collaborators from many centers and countries, its true global scope is limited by gaps in its geographic coverage (eg, countries in Asia, the Middle East, Northern Africa, Australia, etc...including those where risk of pathogen emergence are significant). Understanding if the CREID Network will be limited by its current geographic reach or plans to work to build additional connections (perhaps via strategic partnerships) in other regions will be beneficial from both practical and strategic levels.

Given that the readiness of the CREID Network for future outbreak response (and to be able to perform research in the midst of an outbreak when many challenges prevail) and for pandemic preparedness is a priority for NIAID/DMID, it will be important for the Network to clearly define how they best proactively plan to be able to promptly implement critical research programs when a new pathogen emerges or a previously known one reemerges. It will also be beneficial for the CREID CC and RCs to develop a clear plan (including protocols for coordination, implementation, data sharing and communication) to enable the Network to be able to respond expeditiously to an emerging infectious disease threat. Towards this end, tabletop exercises (or similar) to "pressure test" Network approaches and identify gaps/opportunities for improvement are worth considering.

The EAC is excited about what the CREID CC and RCs, and all of the collaborating CREID investigators, have accomplished in their first year of work and look forward to seeing the innovations and insights the Network will deliver in the future. The EAC recognizes that the CREID Network cannot realistically be "all things for all people", and should not strive to be. WE therefore also look forward to seeing how your Network priorities are further articulated, implemented and measured moving forward.

Additional EAC Impressions

The EAC felt that the Executive Summary of the CREID Network Annual Meeting provided an accurate overview of the meeting proceedings and of the EAC feedback provided at the end of the meeting proceedings. Some specific additional impressions/requests shared by EAC members include:

- Gaining a better understanding of how CREID investigators are interfacing with local governments and ministries, public health authorities (eg, WHO, US CDC, Africa CDC, etc), normative agencies will be helpful, and how learnings of effective approaches should be shared across the Network. In addition, optimization of engagements with other research organizations, enabling disciplines (eg, social science, health economics, health policy, ethics), as well as the medical countermeasures community, will be helpful
- Gaining a better understanding of the experience to date in data sharing efforts and how these can be optimized
- Gaining a better understanding of how bilateral sharing of research materials and specimens can be optimized (given the role of host institutions and government policies) and how these might operate during an outbreak/pandemic
- How the CREID investigators view and are approaching their educational efforts with governments, political leaders and the public, and sharing of best practices for engagement and trust-building
- How the CREID Network is engaging with industry partners that both supply enabling tools and technologies and who may also assist in the development and commercialization of CREID-advanced innovations (eg, diagnostics)
- Opportunities exist to demonstrate the CREID commitment to decolonization of global health (with increased attention to having the voices from LMIC-based investigators better balanced with those of US-based investigators)
- Opportunities exist to better model the Network's and the NIH's commitment to DEI objectives (with increased attention to full representation in all aspects of the work...including presentations, leadership groups, pilot research awards)
- Opportunities for enhancing epidemiology, bioinformatics, digital tools and modeling capacity
- Gaining a better understanding of the role of social and cultural aspects of the outbreak response and communication, and exploring innovative approaches to address them
- Understanding how engagement with governments and other local stakeholders is being pursued to advance capacity strengthening and sustainability goals
- Further articulation of rapid response collaboration frameworks
- Gaining a better understanding of how local priorities influence the prioritization decisions of the CC and RCs
- Gaining a better understanding/"needs assessment" of capacity gaps (eg, BSL-3 training and labs) and how these are being addressed via strategic connections or focused investment
- How "parachute or safari research" is avoided, and how local researchers are engaged as full partners/leaders
- Definition of opportunities to maximize speed and efficiency in research implementation efforts (eg, US permits and in-country regulations, IRB delays, key relationship gaps) needed for prompt outbreak responses
- Value of developing a clear vision and plan for sustainability that maximizes the connection with and contributions of other partners and local governments
- South-South collaboration should be applauded and fostered
- Shared EAC interest in seeing the CREID Network's progress in ongoing database and biorepository workstreams

Appendix B: NIAID CREID Network Program Priorities (April 2022)

(4 main priorities all carry equal weight and are intended to cover research and activities to prepare for and respond to emerging and re-emerging threats.)

- **Conduct innovative research to expand our knowledge of emerging and re-emerging infectious diseases and better prepare to respond to outbreak/pandemic threats**
 - Research Priorities:
 - Pathogen discovery & characterization
 - Pathogen/host surveillance
 - Pathogen transmission
 - Pathogenesis & immunologic responses in the host
 - Natural history & contemporary clinical disease
 - Develop reagents & diagnostic/detection assays
 - Engage in coordinated, Network wide outbreak/pandemic research readiness, differentiated from standard public health responses
- **Establish a collaborative, strategic, and preemptive research Network to ensure coordination of efforts across the Network**
 - Centralize communication
 - Conduct Network wide capacity inventory
 - Establish effective data harmonization and platforms for sharing
 - Harmonize sample collection, biorepositories, and network sharing/agreements
 - Share laboratory assay best practices and protocols
 - Share reagents, diagnostic/detection assays, and other resources
- **Develop and expand flexible domestic and international capacity and readiness to efficiently undertake research required in response to emerging or re-emerging threats**
 - Prioritize and engage with key stakeholders that will enhance network capabilities and integrate into the global health landscape
 - Strengthen and enhance research collaboration and partnerships globally
 - Pivot programmatic priorities and resources when needed for a timely response to emerging or re-emerging pathogen threats
 - Develop protocols for coordination, implementation, data sharing, and communication.
 - Execute tabletop exercises to test, refine, and maintain Network readiness
 - Formulate novel strategies to detect, control, and prevent outbreaks
 - Translate findings to downstream partners to facilitate development of medical countermeasures or preventive interventions
 - Develop adaptable risk assessment tools for evaluating a pathogen threat's potential for significant emergence and impact
- **Contribute to the development of the next generation of emerging/re-emerging infectious disease scientists and leaders**
 - Develop and maintain a pilot research program
 - Foster a diverse and inclusive research environment and program

Hi Eric,

Just sharing an updated version of draft v03 where Lisa and Cait from UNC addressed some of your comments on "Host range, transmissibility, and antigenicity of a pangolin coronavirus", in case you want to know (the paper is under revision, and no preprint). Also attached the final version from Peter for your information.

Cheers,
Hongying

Dear All,

As mentioned at the EID-SEARCH meeting in July, we'll submit an External Advisory Committee (EAC) report for our Research Center in August, so the EAC can evaluate our work as an individual Research Center and the overall CREID Network to give feedback at the CREID annual meeting with DMID, USG, and other stakeholders in September.

Attached please find the very first draft report for your edit and review. We'll greatly appreciate everyone's input on incorporating the EAC recommendations and aligning with NIAID CREID Network Program Priorities as described in the Appendix.

For unpublished data, I tried to keep the information general, will also make sure the CREID keeps all information for internal use only (to the EAC), but please let me know if you have any concerns.

We hope to submit the report on August 19, and your feedback **by August 15 Monday** will be appreciated! Thank you all very much in advance!

All the best,
Hongying

SPECIFIC AIMS

We propose to develop robust analytical approaches for using quantitative serological data to better target novel disease discovery and surveillance in both human and wildlife populations. Multiplex and quantitative serological assays are increasingly used in disease surveillance to identify spillover, but are underutilized because they produce large datasets without a standardized analytical framework. The confounding effects of cross-reactivity, and a lack of true controls in wildlife species or for yet-uncharacterized viruses stymies use of rich quantitative data that they produce. Using PCR and other direct viral detection methods is costly because of the rarity of positive detection. **Our approach will allow more cost effective and statistically powerful serological assays to be used for identifying high risk populations for pathogen spillover.**

We will test and validate our methods using paired serological and viral detection data from extensive surveillance studies of wildlife and human populations collected and curated by our team. Our team has unique experience applying multiplex serological assays in regions of pathogen emergence in parallel with PCR-based viral detection, allowing us to use paired samples to validate our approach. This includes work on SARS-related bat coronavirus spillover in Southeast and East Asia, and filovirus and henipavirus exposure in Africa and Asia. This strategy leverages access to extensive, comparable, field data and also prior investments by NIH and other federal agencies (DTRA, USAID) in zoonotic disease emergence.

Our statistical approaches are applicable to a broad range of serological technologies that can quantify immune response including Luminex, epitope serochips, and quantitative LFIA and ELISA. **They will be published as open-source software packages to enable their rapid adoption and validation.**

Our specific aims are to:

- 1. Develop an approach for identifying and characterize novel viruses from multiplex panels of quantitative serological assays.** We will develop detailed reaction/cross reaction profiles of a broad panel of Luminex serological tests and incorporate these into statistical models with explicit representations of sampling and measurement processes. With these, we will determine whether serological “profiles” are more likely to represent antibodies of known viruses, mixtures of multiple known antiviruses, or previously uncharacterized viruses. We extend techniques of antigenic mapping, using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential
- 2. Create a robust bioinformatics pipeline for multiplex detection platforms.** “Serochips” consist of hundreds of thousands of synthetic epitopes drawn from libraries of viral genetic sequences. While promising platforms for broad surveillance, they suffer from multiple testing dilemmas combined with problems cross-reaction and within-sequence correlation. We will build mechanistic, hierarchical Bayesian models to translate the large data generated by these platforms into usable measures of immune response. Using simulation experiments, we will test reduced-form, simple models against fully structured models so as to develop statistically robust procedures to interpret these data without high-performance computation.
- 3. Use spatio-temporal quantitative serological data to identify populations with distinct profiles indicative of novel pathogens.** We will develop spatio-temporal models that capture population-level immunological patterns from spatially extensive quantitative multiplex serological assays. Using ordination techniques drawn from community ecology, we will scale up the approach to individual-scale serological profiles to populations. We will work directly with an active NIAID-funded CREID research center in Southeast Asia (EID-SEARCH), along with a global consortium of research groups using similar datasets to develop our models. These analyses will allow us to characterize groups and regions with distinct exposure profiles, characterize spatial variation, and identify populations that have unique mixtures of immune assay responses that indicate exposures to novel pathogens or distinct combinations of pathogens – targets for intensive surveillance, viral detection and characterization.

Hi Eric,

After many false starts, I really am planning to submit an R01 on bioinformatics and statistical methods for Luminex serology in the next cycle (due Oct 6). Everyone came back from the BatID conference really jazzed about this. I still think it works best with you and I as co-PIs. If you are still game, want to have a call about it? I'd still like to come down to USU for a day in the next month, too, if you'd like to spend a day working on it and other related issues.

Schedule a call on my calendar here: <https://calendly.com/noamross/60-min-chat>

Last draft of specific aims attached.

Best,

Noam

Mitra, Marcia, Admela (CS) – NSF
Peter, Ehsan, KJO
17 June 2022

Introductions.

Mitra: They needed to consider things other than review scores, had different panels from 4 disciplines. Had to balance across panels and optics (or topics?). Geographic diversity, and various other factors.

Panel summary. Scoring can be high, but in some disciplines like CS, scores are usually low.

Will be funding around 25. They haven't announced them all yet. Can't tell statistics at this point (including how many proposals they received), probably won't be published. Score not only factor.

NSF had 125 internal meetings to develop this project.

Not stopping here, going on to center stage. We can still apply for center stage. Can think about our team as already well formed, maybe we're beyond the planning stage. Can't say how many proposals they got – but had several panels.

Prob not another round of planning grants. Full center RFP expected in 2023. Guessing it will be 5-10 center grants max.

PD: Political issues influence decision at all?
Marcia – no mention of that anywhere in the panel.

KJO was concerned that negative panel summary misread our proposal – e.g. reviewers pick up on China “samples” that we never said existed when we referenced the Sanchez et al. *modeling* study. They noted how are we going to get data was a concern.

Ehsan – EAGR grant to keep momentum up?
Mitra – PIPP is a new program, not like old program where they have extra money around. Maybe can break it down in to smaller pieces and approach other program directors, to submit as separate proposal.

Admela: If you find some aspects of our program that we want to deepen, to submit to keep momentum going. Would be happy to help us navigate that. Many programs in CS, engineering, etc. Try to reshape some to make it more.

EAGER grants are dependent on program director, and you can't just submit for a previously unfunded proposal. A full proposal would be another 1-year timeline. NSF is memory-less,

needs to go from scratch every time. Can't submit EAGER from something that has been turned down.

Mitra does DNA computing, etc. it's a little different than our proposal, so she may not be best person in CS to talk to for EAGER, etc. Approach someone in RIS? Division.

KJO mentioned how the panel summary was based on a mis-read of several aspects of our proposal. Recourse to complain? – there is a formal process but doesn't look at the reviews, just process, i.e. if process was biased.

Mitra: CS perspective that image recognition part wasn't new.

PD: need to be clearer in our language about everything the reviewers pointed out.

EHA being a sub on BU proposal did "not at all" affected our proposal. Did not come in to discussion. Problem would have only been if we proposed to do the same work, which we did not.

Admela: For center scale, need to really strengthen intellectual merit. "Upscaling" (i.e. spillover surveillance) is not an intellectual endeavor, so need to strengthen IM more and discuss in terms of difficulties of scaling up. Make it more intellectually appealing.

For CS – look at data, code, etc as a sharable good. Also highlight what is there for the rest of the community, what will be open and who will use the data.

If we're already part of a team, look for synergistic work – i.e. maybe we team up more w BU.

Will be fewer but bigger Center grants – so building synergistic activities. Could build new activities around that.

Debrief (PD, EH, KO):

Need to keep momentum

Think of specific focus and work on it. Use facebook data and keep in touch w them.

REU – only \$16k if you have an existing grant, so this may not work for support

PD: "Future of epidemiology needs to have computer science in it." So let's work to get ahead of this for our work.

Clue as to why we didn't get it: Geography. They seem to have tried to balance all the top projects in terms of geography or disciplinary focus.

Some real weaknesses mentioned: image recognition wasn't novel enough, and challenge of finding rare events.

BU proposal – Peter will follow up, but probably won't be able to do more work under their proposal. Will need to see if it makes sense to team up on Full Center. Need to review what they proposed to do and revisit.

Ehsan – mystery how 4 reviewers read panel summary and signed off on something that was incorrect.

KJO to reach out to Katarina Ditmar to see if there's anything fundable on the BIO side.

NSF PIPP Panel Summary and reviews

3 June 2022

“PIPP Phase I: Multidisciplinary advances to scale up zoonotic spillover intelligence”. PI Olival
Tracking number: **2201117**

Panel Summary

Panel Summary

1. PROPOSAL OVERVIEW

The grand challenge of this proposal is to capture spillover data quickly enough for it to be actionable. It aims to capture data at a sufficiently wide geographic & temporal scale to measure spillover.

The researchers have an existing model based on the flying fox bat – pig interaction, which can serve as a model for other spillovers. They will develop advances in rapid serological testing with lateral flow assays (LFAs) deployed to the field, to build a zoonotic virus surveillance early warning system. The team was deeply involved in SARS-related viruses, well before COVID-19.

The surveillance data will be merged with social media survey data, human mobility patterns and visual data to map potential spillover sites for further investigation.

2. REVIEW CRITERION I: INTELLECTUAL MERIT

Strengths:

A major intellectual strength is that they have distilled the fundamental problems of pandemic, spillover.

It is a strength that they have already developed a working collaboration and data network with colleagues in the field. In some sense, they are the tip of the spear, working in the field to detect spillover. They have been in field for quite some time, developing expertise.

Expanding their expertise to social media delivered surveys is much faster and broader than in-person surveys. Not particularly innovative, but fast and flexible. This project will use innovative combinations of big data, merging social media survey data, visual data and geographic base layers. Expanding their expertise to social media provides a means to gather data much faster and broader than in person surveys. While not particularly innovative, this approach is fast and flexible.

A major component element of actionable data is the proposed mapping of human/animal interaction. Spatial analysis and mapping will enable targeting and interventions in potential spillover locations before the virus becomes more widespread.

Another major strength is the development of in-field lateral flow assays (LFAs) tests to advance rapid serological testing. They plan to pilot this for Nipah virus antibody detection. This could be a major engineering and biological advancement, in that LFAs have not yet been used in the field for zoonotic virus surveillance. This field based LFA could serve as a critical tool in a virus early warning system.

The focus on viral chatter or sporadic cases in early phases, which leads to pandemics, is especially forward thinking.

Weaknesses:

The proposal makes mention of 50,000 seropositive human cases that have already collected. The proposal could have elaborated on this early finding, citing the MedArchive 2021 preprint.

There would appear to be a weakness in the origin-destination and how is this used to measure exposure. This is not a new methodology. The researchers plan to use Facebook's Space Maps and Co-location Maps. First, question is the issue of ready access to data in China. The second question is, what is the temporal and spatial scale of these tools?

How will interactions be visualized and captured when much exposure is at night. How will they capture that interaction? That was not sufficiently explained in the text.

3. REVIEW CRITERION II: BROADER IMPACTS

Strengths:

This is a strong team, integrated across the disciplines. This is the potential for novel applications such as the merging of computer science, AI, image data and mapping to generate spillover zones of interest.

Another major strength is that they are growing an on-the-ground training and experience network. Individual tasks are embedded with education and training activities. The resulting technology will have benefits far beyond individual viruses or geographic locations.

Weaknesses:

The review team was unsure if there would be barriers to using data from Facebook's Data for Good platform, given the existence of the Chinese Great Firewall. The proposal did not go into sufficient detail on whether or not this is an issue that could affect access to survey results. The same for the Internet-based image data.

4. SOLICITATION-SPECIFIC CRITERIA

Potential for interdisciplinary innovation:

The team has already conducted interdisciplinary work, and that work has advanced science in several innovative ways. The potential for location specific spillover targeting, informed by field testing, visual data, social media surveys and the transformation of those data, is a novel advancement of the science.

Qualification of investigators and team synergy:

The team has already demonstrated their expertise, as well as solid field operations, as a product of their fieldwork. It is a strength that they are already working with Southeast Asian colleagues who provide cultural and scientific expertise necessary for successful fieldwork.

Approach to center scale vision and plan:

This is an excellent "planning proposal" which aims to develop a center for spillover intelligence. It engages a wide range of individuals and institutions.

The proposal clearly lays out the vision for scaling up from a planning and research activity project to a functional Center.

Project management quality:

Their plan calls for an Advisory Board, a Steering Committee and the three focus area research groups will be led by a multidisciplinary team of Co-PIs. Notably, they have designated a Project Manager to administer operations.

5. SUMMARY STATEMENT AND RECOMMENDATION

This is a well-developed proposal that builds on excellent research and results to date. They have already accomplished the formation of a team of collaborators and piloted a data collection system. They are on the cusp of making major advance in basic science (computer and information science, engineering, biological sciences and social and behavioral science), pandemic intelligence, collaboration and education. The rapid serological testing, supported by computer science expertise, merged with a unique combination of social media, will be a major advance for monitoring and alerts. The end product of this planning grant would be the formation of a transdisciplinary center that is devoted to early warnings of zoonotic spillovers that threaten mankind.

The panel recommendation is: Highly Competitive [HC]

This summary was read by the assigned panelists, and they concurred that the summary accurately reflects the panel discussion.

Review

Summary

In the context of the five review elements, please evaluate the strengths and weaknesses of the proposal with respect to intellectual merit.

1. Synopsis

This application from Dr. Kevin Olival and colleagues at EcoHealth Alliance, University of Rochester, and Georgetown University aims to develop a Center for Spillover Intelligence (CSI), an intellectual and operational construct engaging a range of individuals and institutions that will endeavor to develop systems of surveillance and prediction that capture at a sufficiently wide geographic and temporal scales when and where viral spillovers from wildlife or domesticated animals will occur to humans. The concept focuses on the problem of pre-viral emergence and viral chatter, that “gray zone” of spillover transmission when human cases of infection occur sporadically but prior to the generation of human to human transmission and expansion of the spillover phase to outbreak or pandemic conditions. The Grand Challenge statement is a distillation of public health and scientific concerns brought into sharp focus by the COVID-19 pandemic episode, namely, how can actionable data (about the risk of zoonotic spillover and spread at the scale and speed required to prevent outbreaks) be captured? This, of course, is not a new question and is at the heart of any proactive disease surveillance system. The aim for this center is to satisfy the demands of this question through research and training activities of a collaborative nature.

2. Intellectual Merit

Strengths:

1. Somewhat counterintuitively, an intellectual strength of this application is in the way it distills the fundamental problems of pandemic prediction to clear and basic, simple problems (surveillance at adequate scale) and from this rather frank admission proposes specific pathways of case studies to advance knowledge in this research space.
2. The rapid application of technology to measure prevalence of seropositivity as a measure of spillover, while conceptually not new, is an example of the distillation to simple problems as addressed above. The intellectual merit is in re-visiting this old idea not merely with more rapid technology but with the analysis of the information into the decision making framework that is proposed, bridging from Aim 2 to Aim 3.
3. This is an exceptionally qualified team to address the problem of spillover dynamics; it is the science that this group has been doing for some time operationally in real life contexts.

Weaknesses:

1. Conceptually, no one knows if examination of anyone emergence scenario (such as Nipah virus as proposed here) will allow generalizations of the principles under investigation and elucidation for all such scenarios; thus the transformative nature of it (that is, to truly change the way the scientific community and public community can predict spillover leading to pandemic system behavior) is simply uncertain.
2. The argument is well made but generally understood that more intensive, up-scaled surveillance is more likely to capture spillover events than are others. This is not an intellectual bridge to new ways to investigate the problem, but a sort of admission that it is what is needed. The problem is that it has serious limitations: costs, infrastructure, capacity, public support (or lack thereof), and the kind of invasiveness into life that not all people or societies find acceptable or implementable.
3. The case is made that the EHA had evidence of covid bridging from serology data of some 50,000 positive samples in the China study setting, pre-pandemic. It is hard to know from this observation if this empirical finding represents virus bridging dead ends, stuttering, or viral chatter;

indeed these descriptive categories are not entirely separated or epidemiologically recognizable. If pandemic breakouts occur in tandem with these events, and they are results of spillovers or bridge transmission from enzootic reservoirs, what is the frequency of them when pandemic breakouts don't happen? The latter must be a rare event given what appears to be evidence for frequent spillover. That appears to be the intellectual challenge to this application, and is a comment regarding assessment of success: what exactly is an anomalous event?

In the context of the five review elements, please evaluate the strengths and weaknesses of the proposal with respect to broader impacts.

3. Broader Impact Strengths:

The lateral flow technology with multiplex serologic analysis has the potential to allow rapid and broad assessment of changes in seropositivity to suites of pathogens, offering a means of measuring spillover events with large data sets.

Weaknesses:

It is hard to envision the broad impact of the image analysis approach to human / mammal contact as a means to assess the potential for spillover. What are the limitations, such as when contact occurs when it is dark and images cannot be derived, or when the contact is not direct but indirect through excreta or contaminated surfaces? As a generalized methodology with broad impact, this concept has uncertainties. It is also weakened by some individual and societal resistance to the invasiveness required to implement it. One would have to justify the invasion of the privacy of people in public spaces (market settings, for example).

The origin/destination analysis may provide data on human movement and inform pathogen movement through movement networks and pathways, but this is a rather well studied area that has been addressed through such means as cell phone network and use analysis. For example, it has been used to explain the excess of human malaria cases in cities of SubSaharan Africa where the origin of those cases is rural exposure but infection and disease manifests in cities.

Please evaluate the strengths and weaknesses of the proposal with respect to any additional solicitation-specific review criteria, if applicable

1. An ambitious grand challenge. The grand challenge statement regards scientific activities that address the problem of capturing adequate, robust data at scale to inform spillover events that may lead to pandemic outbreaks. This is a fundamental problem that nearly everyone will agree with. How to go to adequate scale (sample size to measure meaningful and real changes confidently) is a true limitation to the science of prediction of outbreaks of disease.
2. Going beyond current science. The utilization of recognition software and imaging systems as means of measuring nonhuman animal hosts of pathogens and human interfaces with them was not convincing.
3. Sub-project innovation and synergy. The three research areas were well defined and synergistic. There is an especially good bridge from Aim 2 to Aim 3.
4. Disciplinary component and context. Cross disciplinary elements are emphasized throughout; the anthropological dimension including development of gamed scenarios was difficult to envision in the context of the other proposed components of the research plan.
5. Center-scale vision and plan. The concept of a Center for Spillover Intelligence is well

articulated and designed. The notion of a Spillover Situation Room has appeal.
6. Project management. A Project Management Plan is evident.

Summary Statement

The application from Dr. Kevin Olival and colleagues at EcoHealth Alliance, University of Rochester, and Georgetown University takes advantage of robust, on going programs of emerging infections to quantify extent of exposure to zoonotic pathogens and predict anomalous spillover events. The basic concept of scaled up surveillance is facilitated by rapid-processing recognition systems and multiplex assessment of seropositivity rates in human populations which information can be integrated quickly into models towards decision making regarding the nature of the spillover. The grand challenge statement, while compelling, admits to the common problem that scale up of surveillance is a limitation that faces nearly public health and disease surveillance, including research, activities and fundamentally becomes a problem of sample size to capture rare events. How to accomplish this in the face of logistic, funding, and societal limitations places constraints on the broader impact of the proposed effort.

Proposal Review 2 : 2201117

Olival, Kevin

Application Title:

PIPP Phase I: Multidisciplinary advances to scale up zoonotic spillover intelligence

Rating:

Excellent

Review

Summary

In the context of the five review elements, please evaluate the strengths and weaknesses of the proposal with respect to intellectual merit.

This proposal tackles a crucial challenge of pandemic prediction and prevention: acquiring actionable intelligence about what happens at the zoonotic spillover boundary fast enough to make a difference. There are two components here: describing conditions where a zoonosis is likely to emerge and become established in a human population, and actually detecting such an event when it occurs. By integrating big-data analytics and social media engagement with established medical anthropology approaches, the investigators aim to identify and map behaviors likely to bring people into contact with potential zoonotic reservoir animals, much faster than was possible with traditional surveys. The investigators have also developed ambitious and potentially transformative approaches to detecting zoonosis emergence through advanced rapid serological testing and looking for behavior anomalies that could signal events of high spillover likelihood or actual disease taking hold.

These approaches represent ambitious but feasible advances in their respective fields and represent synergistic collaborations across disciplines. EcoHealth Alliance has extensive experience uncovering behavioral and ecological conditions that enhance spillover, and the team brings in expertise and massive datasets to develop methods to identify potential spillover events, as well as medical anthropology, network modeling and analysis, and disease assays and surveillance. Resource to begin this work identified for phase I appear to be available at the participating institutions, and the partnership with Facebook is key.

In the context of the five review elements, please evaluate the strengths and weaknesses of the proposal with respect to broader impacts.

This work has strong potential to generate positive broader impacts. The grand challenge of this project has strong potential to provide societal benefit through mediation of spillover prone conditions and early detection of zoonoses that become established and begin to spread among people. The investigators show a thorough grasp of the ethical and privacy considerations of the data they aim to use, and the work would provide a vital opportunity for training and education in multidisciplinary epidemiological and ecological research. They also indicate products will be made publicly available. Finally, the investigators aim to enhance recruitment and participation of underrepresented groups although the specific mechanisms are vague.

Please evaluate the strengths and weaknesses of the proposal with respect to any additional solicitation-specific review criteria, if applicable

This proposal identifies a very specific yet very important and ambitious grand challenge, and the proposal describes a thorough and sophisticated approach to tackling it. The assembled team definitely provides complementary expertise and are connected to broader research and public policy contexts, and the collaborations are vital to success of the effort. The Project Management Plan does a good job of sketching the investigators' roles and the overall management structure. Coordination mechanisms are well described and appropriately ambitious. Metrics for success provided are clear and there is a concrete vision for scaling up to phase II. The budget reflects the activities described.

Summary Statement

This proposal tackles the crucial challenge of providing information at the site and time of zoonotic spillover, potentially allowing pandemics to be prevented or stopped at very early stages. The work described is ambitious yet feasible, and strongly multidisciplinary with strong potential to advance

beyond the existing strengths of the team. Effective prediction and prevention of pandemics would have enormous societal benefits, and the proposed work would enhance knowledge dissemination, generate new research infrastructure, and provide valuable training to students and early researchers.

Proposal Review 3 : 2201117

2201117

Organization:

NSF Program:

PIPP-Pandemic Prevention

PI/PD:

Olival, Kevin

Application Title:

PIPP Phase I: Multidisciplinary advances to scale up zoonotic spillover intelligence

Rating:

Excellent

Review

Summary

In the context of the five review elements, please evaluate the strengths and weaknesses of the proposal with respect to intellectual merit.

This is an excellent “planning proposal” to build a collaborative research and training network with ambitious to grown and scaled up to a future Center for Spillover Intelligence (CSI). Its vision and rationale for “piloting innovative approaches to large-scale spillover intelligence” are clearly articulated and easy to appreciate. The grand challenge is important and has clear societal impact and benefit: How can we capture actionable data about the risk of zoonotic spillover (and early spread) at the scale and speed required to prevent outbreaks? The proposal outlines a truly multidisciplinary team approach and recognizes the need for working beyond “previously siloed scientific domains”. The proposal, pilot projects, network (cross-)membership and project management mechanisms are structured by three clearly articulated aims: 1) Measuring human-animal contact at scale; 2) Detecting zoonotic disease exposure at scale; 3) Rapidly Identifying Anomalous Health Events. Not only are network members linked to specifically to these aims

through designated working groups, but specific education and training events and activities are embedded within them.

2. Intellectual Merit

Strengths: There is considerable potential to advance knowledge of poorly understood zoonotic spillover effects through the network operating in a truly multidisciplinary way beyond siloes. It clearly articulates the need and ambition to undertake disease surveillance and research “across a wide enough geography [and at an appropriate] temporal or spatial scale needed for disease mitigation”. They propose data collection at a global scale using a variety data types.

The proposal contains considerable creativity, originality, and is potentially transformative both in its overall objective of both establishing and providing “spillover intelligence” and also in different data collection and harvesting activities associated with different research aims and associated pilot projects (e.g. quantitative/qualitative behavioral data collection through partnership with Facebook; image recognition and AI to quantify and map human-wildlife contact; first field-forward lateral-flow assay for Nipah virus antibody detection; using machine learning to detect changes in human mobility patterns that may giving warning of potential spillover).

The research plan is particularly well-reasoned, well-organized, and based on a sound rationale, and has appropriate mechanism to assess success including proposed metrics. There is very clear vision to grow the a collaborative research and training network with ambitious to grown and scaled up to a future Center for Spillover Intelligence (CSI) and do this using pilot projects associated with the research aims. Education and training are clearly embedded and communicated with these aims/project and will deliver capacity building.

The multidisciplinary team is extremely well qualified and experienced. It has an outstanding track record in undertaking research, NSF support, publication, and translating research into practice with impressive stakeholder impact.

Weaknesses: I have not identified anything specific at this stage but anticipate others might have (and look forward hearing about these from other panelists).

In the context of the five review elements, please evaluate the strengths and weaknesses of the proposal with respect to broader impacts.

3. Broader Impact

Strengths: There is considerable potential to benefit society through facilitating zoonotic spillover intelligence at global and local scales.

There is considerable creativity originality, and novelty in the proposed plan to implement broader impact. A very strong feature is the plan for capacity building which will to “initiate interdisciplinary program to train a new generation of graduate and undergraduate students understanding medical anthropology, disease surveillance, and data and network science so as to become future leaders in spillover intelligence. Other training and research exchanges related to pilot research projects are also detailed. A wide range of stakeholders are also alluded to (e.g. EcoHealth Alliance).

Is the plan to achieve the BIs is well-reasoned, well-organized, and based on a sound rationale and embedded with the proposed networks activities (i.e. 3 project aims) and project management plan.

Weaknesses: Might have said a little bit more about potential for broader impact activities with non-academic public sector stakeholders

Please evaluate the strengths and weaknesses of the proposal with respect to any additional solicitation-specific review criteria, if applicable

An ambitious grand challenge is presented that is forward-looking, and if successful to provide scientific breakthroughs in large-scale spillover intelligence (see synopsis).

Going beyond current science. The proposal include an innovative vision with potential to be transformative in undertaking truly multidisciplinary research by building a research network for spillover intelligence and developing and proof of concept pilot projects (see intellectual merit) Sub-project innovation and synergy are a particular strength of what is proposed and draws upon the comprehensive multi-disciplinary research team/network. The targeted pilot projects and outputs are well-integrated have focused synergetic goals (c.f. Fig.2). They appear to provide considerable potential to advance the involved disciplines

Disciplinary component and context. This is well articulated as are the inter-disciplinary linkages. Center-scale vision and plan is clearly articulated with vision to grow from a research network to a fully-fledged Centre.

Project management and data management plans are exemplary, clearly articulated and fully

Summary Statement

This is a very thoughtful and realistic truly multi-disciplinary “planning proposal” to build a collaborative research and training network with ambitious to grown and scaled up to a future Center for Spillover Intelligence (CSI). It clearly articulates and timely and important grand challenge with clear societal impact and benefit: How can we capture actionable data about the risk of zoonotic spillover (and early spread) at the scale and speed required to prevent outbreaks? It is an excellent fit with the PIPP Phase 1 solicitation with 3 excellent aims that structure the network, it aims, outputs, membership, and project management mechanisms proposals. It details very suitable and appropriate pilot projects, education and capacity building which is at the Centre of its vision and demonstrate clear impact benefits and activities. In summary compelling case is made for supporting the establishment of research and training network.

Multiple Rating: (Excellent/Very Good)

Review

Summary

In the context of the five review elements, please evaluate the strengths and weaknesses of the proposal with respect to intellectual merit.

1. Synopsis

The research team plans to collaborate among the disciplines of computer science, engineering, data science and Facebook, a.k.a. Meta, to develop an Internet-sourced early warning system using AI, anomaly detection and machine learning. The team will also develop a unique lateral-flow assay field detection device, to be deployed in the field. The plan is premised on global scale data collection. Detection of pathogens is primarily based on the assumption of anomalies in human behavior that would be detected via social media.

2. Intellectual Merit

Strengths:

The background and statement of the problem is strong and compelling.

The research team plans to leverage existing funded research from NIH and DTRA to develop and test novel rapid serology tests and lateral flow assay tests. This increases the likelihood of major advances in the development of rapid bioinformatics and in-field testing, which is critical to a functional early warning system.

The reliance on social media image recognition, while not novel, does access a potentially useful data source.

The overall plan, as well as the initial aims, are well defined, developed and reasonable. Varying degrees of success in realizing the goals will help lay the foundation for a Center moving forward.

The research team is well qualified in terms of experience, past and current projects, collaborations, and resources. As outlined, the team is fully capable of undertaking Phase 1 research.

Weaknesses:

The researchers mention the “SARS-related coronaviruses in China” as a specific example of spillover threat to humans. The team will partner with Facebook’s Data for Good. How will the team pierce the Great Firewall that prevent access to China’s Internet, given that pathogens in China are a specific concern?

Regarding the surveys of specific populations (p. 11 of 167), how will they target geographic areas using Internet-based social media. The researchers will be using the Facebook platform. How ubiquitous is the Internet in edge locations? I would think not very. What alternatives do the research have to conducting surveys where the Internet is not present, or not in high use?

The researchers mention their extensive experience and infrastructure in Southeast Asia. Why not

pilot pre-emergent flu detection, since most flu originates in that region, early detection would facilitate the creation of that season's vaccine and would be beneficial world-wide.

In the context of the five review elements, please evaluate the strengths and weaknesses of the proposal with respect to broader impacts.

3. Broader Impact

Strengths:

The team's aims, if successful, would have broader societal impacts both in terms of advancing scientific knowledge and also, given the collaborations with industry, the development of early warning and surveillance tools for multiple threats.

The team plans to develop lateral flow assays (LFAs), tests that can be conducted in the field. The researchers note that LFAs have not yet been used in field for zoonotic virus surveillance. Such an advance would have societal benefits since such a test would be a critical tool in a virus early warning system, regardless of the particular virus.

Overall, the approach is well-grounded, internally consistent and builds on the team's current experience and expertise.

Weaknesses:

The social media component's reliance on samples of convenience and self-reporting is weak. Any intelligence gleaned from this data would have to be ground truthed which, given the number of "hits" on any day, could mushroom to unsustainable scales.

Please evaluate the strengths and weaknesses of the proposal with respect to any additional solicitation-specific review criteria, if applicable

In addition to the two National Science Board-approved merit review criteria of IM and BI, the PIPP Phase I solicitation has the following program-specific criteria, which need to be addressed:

1. An ambitious grand challenge.

The proposal is ambitious, but not beyond the realm of achievability. It is a logical extension, and in the case of field testing, a technological leap, in developing the tools and methodologies for an early warning system.

5. Going beyond current science.

The greatest innovations appear to be in the field testing and deployment. I leave it to my other reviewers to assess the potential.

6. Sub-project innovation and synergy.

The individual aims, while separate disciplines and domains, are necessary for the development of the final early warning system. The barrier to success will be not successfully integrating the two domains into a cohesive system.

7. Disciplinary component and context

Aim 3 seeks to identify signs of health-seeking behaviors using social media, communication patterns and mobility (cell phone?) patterns. I would caution the team on three points. First, Google's

Flu Trends was eventually abandoned after overestimating flu cases. The primary reason was that on-line health seeking behavior was not as correlated with actual cases as expected, and thus gave rise to inflated estimations. Second, individuals are not trained to recognize symptoms nor ask the right Google questions. Thus flu, colds, seasonal allergies, and hangovers comingled in the Google space. Third, what we are interested in are very, very rare events, assuming that we can identify it before it becomes an epidemic in a region. Thus, the challenge is not only to analyze massive data streams, but also to be able to correctly identify the rare event, without making a false positive or false negative mistake. To put this in perspective, worldwide there are 5.4 BILLION Google searches per day.

The use of Instagram image-recognition should be more fully developed and exploited. Posts and image contain both a time and location stamp, which makes them a valuable source of image remote sensing. Further, I get the sense that the demographics of social media use are becoming skewed away from Facebook. Thus, it become even more important to scrap other social medial platforms in order to capture the younger and higher-use social media posters.

I agree that origin-destination matrices do not typically operationalize a temporal component and are thus less useful for tracking the length of time (spreading infection) at a location. The researchers plan to use Facebook's Activity Space Maps and Colocation Maps. What is the temporal scale and what is the spatial scale of these tools?

The researchers plan to "target areas known to include health care facilities in pursuit of abnormal trends." (p. 16 of 167). Given that these facilities are (relatively) near edge land use, what is the likelihood that the facility can report anomalies quickly (likely lacking electronic medical records) and what is the likelihood that the facility will recognize a novel spill-over quickly?

8. Center-scale vision and plan.

The proposal clearly lays out the vision for scaling from a planning and research activity project to a functional Center.

9. Project management.

Project management will consist of an Advisory Board, a Steering Committee, and the three focus area research groups will be led by a multidisciplinary team of Co-PIs. The management plan calls for meetings every month. I would feel more comfortable with the commitment to meet at least twice monthly, and more like weekly for the initial phase. True collaboration comes from deeply understanding other disciplines, the lens through which they view the work, and the nomenclature that they use. Notably, they do designate a (part-time) Project Manager to administer operations.

Summary Statement

10. Summary Statement:

This is a well-developed proposal, with clearly defined short term objective with an eye toward fleshing out a Center. The research objectives are important extensions to established science, extensions necessary to developing an anomaly and early warning zoonotic intelligence system. The individual aims are reasonable and achievable. The overall research objective appears to be scalable. The research team has the necessary experience in the topical areas and, in some cases, are already doing preliminary research in those areas. As the researchers note, these are fresh collaborations. As such, I would revisit and strengthen the formal and informal channels of communication. The institutional resources and support are appropriate.

[Olival NSF PIPP Panel Summary and reviews 3June2022.docx](#)
[ATT00004.bin](#)

Dear all,

We (me, Ehsan, Peter) had a 1 hour call w NSF on Friday afternoon to discuss our unfunded NSF PIPP proposal. Here are my notes summarizing the call.

In short, we ranked very high but will not get funded. They encouraged us to try and fund parts of the proposal via other mechanisms, but these could involve putting whole proposals together (~1 year time frame before funding), but we will pursue other mechanisms that could be quicker like EAGER grants. I will also follow up w Katharina Ditmar (the BIO NSF PIPP program officer) to get her thoughts.

In any case, this is very frustrating as we were “highly competitive” and clearly came so close to getting funded. I still believe (as I summarized in my previous email to the NSF program officers) that the reviewers just flat out got some things wrong that we laid out quite clearly, esp. 2 of the main negative aspects in the panel summary - but seems we have no real recourse here but to try other funding mechanisms, and/or apply for a Center level grant in ~1 year. We also agreed it would be great to not lose momentum before the RFP for Center level grants, and maybe find ways to do some of what we proposed (albeit without funding!). Chime in if you have some specific ideas.

Appreciate everyone’s hard work on this. Upward and onward.

Cheers,
Kevin

P.S. Sending the panel summary and reviews again too, as I didn’t send them to everyone here before.

Notes - PIPP planning call - 2 September 2021

Participants:

- *EHA*: Kevin Olival, Emma Mendelsohn, Noam Ross, Luke Hamel
 - Unable to attend: Peter Daszak
- *Univ. of Rochester*: Gonzalo Buckstein
 - Unable to attend: Ehsan Hoque
- *USU*: Eric Laing
- *Georgetown University*:
 - Unable to attend: Emily Mendenhall

Action Items:

- **Kevin** to send around 1-page 'Project Summary' by early next week
- **Luke** to request biosketches and other required documents from senior personnel by early next week
- **Noam** to share his method for anomaly detection of serological results, with Gonzalo
- **Kevin** to follow up with Eric to discuss novel serological ideas that could be included on the proposal
- **PIPP team (especially Kevin, Noam, Emma, Gonzalo and Ehsan)** to review meeting notes from the call with Facebook. Explore various links to preprints/datasets/online tools
 - **Gonzalo** to start a notes document and write down ideas about how to leverage the datasets referenced in the notes for our proposal
- **All** to continue thinking about 'broader impacts' and draft any text related to training or outreach at your institution

Agenda/Notes:

- *Introduce Dr. Eric Laing - serology and biosurveillance*
 - (Kevin) Eric works at Uniformed Services University (USU). Extensive experience with serological surveillance
 - (Eric) I'm a molecular virologist by training, but I work on biosurveillance. Doing a lot of COVID-19 work recently
- *Brainstorm intellectual and engineering innovations on "Detecting zoonotic disease exposure at scale" (Serology)*
 - (Kevin) We have a current NIH project sampling people at high risk communities in SE Asia (e.g. bat guano harvesters, people presenting symptoms at health facilities). Using serological platforms to find evidence of spillover (perhaps of novel bat viruses)
 - (Kevin) First question for Eric: Are you working with any engineers/product designers to think about scaling up technologies (cheaper, smaller, easier to use)?
 - (Eric) No we aren't. We haven't looked at anything that's point of care focused. No handheld devices. No antigens on lateral flow.

- This is possible to do, but you wouldn't be able to do multiplex
 - You could develop a small test for a specific virus (e.g. Nipah) but nobody wants to develop it. No money in that venture.
- (Noam)
- I spoke with Linfa Wang (of Duke-NUS) who works on serology. He's less focused on point of care, more focused on working at a larger scale (e.g. working with blood banks to access lots of samples at a larger scale/larger fractions of the population)
 - The main goal of this Phase 1 proposal is to plan for the Phase 2 proposal. Who do we want to bring together to brainstorm big ideas for Phase 2? Question is about piloting different approaches. Show what could be possible in a 5-year project.
 - (Kevin) Also thinking about our working group structure. Eric, given your familiarity with the serological workshop space, **who else would you bring to the table, re next-generation serological multiplexing for zoonoses?** These are the things you (Eric) could help us think about
 - (Eric) Serology is challenging. Always limited by what it is you're looking for. CoVs, paramyxos, filoviruses potentially have the greatest risk for pandemic potential. So do you make rapid tests for those viral families? We have everything we need to develop test for Nipah, but no monetary interest there. What would be needed for ebolaviruses? **Also, I don't know how you'd make a 'disease x' assay**
 - (Kevin) NSF is thinking big picture. So one idea is a 'serochip' assay where you test for 1000s of viruses at once. Maybe this doesn't work that well compared to standard methods, but **this planning grant is focused on thinking about big picture ideas.**
 - (Eric) You can look at this pandemic as a blueprint for moving forward. The research diagnostic field moved very quickly (ELISAs were rapidly approved, etc.)
 - **Re the serochip idea, the big question is more about: Do we have the analytics in place to understand what the data means?**
 - (Noam) Probably not. Even for multiplex of 15 tests, we barely have the bioinformatics set up to run those and have rapid interpretation. **So the rapid analytics side of things needs to be further explored.**
 - (Kevin) Gonzalo, would you and Ehsan be able to assist with anomaly detection of antibody positives?
 - (Noam) **I have a method that I can share with you Gonzalo.**
 - (Gonzalo) That's maybe more in Ehsan's field. I'm more about scaling up methods. I'm happy to take a look though.

(Noam) There are several ideas for scaling serological surveillance. 1. Strategy to test more people, would involve having a more centralized high throughput lab. 2. Another strategy would involve moving more towards point of care. We could talk to **Bill Busa?** Developed lateral flow assay that is optical reader so that lateral flow assay can be calibrated to give quantitative output at point of care scan. It measures light absorption that otherwise would just read positive or negative. 3. **Think about which of these methods would require having a rapid analytical pipeline in place.**

- (Kevin) **How do you detect exposure for a virus you're not looking for (e.g. one that's truly novel, i.e. the 'Disease X' problem?) Problem that I don't know the answer to**
 - With PCR, you can apply a viral family wide primer set, but you don't have that with serology
 - (Eric) Ideally, you make serological tests as specific as possible
- (Noam) In 1st aim (scaling up the measurement of human-animal contact), the idea is to identify (with more granularity and more geographic specificity), populations that are likely encountering probable viral hosts, and to identify the types of contact that are likely to lead to exposure. I think of serology in the same way. We can think about the degree of regional specificity. Looking at particular classes of viruses in certain areas, etc. Or some other stratified, scaling approach where one has higher cost multiplex approaches covering many different viruses, then using that to do more intensive/geographically extensive sampling for particular viruses. **This would be a surveillance design question.**
 - (Kevin) **The problem is that we don't know the geographic extent of pathogen groups. So we can't necessarily target serological testing of particular viruses in particular geographies.**
 - (Eric) So the knowledge gap is that viruses emerge where testing isn't deployed and that viruses diverge enough to avoid serological testing.
 - So if you implemented more serological platforms at more interfaces (e.g. markets), would this be helpful or should we focus on hospitals/clinics?
 - (Noam) There's a low level virus exposure that may not be human to human transmitted that we want to detect.
 - But logical framework is that with many viruses emerging, one of them will go pandemic.

- (Noam) Given the widespread nature of SARS-CoV-2, identifying people who have been exposed to CoVs won't be very helpful (unless we can discriminate between SARS-CoV-2 and other related viruses)
- (Noam) PCR - too much of a "needle in haystack" problem, could be overcome by novel, scaled-up serology approaches.
- (Kevin) **Eric, we should circle back with you on some novel serological ideas.**
 - (Eric) There's a nearby company that does 3D printing. Could 3D print the lateral flow plastic component. Issue would be access to positive controls. If we had outbreak, we could run it and look at acute periods vs. convalescent periods of exposure. Need to think about where we'd get validating serum samples
 - (Kevin) Re: positive control to EHA could potentially help procure samples (perhaps from EHA project w EIDRC on Nipah). **We'll follow up on this**
- *Debrief from Facebook (FB) <-> Rochester discussion earlier today*
 - (Kevin) FB would primarily support Aim 1 re human-animal contact (image recognition) as well as Aim 3 (post-exposure human mobility data)
 - Next steps will be to have discussions with the FB team about exploring the available data and discuss methodology used to weight the co-location dataset. Alex (from FB) will set up discussions with his colleagues.
 - **Think this would be a nice private-public partnership to highlight for NSF**
 - (Gonzalo) I like the fact that FB is thinking seriously about privacy concerns, and that they're transparent about data sharing. Also data is available on a global scale.
 - (Kevin) I agree that it's important we highlight the importance of data privacy
 - **PIPP team** will review the notes from the discussion with Facebook
 - **Gonzalo** will start notes document as he works through datasets mentioned during Facebook call
 - (Kevin) Co-location dataset is available and updated weekly. Activity space dataset should be made available within a month or so. Might be available to us now, just not made public yet?
 - (Emma) **For image recognition, do we want to hone in on a specific geography?**
 - (Kevin) **SE Asia is obviously of interest. Probably pretty good coverage from Facebook too. Central Africa not so much.**
 - (Emma) For surveys, we'll have to refine our geographic scope.

- (Kevin) **We should include a schematic in the proposal for how we hone down our strategy** (e.g. conduct global image recognition of human bat contacts, and where we identify high rates of contact we push out surveys, etc)
 - (Kevin) **It'd be helpful if we could map out all of the wildlife markets in a particular geography (e.g. Thailand), then use the activity map space to look at who's coming in and out of the areas where those markets exist.** Could be an interesting way to look at human flow in and out of markets. Perhaps we could implement a pilot study of this where markets have already been mapped out (Sulawesi bat markets that Alice Latine helped to identify). We could take the GPS coordinates of those markets and look at how human movement in and out of there changes over time.
- *Brainstorm "Broader Impacts" of our proposed 18 months*
 - (Kevin) **Curious what we want our broader impacts to be?**
 - (Gonzalo) Perhaps mention how methodologies could be used for societal good? (e.g. widespread implementation of FB surveys).
 - (Noam) In the past, NSF's broader impacts have been very specific. Typically, they're heavily aimed at bringing underrepresented groups into the research field, with a big focus on the training and education sides of things. **On that front, the best thing to do was to already have a program at your institution that you could partner with. e.g. Are there REU programs that target recruitment of underrepresented groups?** Seems NSF has relaxed a bit about how narrow broader impacts are
 - (Gonzalo) **I think it's important to be creative about your broader impacts.** Rochester has a lot of programs focused on increasing diversity that track success of participants over time.
 - <https://www.rochester.edu/college/kearnscenter/>
 - At the same time, I don't think this piece of the proposal is quite as important as intellectual merit side of the proposal
 - (Noam) We could highlight the EcoHealthNet (EHN) program. Mention that although the project is wrapping up in 2022, that we can extend the EHN model through to this PIPP project. We need to make sure the proposal includes funding for this though (and that we draw from financial numbers from EHN to accurately budget for this)
 - (Eric) I had a friend that was part of an IB program in Maryland. They introduced me to a program that connected high school students to various research opportunities. I'll try to remember what this was.
 - (Kevin) **We should think about this more. Need to be cognizant of diversity on our proposal as well.**

- **(Gonzalo) Other things that I've seen that have been well received include: making lectures public (through Zoom/Zoom recordings) and making datasets open access**
- *AOB*

Dear all,

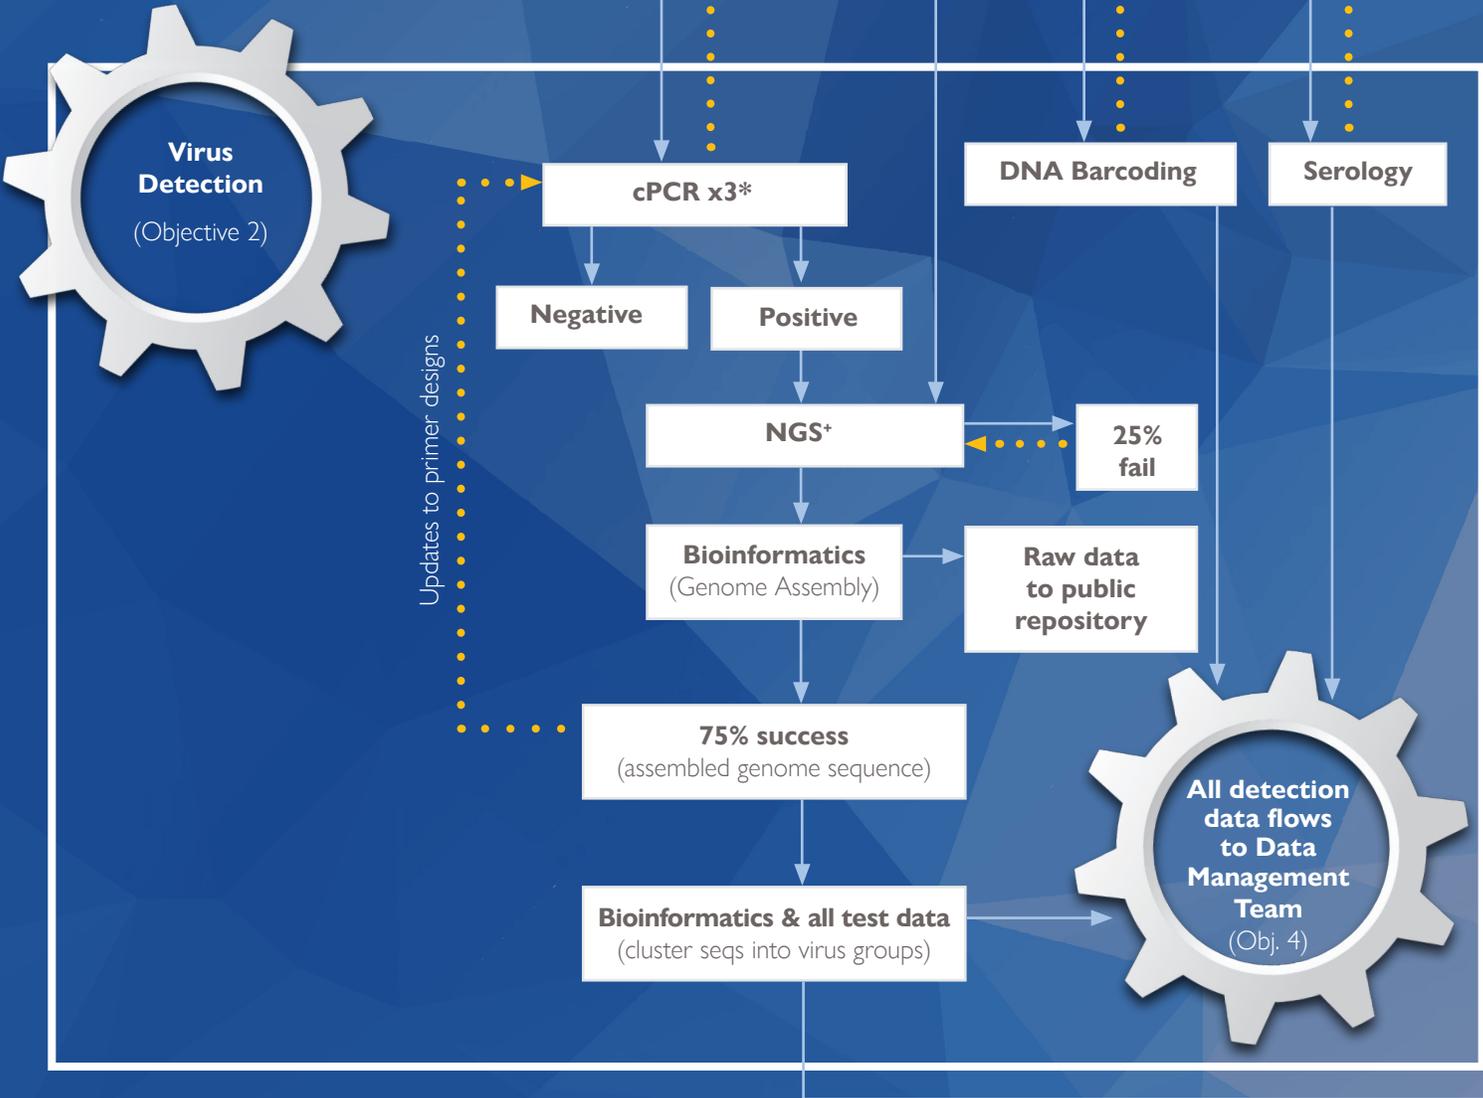

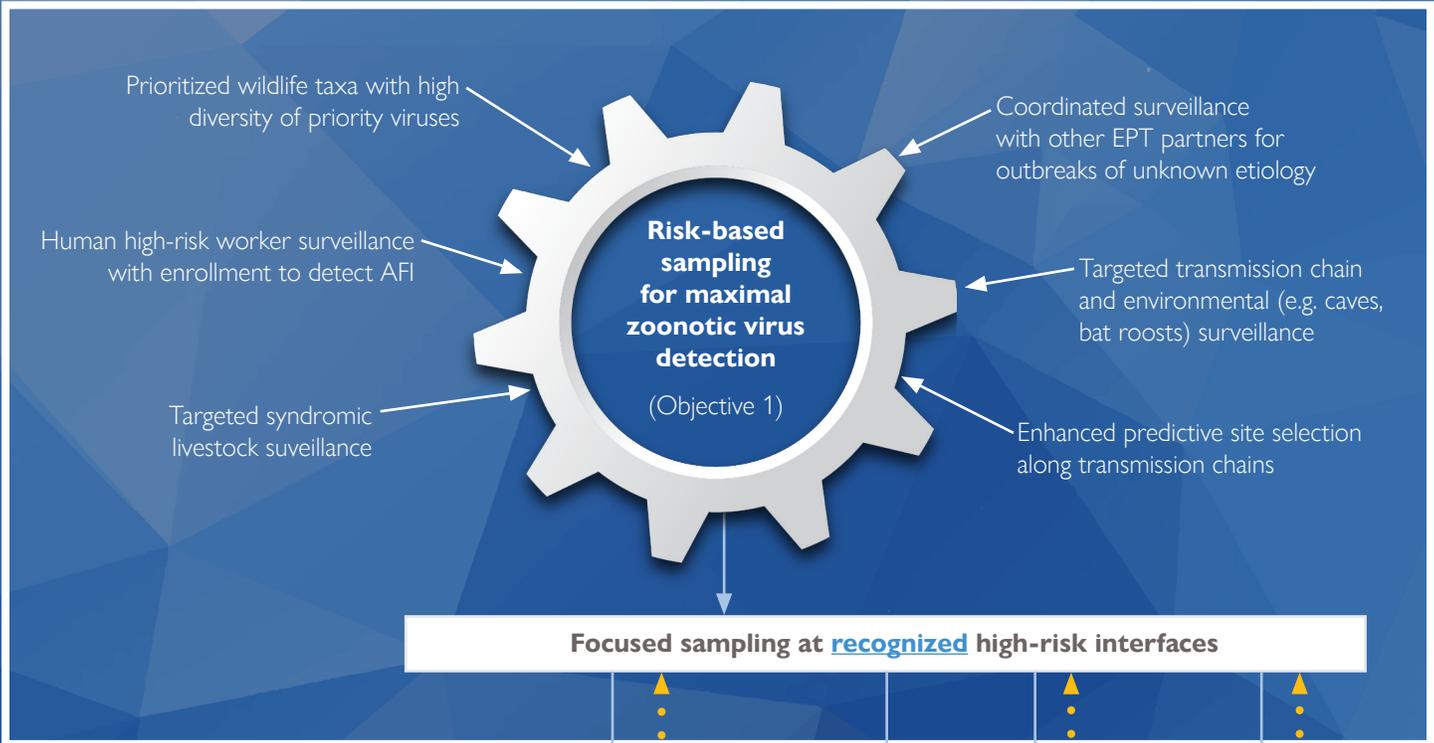

Attached are detailed notes from our NSF PIPP proposal planning call last week Thursday. Hope you all had a good Labor Day weekend. Will be following up throughout this week to start getting our proposal text together, NSF biosketches and Conflict of Interest lists from you, etc.

Cheers,
Kevin

DEEP VZN LABORATORY TOOL BOX

*Detection Assays:

- Consensus PCR: coronaviruses; filoviruses; paramyxoviruses
- NGS: Illumina; Oxford Nanopore
- Serology: Luminex multiplex; ELISA

*Cell Entry:

- Recombinant VSV-GPs
- Pseudotyped VSV-GPs
- Binding Assays

**IFN Antagonism

- Luciferase Assays
- IFN ELISAs
- IFN qPCRs

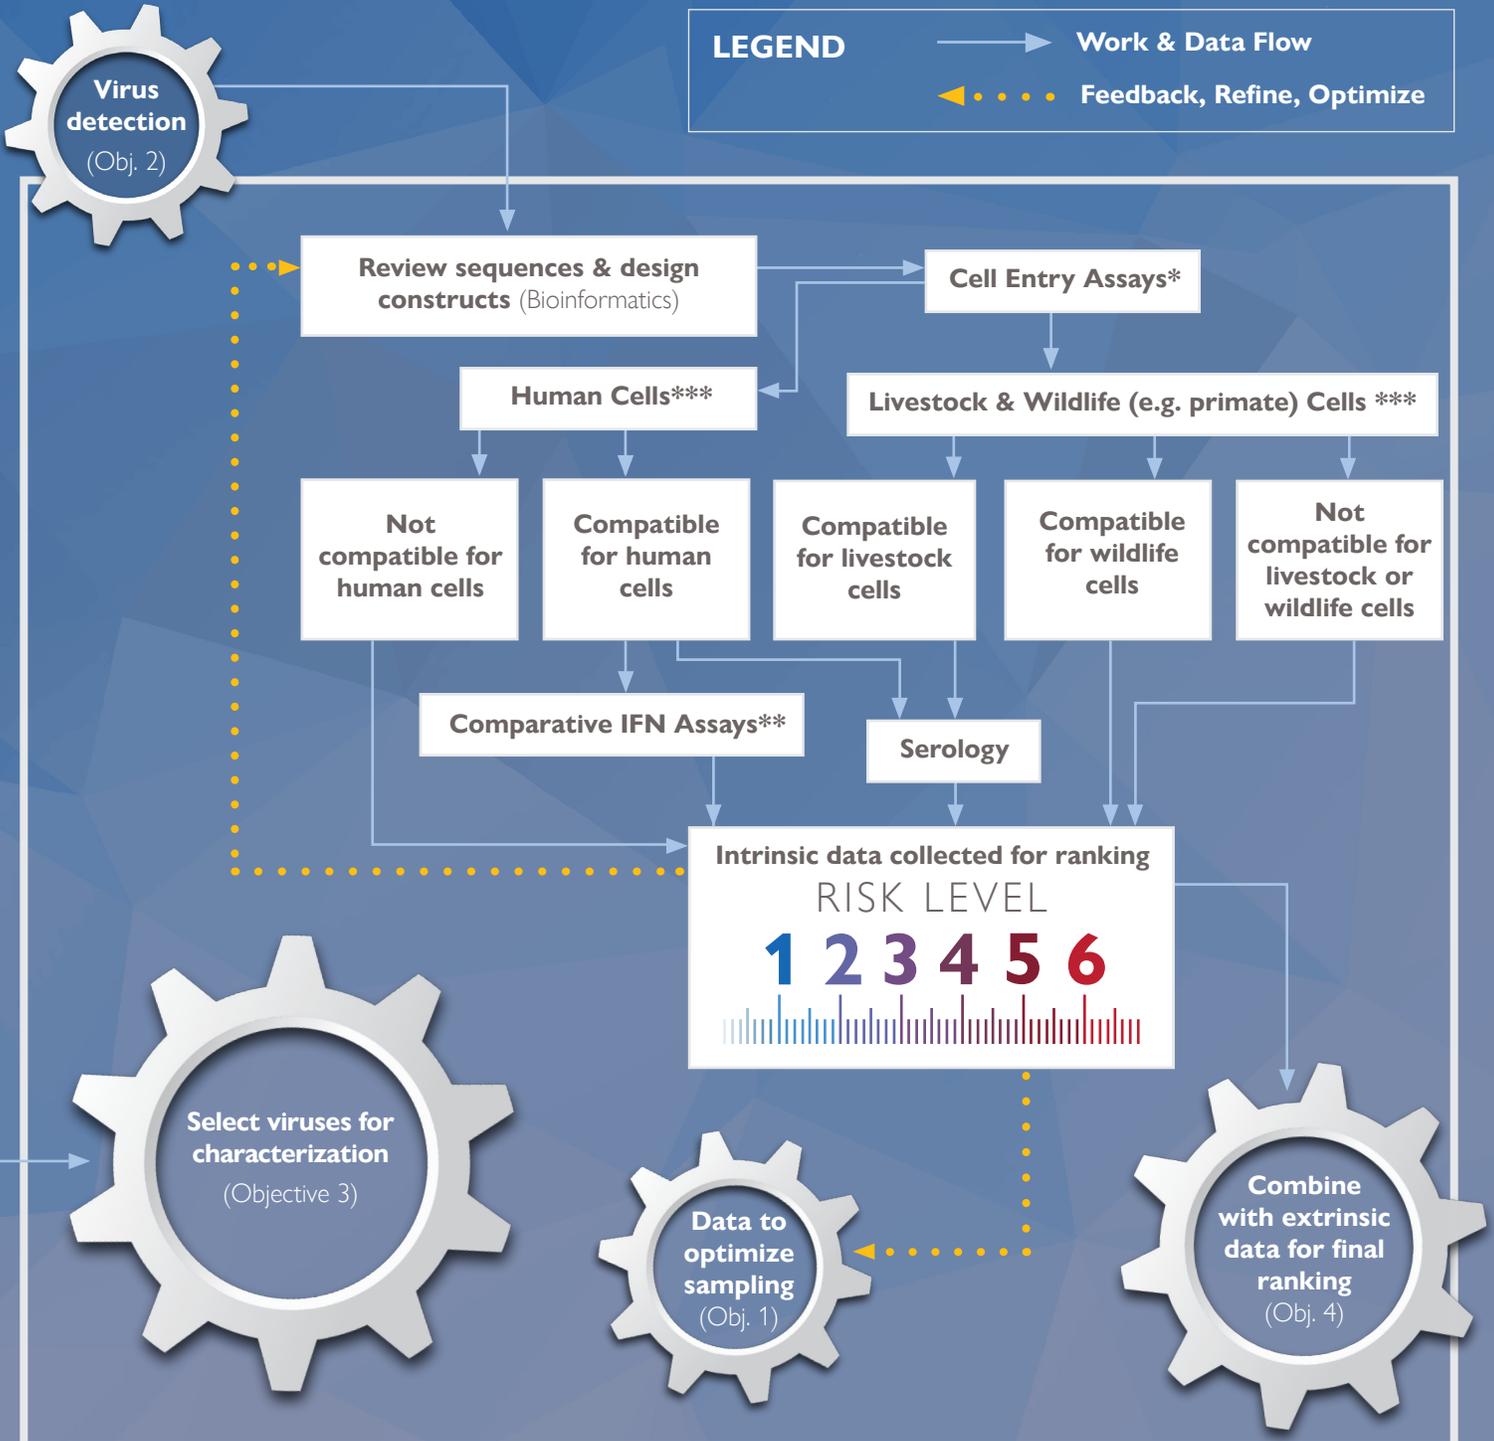

***Cell Types:

TBD, but relevant for each virus being evaluated (e.g. for filoviruses start with Huh7 then move to primary Macrophages)

◀ Feedback, Refine, Optimize

BACKGROUND AND JUSTIFICATION

The increasingly frequent and deadly consequences of emerging virus outbreaks on animal and human health is a global clarion call to action. Even before COVID-19 emerged as the first globally disruptive pandemic in over 100 years, diseases like Ebola, Nipah, MERS, SARS, and others signaled the need for dramatic and transformative approaches to global disease surveillance and zoonotic pathogen characterization. The DEEP VZN project will be a leading light in this transformation. For the first time in history, we have the tools required to forge direct actionable links between field surveillance, virus discovery, pathogen characterization, and countermeasure development. We are poised to move beyond the past centuries of reactionary health response towards comprehensive and prospective global health security paradigms. Our Consortium is the most ambitious formal collaboration of its kind, established to support focus countries in building the capacity to detect, characterize, and analyze novel virus threats and rapidly share data, results, and findings for maximum equitable public health benefit worldwide.

TECHNICAL APPROACH

Our goal is to develop locally-based leaders across a global network capable of working together, and with USAID and other EPT partners, to build a sustainable network of institutions, laboratories, and host-country agencies that can **rapidly assess ongoing and novel threats across the spectrum of wildlife, livestock, and human health, and conduct data analyses that will be of direct relevance to local and global policy makers, health authorities and translational partners** for vaccines, therapeutics, and diagnostics development (Figure 1). Working hand-in-hand with our trusted partners across the globe, we can begin the work described here as our vision for a DEEP VZN that will transform global health security.

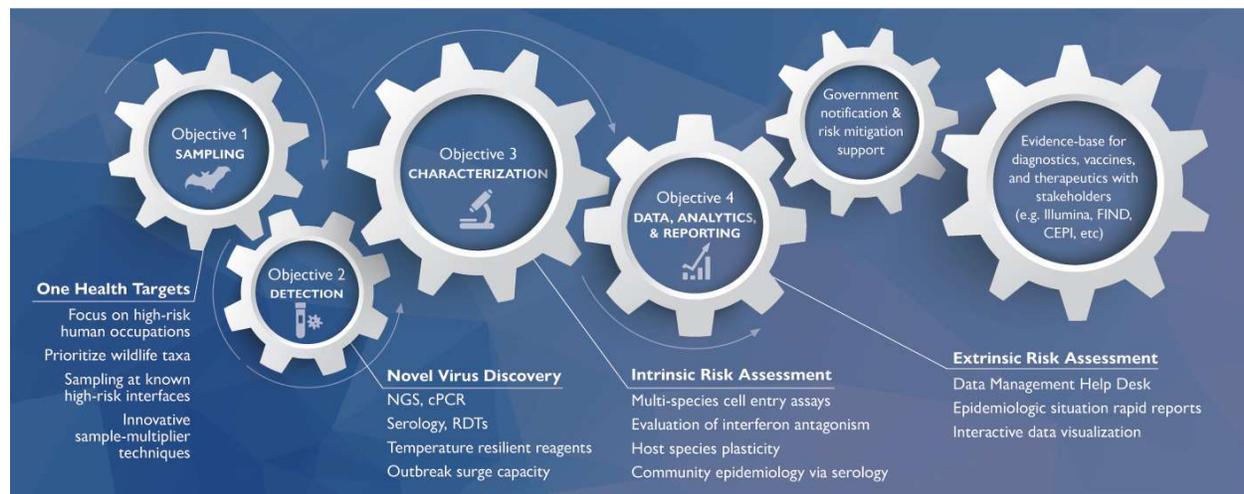

Figure 1: The DEEP VZN technical framework integrating sampling, detection, characterization, and reporting to inform risk mitigation through local leadership.

Objective 1. Conduct Sampling in Focus Countries for Unknown Viruses from the Priority Viral Families

We will leverage decades of success empowering local stakeholders to implement early detection and pre-emergence virus surveillance programs and introduce technological innovations, sampling prioritization models, and new partnerships to cost-effectively scale up sampling and reporting in close to real-time. Our sampling strategy is informed by the many lessons learned

from the ongoing COVID-19 pandemic and our substantial experience in animal and human biosurveillance, recognizing that true resilience from future pandemic threats requires more coordinated local and global viral surveillance. We will use next-generation and cross-cutting analytical approaches combined with scalable surveillance tools to strategically target sites, species, and high-risk human-livestock-wildlife interfaces to begin sampling rapidly as well as iteratively refine sampling to improve rates of novel virus discovery.

DEEP VZN's Data-Driven Sampling Strategy

Biosafety and security. We consider biosafety and biosecurity practices to be the central pillar of our entire approach. To best address this challenge, our Biosafety Officer will oversee all aspects of biosafety from the field to the lab. In consultation with USAID, we also will conduct independent periodic reviews with outside consultants to ensure that we adhere to all best practices, regulations, and procedures across the global network. Our plan to scale up biosecure sampling involves collecting specimens directly into virus inactivating lysis reagents. This will dramatically reduce the biosafety and biosecurity concerns, risks, and costs across the project's global collection of biological specimens.

Innovative sample-multiplier approaches and cost-effective gold-standards. We will implement innovative approaches to scale, automate, and improve the cost efficiency of virus discovery. Approaches we have validated previously include non-invasive sampling of wildlife (e.g., plastic sheets for pooled urine and feces collection; baited ropes or stations for primate oral swabs). We are also collaborating with engineers on development of autonomous air sampling at sites with high animal density (e.g., caves, indoor markets), and water-outflow sampling (e.g., market drainage areas; rivers in bat caves). Teams will leverage our dispersed network of trained professionals for opportunistic samples and utilize new virus inactivation lysis reagents that greatly reduce cold-chain requirements and increase biosafety. Efforts will complement gold standard methods of sampling wildlife using non-lethal, high-quality blood, fecal, urine, and saliva samples conducted by our teams previously.

High priority interfaces. Previous analyses to investigate high priority viruses identified wildlife-human interfaces that yielded 2-5x the number of RNA virus detections over baseline sites. Working with local partners, DEEP VZN will prioritize wildlife, livestock, and human populations at these high-risk transmission pathways, including a) along the wildlife supply chain (e.g., hunting sites, wildlife farms, confiscated animals, large and small live-animal markets), b) cave and roost sites with high bat diversity and human disturbance, and c) areas with ongoing resource extraction (e.g., deforestation, mining). We will collect standardized data on individual, demographic, occupational, and environmental factors that influence spillover and could serve as critical risk mitigation points for disease control.

Key wildlife species. We propose to sample a diversity of bats that serve as reservoirs for the priority virus families (e.g., bats for betacoronaviruses, filoviruses, and henipaviruses), rodents, and primates that can serve as spillover hosts, as well as species from other mammal families found at high-risk interfaces (i.e., traded or synanthropic), that have been inadequately sampled and are predicted to harbor viruses.

High-risk human sampling targets. Molecular detection of novel viruses in healthy asymptomatic people, even those living or working in high-risk zoonotic transmission settings can be difficult. To overcome this challenge, we will conduct focused enrollment of high-risk communities and occupations (e.g., wildlife-associated work) where the risk of spillover is maximized. Surveillance will be supported by community health workers to identify and sample acute febrile illness cases **at the earliest opportunity**. Our consortium's existing network of

clinics and hospitals will be expanded with new partnerships, by establishing formal linkages with national event-based surveillance systems to focus on clusters of disease with unknown origin. In collaboration with government programs, we will be on standby to detect novel viruses in any specimens that meet criteria for non-routine diagnostics.

High-risk livestock sampling targets. At selected sites, we will support syndromic and risk-based surveillance in livestock that meet criteria for non-routine testing. This will be implemented in coordination with international and in-country livestock surveillance systems, to 1) enhance training for the local network of veterinarians and para-veterinary staff to identify and report unusual livestock illnesses, and 2) facilitate earlier detection and characterization of novel viruses from wildlife that could cause devastating diseases in livestock.

Cost-effective sampling. Viral diversity scales with host diversity, thus it is critical to select sites with a maximum diversity of mammalian hosts to maximize efficiencies. We will apply tools developed for species conservation to identify the most cost-effective sites for virus sampling in each country and account for land-use designations (e.g., future logging concessions, development, conversion to cropland) that could project risk.

Scale and scope. Based on our collective experience in wildlife health, we anticipate sampling approximately 10,000 unique individuals or discrete environmental units (e.g., wet-markets, caves, bat roosts, etc.) per country. We hope to expand our sample size estimates several fold over the course of the project if anticipated innovations in technologies being developed by our consortium are validated to provide the level of accuracy needed for this project. Using a data-driven approach across all objectives, teams will sample key wildlife taxa from high-risk interface sites until the local viral discovery curves indicate saturation of predicted novel priority viruses present (beyond which rarer virus discoveries are not cost effective). Based on data from previous projects, we anticipate intensive sampling at 4 sites per country per year, and moving on to new sites once discovery curves are saturated or viruses are being found repeatedly in the same species. This strategy should enable overlapping longitudinal sampling (2-3 years) for 5-10 sites per country over the project period.

Ongoing strategy refinement. We will iteratively refine sampling targets locally using models and data visualization techniques over the course of DEEP VZN with real-time assessments of sampling sites and species to maximize efficiency of novel virus discovery. Local data scientists will be supported in risk modeling to steward their data, guide their sampling teams, transform findings into actionable surveillance strategies, collaborate regionally for trans-boundary inferences, and lead publications.

New Partnerships to Scale-up ‘Trans-sectoral’ One Health Surveillance

Robust One Health surveillance for novel zoonoses is currently hampered by a limited number of trained personnel. Working synergistically with other capacity development projects like OHW-NG and STOP Spillover, we will implement multi-partner stakeholder workshops, dedicated in-service trainings, and specific instructor training to strategically engage new institutional partners, stakeholders, and government sectors typically left out of disease surveillance activities to more efficiently operationalize a scalable virus discovery sampling strategy in the target countries. New partnerships to ensure long-term sustainability of surveillance include academic institutions and natural history and zoology centers personnel, wildlife market vendors and workers, and authorities involved in wildlife management (e.g., customs officials, border patrol, wildlife inspectors, protected area staff, conservation IGOs including IUCN and CITES, and wildlife rehabilitation center staff) to develop communities of practice built around training opportunities. Open-source monitoring and reporting tools will facilitate real-time surveillance at

the wildlife-human interface. We will also engage paravets, paramedics, and community health workers to foster the One Health community approach and make gains in local health security and zoonotic disease awareness as a critical step towards global health security.

Objective 2. Strengthen Detection in Focus Countries for Novel Viruses from the Priority Viral Families

Rapid detection of novel viruses requires a safety-first multi-layered strategy and a “best-fit” approach in alignment with regional and host-country needs and priorities. We will optimize direct peer-to-peer and south-south collaborations to drive the development, optimization, and scale-up of detection assays and analytical approaches to strengthen capabilities and directly synergize with host-country government partners. Innovative technology, training, and detection strategies will be leveraged to augment and reinforce national priorities and virus detection capabilities through the dissemination of knowledge, technical approaches, and training to promote country-level engagement, sustainability, and progression in external frameworks (e.g., IHR, JEE). This will maximize gains for in-country partner laboratories to advance scientific excellence and sustainability and transition laboratories towards regional and global leadership. All laboratories will implement updated and refined standardized protocols along with state-of-the-art platforms for virus detection within the first year of project implementation. Our DEEP-VZN laboratory network spans a wide range of technical capacities, bridging across low to high-resource host-country partners and includes global subject matter experts that together foster a global community of laboratory practice.

DEEP VZN’s Innovative Detection Strategy

Laboratory biosafety/biosecurity and quality-management systems. Coordinated by our dedicated project Biosafety officer with technical input from delegates at each partner laboratory and in consultation with USAID and consortium partner CDC, we will begin with rigorous evaluation of existing practices and identify gaps in BS&S and QMS knowledge and practices at each partner laboratory. We will conduct our initial and ongoing in-service training and education to ensure compliance with all national, regional, and international requirements (e.g., BMBL, WHO Stepwise QMS, etc.). A secure electronic inventory and laboratory data tracking system will be utilized in each partner laboratory for precise and real-time inventory management and tracking of specimen, results, and data.

Rapid training implementation using bio-archived and other surveillance project specimens. Where available, archived and well-curated bio-banked specimens (from the USAID-PREDICT, other consortium surveillance projects, and other USAID programs (e.g., STOP Spillover when synergistic and novel etiologic agents are suspected) will be provided so that each partner laboratory can rapidly begin their training, internal quality assessments, pilot testing, optimization of results, and data handling pipelines even before the first DEEP-VZN prospective specimens are collected. This rapid roll-out and implementation of the testing strategy will allow for optimization to local conditions and further in-service identification of training gaps and infrastructure/equipment needs, as well as lead to enhanced national level technical capacities early-on in the DEEP-VZN project to empower much needed laboratory surge capacity for diagnostic needs during outbreaks of unknown etiology.

Optimized, more thermostable specimen handling and extraction for surge capacity. Semi-automated to automated nucleic acid extraction using newly developed and more thermostable virus inactivation and extraction buffers will be utilized to ensure that medium to high-throughput surge capacity exists in each partner laboratory. These platforms have been utilized and validated by our global consortium in the 2014-2016 West Africa Ebola outbreak and

COVID-19 pandemic and will ensure that both the technical and technological capacity exists in each partner laboratory to conduct virus detection at the robust throughput required.

Prioritized specimen selection and testing. We propose to use a data-driven prioritization scheme developed from more than a decade of experience in novel virus detection and other biosurveillance and virus discovery projects. Thus, time, human and financial resources, and effort will be maximized for efficient novel virus detection across a variety of species and sample types as described in Objective 1 and detailed in the “Decision Tree” (Annex 4).

The DEEP VZN Virus Detection Toolbox

Over the past 10 years, members of our consortium have implemented molecular tools that led to the detection of over 1,000 viruses, including 177 coronaviruses, 230 paramyxoviruses, and 3 filoviruses. With our targeted field surveillance plan (Objective 1) and cutting-edge detection platforms (Objective 2) we expect to greatly surpass these previous discovery efforts, truly transforming the capacity for viral discovery. Our virus detection toolbox addresses **two critical needs** 1) to identify and sequence unknown viruses, and 2) to use laboratory data to refine and optimize sampling activities in Objective 1.

Identify and sequence novel viruses: We will deploy robust NGS protocols and provide low-cost equipment for in-house sequencing of prioritized specimens in near real-time. To target the priority virus families, we will use a **capture-based NGS sequencing approach** that uses a set of nucleic acid probes to enrich samples for coronavirus, paramyxovirus, and filovirus targets. Working with world-leading NGS consortium partner, Illumina, we will update existing capture-based sequencing protocols using data generated from the USAID PREDICT project and will conduct robust training on data processing to build critical bioinformatic capacity to assemble virus genomes from NGS datasets. To validate our NGS protocols, we will routinely sequence a subset of specimens from high-risk species and interfaces using **unbiased NGS approaches** to ensure we can detect highly divergent viruses. Recognizing the likely spectrum of laboratory capacity, we also plan to implement alternative NGS strategies such as **Amplicon based NGS by MinIon (Oxford Nanopore)**. By expanding our NGS toolkit, we maximize our ability to tailor NGS needs to each laboratory or situation (e.g., sequencing in field settings). Amplicon-based sequencing was used successfully to sequence Ebola virus genomes during the 2014-2016 epidemic and offers greater flexibility in less-resourced laboratories. In addition to our highly innovative NGS platforms, we will continue to build on the incredible success of consensus PCR, which was implemented in more than 60 labs and 30 countries during PREDICT and led to the detection of >1000 viruses from >20 viral families. We will update **priority virus family-level consensus RT-PCR detection assays** to pre-screen samples for NGS. This combined strategy will capitalize on the cPCR capacity that was built under PREDICT and maximize cost-effectiveness, sample throughput, and flexibility in the range of laboratory tools available (i.e., ranging from simple methods like cPCR to more complex methods like NGS).

Laboratory assays to refine Objective 1 surveillance: A critical part of our strategy involves optimizing field-based surveillance using laboratory-generated data. To help target species, locations, and populations with signatures of priority viral families, we will use two approaches. First, we will use **serologic assays** to identify species, locations, and populations with evidence of high-priority viruses. Multiple assays, including two advanced multiplexed bead-based assays designed by consortium partners USU and Duke-NUS, will be utilized for the detection of antibodies in humans and animals (including select wildlife species) across the priority virus families. Using tiny volumes of serum (~2µL, feasible for even the smallest insectivorous bat

and rodent species), these quantitative assays rely on expected serologic cross-reactivity across the diversity of each virus family in animals and humans against these target viruses, including those which are unknown but antigenically related. Beyond broad serosurveillance, we will also employ a highly specific and sensitive assay designed to detect neutralizing antibodies that target the specific receptor binding domain (RBD) on the spike protein of each of the known sarbecoviruses (SARS-related viruses, including SARS-CoV-2) to screen both animal and human sera for coronaviruses with zoonotic potential and identify possible reservoirs and exposed human populations. Critically, this newly developed assay will allow us to differentiate antibodies against SARS-CoV-2 from antibodies against other bat-associated CoVs in human sera from populations with frequent exposure to bats or bat excreta. Both of these panels are easily updated when new viral sequences are discovered, making them flexible and powerful screening tools. When coupled with the ecology and exposure history of animals or humans tested, they can provide evidence of an as yet undetected virus or variant of concern from all three high priority viral groups, in the sampled population.

The second approach will be to develop **rapid point-of-collection detection assays** that can provide in-situ and real-time evidence of virus circulation, allowing us to rapidly expand the number of sites that can be evaluated for evidence of priority viruses and transforming the surveillance landscape at scale. In order to assess the ability of current state-of-the-art rapid-diagnostic devices to be brought to scale, we will test, validate, and verify select novel technologies (e.g., Conservation X Labs, and others) in target countries. These approaches will be cross validated with our other detection platforms to determine real-world utility under field conditions. Broad-based rapid detection assays in each priority virus family will be designed to provide an alert-signature indicating the probable existence of high-consequence virus threats. We will evaluate the power of these new technologies to vastly expand the scope of novel pathogen detection across a much broader suite of locations. All of our **laboratory detection assays will be reviewed and updated routinely**, iteratively incorporating new data as it is generated to ensure that the toolbox is robust and remains state-of-the-art. Continuing education and re-training for lab teams will be also conducted across all years of the project implementation.

Objective 3. Strengthening Characterization in Focus Countries of Novel Viruses from the Priority Viral Families

Describing the ‘pre-emergent’ diversity of viruses circulating in bats, rodents, and other high-risk wildlife taxa is a critical component of pandemic prevention. However, finding an unknown viral sequence in wildlife does not reveal whether it has zoonotic or pandemic potential. Using experimental and computational approaches we will explore the compatibility of wildlife viruses for human infection. Our consortium includes some of world’s foremost subject matter experts in coronaviruses, paramyxoviruses, and filoviruses, and together we will build the technical capacity in-country to perform a variety of cutting-edge, biosecure, and informative assays that evaluate the risk of novel viruses and variants of concern.

The DEEP VZN Characterization Toolbox

To evaluate novel viruses detected in Objective 2, we will build a risk characterization toolbox to identify potentially hazardous viruses before they emerge in humans. We define ‘potentially hazardous’ as any virus with the ability to enter a human cell, replicate efficiently, and antagonize host immune responses. Recognizing that there is no singular or definitive method to evaluate these characteristics, we will build a range of tools to identify viruses with the capacity

to infect humans. **These tools will be scalable, versatile, and built specifically for use in standard laboratories without the need to work directly with live viruses that pose an unknown threat to humans.** Our goal is to rank the hazard potential of unknown viruses so that they can be prioritized for the development of downstream countermeasures.

Targeting high-risk viral traits. The genetic factors that determine zoonotic potential are complex and are the result of hundreds of molecular interactions between viral and host-cell proteins. However, viruses with the ability to 1) enter human cells, 2) utilize cellular resources (i.e., replicate efficiently), and 3) avoid or suppress host responses like interferon (IFN) are most likely to establish productive infections in humans. We will characterize these high-risk traits to ‘rank’ viruses according to their zoonotic potential. **Low containment BSL2 tools:** Virus characterization can be a time consuming and costly process that traditionally requires live virus, high-containment facilities (e.g., BSL3 or BSL4), and highly-trained personnel. It is neither feasible nor safe to implement this work where biosecurity is in question. To build much-needed technical capacity for virus characterization, we will use surrogate systems that examine the function of individual viral proteins rather than entire infectious viruses. Surrogate tools targeting proteins involved in cell entry and suppression of host immunity can effectively identify viruses with key zoonotic traits. **Cell entry:** The ability to enter a human cell is the first critical step in infection. Thus, the identification of viruses that can circumvent this primary barrier is a critical component of spillover risk assessment. We will use pseudotyped or recombinant Vesicular Stomatitis virus particles (VSV) as a technique to incorporate coronavirus, paramyxovirus, or filovirus surface glycoproteins (VSV-GPs), and evaluate their ability to enter a range of relevant human cells. As broad host range is an additional risk factor for zoonotic emergence, we will also investigate the ability of these non-hazardous VSV-GPs to enter the cells of animal species relevant to each country and region, in particular the cells of livestock or other wildlife that could serve as intermediate hosts. **Innate Immunity (Interferon; IFN):** The ability to antagonize IFN is a major determinant of pathogenicity, as all viruses express proteins capable of avoiding or suppressing the IFN response. For filoviruses, these proteins include VP35, VP24, and VP40, while for coronaviruses, NSP1, NSP12, and ORF6 contribute to IFN antagonism. The degree to which different viral proteins suppress the human IFN response will have important implications for their pathogenic potential. For instance, Ebola virus (species: *Zaire ebolavirus*) is a potent antagonist of human IFN and is highly pathogenic, whereas the related Reston virus (species: *Reston ebolavirus*) is a less efficient antagonist and is non-pathogenic. Thus, evaluating the ability of novel viruses to suppress IFN will indicate their potential to cause disease. We will use dual luciferase reporter assays and standard ELISAs to measure how effectively different viral proteins antagonize human IFN induction and signaling in vitro. **Serology:** One of the most direct approaches to identifying future viral threats is to look for evidence that spillover has already occurred. Thus, for novel viruses with hazard potential, we will develop specific serologic tools to survey humans, including high-risk workers along key transmission chains and look for evidence of spillover and community transmission. We will utilize the VSV-GPs built for evaluating cell entry and re-purpose them effectively for specific serology, maximizing cost effectiveness, maintaining stringent biosafety conditions, and increasing sustainability. A second strategy will build on our extensive experience with multiplex serology on the Luminex platform, which we have successfully implemented in multiple low resource settings. We will expand our existing multiplex assays to include surface glycoproteins for potentially hazardous viruses, as well as closely related viruses to help evaluate potential cross-reactivity.

High-Containment (BSL3, BSL4) validation of risk assessments. Surrogate tools provide critical insights into the zoonotic potential of viruses. However, it is important to acknowledge that they are reductionist and may not recapitulate the course of natural infection where a multitude of traits are expressed simultaneously. In consultation with and with approval from USAID, in-country governments, and a third-party independent auditor, select viruses will be considered for advanced virus characterization at BSL3 or BSL4 facilities where we can safely recover virus by reverse genetics and verify our surrogate-based assessments of cell entry and IFN antagonism in vitro. As we are not proposing to collect samples into viral preservative for biosafety and security reasons, we will not have the option to isolate viruses directly from samples. Thus, using the recovered viruses under highly secure and permitted conditions will allow us to evaluate other key viral traits such as efficiency of replication in different cell types, including those associated with transmission. This high containment work will only be initiated following a consultative auditing process to assess feasibility and ensure biosafety measures are in place that meet or exceed national and institutional biosafety regulations. In countries where BSL3 or BSL4 containment facilities are not available, we will utilize our DEEP VZN network to perform this work at another facility in the region or the United States as needed. Our consortium partners include institutions with BSL3 facilities (e.g., Thailand, Viet Nam, Singapore, US), and BSL4 facilities (e.g., US CDC, NIH RML, and CSIRO-Australia).

Selecting viruses for characterization. By utilizing surrogate and scalable tools that can be implemented in standard BSL2 laboratories, we will be able to characterize and perform risk assessments for a large number of viruses. We plan to characterize any virus that has not previously been evaluated and for which data on hazard potential is lacking. Based on our previous work, we anticipate fully characterizing approximately 672 distinct novel viruses and 120 variants of concern across the proposed 12 country network.

Ranking criteria for viruses with zoonotic potential. Empirical data generated from the characterization toolbox will be used to rank the hazard potential of viruses using a computational approach that includes phylogenetics, protein modeling, and machine learning. An example of proposed risk levels based on criteria generated by our staged testing strategy is presented in Figure 2. Our goal is to help country-level stakeholders make decisions about which viruses to target for further characterization work, ecological studies, or interventions. Our ranking strategy will be refined throughout the duration of the project with in-country partners.

Examples from Our Previous Work: Successes in Novel Virus Risk Assessment and Characterization

A key focus of our work in DEEP VZN will be to ensure that we provide the knowledge depth required to ensure the long-term sustainability and growth of the characterization toolbox in each country. Below we have highlighted three examples that collectively demonstrate our experience characterizing viruses from all priority regions and virus families. ***Africa Region (Filoviruses):*** A novel ebolavirus, Bombali virus (BOMV), was discovered in insectivorous bats in Sierra Leone. The bats were found roosting in human houses, which was concerning because ebolaviruses can be highly pathogenic. To assess the zoonotic risk of this virus, we generated recombinant VSVs expressing the GP and found that BOMV is able to infect human cells. We then partnered with the US CDC to rescue infectious BOMV under BSL4 conditions and confirmed this finding with authentic virus. Next, we built a serologic assay targeting the BOMV GP to survey humans across multiple countries and found evidence of exposure to BOMV in a single person in the DRC. This validated our in vitro risk assessments and indicated a wider geographic range for the

virus. Indeed, following this discovery other research groups found evidence of the virus also circulating in bats in Kenya confirming a wide distribution across Africa. Finally, we used dual luciferase reporter assays to show that BOMV is a poor antagonist of human IFN, relative to highly pathogenic ebolaviruses, raising questions about its pathogenic potential. Altogether, the data generated to date support the following risk assessment: BOMV can infect humans but there is limited evidence of human-to-human transmission (at this time) and no strong evidence that it has the capacity to cause severe disease. Thus, in its current form BOMV does have zoonotic potential, but limited pandemic potential.

Figure 2: Risk levels ranking the hazard potential of viruses based on a staged testing for virus characterization.

Latin America Region (Paramyxoviruses): We identified a novel bat paramyxovirus from Brazil - Myotis Bat Morbillivirus (MBaMV) - which is related to several viruses of human (e.g., measles (MeV)) and veterinary (e.g., canine distemper) concern. As with BOMV, we generated VSV-GPs with MBaMV surface proteins using a pseudotyping approach and showed that the receptor binding proteins of MBaMV are able to mediate entry into human cells. We rescued infectious virus from the genome sequence and confirmed this ability using human myeloid cells. We also demonstrated that MBaMV replicates in human epithelial cells and uses human NECTIN4 almost as well as MeV. These data demonstrated the unusual ability of MBaMV to infect and replicate in human cells that are critical for MeV pathogenesis and transmission. Critically, MBaMV was not able to replicate efficiently in human lymphoid cells that are required for amplification during the early stages of infection. Thus, based on available data our current risk assessment is that MBaMV has not yet adapted sufficiently to replicate well in critical early cell types, limiting its pandemic potential. If the virus evolves this ability, however,

it would be considered a high-risk virus. *Asia Region (Coronaviruses)*: A bat coronavirus related to SARS-CoV-2 was detected in horseshoe bats in Thailand. This virus, RacCS203, was evaluated for its ability to infect human cells at the sequence, structure, and function levels. We found that while RacCS203 was 91% similar to SARS-CoV-2 across the whole genome, it shared only 71% identity across the spike gene and 61% in the critical receptor-binding domain. Structural modeling predicted that the RacCS203 receptor-binding domain was unlikely to bind with the human ACE2 receptor, which was subsequently confirmed using functional binding assays. We therefore assessed the zoonotic risk of RacCS203 as low, given its inability to use ACE2 to enter human cells. However, we acknowledge the potential for this virus to enter human cells via a different receptor or acquire an ACE2-competent receptor binding domain in the future via subsequent evolution.

Objective 4. Strengthen Host Country Capacities for Data Management and the Viral Characterization Process

Our vision is to enhance capacity for detection and characterization of unknown viruses through data management and ensure that data availability to inform preparedness and response spans the full scope of DEEP VZN. Our efforts are directed at improving the speed and efficiency of generating actionable scientific evidence on virus detections, virus spillover, outbreaks, and novel virus discoveries. Our approach is based on a collaborative peer-to-peer mentorship program, continuous iterative training and technology transfer, tool-building, and networking. Key characteristics of the proposed Data Management approach include:

- DEEP VZN “Data Management Help Desk” to support Objective Teams with data science expertise in engineering, computer science, and computationally complex bioinformatics, as well as technical experts and host country data staff.
- Peer-to-peer community of practice for assistance in data quality assurance, system management and customization, data integration and processing, data analyses, data visualization, and publishing, via in-person and remote trainings.
- Common schema for essential metadata that addresses privacy and security, established with input from Regional Councils, to facilitate querying and augment existing data systems.
- Data transfer software tools to simplify workflows for data packaging, extrinsic dataset integration, data visualization, and deposition of data to local and international platforms.
- Decentralized data management systems to meet local stakeholder needs and priorities with customizable data integration and visualization to promote local ownership of data and support local leadership in data management, data sharing, and publication.

Data Collection. We will facilitate electronic collection tools for field and laboratory metadata standards that builds on data collection platforms optimized over decades of field data collection in a wide range of resource settings. In countries lacking data collection systems, we will use open-source online platforms, designed for low-resource settings to support online, offline, and paper-based data entry. All information required to identify nodes and chains of transmission will be captured, as well as provide epidemiological context for novel viruses to inform risk mitigation strategies. We will work with local and national government partners, international stakeholders, One Health Workforce, One Health Platforms, and national and international data reporting standards and requirements to ensure compatibility and long-term use of a common data schema and data dictionary linked field and lab data.

Data and Metadata Management. Local data managers and bioinformaticians will coordinate data transfer and synthesis between field, lab, analytics, and local and stakeholder outputs. The

Data Management Team will support these day-to-day operations and workflows, organizing data and software distribution. We will ensure access to diverse data streams and the flexibility required to capture local and varied programs in a common data model. This common model will enable more rapid reporting and robust data-sharing by 1) facilitating data exchange in national and regional networks, 2) enabling greater automation of dataset integration, risk modeling, visualization, and reporting, and 3) linking in platforms without loss of information, especially for national and international data-sharing platforms designed for very narrow data types. We will develop data checking and validation tools to test data quality locally and across the entire project.

Data Storage. Where possible, we will build on local experience with data platforms, and use existing project data storage and management systems within local partner laboratories and institutions. This will facilitate integration into relevant national platforms. Systems can be hosted on DEEP VZN servers for rapid start-up and transferred to in-country over the course of the project. In-country data management systems will communicate and share data routinely with a centralized data system for project tracking and management. The project's internal data-deposition system will also serve as a "staging" system to support next steps in data use and management, and peer-to-peer training in data management.

Further Characterization with Extrinsic Datasets for Risk Analyses. Large scale datasets on recognized zoonotic viruses, hosts, host traits, host genomes, ecological niches, and geography will be integrated for local, national and international stakeholder-led analyses. Similarly, extrinsic data sources on future land use, climate projections, and other environmental drivers will also be integrated into local data systems for predictive models estimating future risk. We will support in-country bioinformatics in near-real-time with flexible and automated workflows packaged as open-source software (R, Python, and Jupyter Notebooks). This will enable users to run pre-defined analyses, risk characterization summaries, and interactive visualizations, linking in local data to global open-source extrinsic data that can provide situational context for virus characterization data. These resources will be modular, allowing in-country bioinformaticians to customize analyses for their needs. We will favor low/no-cost open-source software to maximize accessibility.

Rapid Information Sharing. The Data Management Team will support analytical pipelines to provide epidemiological context for highly ranked viruses to share with partners and stakeholders in rapidly produced situation reports. Situation rapid reports will combine intrinsic virus traits described in Objectives 2 and 3 with extrinsic data identified in Objectives 1 and 4 to provide relevant epidemiological context for highly ranked virus findings. In addition, a web-based data visualization system will be optimized to streamline semi-automated reporting of results and sharing situation reports with local, national, and international stakeholders, including USAID. Data visualization will be designed with stakeholders to 1) meet local capacity and need for outputs, 2) provide in-country teams capabilities to customize outputs, and 3) be automatable to allow for quick dissemination of preliminary results with appropriate context for interpretation. The Help Desk will coordinate data validation tests, synthesize datasets, integrate risk characterization tools, and ensure models are tailored into actionable outputs. Along with dissemination of results, these tools will support in-country teams in generating data summaries that can be readily used for data publication.

Results Reporting and Depositions. Data approval procedures and priority contact lists will be established in collaboration with USAID and national government authorities to ensure an informed, transparent, and timely approach to reporting results, securing approvals for broader dissemination, and meeting local, national and international (e.g., IHR and OIE) reporting requirements. At project start in each host country, **data sharing protocols and mechanisms for rapid results communications will be developed and agreed upon in collaboration with local implementing partners and national authorities** spanning Ministries of Health, Agriculture, and Environment, and national One Health platforms (or equivalent) to ensure timely approval and robust public data sharing procedures. Host country data leads in coordination with local partners will jointly identify national, regional, and international scientific data platforms for routine and regular publication of updated DEEP VZN situation reports and accompanying data, while customizing data workflows to target these platforms as needed. Preliminary updates will be shared routinely on biweekly Senior Management Team

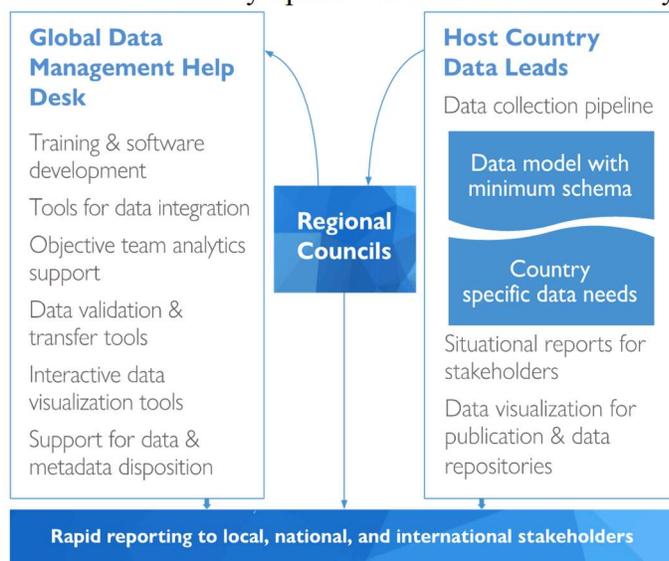

Figure 3: Data management team core activities.

discussions and more immediately as warranted by project findings. Summaries of sampling and testing data will be shared with USAID quarterly or as requested.

Data depository targets will follow best practices in international data disposition, and further promote enhanced metadata inclusion at global data depositories, such as the NIH National Center for Biotechnology Information (NCBI) and the Development Data Library.

Workflows, software, and training will ensure quality assurance during conversion of project data to formats appropriate for publication on each platform.

Strengthening Long-Term Sustainability and Country Ownership

Key to pandemic preparedness and our future legacy is the achievement of independent, sustained, local capabilities in One Health surveillance at high-risk animal interfaces, virus discovery, virus characterization, and data management. Therefore, we must not only ensure specialized training for individuals in these activities, but we must also create an environment in which some of those who are trained become experts who then later train others. Universities are well suited to this challenge, as the nature of academia is such that any given current academic workforce instructs most students broadly, while training some students with interest and aptitude to become the next instructors. Many of our implementing partners will have strong connections to universities that serve as research capacity for their nations, especially in outbreak investigations. Our consortium is therefore poised to not only strengthen capabilities in safe and secure virus surveillance for emerging threats, but to engage local trainees in academic pursuits of research, scholarship, and publication, thus simultaneously establish the next generation of scientific leaders in all aspects of this work in partnership with other USAID projects.

We fully recognize the benefits of training a One Health professional workforce by leveraging existing regional training platforms. Only through experiential training and multidisciplinary mentorship can young faculty and students be empowered to truly take on the pressing global health challenges ahead of us. To meet this demand, we propose that a DEEP-VZN Training Academy be coordinated through AFROHUN and SEAOHUN for their respective regions, with a similar model applied for the Latin America region. Over the life of project, highly talented university undergraduate and graduate students as well as in-service professionals, balanced across genders, will be provided training opportunities in our DEEP-VZN network laboratories, to receive in-depth, state-of-the-art training and mentorship in virology, disease ecology, virus diagnostics, scientific writing and communications. A requirement of participation will be for trainees to put their training towards publication(s) and future work, whether that be through their current jobs or through engaging with academic or government led institutions to invigorate the host-country's virology and disease detection workforce.

MONITORING, EVALUATION, AND LEARNING (MEL)

For over a decade, we have worked with USAID, USG interagency partners, and host country stakeholders to develop collaborative and adaptive approaches to performance monitoring, learning, and capacity strengthening. Our consortium has led efforts with in-country implementing partners to design performance monitoring plans and adapt to challenging and sometimes rapidly evolving international and national priorities such as the GHSA Action Packages and indicators, the WHO's Joint External Evaluations (JEE) and Benchmarks for IHR capacity, and USAID's own Self Reliance Metrics and country road maps. Through EPT-1 and -2 and the current USAID One Health Workforce-Next Generation M&E design and implementation process, we have learned how a more robust and design-centered plan, which strengthens capacity for performance monitoring at the country level, is best grounded in a theory of change, and includes a learning agenda to inform decision making for improved management, collaboration and return on investment.

MEL plan. Based on our theory of change, this Monitoring, Evaluation, and Learning (MEL) plan provides the road map for overall project design and performance. Performance-based MEL elements are built into the core of each objective's activities (along with crosscutting objectives such as capacity strengthening, biosafety and biosecurity, and gender equity). This results and change-focused MEL plan is incorporated into the organizational culture of our consortium and our management approach through a learning agenda that facilitates critical examination of the project for strategic and collaborative decision making.

At project inception, we will engage in-country implementing partners to establish a MEL team, develop our collaborative learning agenda, and design systems for performance tracking, data collection, and information and knowledge management. At this initial stage, we will establish MEL as a foundational element of project design and implementation that is compatible and synergistic with international and country-level monitoring systems and tools. Building on innovations established by the OHW-NG MEL team, we propose to work in close coordination with our Objective 4 Data Management team to create electronic data capture tools for streamlined and effective data collection, reporting, and summaries/visualizations that serve to inform country, regional, and senior management teams of project performance, impact, and opportunities for corrective action and adaptation.

Process and timeline. The MEL team, chaired by the project's Operations Lead, will be led by specialists with experience developing and implementing performance monitoring plans for

USAID and the GHSA communities and will include membership from our Objective Teams, Regional Councils, country-based Implementation Teams, and Biosafety/Biosecurity and Gender consultants. The MEL team will work closely with consortium partners and USAID to create the project's learning agenda, developing core questions that address the project's goals over time and are flexible and responsive in implementation. Our plan is designed around an iterative process that will include feedback and entry points for host country stakeholders, public/private, and government partners (as appropriate) in both development and implementation stages with defined approaches to monitoring and evaluations. The MEL team will meet at least monthly with each objective team and will hold quarterly project-level reviews to track performance progress toward targets and deliverables.

MEL data will be collected in real-time at the activity level and routinely analyzed and prominently featured in project meetings for discussion, enabling routine performance monitoring and opportunities to collaboratively adapt the MEL plan for improved monitoring and enhanced project performance. Data validation will occur bi-annually during the reporting process, enabling a feedback loop with objective and country implementation teams. Performance monitoring will be built into project meetings as they are planned (semi-annual and annual meetings, etc.) with virtual MEL team meetings held routinely throughout project implementation for decision making, adaptation, and improvements in performance, as needed. Our consortium is committed to open data systems, and MEL data collected through this project will be accessible to USAID and other international and GHSA partners as appropriate to support evaluation and inform policy and strategic direction in global health and health security.

External evaluations. Through the leadership of our external advisory committee, we will support and conduct project-level external evaluations at key points in the project lifecycle. Because a core element of DEEP VZN is safe and effective implementation, biosafety and biosecurity assessments will play a major role in monitoring and evaluation, conducted by an external consultant group (to be determined in consultation with USAID). In addition to regular and ongoing evaluation and assessments, additional major overall project and biosecurity evaluations will be planned midway in Years 2 and 4 of the project at critical phases when our activities will be mature for rigorous evaluation and yielding results that will inform project management and strategic direction.

Indicators and targets. We have crafted output, outcome, and long-term impact indicators and will refine these indicators and the MEL framework in collaboration with USAID and implementing partners to ensure buy-in and support of the MEL process. Each indicator will be accompanied by Performance Indicator Reference Sheets that include: rationale or justification for indicator, expected/desired change, calculation and unit of measure, disaggregation, frontline data source, means of verification/data collection methods, frequency of reporting, baseline, targets, and limitations/considerations. We will develop both life of project targets and short-term achievable ones as part of each year's workplan process to enable more real-time performance monitoring. By design, our outcome-level indicators will be continually evolving and informed by project implementation, project data and findings, and through collaborative engagement with key stakeholders. A selection from our proposed MEL framework with illustrative indicators (qualitative and quantitative), targets, country stage gates representing key capacity and sustainability gains, and anticipated long-term impact is provided in Table 1.

Strengthening national systems. Our overarching goal is to strengthen national capacity to detect and characterize unknown viruses with zoonotic and epidemic potential, and our partners include national health authorities and close partners of national programs. To support national

systems, our proposed activities are designed to achieve outcomes in alignment with national WHO Benchmark Technical Areas for enhancing country-level IHR capacities. Indicators, outputs, outcomes, and targets will complement national goals, and we anticipate that our project's investments in capacity strengthening will support national progress towards GHSA and WHO action plans. Through a network of host country and regional partners, virus detection and characterization platforms will integrate with and strengthen national laboratory systems and our data and findings will feed into multisectoral coordination bodies (e.g., national task forces, EOCs, One Health platforms, interagency coordination desks, etc.) to directly inform decision making, policy, and interventions. Within the proposed MEL framework, we highlight key areas of overlap and synergy between the project and WHO Benchmark Technical Areas.

Table 1: Snapshot from proposed MEL framework to highlight objective technical areas, overlap with WHO Benchmarks for IHR capacities, sample output and outcome indicators with associated targets and anticipated long-term impacts.

Objective(s) WHO Benchmark Technical Areas	Illustrative Output Indicators and Sample Targets		Expected Outcome Indicators and Sample Targets		Expected Long- term Impact
Crosscutting Virus Detection (Obj. 2) & Characterization (Obj. 3) - Biosafety and Security, Zoonotic Disease, and National Lab Systems	Outputs 1. # specimens safely collected and secured 2. #,% labs implementing detection & characterization tools 3. % selected viruses fully characterized	Targets 1. Up to 10,000 specimens per country by Y5 2. At least 1 lab/country in Y1; 100% of engaged labs by Y3 3. 100% by the end of the project	Outcomes 1. #,% labs safely performing <u>all</u> project detection and characterization protocols 2. #,% labs sharing data and findings to inform policy, intervention strategies, and potential countermeasures	Targets 1. 100% of engaged labs by Y3 2. 100% of engaged labs by Y5	10-fold increase in detection and characterization rates over current rate, led by in-country lab networks
Crosscutting (Obj. 4) - Capacity & Data Management - Zoonotic Disease, National Lab System, Biosafety and Biosecurity, and Risk Communication	Outputs 1. # individuals trained in full suite of skills and protocols required for safe sample handling, virus detection, characterization, data management, and communications 2. # publications and products led by country teams	Targets 1. ~100 individuals per country 2. At least 2 publications and/or products per country team	Outcomes 1. Improved time from sampling to reporting of sequence data 2. Approx. 675 virus sequences per country published on national and/or international platforms	Targets 1. TBD with in- country partners 2. 100% of all genomes by Y5	Improved national capacity and stronger, more cost-effective systems for safe sampling, virus detection and characterization, risk modeling and analytics, and communication

Learning agenda. Our learning agenda is based on the following proposed questions (to be confirmed post-award in consultation with USAID):

1. Is the viral surveillance, detection, and characterization strategy working (e.g., cost-effective sampling resulting in enhanced detection and characterization of novel priority family viruses and variants of concern)? *To be addressed semi-annually each year.*
2. Are we improving the efficiency and scale of virus discovery in-country each year?
3. Is the strategy safe, secure, and adhering to international and country-related BS&S regulations and best practices? *Addressed on an ongoing basis and systematically reviewed quarterly in close consultation with Objective Teams, Country Implementation Teams, and Biosafety/Biosecurity compliance officers.*
4. Is the strategy adoptable and transitioning well to country partners, institutions, and labs (e.g., is the strategy/technology/approach/platform(s) appropriate for capacity levels in host countries and with host country partners)? *To be addressed semi-annually each year.*
5. Are we expanding human resources and core technical capacities for virus surveillance, detection, characterization, data management, analyses, and reporting? *To be addressed semi-annually each year.*
6. Is our investment coordinated with national health and laboratory systems, and are we contributing data to inform policy (why or why not)? *Addressed quarterly in close consultation with Objective Teams and Country Implementation Teams.*
7. Are our data and findings contributing to policy reform and development of new diagnostics and countermeasures? *Longer-term question to be addressed Years 3-5.*

Learning agenda questions will serve to orient project direction and will be routinely reviewed and updated throughout the project lifecycle. The MEL team will incorporate the learning agenda into quarterly MEL meetings, and performance monitoring data and stakeholder input and feedback (via interviews and surveys) collected through the bi-annual reporting process will inform the agenda. Findings and insights will be summarized and used for decision making and adjustments to the project strategy and activities in collaboration with USAID and key partners.

[DEEP VZN Consortium Technical Application\[37\].docx](#)

Hi everyone!

It has indeed been a great experience for almost 6 months working on this since we first started brainstorming on DEEP Vision. I want to thank everyone for the great insights and world-leading inputs along the way!

I've attached here the main technical section of the proposal we submitted last night, plus the optional decision tree we submitted as an annex that shows the flow of the major testing platforms/concepts and then the feedback loops to refine our various strategies along the way. For best effect, open the decision tree in Acrobat and look at it in the two-page (side-by-side) view. A huge shout-out to Eunah Cho at OHI for taking our initial caveman like etch-a-sketch drawings and turning them into a really neat and unified graphics package!

We of course ask that you keep these documents close hold/confidential within our group since we don't want this floating around somewhere and then somehow interfering with the review process.

I hope everyone has a great weekend, and we'll keep you in the loop as we hear back from USAID... most likely not until August if we're lucky!

Thanks again and all the best,

-Brian

Subject: DEEP VZN proposal submitted!

Colleagues,

Our proposal was submitted late last evening and we received confirmation of receipt by USAID this morning.

Brian will follow up shortly with the final version of the technical application so you can see how this all came together. We hope you will be pleased with this collaborative vision for the next steps in combatting emerging pandemic threats. We greatly appreciate your dedication, talents, and generosity in giving your time to pull this together over the last many months (including thousands of pages for the cost application) - we could not have done this without each of you.

Your collective expertise and experience is humbling. We think we have developed an exceptional proposal that reflects our strengths and a strong vision for the future of this work.

We are very grateful to have you all as partners in this endeavor, wherever this leads. We will be in touch as soon as we hear any news.

In the meantime, enjoy the summer!

/Chris

I. Introduction

Predict Diagnostics

The diagnostic scope of PREDICT is uniquely ambitious, and its success clearly dependent on the availability of good molecular assays. The purpose of this document is therefore to provide a list of recommended molecular assays for PREDICT collaborating laboratories.

The approach taken for molecular testing of PREDICT samples will vary depending on sample, location and laboratory. Our main approach is broad testing for indiscriminate detection of all viruses within a particular family or genus by consensus PCR – and in so doing potentially identify novel agents belonging to that particular taxonomic group. In some instances testing will focus on the detection of specific pathogens of interest, in order to gain information on prevalence and pathogenesis (including host and tissue tropisms) of a known virus. Pathogens and sample types for testing will be prioritized with the lab and field teams based on the interfaces, host species sampled and potential routes of transmission of viruses between the wildlife sampled and humans.

Unfortunately, many of the published protocols for this latter (consensus-PCR) approach are not well validated, and their efficacy on diverse clinical and field samples, such as we have with PREDICT, is currently quite undetermined. Thus, these assays are not considered to be validated diagnostic tests, and are designed more for pathogen discovery. These tests often simply represent primer pairs that have been designed from available sequences for a specific study or purpose. On occasion their use may have been demonstrated on diverse laboratory virus strains within a family or genus, or (infrequently) even on clinical samples. However for the most part, the literature is not rich with protocols that might be fit for our purposes. That is, protocols that will detect divergent members of different viral families and/or genera in clinical and field samples. Thus we have modified and designed a number of these assays in an attempt to develop protocols that are more broadly reactive.

A selection of broadly reactive consensus PCR assays is presented here. However, given the restrictions discussed above it is important that all partner laboratories consider this document to be highly adaptive. There may be changes to primer sequences and/or reaction conditions as we learn more about the performance of these assays on clinical/field samples. Entire protocols may also be replaced by new, better methods as they become available. Any such changes will be reported to all partners in subsequent versions of this document.

Use in Clinical Settings

It is important to recognize that the assays present in these protocols, are not validated diagnostic assays. Their sensitivity and specificity for known pathogens has not been assessed in the majority of cases. There is an important distinction between diagnostics for known pathogens (where sensitivity and specificity are known) and discovery (where they are not). These assays are not intended for diagnostics.

Diagnostic assays are often designed against specific agents and are therefore more sensitive for detecting those specific agents. Consensus PCR is broadly reactive thus their strength is for viral discovery, however, they are not as sensitive and have the potential to result in false negatives. For this reason, they are inappropriate for clinical diagnostics when specific assays exist.

We are not recommending that diagnostic labs or facilities replace specific assays with these consensus PCR assays when screening for known pathogens, but rather start incorporating them into diagnostic investigations when specific assays are unavailable or have failed to produce a positive result. At this point, this would be considered discovery and not diagnostics.

Proprietary Assays

Many of the assays presented here are published assays. Their use may not have been adequately demonstrated on clinical and field samples, as yet, but they are none-the-less freely available for general use. For others, this is not the case. Some assays have been modified (reaction conditions and/or primer sequences), and others represent entirely new assays developed by scientists at CII and UC Davis. For this reason, all details of this manual, including any controls that are supplied to partners, must be considered confidential and can only be distributed to a third party once the Biological Sample Sharing Agreement is in place. This procedure is to ensure the USAID and PREDICT receive acknowledgement in future publications for supplying the protocols and controls.

Reagents

We realize that each laboratory will no doubt be familiar with, or have preference for, certain reagents and PCR kits. All the protocols in this manual have been tested using one set of reagents used routinely in our laboratories and all assays performed well using these reagents. Thus, we suggest PREDICT collaborating laboratories use the same reagents described in our document or in the original publication of a particular assay. The details provided here refer to kits used by scientists at Columbia University's Center for Infection and Immunity (CII), University of California Davis Wildlife Health Center and Global Viral Forecasting Inc.

- RNA extraction is performed with using the Zymo Research Direct-zol RNA MiniPrep Kit . Catalogue number: Zymo Research Cat # **R2050 (kit of 50), R2052 (kit of 200)**; <http://www.zymoresearch.com/rna/total-rna-purification/samples-in-tri-reagent-trizol-etc/direct-zol-rna-miniprep>
- Reverse-transcription is performed using Invitrogen's SuperScript III First-strand cDNA synthesis kit, according to the manufacturer's instructions. Catalogue Number: **18080-400 (50 reactions)**
- PCR is performed using Invitrogen Platinum TAQ DNA polymerase kit, according to the manufacturer's instructions. Catalogue Number: **10966-026 (250 x 25 µl reactions)**

II. Pan (Consensus) RNA Virus Assays

Reverse-Complementation

Samples to be tested for RNA viruses must first be reverse-transcribed (RT) in order to provide a suitable cDNA template for PCR. **We recommend that cDNA is generated prior to PCR in a separate reaction, and primed by random hexamers (ie. perform two-step PCR)** using Invitrogen's SuperScript III First-strand cDNA synthesis kit. This approach has been taken as sample quantity is often limited and budgetary restrictions and/or the availability of reagents also influence the preference to target cDNA (RT performed prior to PCR in a separate reaction).

Coronaviruses

NOTE: Please use both Coronavirus protocols for screening all samples. These two assays target non-overlapping regions of the RNA-Dependent RNA Polymerase in ORF 1b and it is useful to have both regions for phylogenetic discrimination.

PROTOCOL P-001

REFERENCE: Quan, PL et al (2010). MBio 1:1-9 (e00208-10)

NOTES: Reverse-transcription performed separately using Superscript III, followed by nested PCR. On the Human Coronavirus genome (strain 229E) it roughly amplifies the region 17,480-17,820.

TARGET: RNA-Dependent RNA Polymerase (RdRp)

PRIMERS: Round 1:
CoV-FWD1: CGTTGGIACWAAAYBTVCCWYTICARBTRGG
CoV-RVS1: GGTCATKATAGCRTCAVMASWWGCNACATG

Round 2:
CoV-FWD2: GGCWCCWCCHGGNGARCAATT
CoV-RVS2: GGWAWCCCCAYTGYTGWAYRTC

PROTOCOL: 95°C 5 min, then 15 cycles of 95°C for 30 seconds, 65°C for 30 seconds and 72°C for 45 seconds, then 40 cycles of 94°C for 30 seconds, 50°C for 30 seconds and 72°C for 45 seconds. Finish with 72°C for 7 minutes.

Same protocol for round 2 but for 35 cycles.

AMPLICON: First Round: 520 bp
Second Round: 328 bp

CONTROL: Universal Control 1, or appropriate Coronavirus cDNA

PROTOCOL P-002

REFERENCE: Modified from Watanabe, *S et al* (2010). *Emerging Infectious Diseases* 16:1217-1223

NOTE: Like the Quan protocol, this assay also targets the polymerase. However, it targets a different region slightly more upstream. On the Human Coronavirus genome (Strain 229E) it targets roughly nucleotides 14,370-14,750. If you are looking for coronaviruses in bats, this may be a good protocol to use because many of the partial sequences that are published on CoV (in bats) have been generated using these primers. Please note that this assay has been modified from the original publication: Initial primer sequences have been modified to increase the ability of the assay to detect widely variant coronaviruses. A second, heminested step has also been added to increase sensitivity. This step can be performed using a forward primer that is optimized for bat viruses, or other coronaviruses, depending on the sample being investigated.

TARGET: RNA-Dependent RNA Polymerase (RdRp)

PRIMERS: Round 1:
CoV-FWD3: GGTGGGAYTAYCCHAARTGTGA
CoV-RVS3: CCATCATCASWYRAATCATCATA

Round 2:
CoV-FWD4/Bat: GAYTAYCCHAARTGTGAYAGAGC
(or CoV-FWD4/Other: GAYTAYCCHAARTGTGAUMGWGC)
CoV-RVS3: Same reverse primer as round 1

PROTOCOL: 94°C 2 min, then 35 cycles of 94°C for 20 seconds, 50°C for 30 seconds and 72°C for 30 seconds. Finish with 72°C for 7 mins.

Same protocol for both round 1 and round 2.

AMPLICON: First Round: 440 bp
Second Round: 434 bp

CONTROL: Universal Control 1, or appropriate Coronavirus cDNA

Filoviruses

PROTOCOL P-003

REFERENCE: Unpublished, Designed at UCD, modified from Zhai, J *et al* (2007). Journal of Clinical Microbiology, 45:224-226

NOTES: The previous primers used in PREDICT were well validated for known filoviruses, but we were concerned their lack of degeneracy might inhibit their ability to detect novel viruses of this group and that the one round of PCR might not be sensitive enough for our needs with field samples.

Thus we redesigned the set of modified primers to introduce more degeneracy into the sequence to improve their use for pathogen discovery and also to add a nested PCR step to increase sensitivity. These primers are able to detect known Ebola and Marburg viruses, as well as the divergent bat filovirus, Lloviu virus, and we hope will also improve broad reactivity.

Please note that these primers may produce non-specific products of the incorrect size in clinical samples, so labs should not follow up on bands that are clearly the wrong size, and focus only on bands that are approximately 630 bp. All positives must be confirmed by sequencing.

TARGET: L-Gene

PRIMERS: Round 1:
Filo-MOD-FWD: TITTYTCHVTICAAAICAYTGGG
FiloL.conR: ACCATCATRTRCTIGGRAAKGCTTT

Round 2:
Filo-MOD-FWD: TITTYTCHVTICAAAICAYTGGG
Filo-MOD-RVS: GCYTCISMIAHGTGGIACATT

PROTOCOL: 94°C for 5 min, followed by 40 cycles of 94°C for 1min, 52°C for 1min and 72°C for 1min. Finish with a final extension of 72°C for 7min.

Same protocol for rounds 1 and 2.

AMPLICON: First Round: 680 bp (round 1 band may not always be visible)
Second Round: 630 bp

Please note: In the nested round 2 assay a larger second band can sometimes appear at >750 bp, please do not consider this band as positive, the lower 630bp band is the correct size in a positive sample

CONTROLS: Appropriate filovirus control (provided)

Flaviviruses

PROTOCOL P-004

REFERENCE: Moureau, G *et al*, (2007). Vector-borne and zoonotic diseases 7:467-477

NOTES: We perform this assay using conventional PCR on cDNA following reverse-transcription, and recommend this method. This is a good screening assay. Positive samples should be sequenced to confirm the presence of a flavivirus, and then followed with the Unpublished UCD Designed Flavi assay below to try to obtain additional sequence for further identification.

Please note: While this test works very well overall, some species (particularly insects) are known to contain integrated flaviviral sequences that can, on occasion, be detected using this assay. The confirmation of all PCR products by sequencing is therefore extremely important to confirm a positive result.

TARGET: NS5 gene

PRIMERS: Flavi-FWD: TGYRTBTAYAACATGATGGG
Flavi-RVS: GTGTCCCAICCNCGNTRTC

PROTOCOL: 95°C 5 min, then 45 cycles of 94°C for 15 sec, 50°C for 30 sec and 72°C for 45 sec. Finish with 72°C for 10 minutes for final elongation.

AMPLICON: ~270 bp

CONTROL: Universal Control 1, or appropriate flavivirus control.

Paramyxoviruses

PROTOCOL P-005

REFERENCE: Tong, S *et al*, (2008). Journal of Clinical Microbiology, 46:2652-2658

NOTES: This is a conventional hemi-nested PCR, with the same reverse primer used for both rounds. The paper provides good validation of the primers against various paramyxoviruses, but when applied to clinical samples this assay can cross-react with host sequences quite readily. We have seen that this particular problem with bat samples.

Note: When a paramyxovirus is present in a sample, the assay does seem to work well, and (mostly) amplifies a single and specific product, with very little non-specific amplification. Investigators should therefore

proceed cautiously with any sample that looks to have products that are 'almost' the right size, but which also have a high background of non-specific amplification. It is probable that such samples are in fact negative.

TARGET: Polymerase (*pol*) gene

PRIMERS: Round 1

PAR-F1: GAAGGITATTGTCAIAARNTNTGGAC
PAR-R: GCTGAAGTTACIGGITCICCDATRRTTNC

Round 2

PAR-F2: GTTGCTTCAATGGTTCARGGNGAYAA
PAR-R: Same Reverse primer as round 1

PROTOCOL: Round 1:

94°C for 5 min, followed by 40 cycles of 94°C for 1min, 48°C for 1min and 72°C for 1min. Finish with a final extension of 72°C for 7min.

Round 2:

94°C 2 min, then 40 cycles of 94°C for 30 seconds, 48°C for 30 seconds, 72°C for 30 seconds. Finish with 72°C for 7 minutes.

AMPLICON: Round 1: ~639 bp (*Note: Band may not be visible on a gel after Round 1*)
Round 2: ~561 bp

CONTROL: Universal Control 1, or appropriate paramyxovirus RNA

Influenzas

PROTOCOL P-006

REFERENCE: Anthony *et al.* (2012). MBio 3: e00166-12.

NOTE: Two-step PCR is performed using Superscript to make cDNA. This assay has been used successfully identify a variety of 'classic' influenza A viruses in different species. It will not however detect the newly identified divergent bat 'influenza A-like' viruses. A more divergent assay below is provided that is capable of detecting these. Please also note that subtype cannot be inferred from the sequence of the matrix. While sequence(s) may match certain subtypes on blast, this must not be considered diagnostic for that (or any other) subtype. Only amplification of the H and N genes can confirm subtype.

TARGET: M gene

PRIMERS: FLUAV-M-U44: GTCTTCTAACCGAGGTCGAAACG
FLUAV-M-L287: GCATTTTGGACAAAGCGTCTACG

PROTOCOL: 94°C 2 min, then 45 cycles of 94°C for 30 seconds, 52°C for 30 seconds and 72 °C for 30 seconds. Finish with 72°C for 7 minutes.

AMPLICON: 243 bp

CONTROLS: Universal Control 2, or appropriate influenza A RNA

PROTOCOL P-007

REFERENCE: Liang, E. Unpublished. Developed at CII.

NOTES: Consensus based on 2009-2013 published influenza A sequences. This assay was designed to amplify both 'classic' influenza A viruses and the newly identified divergent bat 'influenza A-like' viruses.

This assay uses a touch-down protocol. While a nested assay is presented here, we have (to date) not seen any increased sensitivity from the nested round. For now, we recommend running both rounds in order to assess performance – however be sure to run both rounds out on gels.

Please also note that subtype cannot be inferred from the sequence of the matrix. While sequence(s) may match certain subtypes on blast, this must not be considered diagnostic for that (or any other) subtype. Only amplification of the H and N genes can confirm subtype.

TARGET: PB1

PRIMERS: Round 1
FLUAPB1-F: ATGATGATGGGNATGTTYAAAYATG
FLUAPB1-R: GCNCGNCCNAKDTCRYTRTTDATCAT

Round 2
FLUAPB1-NF: GATGGGNATGTTYAAAYATGYTDAGYAC
FLUAPB1-R: Same reverse primer as Round 1

PROTOCOL: *Note this is a touchdown PCR:*
95°C for 5 min, then 14 cycles of 95°C for 30 seconds, 65°C for 35 seconds (-1°C /cycle) and 72°C for 50 seconds. Then perform 35 cycles of 95°C for 30 seconds, 50°C for 30 seconds and 72°C for 50 seconds. Finish with 72°C for 7 minutes.

Same protocol for both round 1 and 2.

AMPLICON: Round 1: 407 bp
Round 2: 402 bp

CONTROL: Appropriate influenza A control (provided)

IV. Controls

Given the diversity of viral pathogens targeted in PREDICT surveillance strategies, the availability of appropriate control materials is of obvious concern. The ability to distinguish a true positive result from contamination (from control material, or any other source) is also particularly important.

We have produced synthetic DNA constructs for use as ‘universal controls’. These DNA plasmids contain short regions of overlapping viral sequence that act as primer binding sites for different PCR assays (Figures 1-3). They have also been synthesized under the control of a T7-promoter sequence, and can therefore be transcribed into RNA for reverse-transcriptase based assays on RNA pathogens. It is important to note that these controls can *only* be used with the specific assays for which they were designed. Please refer to sections II and III for details of which control to use in each assay.

These constructs offer significant advantage to large-scale laboratory surveillance efforts, such as we have with PREDICT. The sequence spanning any two primer binding regions is unique (it contains the primer binding sites for other assays and will not be found anywhere in nature), allowing for contamination to be readily identified. They can also be produced in large quantities, safely and quickly, and distributed to PREDICT regional partners very easily. *However, there can also be one significant drawback to using these controls!* Given that the controls are in a plasmid construct, they are extremely small particles that are highly stable at room temperature and can be easily transferred onto gloves, tubes, pipettors and other equipment, if not handled carefully and with dedicated pipettors and filter tips. Additionally, since many of the protocols included here are nested PCR assays, the additional handling of PCR products and controls when transferring test samples and controls between round 1 and round 2 PCR reactions, allows ample opportunity for contamination with the controls. The primers and protocols are provided below and should be used to rule out the possibility of contamination in PCR samples prior to shipment of PCR products to other laboratories for sequencing.

Figure 1: Schematic of Universal Control 1

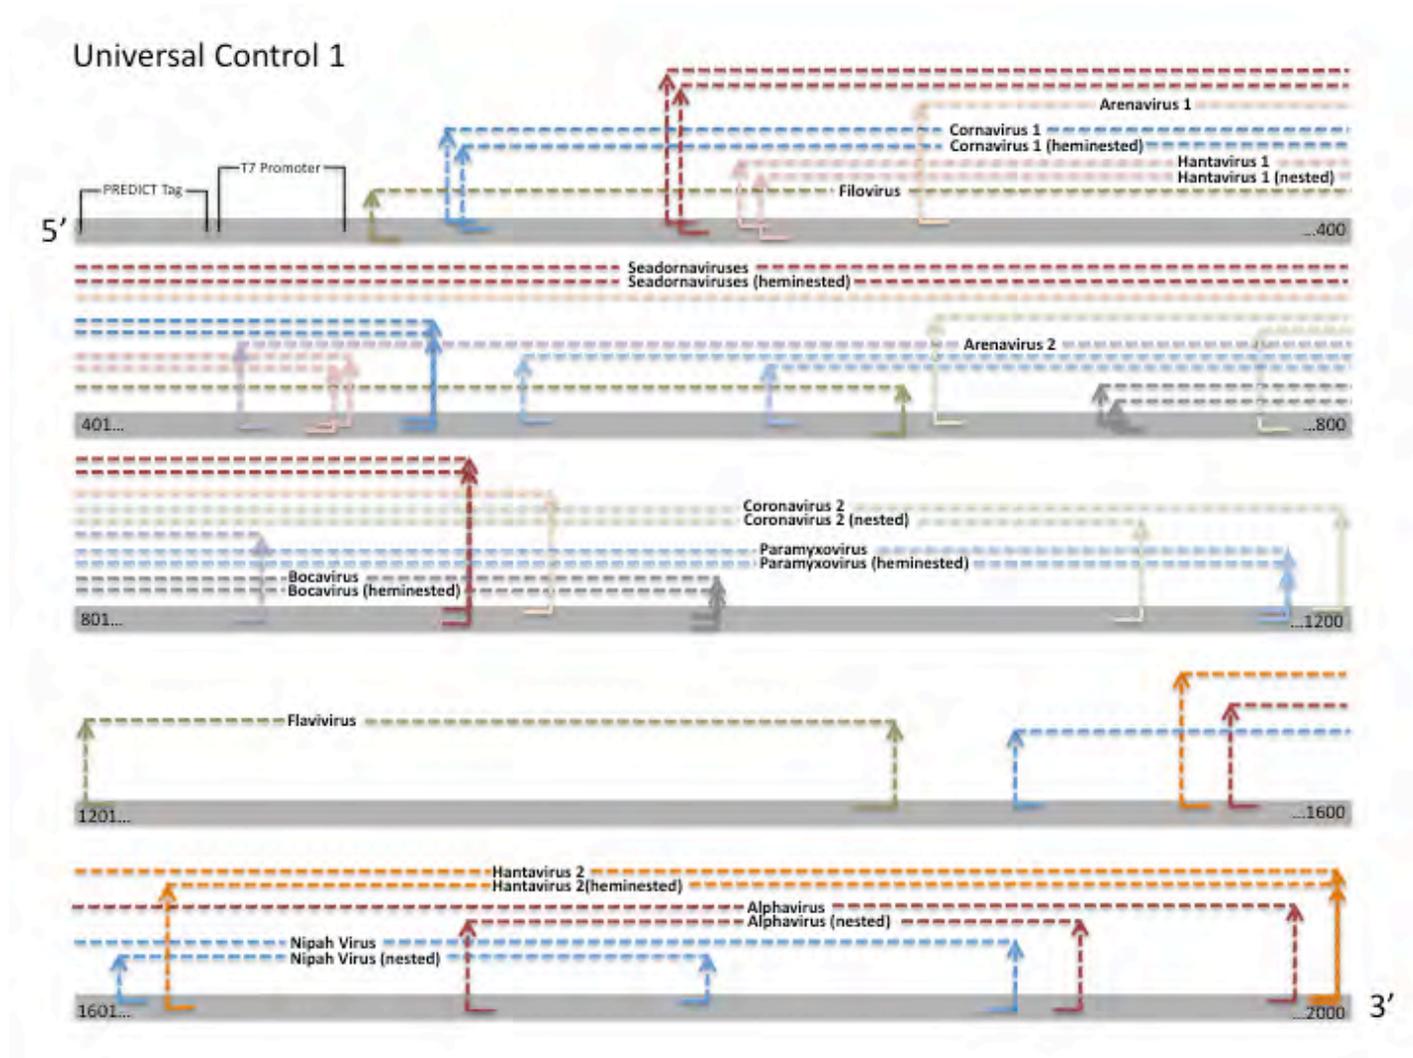

Figure 2: Schematic of Universal Control 2

Contamination Control PCR for Universal Control 1

The primers below should be used to rule out the possibility of contamination in a sample with the Universal Control 1 when a positive PCR result is obtained. This PCR should be run each time a positive result is obtained. The amplified product targets a PREDICT tag of nucleotides that corresponds to amino acid sequence P-R-E-D-I-C-T after sequencing and translation.

PRIMERS: PREDICT-Fwd: GGGCCTAGAGAAGATATTTGTACT
PREDICT-Rvs: CGCCATTGACATCCTCGAAG

PROTOCOL: 94°C for 2 min, then 40 cycles of 94°C for 30 sec, 55°C for 30 sec, 72°C for 1 minute. Finish with 72°C for 2 minutes

AMPLICON: 412 bp

Contamination Control PCR for Universal Control 2

The primers below should be used to rule out the possibility of contamination in a sample with the Universal Control 2 when a positive PCR result is obtained. This PCR should be run each time a positive result is obtained. The amplified product targets a group of nucleotides that correspond to the amino acid sequence D-A-V-I-S after sequencing and translation.

PRIMERS: DAVIS-Fwd: 5'- CGACTCACTATAGGGAGAGACTTTCG -3'
DAVIS-Rvs: 5'- CCGAGTTACATAACGCTTTGATTGCC -3'

PROTOCOL: 94°C for 2 min, then 40 cycles of 94°C for 30 sec, 54°C for 30 sec, 72°C for 1 minute. Finish with 72°C for 2 minutes

AMPLICON: 318 bp

VI. Support

The purpose of this manual is to guide assay selection and control. It is not designed to present comprehensive methodologies or discuss troubleshooting, as we are not seeking to dictate the molecular diagnostics of each laboratory. That said, investigators should feel reassured that additional custom support will be available to provide further guidance beyond this manual, should it be required. Please contact Dr Simon Anthony (anthony@ecohealthalliance.org or sja2127@columbia.edu) and Dr Tracey Goldstein (tgoldstein@ucdavis.edu).

VII Appendices

All of the published papers presented in this document are included here as appendices for reference.

I. Introduction

Predict Diagnostics

The diagnostic scope of PREDICT is uniquely ambitious, and its success clearly dependent on the availability of good molecular assays. The purpose of this document is therefore to provide a list of recommended molecular assays for PREDICT collaborating laboratories.

The approach taken for molecular testing of PREDICT samples will vary depending on sample, location and laboratory. Our main approach is broad testing for indiscriminate detection of all viruses within a particular family or genus by consensus PCR – and in so doing potentially identify novel agents belonging to that particular taxonomic group. In some instances testing will focus on the detection of specific pathogens of interest, in order to gain information on prevalence and pathogenesis (including host and tissue tropisms) of a known virus. Pathogens and sample types for testing will be prioritized with the lab and field teams based on the interfaces, host species sampled and potential routes of transmission of viruses between the wildlife sampled and humans.

Unfortunately, many of the published protocols for this latter (consensus-PCR) approach are not well validated, and their efficacy on diverse clinical and field samples, such as we have with PREDICT, is currently quite undetermined. Thus, these assays are not considered to be validated diagnostic tests, and are designed more for pathogen discovery. These tests often simply represent primer pairs that have been designed from available sequences for a specific study or purpose. On occasion their use may have been demonstrated on diverse laboratory virus strains within a family or genus, or (infrequently) even on clinical samples. However for the most part, the literature is not rich with protocols that might be fit for our purposes. That is, protocols that will detect divergent members of different viral families and/or genera in clinical and field samples. Thus we have modified and designed a number of these assays in an attempt to develop protocols that are more broadly reactive.

A selection of broadly reactive consensus PCR assays is presented here. However, given the restrictions discussed above it is important that all partner laboratories consider this document to be highly adaptive. There may be changes to primer sequences and/or reaction conditions as we learn more about the performance of these assays on clinical/field samples. Entire protocols may also be replaced by new, better methods as they become available. Any such changes will be reported to all partners in subsequent versions of this document.

Use in Clinical Settings

It is important to recognize that the assays present in these protocols, are not validated diagnostic assays. Their sensitivity and specificity for known pathogens has not been assessed in the majority of cases. There is an important distinction between diagnostics for known pathogens (where sensitivity and specificity are known) and discovery (where they are not). These assays are not intended for diagnostics.

Diagnostic assays are often designed against specific agents and are therefore more sensitive for detecting those specific agents. Consensus PCR is broadly reactive thus their strength is for viral discovery, however, they are not as sensitive and have the potential to result in false negatives. For this reason, they are inappropriate for clinical diagnostics when specific assays exist.

We are not recommending that diagnostic labs or facilities replace specific assays with these consensus PCR assays when screening for known pathogens, but rather start incorporating them into diagnostic investigations when specific assays are unavailable or have failed to produce a positive result. At this point, this would be considered discovery and not diagnostics.

Proprietary Assays

Many of the assays presented here are published assays. Their use may not have been adequately demonstrated on clinical and field samples, as yet, but they are none-the-less freely available for general use. For others, this is not the case. Some assays have been modified (reaction conditions and/or primer sequences), and others represent entirely new assays developed by scientists at CII and UC Davis. For this reason, all details of this manual, including any controls that are supplied to partners, must be considered confidential and can only be distributed to a third party once the Biological Sample Sharing Agreement is in place. This procedure is to ensure the USAID and PREDICT receive acknowledgement in future publications for supplying the protocols and controls.

Reagents

We realize that each laboratory will no doubt be familiar with, or have preference for, certain reagents and PCR kits. All the protocols in this manual have been tested using one set of reagents used routinely in our laboratories and all assays performed well using these reagents. Thus, we suggest PREDICT collaborating laboratories use the same reagents described in our document or in the original publication of a particular assay. The details provided here refer to kits used by scientists at Columbia University's Center for Infection and Immunity (CII), University of California Davis Wildlife Health Center and Global Viral Forecasting Inc.

- RNA extraction is performed with using the Zymo Research Direct-zol RNA MiniPrep Kit . Catalogue number: Zymo Research Cat # **R2050 (kit of 50), R2052 (kit of 200)**; <http://www.zymoresearch.com/rna/total-rna-purification/samples-in-tri-reagent-trizol-etc/direct-zol-rna-miniprep>
- Reverse-transcription is performed using Invitrogen's SuperScript III First-strand cDNA synthesis kit, according to the manufacturer's instructions. Catalogue Number: **18080-400 (50 reactions)**
- PCR is performed using Invitrogen Platinum TAQ DNA polymerase kit, according to the manufacturer's instructions. Catalogue Number: **10966-026 (250 x 25 µl reactions)**

II. Pan (Consensus) RNA Virus Assays

Reverse-Complementation

Samples to be tested for RNA viruses must first be reverse-transcribed (RT) in order to provide a suitable cDNA template for PCR. **We recommend that cDNA is generated prior to PCR in a separate reaction, and primed by random hexamers (ie. perform two-step PCR)** using Invitrogen's SuperScript III First-strand cDNA synthesis kit. This approach has been taken as sample quantity is often limited and budgetary restrictions and/or the availability of reagents also influence the preference to target cDNA (RT performed prior to PCR in a separate reaction).

Coronaviruses

NOTE: Please use both Coronavirus protocols for screening all samples. These two assays target non-overlapping regions of the RNA-Dependent RNA Polymerase in ORF 1b and it is useful to have both regions for phylogenetic discrimination.

PROTOCOL P-001

REFERENCE: Quan, PL et al (2010). MBio 1:1-9 (e00208-10)

NOTES: Reverse-transcription performed separately using Superscript III, followed by nested PCR. On the Human Coronavirus genome (strain 229E) it roughly amplifies the region 17,480-17,820.

TARGET: RNA-Dependent RNA Polymerase (RdRp)

PRIMERS: Round 1:
CoV-FWD1: CGTTGGIACWAAAYBTVCCWYTICARBTRGG
CoV-RVS1: GGTCATKATAGCRTCAVMASWWGCNACATG

Round 2:
CoV-FWD2: GGCWCCWCCHGGNGARCAATT
CoV-RVS2: GGWAWCCCCAYTGYTGWAYRTC

PROTOCOL: 95°C 5 min, then 15 cycles of 95°C for 30 seconds, 65°C for 30 seconds and 72°C for 45 seconds, then 35 cycles of 94°C for 30 seconds, 50°C for 30 seconds and 72°C for 45 seconds. Finish with 72°C for 7 minutes.

Same protocol for rounds 1 and 2.

AMPLICON: First Round: 520 bp
Second Round: 328 bp

CONTROL: Universal Control 1, or appropriate Coronavirus cDNA

PROTOCOL P-002

REFERENCE: Modified from Watanabe, *S et al* (2010). *Emerging Infectious Diseases* 16:1217-1223

NOTE: Like the Quan protocol, this assay also targets the polymerase. However, it targets a different region slightly more upstream. On the Human Coronavirus genome (Strain 229E) it targets roughly nucleotides 14,370-14,750. If you are looking for coronaviruses in bats, this may be a good protocol to use because many of the partial sequences that are published on CoV (in bats) have been generated using these primers. Please note that this assay has been modified from the original publication: Initial primer sequences have been modified to increase the ability of the assay to detect widely variant coronaviruses. A second, heminested step has also been added to increase sensitivity. This step can be performed using a forward primer that is optimized for bat viruses, or other coronaviruses, depending on the sample being investigated.

TARGET: RNA-Dependent RNA Polymerase (RdRp)

PRIMERS: Round 1:
CoV-FWD3: GGTGGGAYTAYCCHAARTGTGA
CoV-RVS3: CCATCATCASWYRAATCATCATA

Round 2:
CoV-FWD4/Bat: GAYTAYCCHAARTGTGAYAGAGC
(or CoV-FWD4/Other: GAYTAYCCHAARTGTGAUMGWGC)
CoV-RVS3: Same reverse primer as round 1

PROTOCOL: 94°C 2 min, then 35 cycles of 94°C for 20 seconds, 50°C for 30 seconds and 72°C for 30 seconds. Finish with 72°C for 7 mins.

Same protocol for rounds 1 and 2.

AMPLICON: First Round: 440 bp
Second Round: 434 bp

CONTROL: Universal Control 1 or (when available), or appropriate Coronavirus cDNA

Filoviruses

PROTOCOL P-003

REFERENCE: Modified from Zhai, J *et al* (2007). Journal of Clinical Microbiology, 45:224-226

NOTES: The previous primers used in PREDICT were well validated for known filoviruses, but we were concerned their lack of degeneracy might inhibit their ability to detect novel viruses of this group and that the one round of PCR might not be sensitive enough for our needs with field samples.

Thus we redesigned the set of modified primers to introduce more degeneracy into the sequence to improve their use for pathogen discovery and also to add a nested PCR step to increase sensitivity. These primers are able to detect known Ebola and Marburg viruses, as well as the divergent bat filovirus, Lloviu virus, and we hope will also improve broad reactivity.

Please note that these primers may produce non-specific products of the incorrect size in clinical samples, so labs should not follow up on bands that are clearly the wrong size, and focus only on bands that are approximately 630 bp. All positives must be confirmed by sequencing.

TARGET: L-Gene

PRIMERS: Round 1:
Filo-MOD-FWD: TITTYTCHVTICAAAICAYTGGG
FiloL.conR: ACCATCATRTRCTIGGRAAKGCTTT

Round 2:
Filo-MOD-FWD: TITTYTCHVTICAAAICAYTGGG
Filo-MOD-RVS: GCYTCISMIAHGTGGIACATT

PROTOCOL: 94°C for 5 min, followed by 40 cycles of 94°C for 1min, 52°C for 1min and 72°C for 1min. Finish with a final extension of 72°C for 7min.

Same protocol for rounds 1 and 2.

AMPLICON: First Round: 680 bp (round 1 band may not always be visible)
Second Round: 630 bp

Please note: In the nested round 2 assay a larger second band can sometimes appear at >750 bp, please do not consider this band as positive, the lower 630bp band is the correct size in a positive sample

CONTROLS: Appropriate filovirus cDNA (provided)

Flaviviruses

PROTOCOL P-004

REFERENCE: Moureau, G *et al*, (2007). Vector-borne and zoonotic diseases 7:467-477

NOTES: We perform this assay using conventional PCR on cDNA following reverse-transcription, and recommend this method. This is a good screening assay. Positive samples should be sequenced to confirm the presence of a flavivirus, and then followed with the Unpublished UCD Designed Flavi assay below to try to obtain additional sequence for further identification.

Please note: While this test works very well overall, some species (particularly insects) are known to contain integrated flaviviral sequences that can, on occasion, be detected using this assay. The confirmation of all PCR products by sequencing is therefore extremely important to confirm a positive result.

TARGET: NS5 gene

PRIMERS: Flavi-FWD: TGYRBTTAYAACATGATGGG
Flavi-RVS: GTGTCCCAICCNGCNGTRTC

PROTOCOL: 95°C 5 min, then 45 cycles of 94°C for 15 sec, 50°C for 30 sec, 72°C for 45 sec, and 77°C for 15 sec. Finish with 72°C for 10 minutes for final elongation.

AMPLICON: ~270 bp

CONTROL: Universal Control 1, or appropriate flavivirus control.

Paramyxoviruses

PROTOCOL P-005

REFERENCE: Tong, S *et al*, (2008). Journal of Clinical Microbiology, 46:2652-2658

NOTES: This is a conventional hemi-nested PCR, with the same reverse primer used for both rounds. The paper provides good validation of the primers against various paramyxoviruses, but when applied to clinical samples this assay can cross-react with host sequences quite readily. We have seen that this particular problem with bat samples.

Note: When a paramyxovirus *is* present in a sample, the assay does seem to work well, and (mostly) amplifies a single and specific product, with very little non-specific amplification. Investigators should therefore proceed cautiously with any sample that looks to have products that are 'almost' the right size, but which also have a high background of non-specific amplification. It is probable that such samples are in fact negative.

TARGET: Polymerase (*pol*) gene

PRIMERS: Round 1
PAR-F1: GAAGGITATTGTCAIAARNTNTGGAC
PAR-R: GCTGAAGTTACIGGITCICCDATRTTNC

Round 2
PAR-F2: GTTGCTTCAATGGTTCARGGNGAYAA
PAR-R: Same Reverse primer as round 1

PROTOCOL: Round 1:
94°C for 5 min, followed by 40 cycles of 94°C for 1min, 48°C for 1min and 72°C for 1min. Finish with a final extension of 72°C for 7min.

Round 2:
94°C 2 min, then 40 cycles of 94°C for 30 seconds, 48°C for 30 seconds, 72°C for 30 seconds. Finish with 72°C for 7 minutes.

AMPLICON: Round 1: ~639 bp (*Note: Band many not be visible on a gel after Round 1*)
Round 2: ~561 bp

CONTROL: Universal Control 1, or appropriate paramyxovirus RNA

Influenzas

PROTOCOL P-06

REFERENCE: Anthony *et al.* (2012). MBio 3: e00166-12.

NOTE: Two-step PCR is performed using Superscript to make cDNA. This assay has been used successfully identify a variety of 'classic' influenza A viruses in different species. It will not however detect the newly identified divergent bat 'influenza A-like' viruses. A more divergent assay below is provided that is capable of detecting these. Please also note that subtype cannot be inferred from the sequence of the matrix. While sequence(s) may match certain subtypes on blast, this must not be

considered diagnostic for that (or any other) subtype. Only amplification of the H and N genes can confirm subtype.

TARGET: M gene

PRIMERS: FLUAV-M-U44: GTCTTCTAACCGAGGTCGAAACG
FLUAV-M-L287: GCATTTTGGACAAAGCGTCTACG

PROTOCOL: 94°C 2 min, then 45 cycles of 94°C for 30 seconds, 52°C for 30 seconds and 72 °C for 30 seconds. Finish with 72°C for 7 minutes.

AMPLICON: 243 bp

CONTROLS: Universal Control 2, or appropriate influenza A RNA

PROTOCOL P-07

REFERENCE: Liang, E. Unpublished. Developed at CII.

NOTES: Consensus based on 2009-2013 published influenza A sequences. This assay was designed to amplify both 'classic' influenza A viruses and the newly identified divergent bat 'influenza A-like' viruses.

This assay uses a touch-down protocol. While a nested assay is presented here, we have (to date) not seen any increased sensitivity from the nested round. For now, we recommend running both rounds in order to assess performance – however be sure to run both rounds out on gels.

Please also note that subtype cannot be inferred from the sequence of the matrix. While sequence(s) may match certain subtypes on blast, this must not be considered diagnostic for that (or any other) subtype. Only amplification of the H and N genes can confirm subtype.

TARGET: PB1

PRIMERS: Round 1
FLUAPB1-F: ATGATGATGGGNATGTTYAAYATG
FLUAPB1-R: GCNGGNCCNAKDTCRYTRTTDATCAT

Round 2
FLUAPB1-NF: GATGGGNATGTTYAAYATGYTDAGYAC
FLUAPB1-R: Same reverse primer as Round 1

PROTOCOL: *Note this is a touchdown PCR:*

95°C for 5 min, then 14 cycles of 95°C for 30 seconds, 65°C for 35 seconds (-1°C /cycle) and 72°C for 50 seconds. Then perform 35 cycles of 95°C for 30 seconds, 50°C for 30 seconds and 72°C for 50 seconds. Finish with 72°C for 7 minutes.

Same protocol for both round 1 and 2.

AMPLICON: Round 1: 407 bp
Round 2: 402 bp

CONTROL: Appropriate influenza A cDNA (provided)

IV. Controls

Given the diversity of viral pathogens targeted in PREDICT surveillance strategies, the availability of appropriate control materials is of obvious concern. The ability to distinguish a true positive result from contamination (from control material, or any other source) is also particularly important.

We have produced synthetic DNA constructs for use as ‘universal controls’. These DNA plasmids contain short regions of overlapping viral sequence that act as primer binding sites for different PCR assays (Figures 1-3). They have also been synthesized under the control of a T7-promoter sequence, and can therefore be transcribed into RNA for reverse-transcriptase based assays on RNA pathogens. It is important to note that these controls can *only* be used with the specific assays for which they were designed. Please refer to sections II and III for details of which control to use in each assay.

These constructs offer significant advantage to large-scale laboratory surveillance efforts, such as we have with PREDICT. The sequence spanning any two primer binding regions is unique (it contains the primer binding sites for other assays and will not be found anywhere in nature), allowing for contamination to be readily identified. They can also be produced in large quantities, safely and quickly, and distributed to PREDICT regional partners very easily. *However, there can also be one significant drawback to using these controls!* Given that the controls are in a plasmid construct, they are extremely small particles that are highly stable at room temperature and can be easily transferred onto gloves, tubes, pipettors and other equipment, if not handled carefully and with dedicated pipettors and filter tips. Additionally, since many of the protocols included here are nested PCR assays, the additional handling of PCR products and controls when transferring test samples and controls between round 1 and round 2 PCR reactions, allows ample opportunity for contamination with the controls. The primers and protocols are provided below and should be used to rule out the possibility of contamination in PCR samples prior to shipment of PCR products to other laboratories for sequencing.

Figure 1: Schematic of Universal Control 1

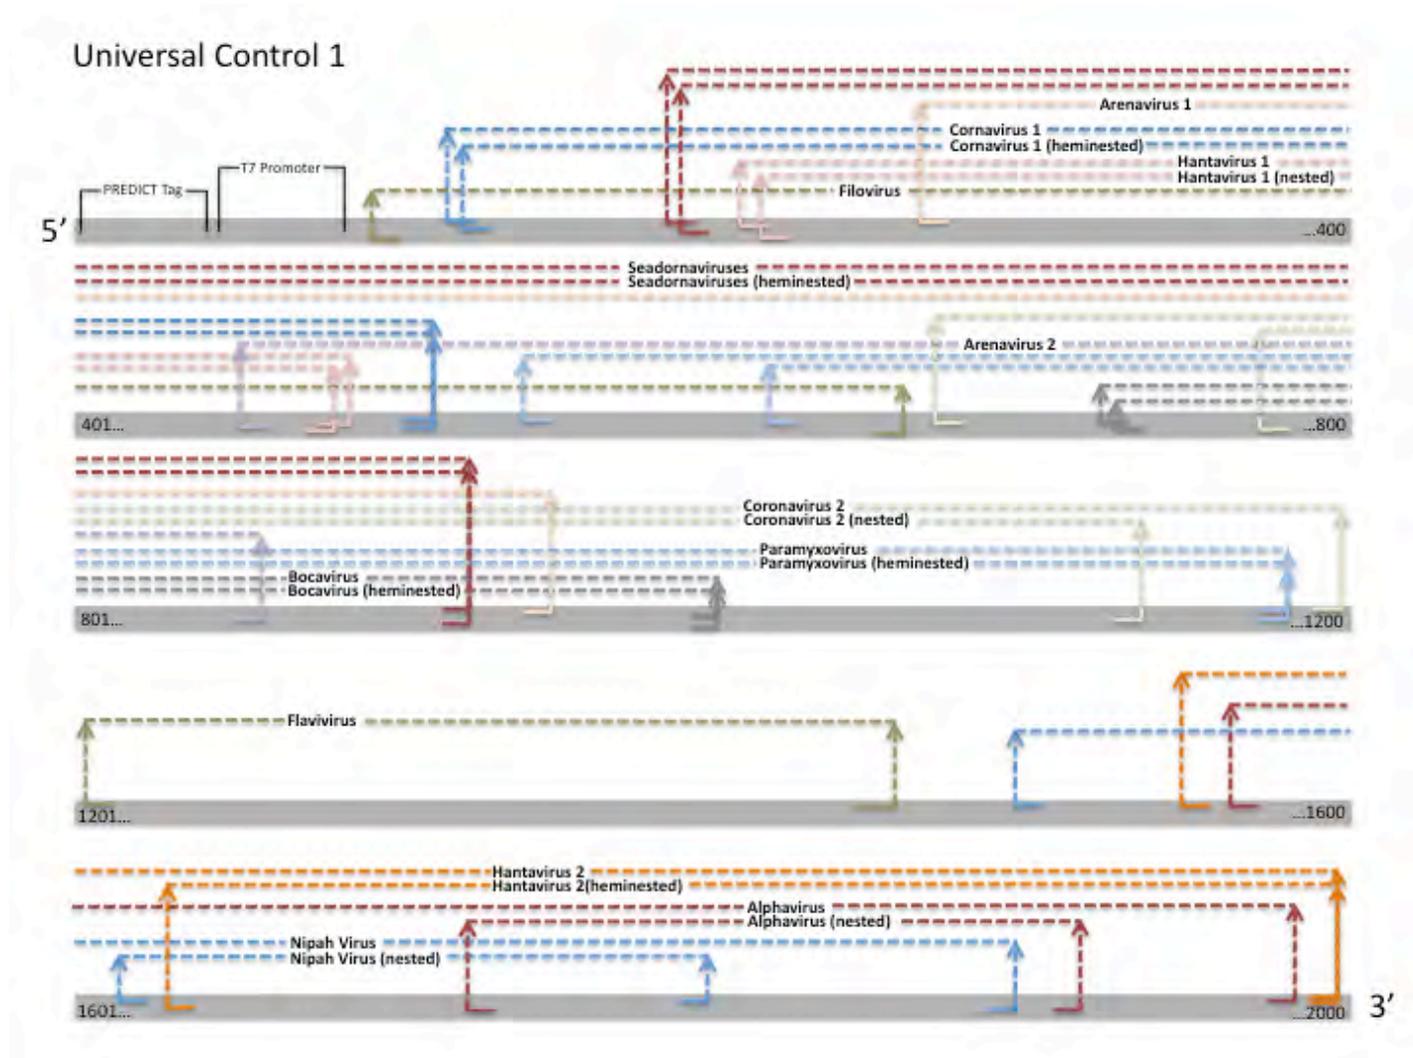

Figure 2: Schematic of Universal Control 2

Contamination Control PCR for Universal Control 1

The primers below should be used to rule out the possibility of contamination in a sample with the Universal Control 1 when a positive PCR result is obtained. This PCR should be run each time a positive result is obtained. The amplified product targets a PREDICT tag of nucleotides that corresponds to amino acid sequence P-R-E-D-I-C-T after sequencing and translation.

PRIMERS: PREDICT-Fwd: GGGCCTAGAGAAGATATTTGTACT
PREDICT-Rvs: CGCCATTGACATCCTCGAAG

PROTOCOL: 94°C for 2 min, then 40 cycles of 94°C for 30 sec, 55°C for 30 sec, 72°C for 1 minute. Finish with 72°C for 2 minutes

AMPLICON: 412 bp

Contamination Control PCR for Universal Control 2

The primers below should be used to rule out the possibility of contamination in a sample with the Universal Control 2 when a positive PCR result is obtained. This PCR should be run each time a positive result is obtained. The amplified product targets a group of nucleotides that correspond to the amino acid sequence D-A-V-I-S after sequencing and translation.

PRIMERS: DAVIS-Fwd: 5'- CGACTCACTATAGGGAGAGACTTTCG -3'
DAVIS-Rvs: 5'- CCGAGTTACATAACGCTTTGATTGCC -3'

PROTOCOL: 94°C for 2 min, then 40 cycles of 94°C for 30 sec, 54°C for 30 sec, 72°C for 1 minute. Finish with 72°C for 2 minutes

AMPLICON: 318 bp

VI. Support

The purpose of this manual is to guide assay selection and control. It is not designed to present comprehensive methodologies or discuss troubleshooting, as we are not seeking to dictate the molecular diagnostics of each laboratory. That said, investigators should feel reassured that additional custom support will be available to provide further guidance beyond this manual, should it be required. Please contact Dr Simon Anthony (anthony@ecohealthalliance.org or sja2127@columbia.edu) and Dr Tracey Goldstein (tgoldstein@ucdavis.edu).

VII Appendices

All of the published papers presented in this document are included here as appendices for reference.

Identification of a Severe Acute Respiratory Syndrome Coronavirus-Like Virus in a Leaf-Nosed Bat in Nigeria

ABSTRACT Bats are reservoirs for emerging zoonotic viruses that can have a profound impact on human and animal health, including lyssaviruses, filoviruses, paramyxoviruses, and severe acute respiratory syndrome coronaviruses (SARS-CoVs). In the course of a project focused on pathogen discovery in contexts where human-bat contact might facilitate more efficient interspecies transmission of viruses, we surveyed gastrointestinal tissue obtained from bats collected in caves in Nigeria that are frequented by humans. Coronavirus consensus PCR and unbiased high-throughput pyrosequencing revealed the presence of coronavirus sequences related to those of SARS-CoV in a Commerson's leaf-nosed bat (*Hipposideros commersoni*). Additional genomic sequencing indicated that this virus, unlike subgroup 2b CoVs, which includes SARS-CoV, is unique, comprising three overlapping open reading frames between the M and N genes and two conserved stem-loop II motifs. Phylogenetic analyses in conjunction with these features suggest that this virus represents a new subgroup within group 2 CoVs.

IMPORTANCE Bats (order Chiroptera, suborders Megachiroptera and Microchiroptera) are reservoirs for a wide range of viruses that cause diseases in humans and livestock, including the severe acute respiratory syndrome coronavirus (SARS-CoV), responsible for the global SARS outbreak in 2003. The diversity of viruses harbored by bats is only just beginning to be understood because of expanded wildlife surveillance and the development and application of new tools for pathogen discovery. This paper describes a new coronavirus, one with a distinctive genomic organization that may provide insights into coronavirus evolution and biology.

Coronaviruses (order *Nidovirales*, family *Coronaviridae*, subfamily *Coronavirinae*) infect a wide range of vertebrates and cause respiratory, enteric, or less frequently, neurological diseases (1, 2). Coronaviruses were originally divided into three groups based on their antigenic cross-reactivities and nucleotide sequences (3). They have been recently reclassified by the International Committee on Taxonomy of Viruses into 3 genera, designated *Alphacoronavirus* (former group 1), *Betacoronavirus* (former group 2), and *Gamma-coronavirus* (former group 3) (4). Whereas the alphacoronaviruses and betacoronaviruses are associated with diseases of mammals, including humans, the gammacoronaviruses are implicated chiefly in diseases of birds. Interest in coronaviruses was largely focused on their impact on domestic porcine and avian husbandry and their utility in animal models of virus-induced demyelination (5) until the emergence of severe acute respiratory syndrome (SARS) in 2003 (6). Thereafter, with recognition of the causative agent SARS coronavirus (SARS-CoV) (7–10) and of the presence of SARS-CoV-like viruses in Chinese horseshoe bats (*Rhinolophus* spp.) (11), efforts to explore the genetic diversity of coronaviruses and their host range intensified (12).

Bats are suggested to be important reservoir hosts of many zoonotic viruses with significant impact on human and animal health, including lyssaviruses, henipaviruses, filoviruses, and coronaviruses (13–17). Viruses of bats may be transmitted to humans directly through bites or via exposure to saliva, fecal aerosols, or infected tissues as well as indirectly through contact with infected intermediate hosts, such as swine (18). In the course of a project focused on pathogen discovery in situations where human-bat contact might facilitate more efficient interspecies transmission of emerging viruses, we surveyed bats in Nigeria. Through consensus PCR (cPCR) and unbiased high-throughput pyrosequencing (UHTS) of bat tissue samples, we identified a coronavirus that is most closely related to the genus *Betacoronavirus* (subgroup 2b), which includes SARS-CoV and SARS-CoV-like viruses. However, the genomic organization of this coronavirus, obtained from a Commerson's leaf-nosed bat (*Hipposideros commersoni*), is unique in that it is comprised of three overlapping open reading frames (ORFs) between the M and N genes and two conserved stem-loop II motifs (s2m). Based on these observations and phylogenetic analyses, we propose that this new member of

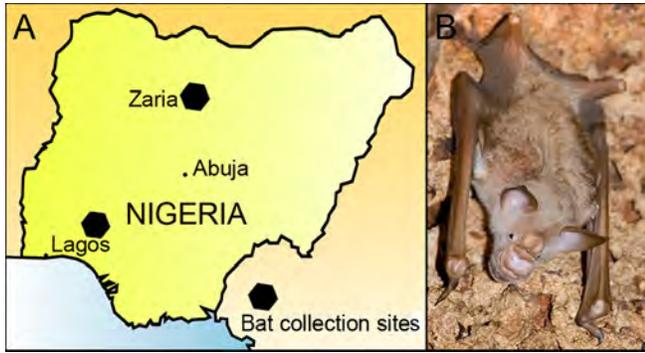

FIG 1 (A) Map of Nigeria showing the locations of bat collection sites. (B) Photograph of a male Commerson's leaf-nosed bat (*Hipposideros commersoni*), courtesy of Ivan V. Kuzmin, reproduced with permission.

the family *Coronaviridae*, tentatively named Zaria bat coronavirus (ZBCoV) after the city near to where the bat was captured, represents a new subgroup of group 2 CoVs.

RESULTS

Identification of a coronavirus in intestinal tissue of a Commerson's leaf-nosed bat (*Hipposideros commersoni*). Total RNA extracts from gastrointestinal tract (GIT) specimens obtained from 33 bats of 6 different species (*Eidolon helvum*, *Hipposideros com-*

mersoni, *Pipistrellus* sp., *Rousettus aegyptiacus*, *Scotophilus nigrita*, and *Scotophilus leucogaster*) captured at 2 different sites from a roost inside a cave in Nigeria (Fig. 1A) were screened for the presence of coronaviruses by consensus PCRs of a 400-nucleotide (nt) fragment of the RNA-dependent RNA polymerase (RdRp) gene. One specimen obtained from a Commerson's leaf-nosed bat (Fig. 1B) yielded products that shared no more than 70% nt identity to any known coronavirus. RNA from ZBCoV was submitted for UHTS, resulting in a library comprising 74,133 sequence reads. Alignment of unique singleton and assembled contiguous sequences to the GenBank database (<http://www.ncbi.nlm.nih.gov/>) using the Basic Local Alignment Search Tool (Blastn and Blastx) (19) indicated coverage of approximately 6,500 nt of sequence distributed along coronavirus genome scaffolds and homology to regions of replicase, spike (S), and nucleocapsid (N) sequences.

Genome organization and coding potential of ZBCoV. The additional genomic sequence of ZBCoV was determined by filling in gaps between UHTS reads, applying consensus PCRs, and 3' and 5' rapid amplification of cDNA ends (RACE). Overlapping primer sets based on the draft genome were synthesized to facilitate sequence validation by conventional dideoxy sequencing. Due to exhaustion of the sample, we were unable to completely sequence the open reading frame 1ab (ORF 1ab) region (Fig. 2A).

ZBCoV has a genome organization similar to that of other coronaviruses, with the following characteristic gene order:

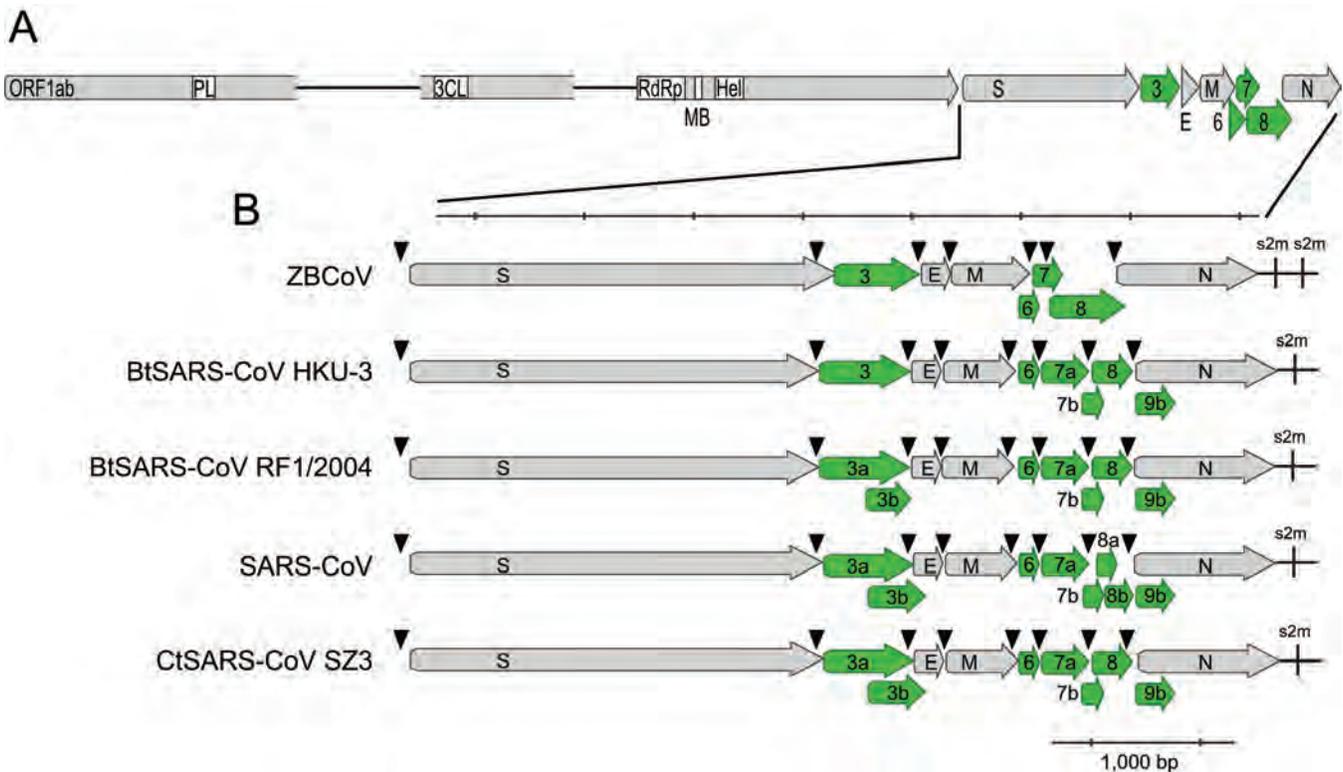

FIG 2 Genome organization of ZBCoV in comparison to that of representative coronaviruses from subgroup 2b. (A) Overall genome organization of ZBCoV. The ORF 1ab, spike (S), envelope (E), membrane (M), and nucleocapsid (N) genes are shown in gray arrows, whereas putative accessory genes ORF 3, ORF 6, ORF 7, and ORF 8 are indicated as 3, 6, 7, and 8 and illustrated by green arrows. The following conserved functional domains in ORF 1ab are represented in boxes: papain-like protease (PL), 3C-like protease (3CL), RNA-dependent RNA polymerase (RdRp), metal ion-binding domain (MB), and helicase (Hel). The two regions in ORF 1ab where sequences are incomplete are indicated by black lines. (B) Expanded diagram of the 3' region of the ZBCoV genome in comparison to representative CoVs from subgroup 2b. TRS motifs and s2m are represented by black arrowheads and vertical lines, respectively.

TABLE 1 ORFs and putative TRS motifs

ORF	Length in:		TRS
	nt	aa	
1ab	NC ^a	NC	ACGAAC ₂₂₁ AUG
Spike	3,897	1,299	ACGAACAUG
3	750	250	ACGAAC ₂₈ AUG
Envelope	237	79	ACGAAC ₂₃ AUG
Membrane	729	243	ACGAAC ₃₀ AUG
6	147	49	NA ^b
7	237	79	ACGAAC ₃ AUG
8	654	218	ACGAAC ₁₀ AUG
Nucleocapsid	1,260	420	ACGAAC ₁₂ AUG

^a NC, not complete.

^b NA, not applicable.

5'-replicase ORF 1ab-spike (S)-envelope (E)-membrane (M)-nucleocapsid (N)-3'. Both the 5' and 3' ends contain short untranslated regions of 297 nt and 363 nt, respectively. The conserved putative transcription regulatory sequence (TRS) motif 5'-ACGAAC-3' identified in subgroup 2b, 2c, and 2d viruses (2) is present in ZBCoV at the 3' end of the leader sequence and upstream of potential initiating methionine residues of each ORF except ORF 6 (Table 1).

All domains within replicase polyproteins of coronaviruses that are implicated in viral replication are found in ZBCoV, including the papain-like protease (PL^{pro}), 3C-like protease (3CL^{pro}), RNA-dependent RNA polymerase (RdRp), and helicase (Hel) domains (Fig. 2A). ORFs consistent with the S, E, M, and N proteins present in all other coronaviruses are also present in ZBCoV (Table 1; Fig. 2). Pairwise identity (I) and similarity (S) comparisons of a deduced amino acid sequence of ZBCoV to that of representative coronaviruses in other groups showed that the predicted proteins of ZBCoV are more similar to those of subgroup 2b CoVs than to those of other subgroups, with Hel and RdRp having the highest homologies (Hel: I, 80%; S, 90%; RdRp: I, 74%; S, 85%) and the S protein having the lowest (I, 36 to 38%; S, 50 to 53%) (<http://cait.cumc.columbia.edu:88/dept/greeneidlab/IdentificationofaSARS-Coronavirus-likevirusinalaef-nosedbatinNigeria.html>).

The putative spike (S) protein of ZBCoV, comprising 1,299 amino acids (aa) in length, is slightly larger than those of other subgroup 2b CoVs (see Table S8 in the supplemental material). ZBCoV showed the highest amino acid conservation to human and civet SARS-CoV (I, 38%; S, 53%) (<http://cait.cumc.columbia.edu:88/dept/greeneidlab/IdentificationofaSARS-Coronavirus-likevirusinalaef-nosedbatinNigeria.html>). Pfam (20) analysis identified a spike receptor binding domain (PF09408) that corresponds to the immunogenic receptor binding domain that binds to angiotensin-converting enzyme 2 (ACE2) and the coronavirus S1 (PF01600) and S2 (PF01601) spike glycoprotein domains. Transmembrane region prediction (TMHMM 2.0) (21) revealed a long ectodomain (aa 1 to 1240), a transmembrane domain near the C-terminal end (aa 1241 to 1263), and a short cytoplasmic tail (aa 1264 to 1298). A predicted signal peptide (SignalP 3.0) ($P = 1$) (22) was identified with a cleavage site ($P = 0.768$) between residues A₁₆ and A₁₇. NetNGlyc 1.0 identified 25 putative N-linked glycosylation sites. The S protein of ZBCoV displays major sequence differences compared to that of subgroup 2b CoVs, especially in the S1 domain involved in receptor binding. The critical residues suggested to be important for the cleavage of the SARS-CoV S protein are present in the S protein of ZBCoV (23–25) (see

Fig. S1A in the supplemental material). Motifs at the carboxyl terminus of the S protein that are conserved among coronaviruses are also found in the ZBCoV S protein, including the conserved motif Y(X)KWPW(Y/W)(V/I)WL present as Y₁₂₃₇EKWPWYIWL and the cysteine-rich cytoplasmic tail (10) (see Fig. S1B in the supplemental material).

In addition to the five genes present in all genomes, coronaviruses also have several group-specific genes between the S gene and the 3' end of the genome that encode accessory proteins (Fig. 2) (26, 27).

An ORF (ORF 3) encoding a putative 250-aa protein was observed between the S and E proteins of ZBCoV (Table 1). ORF 3 corresponds to the genomic position of ORF 3a in subgroup 2b CoVs. Similar to subgroup 2b CoVs, ORF 3 is the largest accessory gene of ZBCoV and is 75 nt shorter than ORF 3a of subgroup 2b CoVs (see Table S8 in the supplemental material). ORF 3 shows 21 to 23% aa identity and 31 to 35% aa similarity to the ORF 3a protein of subgroup 2b CoVs (see Table S9 in the supplemental material). Pfam analysis showed a relationship with PF11289, a viral family protein of an unknown function; TMHMM analysis predicts the presence of 4 transmembrane regions, spanning residues P₄₃ to L₆₅, A₇₂ to E₉₄, V₉₉ to L₁₂₁, and Y₁₉₆ to V₂₁₈. NetOGlyc 3.1 predicted two potential O glycosylation sites in ZBCoV. ORF 3 contains only a portion of the cysteine-rich domain identified in the ORF 3a protein of SARS-CoV; however, the cysteine potentially involved in ORF 3a protein polymerization (28) is present in ORF 3. No signal peptide, YXXΦ, or diacidic motifs were identified in ORF 3 of ZBCoV (29).

ZBCoV has a set of ORFs located between the M and N genes that are not shared by any of the known coronaviruses. These ORFs, ORF 6, ORF 7, and ORF 8, encode predicted proteins of 49, 79, and 218 aa, respectively (Table 1). A TRS was identified upstream of ORF 7 and ORF 8 but not ORF 6. ORF 6 overlaps with the M gene at the 3' end by 101 nt, ORF 7 overlaps with ORF 6 by 31 nt, and ORF 8 overlaps with ORF 7 and the N gene by 83 and 35 nt, respectively. Blastx and Pfam analyses of ORF 6, ORF 7, and ORF 8 revealed no significant similarities or functional domains. Pfam analysis of ORF 7 indicated nonsignificant associations to the PRA1 (prenylated Rab acceptor 1) proteins (PF03208) (E value = 0.02) and the 7 transmembrane G-protein-coupled-receptor protein families (PF10323) (E value = 0.025). TMHMM analysis of ORF 7 suggested the presence of a transmembrane region between residues L₁₀ and I₃₂. No signal peptide was predicted.

TMHMM and SignalP analyses of ORF 6 indicated no transmembrane region or signal peptide. TMHMM analysis of ORF 8 predicted 2 transmembrane regions, and a third transmembrane region located downstream was predicted by TMpred (30). SignalP revealed a signal peptide ($P = 0.988$) with a putative cleaved signal sequence ($P = 0.804$) between residues G₂₉ and A₃₀.

At only 788 nt, the region in ZBCoV between the M and N genes is significantly shorter than those observed for subgroup 2b CoVs (see Table S8 in the supplemental material). Alignment of the region between the M and N genes of ZBCoV with those of subgroup 2b CoVs indicated large deletions in ZBCoV (see Fig. S2 in the supplemental material).

Another distinctive genomic feature of ZBCoV is the presence downstream from the N gene of two conserved motifs corresponding to the conserved stem-loop II motif (s2m) (31). A unique s2m is observed in coronaviruses from subgroups 2b, 3a, and 3c and in astroviruses and in the picornavirus equine rhinitis

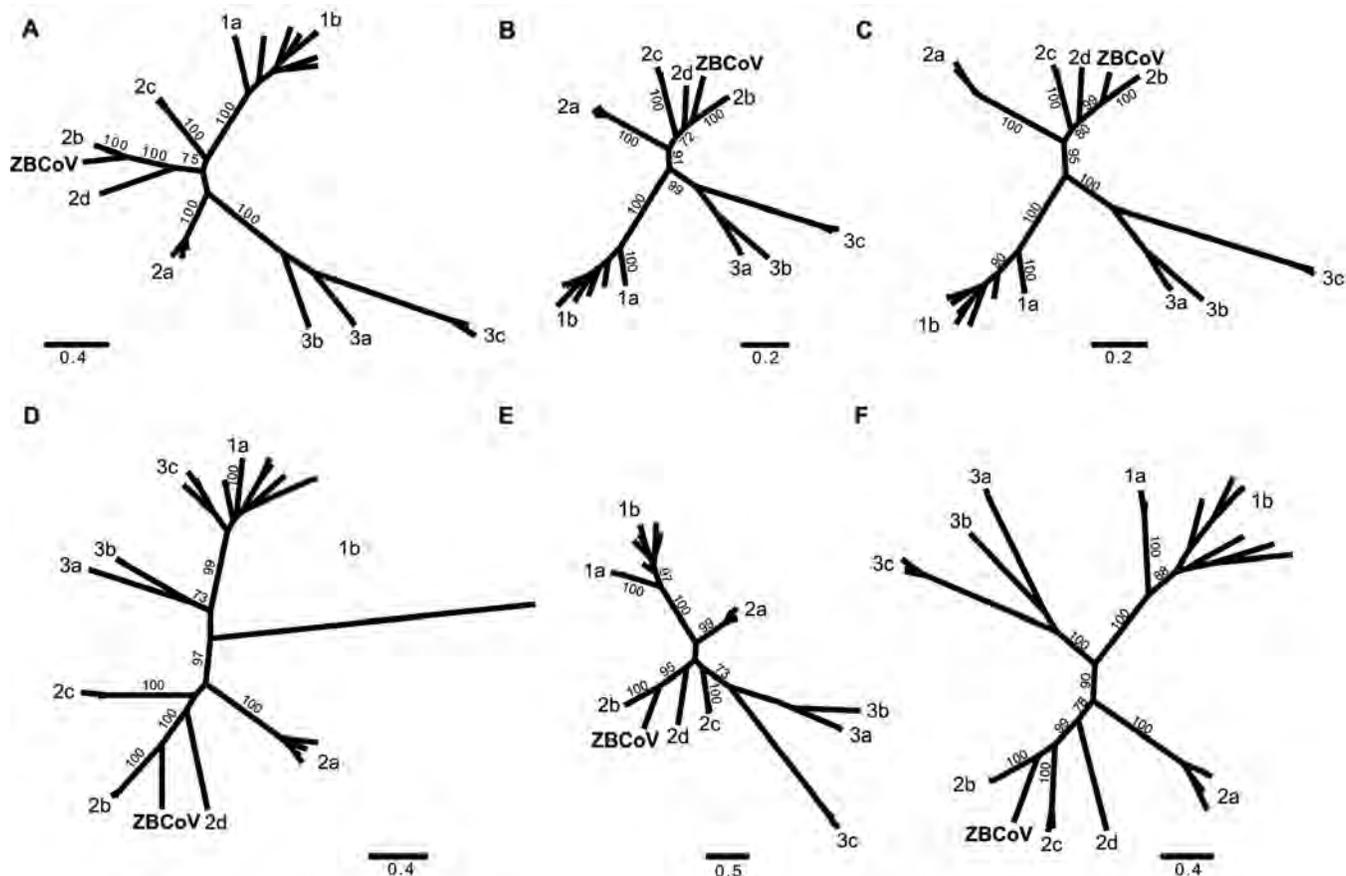

FIG 3 Phylogenetic analysis of the 3CL^{Pro}, RdRp, Hel, S, M, and N proteins of ZBCoV. Unrooted maximum likelihood phylogenies of the 3CL^{Pro} (A), RNA-dependent RNA polymerase (B), helicase (C), spike (D), membrane (E), and nucleocapsid (F) proteins. All phylogenies were constructed using the complete amino acid alignments of each protein, with the exception of RdRp (partial region available) and spike (only an 884-aa region could be reliably aligned). The scale bar indicates the number of substitutions per amino acid site. The numbers at each branch node represent the maximum likelihood bootstrap support; only major nodes where values exceed 70% are shown. The CoV subgroups are indicated as 1a and b, 2a to d, and 3a to c, and the following sequences obtained from GenBank were included, with the GenBank accession numbers given in parentheses: PRCV, porcine respiratory coronavirus (DQ811787); FIPV, feline infectious peritonitis virus (AY994055); HCoV-229E, human coronavirus 229E (NC_002645); HCoV-NL63, human coronavirus NL63 (NC_005831); BtCoV-512/2005, bat coronavirus 512/2005 (NC_009657); BtCoV-HKU2, bat coronavirus HKU2 (NC_009988); BtCoV-1B, bat coronavirus 1 B (NC_010436); BtCoV-1A, bat coronavirus 1A (NC_010437); BtCoV-HKU8, bat coronavirus HKU8 (NC_010438); BCoV, bovine coronavirus (NC_003045); HCoV-OC43, human coronavirus OC43 (NC_005147); HCoV-HKU1, human coronavirus HKU1 (NC_006577); MHV, mouse hepatitis virus (NC_006577); PHEV, porcine hemagglutinating encephalomyelitis virus (NC_007732); ECoV, equine coronavirus (NC_010327); BtSARS-CoV HKU3, bat SARS coronavirus HKU3 (NC_009694); CtSARS-CoV SZ3, civet SARS coronavirus SZ3 (AY304486); SARS-CoV, SARS coronavirus (NC_004718); BtSARS-CoV Rp3, bat coronavirus Rp3 (NC_009693); BtSARS-CoV Rf1/2004, bat coronavirus Rf1/2004 (NC_009695); BtSARS-CoV RM1, bat coronavirus RM1 (NC_009696); BtCoV-HKU4, bat coronavirus HKU4 (NC_009019); BtCoV HKU5, bat coronavirus HKU5 (NC_009020); BtCoV HKU9, bat coronavirus HKU9 (NC_009021); IBV, infectious bronchitis virus (NC_001451); TCoV, turkey coronavirus (NC_010800); SW1, beluga whale coronavirus (NC_010646); BuCoV HKU11, Bulbul coronavirus HKU11 (NC_011548); ThCoV HKU12, thrush coronavirus HKU12 (NC_011549); and MuCoV HKU13, Munia coronavirus HKU13 (NC_011550).

B virus (ERBV) (31–33) (see Fig. S3A in the supplemental material). Alignment of the 3' end of ZBCoV with subgroup 2b CoVs showed deletions in the genome of subgroup 2b CoVs where the second s2m of ZBCoV is identified (see Fig. S3B). The s2m of ZBCoV are almost identical in sequence and are separated by 19 nt (see Fig. S3B). mfold prediction (34) of RNA secondary structure indicated that both s2m fold into RNA stem-loop motifs (see Fig. S3C).

Phylogenetic analyses. Phylogenetic trees constructed from 3CL^{Pro}, RdRp, Hel, S, M and N amino acid sequences of ZBCoV and representative coronaviruses show that ZBCoV is most closely related to but distinct from the subgroup 2b CoVs, which include SARS-CoV and SARS-CoV-like viruses (Fig. 3). This

finding is in accord with results obtained from pairwise amino acid comparisons of ZBCoV and other coronaviruses (<http://cait.cumc.columbia.edu:88/dept/greeneidlab/IdentificationofaSARS-Coronavirus-likevirusinaleaf-nosedbatinNigeria.html>). To further define the phylogenetic position of ZBCoV, an additional phylogeny was constructed using a conserved 659-nt sequence of RdRp, and the time to the most recent common ancestor (TMRCA) between ZBCoV and related coronaviruses was estimated. Based on the best-fit model (SRD06 with informative rate prior), the results of this analysis indicated that ZBCoV is most closely related to GhanaBt-CoV, a recently identified coronavirus found in bats in Ghana (35) (Fig. 4). Furthermore, ZBCoV and GhanaBt-CoV together form a well-supported clade distinct from that of the subgroup 2b CoVs. The

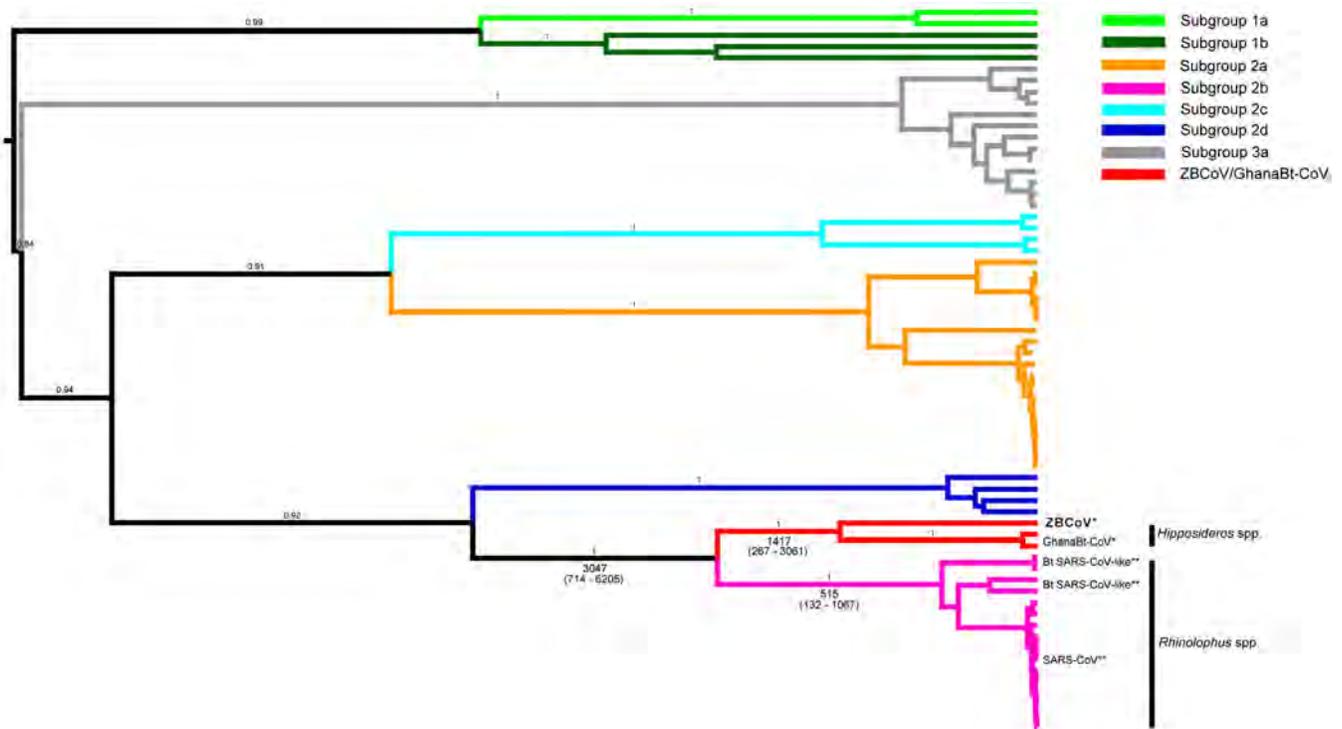

FIG 4 Estimation of the time of divergence between ZBCoV and representative coronaviruses. Bayesian MCMC phylogeny of a 659-nt region of the RNA-dependent RNA polymerase gene of ZBCoV and representative members of group 1, 2, and 3 coronaviruses. The host bat species and their geographic origins (*, Africa; **, Asia) are indicated for ZBCoV, GhanaBt-CoV, and subgroup 2b CoVs. The times given at branch tips represent the dates of viral sampling, and the tree is rooted through the use of a relaxed molecular clock. Bayesian posterior probability values greater than 0.8 are shown above the branches leading to each major node. The mean TMRCA for the taxa in subgroup 2b CoVs and ZBCoV are given below each branch, with the 95% highest probability densities indicated in parentheses. The following sequences from GenBank were included, with the GenBank accession numbers given in parentheses: for subgroup 1a CoVs, feline coronavirus (FJ938055) and canine coronavirus (GQ477367); for subgroup 1b CoVs, bat coronavirus HKU2 (DQ249213), bat coronavirus BtCoV/512/2005 (DQ648858), and human coronavirus NL63 (DQ445911); for subgroup 2a CoVs, murine hepatitis virus (AB551247), human coronavirus HKU1 (AY597011, DQ422731, DQ422728, DQ422732, DQ422737, and DQ422733), bovine respiratory coronavirus (AF220295, AF391541, AF391542, EF424615, EF424620, FJ938066, and U00735), equine coronavirus (EF446615), human enteric coronavirus 4408 (FJ415324), human coronavirus OC43 (AY391777 and AY903460), and waterbuck coronavirus (FJ425184); for subgroup 2b CoVs, bat SARS coronavirus Rf1 (DQ412042 and DQ648856), SARS coronavirus (AY313906, AY545914, AY559085, AY559097, AY595412, DQ071615, FJ882929, FJ882931, FJ882941, FJ882944, FJ882959, and FJ88686), bat SARS coronavirus HKU3 (DQ084199), and bat SARS coronavirus RM1 (DQ412043); for subgroup 2c CoVs, bat coronavirus HKU5 (DQ249217 and DQ249218), bat coronavirus HKU4 (DQ074652), and bat coronavirus BtCoV/133/2005 (DQ648794); for subgroup 2d CoVs, bat coronavirus HKU9-1 (EF065513), bat coronavirus HKU9-2 (EF065514), bat coronavirus HKU9-3 (EF065515), and bat coronavirus HKU9-4 (EF065516); and for subgroup 3a CoVs, avian infectious bronchitis virus (AY514485, AY641576, AY646283, DQ001339, DQ646405, EU714029, FJ888351, FN430414, FN430415, HM245923, and HM245924) and turkey coronavirus (GQ427174, GQ427175, and GQ427176).

TMRCAs between ZBCoV and GhanaBt-CoV was estimated at 1,417 years before present (ybp) (95% highest population density [HPD] = 267 to 3,061 ybp). The TMRCAs between the ZBCoV/GhanaBt-CoV clade and subgroup 2b CoVs was estimated at 3,047 ybp (95% HPD = 714 to 6,205 ybp), whereas the TMRCAs between SARS-CoVs and SARS-CoV-like viruses was only 515 ybp (95% HPD = 132 to 1,067 ybp). Estimates of the TMRCA between subgroup 2b CoVs and the rest of the coronavirus groups are not provided due to the potential for nucleotide site saturation at deeper phylogenetic levels to artificially create too recent TMRCAs.

Whereas the mean pairwise nucleotide similarity of the partial RdRp gene region was 85% (standard deviation [SD] = 9.75) within coronavirus subgroups (excluding ZBCoV/GhanaBt-CoV), the mean pairwise similarity between coronavirus subgroups was 66% (SD = 5.14) (see Fig. S4 in the supplemental material). Based on the results of the Mann-Whitney U test, these distributions are statistically different ($P < 0.0001$). Additionally, whereas the mean pairwise similarity within the clade ZBCoV/

GhanaBt-CoV was 85% (SD = 9.01), the pairwise similarity between the clade ZBCoV/GhanaBt-CoV and subgroup 2b CoVs was only 73% (SD = 0.84). Based on the results of the Mann-Whitney U test, these distributions are statistically different ($P = 0.0092$). Together, these findings indicate that the clade containing ZBCoV and GhanaBt-CoV should be considered a separate subgroup within group 2 CoVs, distinct from subgroup 2b CoVs (see Fig. S4 in the supplemental material).

DISCUSSION

Differences in phylogenetic relationships and genomic organization and the low amino acid similarities of ORF 3 and the S protein of ZBCoV compared to the ORF 3a and S proteins of subgroup 2b CoVs suggest that ZBCoV represents a new subgroup of coronaviruses within the group 2 CoVs. Although ZBCoV has features found in subgroup 2b CoVs, including the TRS, a unique PL^{Pro}, ORFs between the M and N genes, and the presence of the s2m, ZBCoV forms a unique branch distinct from subgroup 2b CoVs in

all phylogenetic trees analyzed. Furthermore, it differs from subgroup 2b CoVs in that ZBCoV contains three (versus four to five) ORFs between the M and N genes and has two (versus one) s2m.

Whereas the S proteins of subgroup 2b CoVs share 78 to 98% aa sequence identity, the S protein of ZBCoV has only 36 to 38% identity in the deduced amino acid sequence with those of subgroup 2b CoVs. Despite limited primary sequence conservation of the spike protein among ZBCoV and subgroup 2b CoVs, particularly in the S1 domain, Pfam analyses indicated the presence of a receptor domain that binds to the receptor ACE2, the cellular receptor for SARS-CoV (36). However, the residues in SARS-CoV that interact with the human ACE2 molecule are not conserved in ZBCoV, suggesting that human ACE2 is not a *bona fide* receptor for ZBCoV (37).

ORF 3, located between the S and E proteins of ZBCoV, is slightly shorter than the 3a proteins of subgroup 2b CoVs and has at most only 22% aa identity to the 3a proteins of subgroup 2b CoVs. In contrast, the 3a proteins of subgroup 2b CoVs share 81 to 98% aa identity. ORF 3 is predicted to contain four transmembrane domains with extracellular N and C termini. In contrast, ORF 3a of SARS-CoV is predicted to contain three transmembrane domains with extracellular N termini and intracellular C termini (28, 29). Whereas four O glycosylation sites are predicted in the ORF 3a protein of SARS-CoV (38), only two putative O glycosylation sites were identified in the ORF 3 of ZBCoV. The 3a protein of SARS-CoV has a cysteine-rich region important for polymerization and ion channel activity (28), as well as YXX Φ and diacidic motifs suggested to be involved in the intracellular trafficking (29). These domains were recently suggested to be important for the proapoptotic function of ORF 3a of SARS-CoV (39). However, ORF 3 of ZBCoV contains only a portion of the cysteine-rich domain and has no YXX Φ diacidic motifs. In contrast to human and civet SARS-CoV and bat RF1/2004, there is no ORF 3b in ZBCoV. The 3b protein may function as an interferon antagonist (40).

ZBCoV contains a unique set of ORFs located between the M and N genes. In subgroup 2b CoVs, ORF 6, ORF 7, and ORF 8 between the M and N genes do not overlap. In contrast, the three ORFs between the M and N genes overlap in ZBCoV. Alignment with subgroup 2b CoVs indicated deletions in ZBCoV, and as a result, one continuous ORF, ORF 8, is present in ZBCoV in place of ORFs 7a, 7b, 8, 8a, and 8b of subgroup 2b CoVs.

Similar to SARS-CoV, the putative products of ORF 6, ORF 7, and ORF 8 of ZBCoV show no sequence homology to other viral proteins. No TRS upstream of ORF 6 is found, suggesting that if ORF 6 encodes a *bona fide* protein, that protein is likely expressed by the subgenomic RNA M. There is precedent in SARS-CoV for functional bicistronic RNAs in the expression of ORF 3b, ORF 7b, ORF 8b, and ORF 9b (26, 41). Coronaviruses possess accessory genes, the size and location of which are group specific (2). By analogy to SARS-CoV, ORF 6, ORF 7, and ORF 8 of ZBCoV may encode accessory proteins important for virus-host interactions that may contribute to virulence and pathogenesis (26). Recent studies suggest that the SARS-CoV accessory proteins 6 and 7b are incorporated into virus particles and that 3a, 7a, and 9b are structural components of the virion (26, 41, 42). The SARS-CoV accessory proteins are suggested to have biological functions that include virus release, interferon antagonism, apoptosis induction, and inhibition of cellular protein synthesis (26, 41).

Another unique feature of ZBCoV is the presence of two highly conserved RNA sequences (s2m) downstream of the N gene. A single s2m is identified at the 3' end of the genomes of members of several RNA virus families, including the *Coronaviridae* and *Astroviridae*, as well as the picornavirus ERBV (31–33). Recent data suggest that the SARS-CoV s2m RNA is a functional molecular mimic of the 530 stem-loop region in small-subunit ribosomal RNA, which could facilitate viral hijacking of the host's protein synthesis machinery (43). The presence of a second s2m in ZBCoV may further increase the efficiency of this process. Interestingly, secondary structures downstream of the N gene, including bulged stem-loop and pseudoknot structures, are also identified in the genomes of subgroup 2a and 2c CoVs (44, 45).

Lagos bat virus (family *Rhabdoviridae*, genus *Lyssavirus*) was initially identified in Nigeria in the 1950s. The discovery of ZBCoV in a bat of the genus *Hipposideros* (family *Hipposideridae*), is the first identification of a coronavirus in wildlife from Nigeria. Recently, bat coronaviruses closely related to ZBCoV were isolated from roundleaf bats (*Hipposideros caffer* and *Hipposideros ruber*) in Ghana, a country that is close to Nigeria (35). Phylogenetic analysis indicates that ZBCoV and GhanaBt-CoV form a unique clade that is distinct from those in subgroup 2b CoVs. However, as the only sequence available for GhanaBt-CoV is a fragment of the RdRp gene, a comparison of the genome organization between ZBCoV and GhanaBt-CoV is not possible. Our findings and recent published data, wherein a SARS-CoV-like virus was found to lack ORF 8, suggest that there is considerable diversity in the genome organization of SARS-CoV-like viruses (46).

SARS-CoV-like viruses have been isolated from various rhinolophid bats (family *Rhinolophidae*, genus *Rhinolophus*), common insectivorous bats found in Africa and Eurasia. However, despite extensive studies, no SARS-CoV-like viruses have been reported in *Hipposideros* sp. bats in China (32). The *Rhinolophus* species suggested as reservoirs of SARS-CoV-like viruses are not present in Africa. A sequence fragment of a SARS-CoV-like virus was identified in Kenya in bats of the *Chaerephon* genus (family *Molossidae*) (47), and antibodies reactive with SARS-CoV antigen have also been detected in the sera of seven different genera of insectivorous and fruit bats sampled in central and southern Africa (48). In concert, these findings suggest that there may be no strict species-specific host restriction of SARS-CoV-like viruses in African bats.

Our phylogenetic analysis indicates that the clade containing ZBCoV and GhanaBt-CoV occupies an ancestral position to the group 2b CoVs, which include SARS-CoV and SARS-CoV-like viruses. Similar to previous estimates, the TMRCA of these two clades was estimated at ~3,047 ybp (although with large 95% HPDs). Although SARS-CoV-like viruses have been identified exclusively in bats in China, a recent sequence fragment (~120 bp) recovered from a Kenyan bat was found to occupy a position just outside subgroup 2b and may represent the ancestral African lineage of all subgroup 2b CoVs (47). Together with the position of the African clade of ZBCoV/GhanaBt-CoV relative to subgroup 2b CoVs, this finding suggests that a migration event from Africa to China within the last 100 to 1,000 years may have resulted in the subgroup 2b lineage of CoVs. Indeed, the geographic distribution and the phylogenetic relationships of bat coronaviruses seen both here (Fig. 4) and in previous work (35) suggest the presence of multiple independent migration events between Africa and Asia

throughout the history of bat coronaviruses. Additional sequence data for the bat coronaviruses identified in Kenya along with increased sampling for coronaviruses in Africa as well as central and eastern Asia will likely be necessary to unveil the timing and origin of this diverse group of coronaviruses.

Bats are important reservoir hosts of zoonotic viruses with significant impact on human health, including rabies, Nipah virus, Hendra virus, Zaire Ebola virus, Marburg virus, and SARS-CoV. The wide genetic diversity that exists among zoonotic viruses in bats may allow an increased emergent potential of interspecies variants that may cause outbreaks of disease in humans and domestic animals. The giant leaf-nosed bat, *Hipposideros commersoni*, is widespread in sub-Saharan Africa, from Gambia to Ethiopia, Mozambique, and Madagascar, but little is known concerning its ecology, population biology, or vector competence. Clearly, in order to enhance our knowledge of the diversity and cooccurrence of potential reservoir hosts, it is essential to better understand emerging pathogen dynamics and public health relevance as a means to prevent and control future disease outbreaks.

MATERIALS AND METHODS

Bat sample collection. During June 2008, bats were collected with mist netting in caves and around human dwellings or manually from roost locations near Idanre and Zaria, Nigeria. All bats appeared clinically normal. Captured bats were anesthetized by intramuscular inoculation with ketamine hydrochloride (0.05 to 0.1 mg/g of body weight) and euthanized under sedation by intracardiac exsanguination and cervical dislocation. The species of each captured bat was recorded, as well as the sex, forearm and body lengths (in cm), and weight. All samples were initially stored, transported on ice packs, and stored thereafter at -20°C , until shipment on dry ice and final storage at -80°C . No lyssavirus-specific antigens were identified in bat brains by use of direct fluorescent antibody testing.

Coronavirus consensus PCRs. Coronavirus screening was performed by nested PCR, amplifying a 400-nt fragment of the RdRp genes of coronaviruses using consensus primer sequences 5'-CGTTGGIACW AAYBTVCWCWYTICARBTRGG-3' and 5'-GGTCATKATAGCRTCA VMASWWGCNACNACATG-3' for the first PCR and consensus primer sequences 5'-GGCWCCWCHGGNGARCAATT-3' and 5'-GGWAWCCCCAYTGYTGWAYRTC-3' for the second PCR. Primers were designed by multiple alignments of the nucleotide sequences of available RdRp genes of known coronaviruses. Reverse transcription was performed using the SuperScript III kit (Invitrogen, San Diego, CA). PCR primers were applied at 0.2- μM concentrations with 1 μl cDNA and Hot-Star polymerase (Qiagen, Valencia, CA). Cycle conditions used were as follows: 1 cycle at 95°C for 15 min; 15 cycles at 95°C for 30 s, 65°C for 30 s ($-1^{\circ}\text{C}/\text{cycle}$), and 72°C for 45 s; 35 cycles at 94°C for 30 s, 50°C for 30 s, and 72°C for 45 s; and 1 cycle at 72°C for 5 min.

UHTS. Total RNA obtained from the gastrointestinal tract specimen positive for coronavirus was extracted for UHTS. Purified RNA (0.5 μg) was DNase I digested (DNA-free; Ambion, Austin, TX) and reverse transcribed using a Superscript II kit (Invitrogen) with random octamer primers linked to an arbitrary, defined 17-mer primer sequence (MWG, Huntsville, AL). cDNA was RNase H treated prior to random amplification by PCR, applying a 9:1 dilution mixture of a primer corresponding to the defined 17-mer sequence and the octamer-linked 17-mer sequence primer, respectively. Products of >70 bp were purified (MinElute; Qiagen) and ligated to linkers for sequencing on a GS FLX sequencer (454 Life Sciences, Branford, CT).

Genome sequencing. PCR primers for amplification across sequence gaps were designed (available upon request) based on the UHTS data, and the draft genome was sequenced by overlapping PCR products. Products were purified (QIAquick PCR purification kit; Qiagen) and directly dideoxy sequenced in both directions with ABI Prism BigDye Terminator

1.1 cycle sequencing kits (PerkinElmer Applied Biosystems, Foster City, CA). Additional methods applied to obtain the genome sequence included additional consensus PCR and 3' and 5' RACE (Invitrogen).

Phylogenetic and sequence analyses. Alignments were constructed using MUSCLE 3.7 (49) and adjusted manually using Se-AL (50). Maximum likelihood (ML) phylogenetic trees containing representative taxa from each coronavirus genus ($n = 31$) (Fig. 3, legend) were constructed using the subtree pruning and regrafting (SPR) method of branch swapping in PhyML (51). Phylogenies were constructed using amino acid alignments for the complete proteins of 3CL, Hel, M, and N and partial protein alignments for the available RdRp protein sequence and for the S protein after regions with low alignment confidence were removed. In all cases, the Whelan and Goldman model of amino acid replacement was used (52), with a gamma distribution of rate heterogeneity. The value of the shape parameter for gamma (α) was estimated from the data and approximated by six rate categories. The reliability of each branch in all phylogenies was estimated using a bootstrap resampling procedure, with 100 ML replications.

To estimate the time to the most recent common ancestor (TMRCA) for the taxa contained within subgroup 2b CoVs and including ZBCoV, an additional 659-nt alignment of the RdRp gene was constructed and chosen for homology to the gene region sequenced for the coronaviruses most closely related to ZBCoV (GhanaBt-CoV). All sequences for which time-of-sampling information was available were included ($n = 64$). TMRCA estimates were estimated using the Bayesian Markov chain Monte Carlo (MCMC) method with the BEAST package, version 1.5.2 (53), and both the general time-reversible (GTR) model plus Γ distribution and the SRD06 model of nucleotide substitution. A relaxed uncorrelated lognormal molecular clock was used, calibrated by the time-stamped sequences, both with and without informative rates prior on the molecular clock of $2.0 \times 10^{-4} \pm 0.0009$ nt substitutions/site/year (35). This analysis was run until all parameters converged, with 10% of the MCMC chains discarded as burn-in. Statistical confidence in the TMRCA estimates is given by the 95% highest probability density (HPD) interval around the marginal posterior parameter mean.

The classification of ZBCoV and GhanaBt-CoV as a putative new subgroup within group 2 CoVs was determined by first calculating the percent pairwise nucleotide similarity of the same 659-nt region of RdRp genes between and within the existing subgroups of coronaviruses and then extending this comparison to include the clade ZBCoV/GhanaBt-CoV. To verify this approach, a nonparametric Mann-Whitney U test was used to assess if the pairwise nucleotide similarity within the currently accepted subgroups is different from that between subgroups. This test was then used to determine if the percent pairwise similarity within the clade ZBCoV/GhanaBt-CoV is statistically different from that of the most closely related subgroup 2b CoVs.

Protein family analysis was performed using Pfam (<http://pfam.sanger.ac.uk/>). Predictions of signal peptide cleavage sites, glycosylation sites, and transmembrane domains were performed using respective prediction servers available at the Center for Biological Sequence Analysis (<http://www.cbs.dtu.dk/services/> and http://www.ch.embnet.org/software/TMPRED_form.html). The percent amino acid sequence identity and similarity were calculated using the Needleman algorithm with an EBLO-SUM62 substitution matrix (gap open/extension penalties of 10/0.1 for nucleotide and amino acid alignments; EMBOSS [54]), using a Perl script to iterate the process for all versus all comparisons. Prediction of RNA secondary structures was performed with the mfold program (<http://mfold.bioinfo.rpi.edu/>).

Nucleotide sequence accession number. The GenBank accession number for the ZBCoV sequence is HQ166910.

Bat Coronaviruses and Experimental Infection of Bats, the Philippines

Shumpei Watanabe, Joseph S. Masangkay, Noriyo Nagata, Shigeru Morikawa, Tetsuya Mizutani, Shuetsu Fukushi, Phillip Alviola, Tsutomu Omatsu, Naoya Ueda, Koichiro Iha, Satoshi Taniguchi, Hikaru Fujii, Shumpei Tsuda, Maiko Endoh, Kentaro Kato, Yukinobu Tohya, Shigeru Kyuwa, Yasuhiro Yoshikawa, and Hiroomi Akashi

Fifty-two bats captured during July 2008 in the Philippines were tested by reverse transcription–PCR to detect bat coronavirus (CoV) RNA. The overall prevalence of virus RNA was 55.8%. We found 2 groups of sequences that belonged to group 1 (genus *Alphacoronavirus*) and group 2 (genus *Betacoronavirus*) CoVs. Phylogenetic analysis of the RNA-dependent RNA polymerase gene showed that groups 1 and 2 CoVs were similar to Bat-CoV/China/A515/2005 (95% nt sequence identity) and Bat-CoV/HKU9–1/China/2007 (83% identity), respectively. To propagate group 2 CoVs obtained from a lesser dog-faced fruit bat (*Cynopterus brachyotis*), we administered intestine samples orally to Leschenault rousette bats (*Rousettus leschenaulti*) maintained in our laboratory. After virus replication in the bats was confirmed, an additional passage of the virus was made in Leschenault rousette bats, and bat pathogenesis was investigated. Fruit bats infected with virus did not show clinical signs of infection.

Severe acute respiratory syndrome (SARS) coronavirus (SARS-CoV) is a newly emerged zoonotic CoV that caused an international epidemic in 2003. Epidemiologic studies have demonstrated that the first human cases of SARS were caused by CoVs closely related to those found in Himalayan palm civets and raccoon dogs in wildlife markets (1). This finding accelerated surveys of CoVs specific for various animals in Southeast Asia to identify reser-

DOI: 10.3201/eid1608.100208

voirs for SARS-CoV. These survey findings suggested that palm civets and raccoon dogs are an intermediate host of, but not a primary reservoir for, SARS-CoV because of the low prevalence of SARS-like CoVs in these animals (2). Moreover, a large variety of novel CoVs in these surveys, including bat SARS-like CoVs, were detected in many bat species in the People's Republic of China and Hong Kong Special Administrative Region (3–6).

Phylogenetic analysis of bat CoVs and other known CoVs suggested that the progenitor of SARS-CoV and all other CoVs in other animal hosts originated in bats (5,7). Recently, bat CoVs in North and South America, Europe, and Africa were also reported (8–12). Although extensive bat surveys have been conducted, no infectious bat CoVs have been isolated from cell cultures, which hinders characterization of bat CoVs and evaluation of the risks posed by these viruses to public health.

In this study, we detected bat CoVs in the Philippines. We attempted to isolate bat CoVs and virus RNA from cell cultures and from Leschenault rousette bats (*Rousettus leschenaulti*) orally infected with intestinal tissues and contents from a lesser dog-faced fruit bat (*Cynopterus brachyotis*). After infection, clinical signs of infected bats were examined, and pathogenesis in bats was investigated.

Materials and Methods

Bat Collection

We obtained 52 bats of 6 species during July 2008 from Diliman and Los Baños, the Philippines, after receiving permission from the government. All captured bats were anesthetized with an intraperitoneal injection (15 mg/kg) of tiletamine and zolazepam (Virbac, Carros, France) and killed by cardiac exsanguination. The experiment was conducted in accordance with the Guidelines for the Care

and Use of Laboratory Animals, Graduate School of Agriculture and Life Sciences, University of Tokyo.

Extraction of RNA and Reverse Transcription

Virus RNA was extracted from samples obtained from field bats and from experimentally infected bats by using an SV Total RNA Isolation System Kit (Promega, Madison, WI, USA) according to the manufacturer's instructions. Extracted RNA was eluted in 50 μ L of RNase-free water. For cDNA synthesis, RNA (5 μ L), a random hexamer, and a SuperScript III Kit (Invitrogen, Carlsbad, CA, USA) were used.

PCR and DNA Sequencing

All cDNA samples obtained from field bats and experimentally infected bats were tested by using conventional and nested PCR. On the basis of previous reports, we used a PCR and a pair of consensus primers specific for a highly conserved region of the RNA-dependent RNA polymerase (RdRp) gene (13).

Two microliters of cDNA was added to a 25- μ L reaction mixture containing 2 \times GoTaq PCR Master Mix (Promega) and 0.2 μ M of 5'-GGT TGGGACTATCCTAAGTGTGA-3' (primer 1) and 5'-CCATCATCAGATAGAATCATCATA-3' (primer 2). The PCR conditions were 2 min at 94°C; 35 cycles for 20 s at 94°C, 30 s at 50°C, and 30 s at 72°C; and 1 min at 72°C. PCR amplicons were gel purified by using NucleoSpin Extract II (Machrey-Nagel, Düren, Germany) and cloned by using a TOPO-TA pCR2.1 Cloning Kit (Invitrogen). Sequencing was performed in an ABI 3130 XL DNA analyzer (Applied Biosystems, Foster City, CA, USA).

On the basis of the sequences obtained, we designed new specific primer pairs for the Bat-CoV/Philippines/Diliman1552G1/2008 sequence (5'-TGATTT CTGCAATGATACTTGGTTC-3' and 5'-ACTTGATGAT CTGTAACAACAATCG-3') and for the Bat-CoV/Philippines/Diliman1525G2/2008 sequence (5'-TACAAC CTACGCTGCAACTC-3' and 5'-ATGAGTGTGCACAA GTGCTTAG-3'). These primers were used as the inner primer set for the nested PCR after the first PCR was performed with primers 1 and 2. Aliquots (2 μ L) of cDNA for primary amplification were added to 2 \times GoTaq Master Mix (Promega) and primers 1 and 2. Amplification was performed by using 15 cycles at conditions described above. Aliquots (2 μ L) of primary amplification products were used for the second PCR with GoTaq Master Mix and the inner primers. The second PCR was performed by using 35 cycles at the conditions described above. PCR products were extracted from gels by using NucleoSpin Extract II and subjected to direct sequencing or TA cloning.

Bat Samples

Leschenault rousette bats were obtained from zoos in Japan. Seven bats were randomly selected for the experiments. In each experiment, 2 bats were placed in a negative-pressure isolator. One additional bat was kept in a separate isolator as a control. A sample of large intestine from a lesser dog-faced fruit bat (*C. brachyotis*) was homogenized in a sterile mortar. After low-speed centrifugation (2,000 \times g for 10 min), the supernatant was used for oral infection. Experimentally infected bats were examined daily for clinical signs of infection. Fecal specimens were obtained from a clean translucent plastic sheet spread along the bottom of the cage. All bats were killed after being anesthetized with diethyl ether, and organs (liver, kidney, spleen, lung, brain, and intestine) and serum samples were obtained.

Detection of Virus mRNA in Bats

To determine membrane, nucleocapsid, nonstructural (Ns)7a, Ns7b, and Ns7c protein nucleotide sequences, we conducted PCR and DNA sequencing in the same manner as for determination of partial RdRp nucleotide sequence described above by using the HKU9-Leader42–64 primer (5'-CCGTTTCGCTTGTACGAATCAC-3') and the 3siteAd20T primer (5'-CTGATCTAGAGGTACCGGATCCTTTTTTTTTTTTTTTTTTTTTT-3'). To detect virus mRNA, we conducted reverse transcription-PCR (RT-PCR) by using 2 primer sets: HKU9-Leader42–64 and N468–448r (5'-GTTACGTGTGCCCATGTCACC-3') and HKU9-Leader42–64 and Ns7a440–420r (5'-CAAGCCA CAACAACATTAGG-3').

Quantitative Real-Time RT-PCR

cDNA synthesis was performed by using 0.5 μ L total RNA and the PrimeScript RT Reagent Kit (TaKaRa, Shiga, Japan) according to the manufacturer's protocol. Virus RNA was quantified by using Power SYBR Green PCR Master Mix (Applied Biosystems) with 2 μ L of reverse-transcribed cDNA. Quantitative real-time PCR was performed by using the Thermal Cycler Dice System (TaKaRa). The temperature program consisted of an initial denaturation at 95°C for 10 min, followed by 40 cycles at 95°C for 15 s and 60°C for 1 min. The primer pair for the real-time PCR was designed on the basis of the partial RdRp sequences of Bat-CoV/Philippines/Diliman1525G2/2008; primers used were 5'-TCCTAAGTGTGATAGAGCTATGCC-3' and 5'-GTGCACACTCATTTGCTAACCG-3'. In each experiment, 10-fold serial dilutions of plasmid DNA containing the partial RdRp gene were tested in duplicate to establish a standard curve for calculating the relative amount of RNA in each sample. All samples were analyzed at least 3 times. To confirm the specificity of each PCR product, we conducted a melting curve analysis immediately after

the amplification phase of each PCR. The amount of RNA in each sample was expressed as the average value (copy number per weight [milligrams] of sample).

Results

Virus Detected

During July 2008, a total of 52 bats were obtained at 3 locations in Diliman and 1 location in Los Baños, the Philippines (Table 1). RT-PCRs for a 440-bp fragment in the RdRp gene of CoVs were performed for large intestine samples, including intestinal contents; 9 (17.3%) of 52 bats were positive. Differences in the 440-nt sequence in the RdRp region were determined after TA cloning of the 9 positive samples. Sequences indicated that the 2 groups of sequences obtained belonged to group 1 CoV (genus *Alphacoronavirus*) (n = 4) and group 2 CoV (genus *Beta-coronavirus*) (n = 5).

A 440-bp consensus nt sequence of the group 1 CoV was obtained on the basis of alignment of 4 group 1 CoV sequences detected (>98% nt identity with each other) and deposited in GenBank as Bat-CoV/Philippines/Diliman1552G1/2008 (DNA Database of Japan [DDBJ] accession no. AB539080). BLAST (www.ncbi.nlm.nih.gov/BLAST) search findings of GenBank indicated that the partial RdRp sequence was most similar to that of Bat-CoV/China/A515/2005 (95% nt identity).

A 440-bp consensus nt sequence of group 2 CoVs was also obtained (>98% nt identity with each other) and deposited in GenBank as Bat-CoV/Philippines/Diliman1525G2/2008 (DDBJ accession no. AB539081). A BLAST search suggested that the partial RdRp sequence was novel but most similar to that of Bat-CoV/HKU9-1/China/2007 (83% nt identity). A phylogenetic tree was constructed with the partial RdRp-deduced amino acid sequence (120 aa) and available sequences of known CoVs (Figure 1). Data in the tree suggested that Bat-CoV/Philippines/Diliman1552G1/2008 belonged to group 1b CoVs

and Bat-CoV/Philippines/Diliman1525G2/2008 belonged to group 2d to CoVs.

Specific and nested primer pairs for group 1b bat CoV and group 2d bat CoV sequences were designed, and nested PCR was performed by using cDNAs of all samples. Twenty additional amplicons (≈200-bp sequences) were obtained by using primers specific for group 2d bat CoVs. After direct sequencing or TA cloning, partial sequences of all amplicons obtained were found to be nearly identical to group 2d bat CoVs (>98% nt identity) and resulted in a total CoV prevalence of 55.8% (Table 1). All sequences of group 1b bat CoVs were obtained from insectivorous bats (4/7, 57.1%), and all sequences of group 2d bat CoVs were obtained from frugivorous bats (25/45, 55.6%).

Virus in Cell Cultures

Cytopathic effects were not observed in any of the cells (Vero E6, Vero, Hrt18, A549, fcwf-4, BKT-1, Tb-1 Lu, or primary kidney cells derived from Leschenault rousette bats) tested with bat intestinal specimens positive for both detected viruses by RT-PCR. Results of RT-PCR for cell lysates to detect viral replication also were negative.

Virus Propagation in Fruit Bats

To obtain bat CoVs from field samples, we administered virus orally to 2 Leschenault rousette bats maintained in the Department of Biomedical Science, Graduate School of Agricultural and Life Sciences, University of Tokyo. The volume of intestine samples collected from insectivorous bats was less than that from fruit bats because of their body size, and all positive samples for the group 1b bat CoV genome were derived from small insectivorous bats. Oral infection was conducted only with samples positive for the group 2d bat CoV genome. A homogenized large intestine sample (60 mg) derived from a lesser dog-faced fruit bat, which contained 7.8×10^6 copies of viral genome, was given orally to 2 fruit bats (bats A and B). After confirmation that these bats showed

Table 1. Prevalence of coronavirus in bats, the Philippines

Sampling site	Common name (species)	No. intestine samples tested	No. positive (group 1)	No. positive (group 2)
Los Baños	Lesser dog-faced fruit bat (<i>Cynopterus brachyotis</i>)	4	0	2
	Cave nectar bat (<i>Eonycteris spelaea</i>)	3	0	2

Total		52	4	25

no clinical signs of infection, they were killed 6 days after infection.

Virus genome was detected only in the small and large intestines of both bats by RT-PCR (Table 2). Virus was not detected in these intestine samples by cell cultures. Virus genome was detected by RT-PCR in fecal samples obtained during daily observations for clinical signs, and

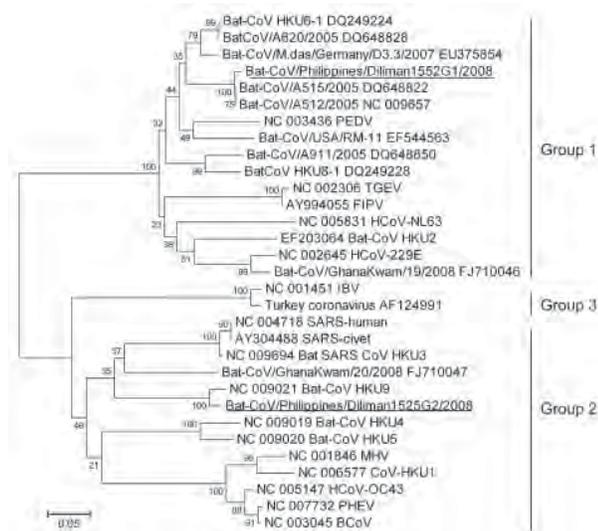

Figure 1. Phylogenetic tree based on deduced amino acid sequences of partial RNA-dependent RNA polymerase of coronaviruses (CoVs), the Philippines. The 2 new viruses detected in this study are underlined. Percentage of replicate trees in which the associated taxa clustered in the bootstrap test (1,000 replicates) is shown next to the branches. The tree is drawn to scale, with branch lengths in the same units as those of the evolutionary distances used to infer the phylogenetic tree. Evolutionary distances were computed by using the Poisson correction method and are shown as number of amino acid substitutions per site. All positions containing gaps and missing data were eliminated from the dataset. The final dataset included 120 positions. Phylogenetic analyses were conducted in MEGA4 (14). Coronaviruses used for comparisons and their GenBank accession numbers are human coronavirus (HCoV) 229E (HCoV-229E) (NC_002645), porcine epidemic diarrhea virus (PEDV) (NC_003436), transmissible gastroenteritis virus (TGEV) (NC_002306), feline infectious peritonitis virus (FIPV) (AY994055), human coronavirus NL63 (HCoV-NL63) (NC_005831), bat-CoV/A512/2005 (NC_009657), bat-CoV/A515/2005 (DQ648822), bat-CoV/A620/2005 (DQ648828), bat-CoV/A911/2005 (DQ648850), bat-CoV/GhanaKwan/19/2008 (FJ710046), bat-CoV/GhanaKwan/20/2008 (FJ710047), bat-CoV/M.das/Germany/D3.3/2007 (EU375854), bat-CoV/USA/RM-11 (EF544563), bat-CoV HKU2 (EF203064), HKU4 (NC_009019), HKU5 (NC_009020), HKU6 (DQ249224), HKU8 (DQ249228), HKU9 (NC_009021), CoV-HKU1 (NC_006577), human coronavirus (HCoV-OC43) (NC_005147), murine hepatitis virus (MHV) (NC_001846), bovine coronavirus (BCoV) (NC_003045), porcine hemagglutinating encephalomyelitis virus (PHEV) (NC_007732), human severe acute respiratory syndrome coronavirus (SARS) (SARS-human) (NC_004718), civet SARS-like coronavirus (SARS-civet) (AY304488), bat-SARS-like coronavirus HKU3 (bat-SARS-CoV HKU3) (NC_009694), infectious bronchitis virus (IBV) (NC_001451), and turkey coronavirus (AF124991).

viral genome copy number was determined by real-time RT-PCR (Table 3). Virus copy number peaked on day 3. On day 4, a fecal sample was not collected because feces were not found on the bottom of the isolator.

Virus mRNA in Experimentally Infected Bats

For murine hepatitis virus and several CoVs, an ≈ 70 -bp leader sequence is added to the 5' end of the transcription regulatory sequence of each nested mRNA during mRNA processing (15,16). For bat CoV HKU9-1, which was most similar to group 2d bat CoV, a complete genome sequence and putative transcription regulatory sequence of Bat-CoV HKU9 were predicted (17). On the basis of that report, primer HKU9-Leader42–64, including a leader sequence, was designed (Figure 2). The HKU9-Leader42–64 primer and 3siteAd20T primer, which included the oligo dT sequence, were used for PCR with RNA extracted from intestines of bats A and B. Amplicons were cloned, and partial genomic sequences of group 2d bat CoV membrane, nucleocapsid, Ns7a, Ns7b, and Ns7c genes were determined. These sequences were deposited in GenBank (DDBJ accession no. AB543561). A phylogenetic tree was also constructed with the deduced amino acid sequence (463 aa) of the complete N gene of group 2d bat CoV and available sequences of known CoVs. The tree showed the same topology as that constructed with deduced amino acid sequence of the partial RdRP gene. The N gene nucleotide sequence was most similar to that of Bat-CoV/HKU9-1/China/2007 (72% identity).

To confirm presence of transcribed virus mRNA in bats A and B (Table 2), RT-PCR specific for mRNA of the group 2d bat CoVs was conducted with HKU9-Leader42–64, N468–448r, and Ns7a440–420r primers. Virus mRNAs were detected in RNA extracted from the small intestines of bats A and B (Figure 3). All amplicons were sequenced and included the nucleotide sequence of the HKU9-Leader42–64 primer sequence at the 5' end of the sequences obtained (Figure 2). These results suggest that virus mRNAs were transcribed in bats A and B.

Experimental Infection of Bats

To determine whether this 2d bat CoV was pathogenic, we experimentally infected 5 *R. leschenaulti* fruit bats. A 60-mg sample of the small intestine from bat A was given orally to 2 bats (bats C and D), and 500 μ L of phosphate-buffered saline was given orally to 1 bat (bat E) as a control. These bats were killed 6 days after infection. Clinical signs were not observed in the experimentally infected bats. Virus genome amplification was not detected by RT-PCR in any samples (serum, brain, kidney, liver, lung, spleen, and feces). However, virus RNA was detected in the small intestine (Table 4). No pathologic changes were observed in the intestines or other organs.

Table 2. PCR results for bat coronavirus in fruit bats infected by using bat intestinal samples, the Philippines*

Bat	Assay	Liver	Kidney	Lung	Spleen	Brain	Small intestine	Large intestine	Serum
A	RT-PCR	–	–	–	–	–	–	+	–
	qRT-PCR	ND	ND	ND	ND	ND	1.25 × 10 ⁶	3.53 × 10 ⁶	ND
B	RT-PCR	–	–	–	–	–	+	+	–
	qRT-PCR	ND	ND	ND	ND	ND	1.47 × 10 ⁶	1.50 × 10 ⁶	–

Table 3. Time course of detection of coronavirus viral genome by PCR in feces from 2 fruit bats, the Philippines*

Test	Days after infection					
	0	1	2	3	4	5
RT-PCR	–	–	–	+	ND	+
Quantitative RT-PCR	–	–	5.31 × 10 ⁴	1.74 × 10 ⁷	ND	1.5 × 10 ⁶

*Values are copies per milligram. RT-PCR, reverse transcription–PCR; –, virus RNA not detected; +, virus RNA detected; ND, not done.

Because virus growth in fruit bats was weaker than virus growth in bats after primary infection with field samples, experimental conditions were changed. Samples (300 mg) from the small intestine of 2 bats (A and B) were given orally to 2 other bats (F and G), which were killed 3 days after infection. Six intestinal samples were obtained from each bat to determine site specificity of virus growth. The entire intestine (duodenum to the large intestine) was divided into 6 equal parts (1–6). Virus RNA was detected only by RT-nested PCR in the small and large intestines (Table 4), and no pathologic effect was detected in these bats. Virus RNA was detected in the lower region (parts 3–4 from bat F and parts 3–6 from bat G). However, we could not determine the specific site of virus replication.

Discussion

After the SARS epidemic in 2003, bats were identified as carriers of CoVs in China. Recently, bat CoVs have also been detected in several other regions, including Germany, North and South America, and Africa. In the current study, we confirmed the presence of 2 CoVs in bats in the Philippines. Our findings suggest that CoV circulation in bats is worldwide. Although only 52 bats were tested, CoV RNA was present in 55.8% of large intestine samples from these bats. Moreover, all bats tested seemed to be healthy. Thus, bats may be persistently infected carriers of CoVs. These data are consistent with results of previous reports of CoV detection in bats (3–6).

RNA of group 1b bat CoV was detected in 4 (57.1%) of 7 insectivorous bats. All bats positive for group 1b bat CoV RNA belonged to the same species, the Lesser Asiatic yellow bat (*Scotophilus kuhlii*). However, the partial RdRp sequence of the virus was most similar to that of Bat-CoV/People’s Republic of China/A515/2005 (95% nt sequence identity), which was also detected in bats of the same species in the southern China on Hainan Island (5). The Lesser Asiatic yellow bat is distributed widely in eastern Asia in Phil-

ippines, Pakistan, Hainan Island, Taiwan, and Borneo (18). High similarities of sequences between group 1b bat CoV and Bat-CoV/China/A515/2005 suggest that these viruses are distributed widely in bats enzootic to eastern Asia.

Although group 1 bat CoV was detected in 1 species of insectivorous bats, group 2d bat CoV was detected in 4 species of frugivorous bats. Five of the 45 frugivorous bats were positive by RT-PCR, and an additional 20 were positive by RT-nested PCR (prevalence 55.6%). This finding suggests that replication of group 2d bat CoV in the intestine is low.

The complete N sequence of group 2d bat CoV suggests that it is a novel virus and most similar to that of Bat-CoV/

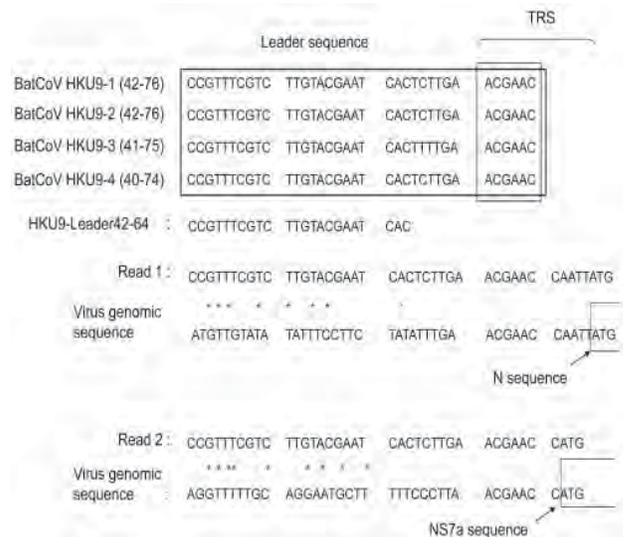

Figure 2. Comparison of mRNA sequences of bat coronavirus (BatCoV) with viral genomic sequences. Read 1 was obtained by using reverse transcription–PCR and HKU9-Leader42–64 and N468–448r primers. Read 2 was obtained by using HKU9-Leader42–64 and Ns7a440–420r primers. Asterisks indicate sequence identity for read and virus genome sequences. TRS, transcription regulatory sequence; N, nucleocapsid; NS, nonstructural.

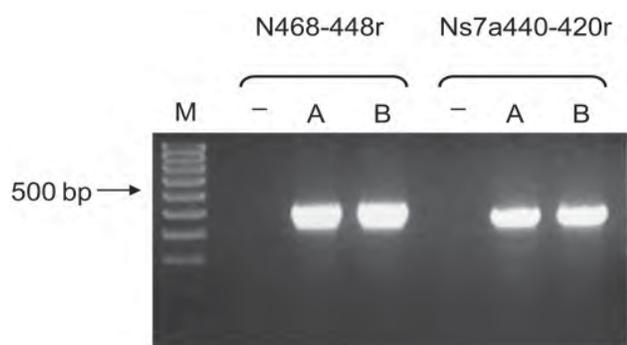

Figure 3. Bat coronavirus/Philippines/Dilliman1525G2/2008 mRNA in experimentally infected fruit bats, the Philippines. Reverse transcription–PCR results for small intestines of bats A and B. Lane M, 100-bp DNA ladder; lane –, nontemplate control.

HKU9–1/China/2007 (77% aa sequence identity). Woo et al. (17) detected Bat-CoV/HKU9–1/China/2007 and classified the viral nucleotide sequence as that of group 2d CoV. Our phylogenetic data (Figure 1) suggest that group 2d bat CoV and Bat-CoV/HKU9–1/China/2007 belong to the same group.

We attempted to isolate bat CoVs from several cell lines and primary cultured cells. However, virus replication was not observed, which is consistent with results of a previous report (17). No infectious bat CoV has been isolated from cell culture. In the current study, the amount of large intestine obtained per bat was ≤ 100 mg. Therefore, most samples were inadequate for virus isolation, especially virus-positive samples for group 1 bat CoVs from insectivorous bats.

To obtain sufficient tissue to isolate virus RNA, we attempted to infect fruit bats with bat CoV. Although we could not obtain bats of the species from which group 2d bat CoV was detected in the field survey, we obtained *Leschenault rousette* bats from zoos in Japan. In addition, Bat-CoV/HKU9–1/China/2007, which was most similar to group 2d bat CoVs by phylogenetic analysis, was identified

in this species in Hong Kong (17). This finding indicates that fruit bats can be infected with this virus. No signs of clinical disease were observed after oral infection with an intestine sample derived from a lesser dog-faced fruit bat. However, virus RNA was detected in the small and large intestines (Table 2), and these intestinal samples contained more genome copies than input copies. Furthermore, virus RNA was amplified in fecal samples by real-time PCR, and viral mRNAs were detected in bats A and B (Figure 3). These findings indicate that group 2d bat CoVs can be orally transmitted to fruit bats and replicate in them.

Experimental infection was conducted in fruit bats by using tissues from virus-infected bats to determine virus pathogenicity. However, infected bats showed no signs of a pathologic effect, although low levels of virus RNAs were detected in the small and large intestines of these bats. These findings suggest that fruit bats can be infected with bat CoV without showing any signs of infection. However, compared with primary infection by field samples obtained from *C. brachyotis*, the level of viral genome amplification was low in experimental infection. This finding may have been caused by a difference in viral replication in bats of different species. In the field survey, partial nucleotide sequences of group 2d bat CoVs, were detected in 4 bat species. A high prevalence of virus RNA was observed in each bat species (Table 1). These findings suggest that the group 2d bat CoVs may infect fruit bats of many species. The oral infection study showed that CoV is easily transmitted across species. These results, and the fact that most reported bat CoV sequences have been detected in several bat species (12,17), imply that interspecies transmission in bats may be common.

Further investigation of bat CoV ecology is needed to better understand the risk for infection with this virus. Knowing this risk could help elucidate emergence of SARS. Although we demonstrated *in vivo* propagation of a bat CoV, a bat CoV culture system is needed to obtain additional information about this virus.

Table 4. Results of nested and quantitative RT-PCRs of cDNA from bat samples, the Philippines*

A Real-Time RT-PCR Method for the Universal Detection and Identification of Flaviviruses

G. MOUREAU,¹ S. TEMMAM,¹ J.P. GONZALEZ,² R.N. CHARREL,¹ G. GRARD,¹
and X. DE LAMBALLERIE¹

ABSTRACT

Here we describe an optimized molecular protocol for the universal detection and identification of flaviviruses. It combines the convenient real-time polymerase chain reaction (PCR) format with a broad spectrum of flavivirus detection. This assay, based on the amplification of a 269–272 nt (depending on the flavivirus tested) region at the N terminal end of the NS5 gene, enabled the amplification of 51 flavivirus species and 3 tentative species. Sequencing of the amplicons produced by reverse transcriptase (RT)-PCR permitted the reliable taxonomic identification of flavivirus species by comparison with reference sequences available in databases, using either the BLASTN algorithm or a simple phylogenetic reconstruction. The limit of detection of the assay (2–20,500 copies/reaction depending on the virus tested) allowed the detection of different flaviviruses from a series of human sera or veterinary samples. Altogether, the characteristics of this technique make it a good candidate for the identification of previously identified flaviviruses in cell culture and the investigation of field samples, and also a promising tool for the discovery and identification of new species, including viruses distantly related to “classical” arthropod-borne flaviviruses.

INTRODUCTION

THE GENUS *Flavivirus* COMPRISES more than 50 recognized species (of which approximately one half are human pathogens responsible for biphasic fever, encephalitis, or hemorrhagic fever) and a number of tentative species, according to the VIIIth report of the ICTV (Thiel et al. 2005). It has been suggested that the genus may include a large number of additional virus species yet to be identified (Pybus et al. 2002). The recent discovery of new arboviruses transmitted by *Culex mosquitoes* (Bakonyi et al. 2005, Kono et al. 2000, Nisbet et al. 2005) supports this hypothesis. However, the characterization of Tamana bat virus (de Lamballerie et al. 2002) and new strains of Cell fusing agent in the New World (Cook et al.

2006), together with the discovery of Kamiti River virus (Crabtree et al. 2003, Sang et al. 2003), Cell Silent agents 1 and 2 (Crochu et al. 2004), Ngoye virus (Grard et al. 2006), and “*Culex flavivirus*” (Hoshino et al. 2007), suggest that a large number of viruses distantly related to the group of classical arthropod-borne flaviviruses also remains to be discovered. Crucial in the identification of new flaviviruses has been the use of molecular amplification systems employing highly conserved enzymatic motifs of the NS3 and NS5 genes, and it is evident that they will continue to constitute valuable tools for the discovery of classical and atypical flaviviruses.

In the past, such systems have been described (Ayers et al. 2006, Chao et al. 2007, Chow et al. 1993, Dyer et al. 2007, Eldadah et

¹Unité des Virus Emergents, Faculté de Médecine, Marseille, France.

²IRD-UR0178 Mahidol University, Research Center for Emerging Viral Diseases/Center for Vaccine Development Institute of Sciences, MU, Salaya, 25/25 Phutthamonthon 4, Nakhonpathom 73170 Thailand.

al. 1991, Figueiredo et al. 1998, Fulop et al. 1993, Gaunt et al. 2005, Kuno 1998a, Kuno et al. 1998b, Pierre et al. 1994, Puri et al. 1994, Sanchez-Seco et al. 2005, Scaramozzino et al. 2001, Tanaka 1993). However, their ability to detect a large number of species was, in most cases, based only on sequence analysis and the virus identification has been experimentally confirmed only for a few species. Moreover, their use in large screening analyses was hampered by the traditional reverse transcriptase polymerase chain reaction (RT-PCR) format and the frequent use of nested PCR, a common cause of false-positive results arising from PCR contamination.

The detection system presented in this study makes available a modern, high-performance molecular tool for the study of flaviviruses. It has proved its capability to detect 54 different recognized or tentative flavivirus species using a convenient one-step real-time RT-PCR amplification protocol. In addition, phylogenetic clustering of the derived amplicons with the previously published reference sequences (Kuno et al. 1998b), allowed the valid identification of the viruses detected. In combination with sequencing, our protocol represents a simple tool for the identification of flaviviruses and the discovery of new flavivirus species.

MATERIALS AND METHODS

Viruses and cell culture

All flaviviruses were handled and propagated according to their biosafety level requirement to comply with safety regulation in use at the Université de la Méditerranée. *Aedes* spp and *Culex* spp-associated viruses were propagated in *Aedes albopictus* C6/36 cells grown at 28°C in Leibovitz' 15 medium supplemented with 3% decomplexed calf serum, 5% tryptose phosphate broth and penicillin G, streptomycin, at 100 IU/mL and 100 µg/mL, respectively. Tick-borne viruses or viruses with no known vector were propagated in human (SW13), Green monkey (Vero), or hamster (BHK 21) cells cultured as monolayers at 37°C under 5% CO₂ in Eagle's minimum essential medium with 3% calf serum and peni-

cillin G, streptomycin, at 100 IU/mL and 100 µg/mL, respectively (Table 1). Bukalasa bat virus was tested from an infected mouse brain suspension, kindly provided by Dr. E.A. Gould.

RNA isolation

In the case of cell cultures prepared at the Unité des Virus Emergents, viral RNAs were extracted from supernatant medium onto a Biorobot EZ1 automat (Qiagen) using the EZ1 Virus mini kit v2.0 in the presence of RNA Carrier (Qiagen, Poly-A, 30 µg/mL) according to the manufacturer's recommendations. Human and veterinary samples received at the Unité des Virus Emergents were preserved and inactivated using phenol-guanidinium thiocyanate solution (RNA Now TM TC-Kit, Biogenex Inc.). Viral RNA extraction was performed according to the manufacturer's recommendation.

Oligonucleotide primers

A first pair of primers (Cook et al. 2006, Crochu et al. 2004, Grard et al. 2006), [PF1S: 5'-TGY-RTB-TA Y -AA C- ATG-ATG-GG, positions 8869–8888 of yellow fever virus strain 17D open reading frame (ORF) (GenBank accession number NC_002031) and PF2R: (5'-GT-GTC -CCA-DCC-DGC-DGT-RTC, positions 9, 121-9, 140], was designed to amplify a 269–272 nucleotides sequence (according to the flavivirus tested). The region amplified is located in the N-terminal end of the RNA-dependent RNA polymerase domain, between Motif 2 of the methyltransferase and Motif A of the polymerase (the reverse primer is located within Motif A). The existence of these highly conserved patterns was previously identified by Kuno and collaborators and used to design a first generation of consensus primers (FU1/MA -cFD2 primer set) (Kuno et al. 1998a). The PF1S-PF 2R primers were originally degenerated to take into account the variability of the sequence among a large number of flaviviruses and to allow a strong hybridization at the 3' termini (the 3' terminal nucleotide is either at the first or second position of the corresponding codon).

Several modifications of this original set of

primers were performed and tested. Here, we present an improved version of the reverse primer, PF2R-bis (5'-GTG-TCC-CA I-CCN-GCN-GTR-TC) the design of which was based on an alignment of all available sequence within the genus *Flavivirus*. Several modifications of the PF1S primers were also tested, but they did not improve the detection performance (data not shown).

Real-time PCR protocol

Assay format. The primers were used to elaborate a one-step RT-PCR assay performed in a real-time PCR format, using the QuantiTect[®] SYBR[®] Green RT-PCR (Qiagen) onto an ABI Prism 7000 Sequence Detection System (Applied Biosystems).

Choice of optimized primers. This was made after testing 10-fold serial dilutions of RNA (10^0 – 10^{-13}) of 14 representative viruses of the genus in an RNA carrier solution (Qiagen, Poly-A, 30 $\mu\text{g}/\text{mL}$): DENV-2 strain Trinidad 1751, WNV strain NY-99, W-TBEV strain Hypr, YFV strain 17D, CFA V strain Rio Piedras, KRV, APOIV, DB V, MMLV, PPB V, MODV, RBV, SV V, JUTV (see Table 1 for more details) and a standard amplification protocol (1 μM for each primer, hybridization temperature at 52°C).

Optimization of the amplification protocol. This was performed using 5 viruses (DENV—2 strain Trinidad1751, YFV, WNV strain NY -99, W-TBEV strain Hypr, MMLV) and the ultimate RNA dilution that enabled detection using standard amplification parameters according to the manufacturer's instructions. Several concentrations of primers (0.3–1 μM of each primer) and of MgCl_2 (5–6 mM), and different annealing temperatures (48°C–55°C) were tested.

Evaluation of the optimized protocol. The protocol was further evaluated using synthetic flavivirus RNAs. Specific PCR products carrying the sequence of the T7 promoter and the specific targeted NS5 region were prepared for 12 different flaviviruses (Stram et al. 2005) and directly transcribed using the T7-MEGAsort

script kit (Ambion) (Table 2). RNA was submitted to DNase digestion, purified using the MEGAclean columns (Ambion) according to the manufacturer's instructions, and quantified by ultraviolet spectrophotometry (1A 260 unit of single-stranded RNA = 40 $\mu\text{g}/\text{mL}$).

The RNA concentration (copies/ μL) was calculated as follows: $N = (C \times 10^{-3} \times 6.023 \cdot 10^{23}) / (L \times 330 \cdot 10^{-6})$ where C represents the concentration of RNA ($\mu\text{g}/\text{mL}$) assessed by OD measurement; $6.023 \cdot 10^{23}$ is the Avogadro number; L is the length of the synthetic RNA (nt); and 330 is an approximation of the molecular weight of a nucleotide (g/mol).

The limit of detection (LOD) of the assay was evaluated using 10-fold serial dilutions of synthetic RNA in an RNA carrier solution (Qiagen, Poly -A, 30 $\mu\text{g}/\text{mL}$) tested in triplicate.

Detection and characterization of different flavivirus species

Eighty-six strains of flaviviruses representing 51 species and 3 tentative species (Table 1) were submitted to RNA extraction. Viral RNA and a 10^{-1} RNA dilution were tested using the optimized protocol as described above. In addition, human sera from Saudi A rabian patients ($n = 11$) testing positive for Alkhurma virus infection (as determined using specific primers (Charrel et al. 2005)), human sera from either Thai ($n = 12$) or Senegalese ($n = 1$) patients who had tested positive for Dengue virus infection (as determined using specific primers), mosquito pools from Puerto Rico (Cook et al. 2006), and pools of ticks from Senegal (Grard et al. 2006) and Saudi Arabia (Charrel et al. 2007) were also tested.

All PCR products were submitted to direct sequencing using the amplification primers for initiation of the polymerization reaction. Raw nucleotide sequences were refined and analyzed with the Sequencher software version 4.7 (Gene Codes Corporation) and compared with those available in the GenBank database using the BLASTN algorithm (<http://www.ncbi.nlm.nih.gov/BLAST/>).

Flavivirus nucleotide sequences in the ~1.0-kb part of the NS5 region (nt 8899 to 9943 according to the YFV strain 17D ORF) previously used by Kuno et al. (Kuno et al. 1998b) for phy-

* T7 promoter sequence is underlined

** The number of copies indicated corresponds to the last 10-fold dilution of a synthetic RNA template that provided reproducible positive results. It was evaluated from the 260 nm OD of an RNA solution as indicated in the text.

logenetic analysis of the genus *Flavivirus* were retrieved from GenBank and used for multiple alignments using the ClustalX version 1.8 software (Thompson et al. 1997). Phylogenetic analysis was then carried out using the neighbor-joining method and the MEGA version 3 software (Kumar et al. 2004). In brief, a phylogenetic backbone was constructed using the ~1.0-kb NS5 data set. Each of the PF1S/ PF2R-bis sequences generated in the current study (nt 8889–9120 according to the YFV strain 17D ORF) was subsequently injected in the alignment, and the localization of the sequence within the evolutionary tree was analyzed using the *p*-distance algorithm and the neighbor-joining method. The robustness of the branching pattern was tested using 500 bootstrap replications.

RESULTS

Optimized protocol

The final optimized protocol was as follows, using the PF1S sense primer and the PF2R-bis reverse primers in a 25- μ L final volume: each reaction mixture contained 5 μ L of RNA, 12.5 μ L of 2X QuantiTect[®] (Qiagen France, Courtaboeuf) RT-PCR Master Mix, 0.25 μ L of QuantiTect RT Mix, 0.55 μ M of each primer. The cycling program was 50°C for 30 min, 95°C for 15 min, followed by 40 cycles consisting of 94°C for 15 s, 50°C for 30 s, and 72°C for 45 s. Analysis of the melting curve of specific PCR products was performed by slowly raising the temperature from 60°C to 95°C by means of regular fluorescence measurements.

Compared to the PF1S/PF2R primers set, the PF1S/ PF2R-bis primers pair resulted in earlier detection signals as evaluated by the comparison of Ct values.

Limit of detection

The protocol was further evaluated using quantified serial dilutions of 12 synthetic flavivirus RNAs. The LOD was <21,000 copies/reaction for all RNAs tested, reaching values <50 copies/reaction for TBEV, KADV, SLEV, and APOIV, and <3 copies/reaction for CFAV and KRV (Table 2).

Spectrum of detection of flaviviruses

Flavivirus RNA could be detected from all 86 cultured strains or biological samples tested (either from undiluted samples or from a 10⁻¹ RNA dilution), representing 51 species and 3 tentative species.

The amplicons obtained from the different flaviviruses were identified by analysis of dissociation plots. The melting temperature of amplification products varied from 78.9°C to 84.1°C (see Table 1 for more details), and could be unambiguously distinguished from primer dimers (dissociation temperature <74°C) (Macpherson et al. 2006).

Clinical and veterinary samples

In addition to virus strains and synthetic RNAs, a series of biological samples previously found positive for the presence of different flaviviruses based on specific PCR protocols was tested using the optimized protocol. The ALKV genome could be detected from 11 human sera, and the DENV genome from 13 sera (serotype 1, *N* = 2; serotype 2, *N* = 9; serotype 4, *N* = 2), from patients who developed clinical symptoms.

The CFAV genome could be detected from 67 pools of mosquito es from the Puerto Rico area, the NGOV genome from 2 crushed ticks from Senegal and the ALKV genome from 1 crushed tick from Saudi Arabia.

Specificity

The PF1S/PF2R-bis system was tested using nucleic acid extracts from three different mammalian cell lines (VERO, BHK -21, SW13), an insect cell line (C6/3 6), known negative human serum samples, and several pools of uninfected mosquitoes and ticks. In a further negative control, water was substituted for RNA. No false-positive results were observed, implying high specificity for the flavivirus sequences.

Sequence analysis

Identification of the different flaviviruses was tested using sequences obtained from the direct characterization of amplicons. Using the BLASTN program and the nr/nt database (at

the NCBI website), all virus species for which a reference sequence was available were precisely identified with an e value between $2e^{-114}$ and $2e^{-94}$, and a 94–100% coverage value (percentage of length allowing significant matching). A 94% coverage value was found for all viruses of the Kuno data set (Kuno et al. 1998b), for which only partial NS5 sequences are available (i.e., 13 nt at the 5' end of PF1S/PF2R-bis sequence are missing). In the case of ITV and BAGV, the correct identification was obtained with e values at $2e^{-107}$ and $2e^{-114}$, respectively, but BAGV scored at $7e^{-101}$ and ITV at $7e^{-95}$ as a second-rank identification for ITV and BAGV, respectively. However, phylogenetic analysis unambiguously confirmed the correct taxonomic identification in both cases (see *infra*). For all other sequences tested, distinction between the first and second rank identifications was obvious, with e values between $2e^{-86}$ and $2e^{-32}$ for the latter.

A phylogenetic analysis was performed by injecting individual PF1S/ PF2R-bis sequences within an NS 5 tree based on the Kuno dataset. All the sequences produced using the PF1S/ PF2R-bis amplification system clustered with the corresponding reference sequence, when available (Fig. 1).

In the case of WESSV and NGOV, there was no reference sequence available in the databases. The first rank identification for WESSV was SEPV with a low e value ($9e^{-43}$), clearly indicating that the two sequences originated from distinct virus species. This was confirmed by analysis of genetic distances (identity = 79%) and of

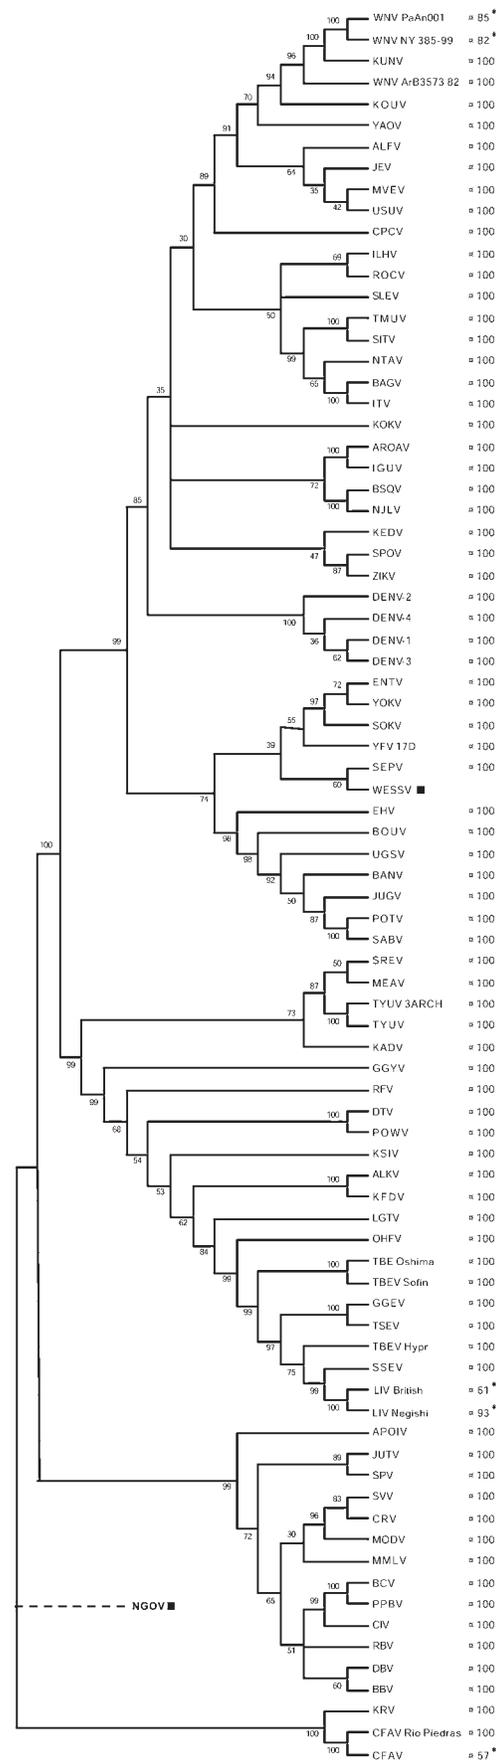

FIG. 1. Phylogenetic reconstruction in the NS5 gene. Phylogenetic reconstruction was performed using the *p*-distance algorithm and the NJ method implemented in Mega. A condensed tree is presented in which the length of horizontal lines is not proportional to genetic distances. The percent bootstrap values corresponding to 500 replications are indicated with a cutoff value of 30%. Sequences used correspond to positions 8899 to 9943 according to the YFV strain 17D ORF, except for NGOV and WESSV (■) (nt 8889–9120). The (○) sign indicates sequences generated using the PF1S/PF2R-bis system that clustered with the corresponding viral sequence within the reference tree. The bootstrap resampling value supporting grouping is indicated (*). In the case of CFAV, LIV, and WNV, the bootstrap value supporting clustering with the precise homologous isolate was lower. However, clustering within the corresponding virus species was supported by 100% boots trap values in all cases.

the phylogenetic topology. However, the proposed genetic relationship between SEPV and WESS constituted a valuable clue for the taxonomic assignment of WESSV (both belong to the group of *Aedes*-borne flaviviruses).

For NGOV, the first rank identification was EHV, with an extremely low *e* value ($1e^{-34}$), indicative of distant taxons. This was confirmed by phylogenetic analysis. The analysis of genetic distances showed an identity value at 61%, and the phylogenetic topology suggested a distant taxonomic relationship with other flaviviruses.

Altogether, these results demonstrate that sequences produced using this detection protocol allow a robust taxonomic identification of flaviviruses.

DISCUSSION

The elaboration of molecular assays allowing the consensus detection of flaviviruses is challenging, considering the enormous genetic diversity within this evolutionary lineage. We propose here a PCR protocol, which is the most efficient among those proposed to date for the consensus detection of flaviviruses. It combines the convenient real-time PCR format (that allows large-scale detection screening without any risk of PCR contamination) and a broad-spectrum of flavivirus detection (possible detection of all tested 50 species and 3 tentative species). By comparison, the assay proposed by Kuno and collaborators (Kuno 1998a), using closely related NS5 primers, allowed the detection of 52 species and 1 tentative species, but was based on a standard PCR format that requires electrophoresis of amplicons onto agarose gels, and sensitivity was not reported. An assay by Scaramozzino and colleagues (Scaramozzino et al. 2001) was also proposed for use in either real-time PCR or nested PCR format using the NS5 gene, but it was tested on 8 flavivirus species only. Another study (Gaunt et al. 2005) used a standard nested PCR protocol in the E gene followed by restriction enzyme analysis that allowed the detection of 40 species and 1 tentative species.

Two other aspects of the performances of this molecular assay deserve further comments. First, the test sensitivity was found to be surprisingly high, considering that it was based on

the use of degenerate primers. The limit of detection of the assay cannot compare for all viruses with specific detection real-time detection techniques, but the sensitivity is good for most of the viruses tested and excellent for some of them (lower than 50 copies/reaction for TBEV, KADV, SLEV, APOIV, and CFAV-related viruses). This sensitivity allowed the detection of different flaviviruses from a series of human sera or field samples. Second, it is interesting to note that the short NS5 region amplified by the proposed protocol (229 to 232 nt—primers excluded—depending on the different virus species) is usable for the reliable taxonomic identification of flaviviruses.

In summary, the convenient format of this assay and its performances for detecting and identifying flaviviruses make it a good candidate for the identification of previously identified flaviviruses in cell culture and the investigation of field samples. Moreover, due to the design of the primers in highly conserved patterns of the viral genomes and to its ability to detect recently discovered species (e.g., Ngoye virus or Kamiti River virus), it also constitutes a promising tool for the discovery and identification of new flavivirus species, including viruses distantly related to the “classical” arthropod-borne flaviviruses.

Sensitive and Broadly Reactive Reverse Transcription-PCR Assays To Detect Novel Paramyxoviruses[∇]

Suxiang Tong,* Shur-Wern Wang Chern, Yan Li, Mark A. Pallansch, and Larry J. Anderson

Division of Viral Diseases, National Center for Immunization and Respiratory Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia 30333

Received 30 January 2008/Returned for modification 13 April 2008/Accepted 16 June 2008

We have developed a set of reverse transcription-PCR assays for the detection and identification of known and novel paramyxoviruses in clinical specimens. Primers were designed from the conserved motifs of the polymerase *pol* gene sequences to detect members of the *Paramyxovirinae* or *Pneumovirinae* subfamily or groups of genera within the *Paramyxovirinae* subfamily. The consensus-degenerate hybrid oligonucleotide primer design and seminested or nested PCR assay design were used to enhance the breadth of reactivity and sensitivity of the respective assays. Using expressed RNA and 10-fold dilution series of virus-infected tissue culture isolates from different members of the family or genera, these assays were able to detect on average between 100 and 500 copies of template RNA. The assays were specific to the respective group of genera or subfamily viruses. This set of primers enhances our ability to look for novel viruses in outbreaks and diseases of unknown etiology.

The paramyxoviruses are ubiquitous pathogens and have been identified in a variety of hosts, including birds (chickens and turkeys), aquatic animals (salmon, whale, seal, dolphin, and porpoise), rodents (mice and rats), dogs, cats, sheep, reptiles (snake and lizards), horses, cattle, bats, pigs, simians, and humans. In humans, paramyxoviruses have been associated with a wide range of diseases, including croup, bronchiolitis, pneumonia, encephalitis, meningitis, parotitis, orchitis, spontaneous abortion, rash illnesses, and persistent infections (7, 10, 12, 16). Recently a variety of new members of the *Paramyxoviridae* family have been identified in animals, and some, most notably Nipah and Hendra viruses, have caused serious and sometimes fatal human infections (1, 2, 4). It is likely that there are additional, as yet unidentified members of this family and some will likely infect and cause disease in humans. Therefore, we believe the *Paramyxoviridae* constitute an important target for improved methods to detect novel viruses.

Detection of most paramyxoviruses has been routinely carried out by cell culture isolation, electron microscopy, antigen detection assays (immunofluorescence assays or enzyme immunoassays [EIA]), serologic assays, and genome-based assays, such as PCR assays. Each system has limitations. Traditional genome-based, antigen-based, and antibody-based assays usually are too specific to detect novel viruses. Cell culture isolation will allow detection only of viruses that grow and replicate in the culture system used and will require further characterization, usually by antigen- or genome-based assays. Electron microscopy requires a fairly high titer of virus for visualization and also requires further characterization.

To increase our ability to detect novel viruses, we chose to

develop broadly reactive PCR assays. This strategy has been used very successfully to identify and characterize a number of novel human viruses, including severe acute respiratory syndrome coronavirus (5), hepatitis G virus (17), Sin Nombre virus (8), human retrovirus 5 (3), and novel animal viruses, such as the macaque gammaherpesvirus (15) and pig endogenous retrovirus (9). The present article describes the development of a set of PCR assays that should detect all known and novel paramyxoviruses. The primers for these assays were developed from highly conserved regions of the genome. We applied the consensus-degenerate hybrid oligonucleotide primer methodology (13, 14) in primer design and seminested PCRs to optimize the specificity and sensitivity of these broadly reactive assays.

MATERIALS AND METHODS

Virus and isolation of viral RNA. The reference viruses or viral RNA used in this study are listed in Table 1 and include three strains from the genus *Avulavirus*, two strains from the genus *Henipavirus*, five strains from the genus *Morbillivirus*, seven strains from the genus *Respirovirus*, five strains from the genus *Rubulavirus*, four strains from the genus *Pneumovirus*, three strains from the genus *Metapneumovirus* and three newly isolated unclassified paramyxoviruses. RNAs were extracted from 100 μ l of supernatant fluid of virus-infected cells with the QIAamp viral RNA kit (Qiagen, Santa Clarita, CA) according to the manufacturer's instructions. The RNA was eluted from the column in 50 μ l of RNase-free water. RNAs for the Hendra virus, Nipah virus, Menangle virus, and Fer-de-Lance virus (FDLV) strains were obtained from Paul Rota (Centers for Disease Control and Prevention) as extracts in Trizol, which were prepared according to the instructions provided by the commercial source (Invitrogen, Carlsbad, CA).

Broadly reactive oligonucleotide primer selection. Conserved amino acid sequences for the family, subfamily, and genera were selected from alignment of deduced L-protein-coding sequences recorded in GenBank (National Institutes of Health, Bethesda, MD). A total of 33 nonredundant paramyxovirus L-protein sequences were used and aligned using the Clustal W program. We selected highly conserved domains between 8 and 10 amino acids in length and back translated into degenerate nucleotide sequences to represent all possible codons for the corresponding amino acids. To minimize the number of primers, primers were designed with mixed degenerate bases restricted to between 9 and 12 nucleotides in the 3' portion of the primers, and inosines (maximum of four) and consensus nucleotides were used for the remaining middle and 5' portion of the

primers. In addition, primers were designed to achieve similar reaction conditions and an amplicon size between 200 and 500 bp. To minimize the potential for nonspecific cross-reactivity, a Blastn search analysis of GenBank was performed for similarities with known sequences. The primers were synthesized at the Biotechnology Core Facility, Division of Scientific Resources of the Centers for Disease Control and Prevention (CDC).

RT-PCR and nested RT-PCR amplification. To maximize sensitivity and specificity, we nested or seminested PCR assays and optimized reaction conditions, including primer concentration, magnesium (Mg^{2+}) concentration, and thermal cycling temperatures and profiles. For the first PCR in the seminested assay, we used the SuperScript III One-Step reverse transcription-PCR (RT-PCR) kit (Invitrogen, Carlsbad, CA). The optimized PCR mixtures contained 50 pmol each of forward and reverse primers, 1× buffer with a final concentration of 2.0 mM $MgSO_4$ and 200 μM (each) deoxynucleoside triphosphates, 20 U of RNase inhibitor, a 5- μl aliquot of RNA/DNA extracts, and 1 U of SuperScript III RT/Platinum *Taq* mix. Water was then added to achieve a final volume of 50 μl . The RT-PCR mixture was sequentially incubated at 60°C for 1 min for denaturing, 44 to 50°C for 30 min (for RT), 94°C for 2 min (for hot start), and then 40 cycles at 94°C for 15 s, 48 to 50°C for 30 s, 72°C for 30 s, and a final extension at 72°C for 7 min. For the second amplification in the seminested PCR assay, we used 1× buffer (Platinum *Taq* kit; Invitrogen), 2 mM $MgCl_2$, 200 μM (each) of

deoxynucleoside triphosphates, 50 pmol (each) of forward and reverse primers, 1 U Platinum *Taq*, one 2- μl aliquot from the first reaction, and water to achieve a final volume of 50 μl . The mixture was first heated to 94°C for 2 min. The cycling conditions were 40 cycles with the same conditions as for the first amplification: 94°C for 15 s, primer annealing at 48 to 50°C for 30 s, and 72°C for 30 s. A final extension was carried out at 72°C for 7 min. The final nested or seminested PCR products were visualized by UV light after electrophoresis on a 2% agarose gel containing 0.5 $\mu g/ml$ ethidium bromide in 0.5× Tris-borate buffer (pH 8.0). A DNA VIII marker (Roche, Indianapolis, IN) was run in the gels to estimate amplicon size.

Specificity and sensitivity. Initial primer validation and selections were performed using one reference RNA template from the subfamily or genera for which the PCR assay was designed. Mumps virus RNA was used for the *Rubulavirus-Avulavirus* genus subgroup-specific primers and the *Paramyxovirinae* subfamily primers, Hendra RNA for the *Morbillivirus-Respirovirus-Henipavirus* genus subgroup-specific primers, and respiratory syncytial virus A RNA for the *Pneumovirinae* subfamily-specific primers. Following the initial screening, the selected primer pairs were then tested against the representative paramyxoviruses listed in Table 1. Finally, to test for unanticipated nonspecific reactivity, the PCR assays were tested against pooled nucleic acids of influenza A and B viruses, rhinoviruses, adenovirus, two distinct human coronaviruses, human coronavirus

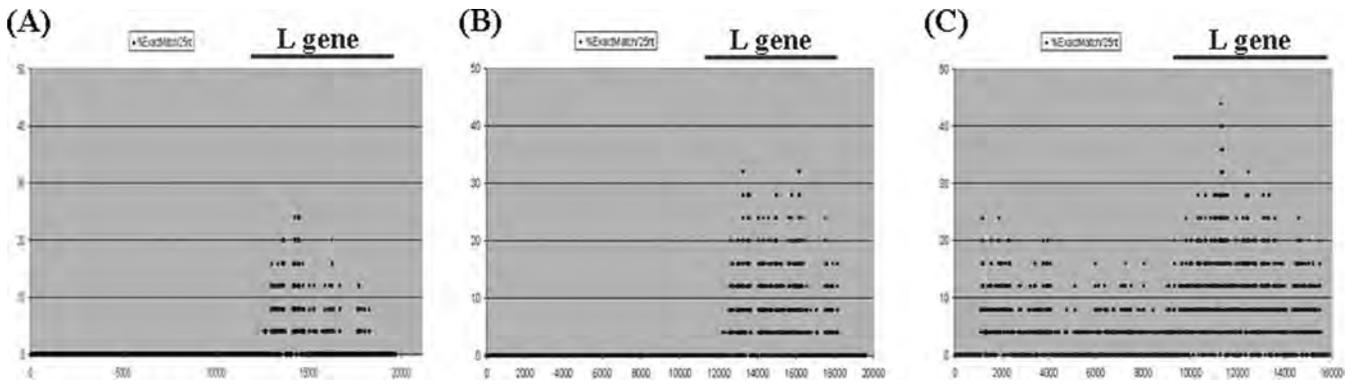

FIG. 1. Similarity plots of the aligned paramyxoviruses' genomes. The plots were obtained using an in-house program based on multiple alignments of viral genomes from 29 different strains in the *Paramyxoviridae* (A), 22 different strains in the *Paramyxovirinae* (B), and 7 different strains in the *Pneumovirinae* (C). The identity percentage score given on the y axis was calculated based on the exact-match percentage with a window of 25 nucleotide positions, and the window was progressively moved across the alignment in 1-nucleotide-position steps. The x axis shows the first position of the window in the multiple alignments of the viral genomes.

229E, and human coronavirus OC-43 and bacteria (*Chlamydia pneumoniae*, *Haemophilus influenzae*, *Streptococcus pneumoniae*, and *Mycoplasma pneumoniae*).

The sensitivities of the PCR assays were determined using two sources of RNA: RNA that was extracted from each dilution of a 10-fold dilution series of virus-infected cell culture with known infectivity titers (PFU) and serial dilutions of synthetic RNA that was transcribed in vitro from cloned genome fragments as previously described (18).

Sequencing. Amplicons from the final round of PCR were purified using the QIAquick PCR purification kit (Qiagen, Inc., Valencia, CA). Both strands of the amplicons were sequenced with a BigDye Terminators v1.1 ready reaction cycle sequencing kit on an ABI Prism 3100 automated sequencer (Applied Biosystems, Foster City, CA) using the corresponding PCR primers. The remaining reaction conditions were according to the manufacturer's instructions.

RESULTS

Development of consensus degenerate primers. To design family- or subfamily-specific primers, all full-length genome sequences were obtained from the *Paramyxoviridae* family viral sequences archived in the GenBank viral database. Viral sequences with more than 95% similarity were treated as identical; the resulting 29 nonredundant full-length genome sequences were used initially to design primers for this study. First, a multiple full-length genome sequence alignment was performed by using Clustal W and was scanned according to a program written in house to identify genes that have the most-conserved multiple regions from the broadest possible group-

ing in the family *Paramyxoviridae*. The plot (Fig. 1) showed that the RNA polymerase (L) coding sequences were the most conserved, and thus, this gene was selected as the locus for the broadly reacting PCR assays. For the final primer design, we used an additional four L-gene sequences available in GenBank for a total of 33 L-gene-specific nonredundant sequences. Since the subfamilies, *Paramyxovirinae* and *Pneumovirinae*, are so genetically distinct, primers were designed for each separately. The highly conserved amino acid regions with minimal length of six amino acids were checked for possible presence in other nontarget organisms by a BLAST search to avoid nonspecific amplification in PCR. Primers were designed from these highly conserved regions using all codon possibilities for 9 to 12 bases at the 3' end of the primer and consensus sequences or inosines at positions of fourfold degeneracy for a "consensus clamp" at the 5' end. After comparative analysis including sizes of amplicons, the similarity of reaction kinetics, nonspecific cross-reactivity, and experimental evaluation, three consensus degenerate primers (two for the first PCR and the third for the second, seminested PCR) corresponding to the most-conserved motifs were selected as the pan-*Paramyxovirinae* primers and three consensus degenerate primers corresponding to the most-conserved motifs were selected as the pan-*Pneumovirinae* primers, as shown in Table 2. Since the subfamily *Paramyxovirinae* has greater diversity

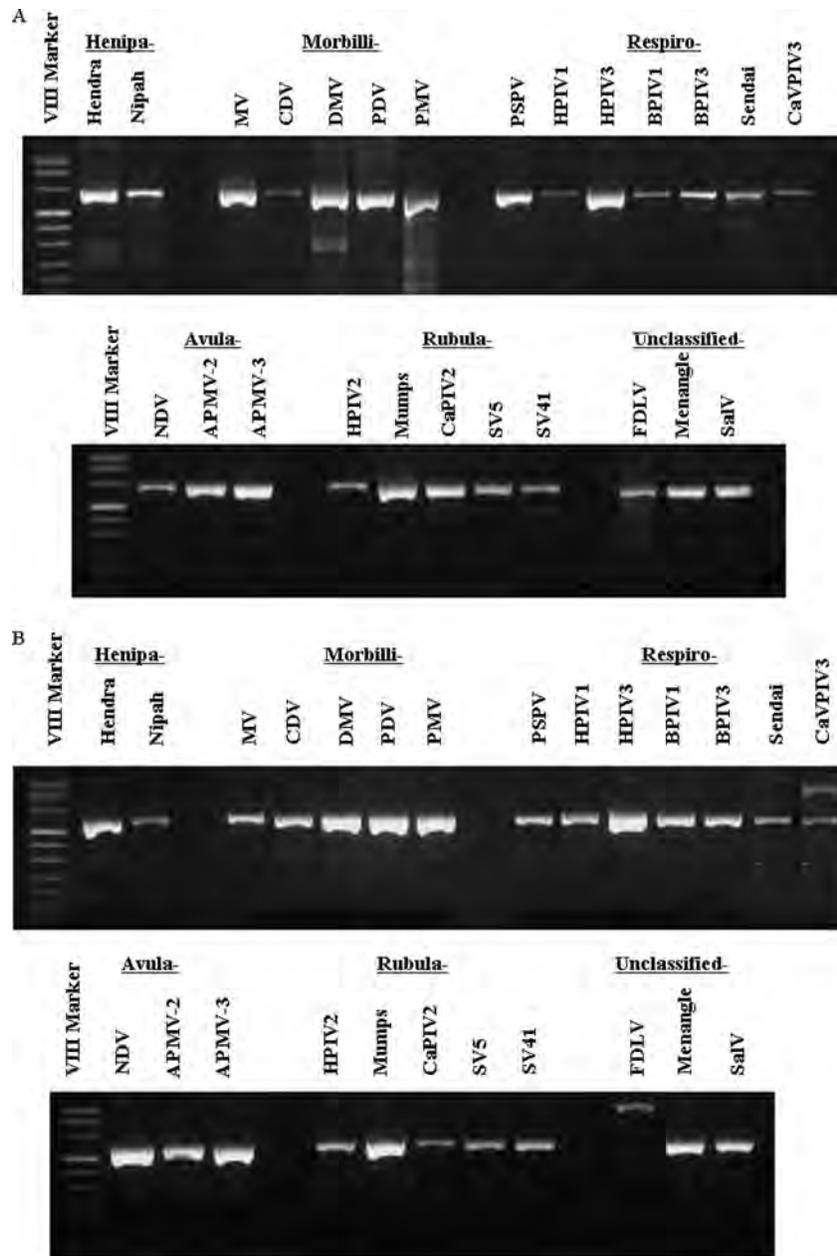

FIG. 2. Amplification of RNAs from 25 different viral members in the subfamily *Paramyxovirinae* by one-step RT-PCR using the pan-PAR-F1/PAR-R primer pair (A) or the pan-PAR-F2/PAR-R primer pair (B). Viral names are abbreviated as shown in Table 1.

among its members than the subfamily *Pneumovirinae*, we further divided the *Paramyxovirinae* into two subgroups of genera based on RNA polymerase gene relatedness, the *Morbillivirus-Respirovirus-Henipavirus* subgroup and the *Rubulavirus-Avulavirus* subgroup, and further developed primers to achieve less degeneracy and greater sensitivity, as noted in Table 2.

Standardization of optimized conditions. Different combinations of RT and PCR steps including one tube/one step, one tube/two steps, and two tubes/two steps, have a significant effect on the outcome of the assays. By comparative testing, we observed that a one-tube/one-step RT-PCR protocol was not only more convenient and more sensitive (data not shown) but also minimized risk of handling cross-contamination. RT-PCRs were optimized for band intensity and low background

by evaluating combinations of primer concentration, Mg^{2+} concentration, and annealing temperatures.

Broad reactivity of consensus degenerate primers. As shown in Fig. 2A and B, all of the 25 reference viruses representing five genera from the *Paramyxovirinae* subfamily were successfully detected by pan-*Paramyxovirinae* primers. As shown in Fig. 3 and 4, members of the two groups of genera within this subfamily were also detected by the appropriate subgroup-specific primers. The observed variation in amplicon intensity was probably due at least in part to differences in amount of template RNA for the respective viruses. No amplicons were detected for the PCR assays against the pooled "other respiratory pathogen genomes" or the negative controls (see Fig. 6). Two previously unclassified paramyxoviruses, FDLV and Sa-

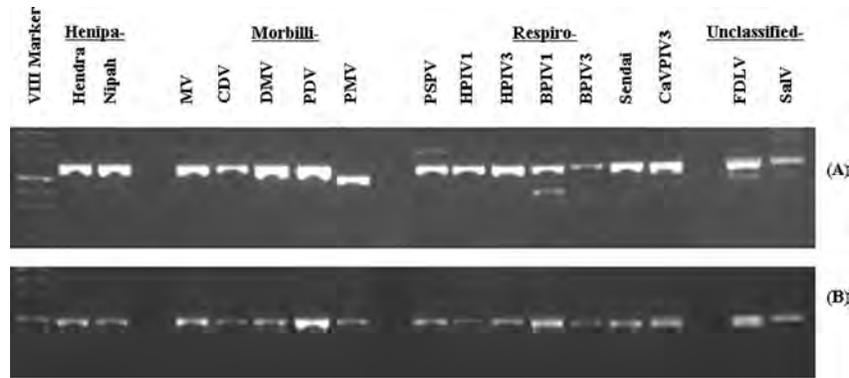

FIG. 3. Amplification of RNAs from 14 different viral members in the genera of *Henipavirus*, *Morbillivirus*, and *Respirovirus* and two unclassified viral members in the subfamily *Paramyxovirinae* by one-step RT-PCR using the pan RES-MOR-HEN-F1/RES-MOR-HEN-R primer pair (A) or the pan RES-MOR-HEN-F2/RES-MOR-HEN-R primer pair (B). Each viral name is abbreviated as shown in Table 1.

lem virus (SaIV), were amplified only by the *Morbillivirus-Respirovirus-Henipavirus* genus subgroup-specific primers and Menangle virus only by the *Rubulavirus-Avulavirus* genus subgroup-specific primers. These results suggest that FDLV and SaIV strains are more closely related to the *Morbillivirus-Respirovirus-Henipavirus* subgroup and the Menangle strain to the *Rubulavirus-Avulavirus* subgroup.

As shown in Fig. 5, the *Pneumovirinae* seminested PCR assay detected all of the seven tested reference viruses, and the specificity of the amplification was confirmed by sequence studies. These primers did not amplify RNA from other common respiratory viruses or the negative controls (Fig. 6).

Sensitivity of consensus degenerate PCR assay. To test the sensitivity of the PCR assays, we used mumps virus RNA for both the *Paramyxovirinae* subfamily-specific primers and the *Rubulavirus-Avulavirus* genus subgroup-specific primers. Hendra

viral RNA was used to evaluate the *Morbillivirus-Respirovirus-Henipavirus* genus subgroup-specific primers and respiratory syncytial virus RNA for the *Pneumovirinae* subfamily-specific primers. Generally, sensitivity was improved at least 10-fold with the addition of the nested or seminested step (Fig. 7). The same 10-fold serial dilutions of mumps virus RNA were used to compare the sensitivity between the *Paramyxovirinae* subfamily-specific RT-PCR and the *Rubulavirus-Avulavirus* genus subgroup-specific RT-PCR. As expected, the *Rubulavirus-Avulavirus* genus subgroup-specific primers with less degeneracy resulted in a 10-fold- to 100-fold-higher sensitivity than the *Paramyxovirinae* subfamily-specific primers. By using serial dilutions of RNA transcripts, the sensitivity limit was calculated as between 10 and 100 RNA copies for the *Rubulavirus-Avulavirus* subgroup-specific PCR, the *Morbillivirus-Respirovirus-Henipavirus* subgroup-specific PCR, and the *Pneumovirinae*

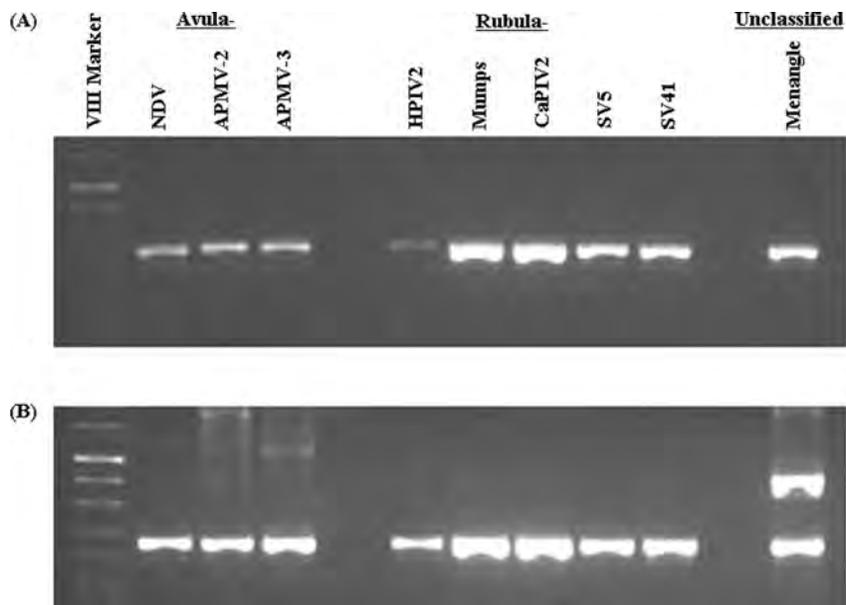

FIG. 4. Gel electrophoresis of amplification products of a one-step RT-PCR assay against RNA from eight different members of *Avulavirus* and *Rubulavirus* genera and one previously unclassified member of the subfamily *Paramyxovirinae*. The pan AVU-RUB-F1/AVU-RUB-R primer pair (A) or the pan AVU-RUB-F2/AVU-RUB-R primer pair (B) was used. Each virus gives an appropriately sized band and is identified by its abbreviation as shown in Table 1.

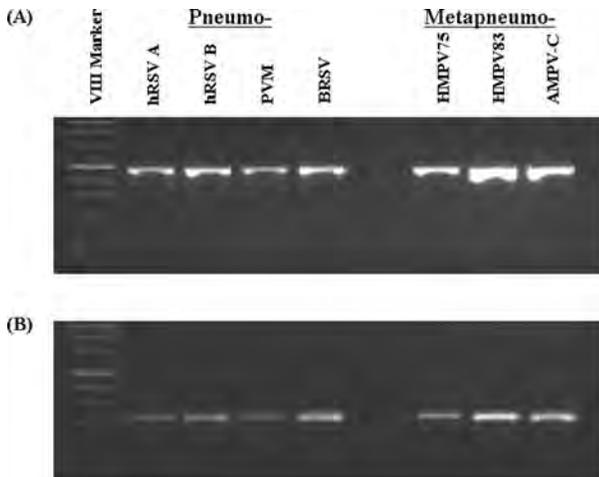

FIG. 5. Gel electrophoresis of amplification products of one-step RT-PCR assays against RNA from seven different members of the subfamily *Pneumovirinae*. (A) Pan PNE-F1/PNE-R primer pair. (B) Pan PNE-F2/PNE-R primer pair. Each virus gives an appropriately sized band and is identified by its abbreviation as shown in Table 1.

subfamily-specific PCR and between 500 and 1,000 copies for the *Paramyxovirinae* subfamily-specific PCR (data not shown).

Validation with clinical specimens. To validate further the specificity and sensitivity of each of these group-specific PCRs with clinical samples, we tested a panel of 14 blinded samples provided by Dean Erdman (CDC), consisting of paramyxovirus-containing clinical samples, non-paramyxovirus-containing clinical samples, and cell culture isolates in different dilutions, which had been tested by agent-specific assays. As noted in Table 3, the appropriate subfamily-specific or genus subgroup-specific PCR assays correctly identified each of the specimens with the correct specificity.

FIG. 6. Gel electrophoresis of amplification products with subfamily and genus group seminested RT-PCR assays showing the appropriately sized positive band for the positive control material for the respective RT-PCR assay and no appropriately sized band for negative-control material or a pool of RNA from other common respiratory pathogens, as described in Materials and Methods. The seminested RT-PCR assays are pan-PAR (*Paramyxovirinae* subfamily), pan RES-MOR-HEN (group of *Respirovirus*, *Morbillivirus*, and *Henipavirus* genera), pan-AVU-RUB (group of *Avulavirus* and *Rubulavirus* genera), and pan-PNE (*Pneumovirinae* subfamily). Lanes: 1, positive control; 2, negative control (water); 3, blank; 4, pool of RNA from other common respiratory pathogens.

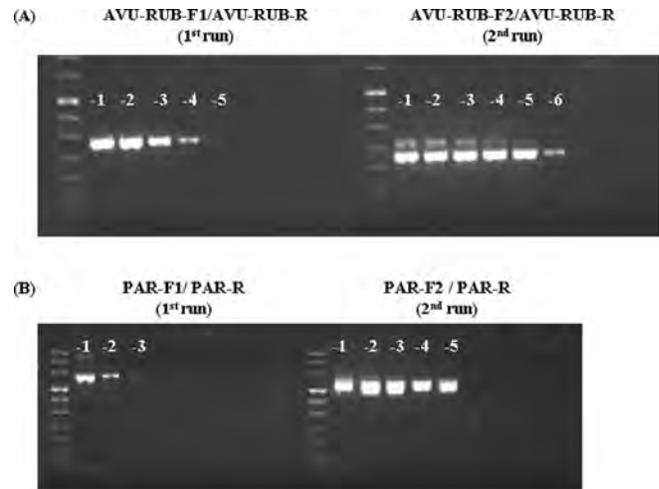

FIG. 7. Improved detection sensitivity by seminested RT-PCR and by genus subgroup primers with less degeneracy. (A) Seminested RT-PCR amplification of RNA extracted from 10-fold serial dilution of mumps virus stock using the pan-AVU-RUB-F1/AVU-RUB-R primer pair (1st run) and the pan-AVU-RUB-F2/AVU-RUB-R primer pair (2nd run). (B) Seminested RT-PCR amplification of RNA extracted from 10-fold serial dilution of mumps virus stock using the pan-PAR-F1/PAR-R primer pair (1st run) and the pan-PAR-F2/PAR-R primer pair (2nd run).

DISCUSSION

In this report, we describe successful development of a set of broadly reactive PCR assays for *Paramyxoviridae*. These assays were developed by identifying conserved sequences among members of various groups in the family *Paramyxoviridae*, using degenerate and inosine-containing primers to account for mismatches, a second, nested, PCR to improve sensitivity, and the consensus-degenerate hybrid oligonucleotide primer strategy (13) to improve sensitivity and specificity. In designing the broad-range primers, we first looked for conserved amino acid sequences in the RNA-dependent RNA polymerase protein coded by the L gene, the most conserved viral gene in the family *Paramyxoviridae*. The analysis of the RNA-dependent RNA polymerase proteins of paramyxoviruses indicated that they encompass three conserved domains (I, II, and III) separated by two nonconserved hinge regions, and strong selective constraints act against amino acid sequence changes in these three conserved domains (6, 11). They are predicted to be essential for the key functions of RNA binding, RNA replication, and protein kinase activity and may have retained the same structure, that of their putative common ancestor, as they have diverged in sequence. The invariance of these conserved sequences suggests that they may be ideal targets for the exploration of unidentified members in the *Paramyxoviridae*. The broad-range primers in this report were designed from the highly conserved domain I and II among paramyxovirus members.

The extensive variability within this family and the drop in sensitivity with increased primer degeneracy prevented us from developing a single assay for the family but instead led us to develop subfamily-specific and two genus subgroup PCR assays to achieve the desired level of sensitivity, <100 copies of RNA in the reaction mixture. The two genus subgroup assays took advantage of more closely related genera, i.e., a group of

^a Pos, positive; Neg, negative. For other abbreviations, see Table 1.

^b The specimen 2002023644 had a low viral load (<10 copies/5 μl template) which is below the detection limit of the pan-Pneumovirinae RT-PCR.

^c hRSV-B1, human RSV-B1.

the *Rubulavirus* and *Avulavirus* genera and a group of the *Morbillivirus*, *Respirovirus*, and *Henipavirus* genera. The two genus subgroup assays reached the desired level of sensitivity, 10 and 100 copies, while the corresponding *Paramyxovirinae* subfamily assay achieved a sensitivity of 500 to 1,000 copies.

In summary, we have developed a set of seminested RT-PCR assays for detection of paramyxoviruses. The broad reactivity of these RT-PCR assays should allow us to detect known and novel members of the family *Paramyxoviridae* within genera described to date. The utility of these assays in discovery of novel members is supported by our ability to detect and classify eight recently isolated paramyxovirus species, *Porpoise morbillivirus*, *Pacific salmon paramyxovirus*, *Bovine parainfluenza virus 1*, *Guinea pig parainfluenza virus 3*, *Canine parainfluenza virus 2*, *Canine parainfluenza virus 3*, *Menangle virus*, and *Salem virus*, whose sequences were not available when the primers were designed. These pan-paramyxovirus PCR assays and similar assays for other viral families should enhance our ability to quickly identify, by virus family, subfamily, or genus, a wide range of novel viral pathogens and should enhance our ability to respond to and characterize outbreaks and diseases of unknown etiology.

ACKNOWLEDGMENTS

We acknowledge many people who provided reference viruses and/or clinical specimens for this study. ABSTRACT From September to December 2011, 162 New England harbor seals died in an outbreak of pneumonia. Sequence analysis of postmortem samples revealed the presence of an avian H3N8 influenza A virus, similar to a virus circulating in North American waterfowl since at least 2002 but with mutations that indicate recent adaptation to mammalian hosts. These include a D701N mutation in the viral PB2 protein, previously reported in highly pathogenic H5N1 avian influenza viruses infecting people. Lectin staining and agglutination assays indicated the presence of the avian-preferred SA α -2,3 and mammalian SA α -2,6 receptors in seal respiratory tract, and the ability of the virus to agglutinate erythrocytes bearing either the SA α -2,3 or the SA α -2,6 receptor. The emergence of this A/harbor seal/Massachusetts/1/2011 virus may herald the appearance of an H3N8 influenza clade with potential for persistence and cross-species transmission.

IMPORTANCE The emergence of new strains of influenza virus is always of great public concern, especially when the infection of a new mammalian host has the potential to result in a widespread outbreak of disease. Here we report the emergence of an avian influenza virus (H3N8) in New England harbor seals which caused an outbreak of pneumonia and contributed to a U.S. federally recognized unusual mortality event (UME). This outbreak is particularly significant, not only because of the disease it caused in seals but also because the virus has naturally acquired mutations that are known to increase transmissibility and virulence in mammals. Monitoring the spillover and adaptation of avian viruses in mammalian species is critically important if we are to understand the factors that lead to both epizootic and zoonotic emergence.

Fatal pulmonary epizootics of influenza have been observed previously in seal populations, including outbreaks of H7N7 in 1979 to 1980 (1, 2), H4N5 in 1983 (3) and H4N5 and H3N3 in 1991 to 1992 (4). Such outbreaks are significant not just because of the detriment they pose to animal health but because influenza in mammals can act as a source for human pandemics (5).

In a <4-month period beginning in September 2011, 162 harbor seals (*Phoca vitulina*) were found dead or moribund along the New England coast. This number is approximately four times the expected mortality for this period. Most of the affected individuals were less than 6 months old, and common causes of death (including malnourishment) were ruled out. Five of the affected animals were investigated to identify a causative agent, and here we demonstrate that avian influenza virus subtype H3N8 was responsible for the observed clinical and pathological signs in these animals. Unlike any previous outbreak in seals, this H3N8 virus has naturally acquired mutations that reflect adaptation to mammalian hosts and that are known to increase virulence and transmissibility in avian H5N1 viruses infecting mammals. The virus has fur-

ther acquired the ability to use the SA α -2,6 receptor commonly found in the respiratory tracts of mammals, including humans. The existence of a transmissible and pathogenic influenza is of obvious public concern.

RESULTS AND DISCUSSION

Five animals were submitted for anatomical and microbiological analysis. All were collected from the peak of the outbreak (late September to October) and had pneumonia and ulcerations of the skin and oral mucosa (Fig. 1). Nucleic acids extracted from lung, trachea, liver, kidney, thoracic lymph node, mesenteric lymph node, spleen, skin lesion, and oral mucosa were tested by PCR for the presence of a wide range of pathogens, including herpesviruses, poxviruses, adenoviruses, polyomaviruses, caliciviruses, paramyxoviruses, astroviruses, enteroviruses, flaviviruses, rhabdoviruses, orbiviruses, and influenza viruses. Influenza A virus was detected in several tissues from all five animals, and PCR cloning and sequencing of genes for hemagglutinin (HA) and neuraminidase (NA) revealed the subtype to be H3N8, a subtype

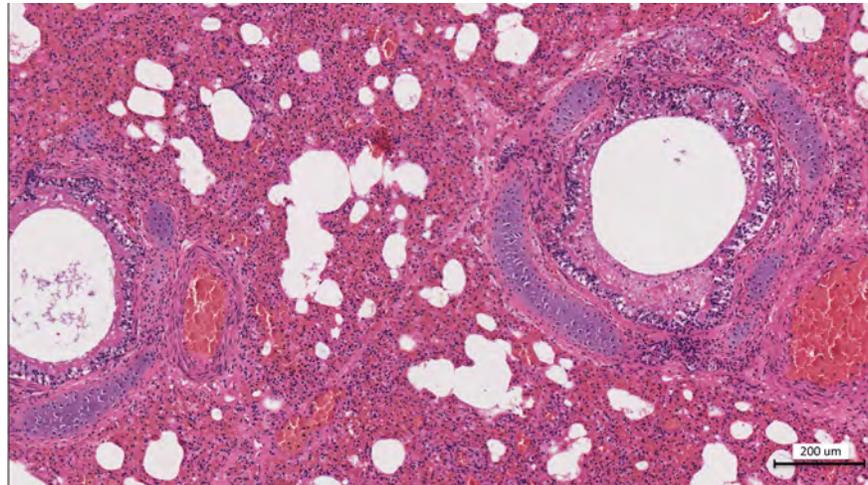

FIG 1 Hematoxylin and eosin staining of the lung at a $\times 10$ magnification. There is diffuse acute interstitial pneumonia and a mix of acute hemorrhagic alveolitis with necrotizing bronchitis. Multifocally, alveoli are either filled with hemorrhage and scant inflammatory cells or expanded with emphysema. There is irregularity to the bronchial mucosa due to necrosis, a mild to moderate edema, and mucous partially filling the bronchial lumen. There is mild to moderate expansion of the interlobular septa, with edema and hemorrhage.

typically associated with infection of avian, equine, and canine hosts (6-8). Influenza virus was isolated from the allantoic fluid of specific-pathogen-free (SPF) eggs inoculated with homogenates of PCR-positive tissues, including lung, lymph nodes, tonsil, and kidney, and all isolates were reconfirmed to be H3N8. In accord with conventional nomenclature, the virus is provisionally named A/harbor seal/Massachusetts/1/2011.

In situ hybridization (ISH) using oligonucleotide probes for influenza virus H3N8 segments 4 (HA) and 7 (matrix) and immunohistochemistry using polyclonal antibodies against H3N8 HA antigen confirmed the presence of influenza virus in lung, where signal was concentrated in the bronchiole epithelium and mucosa of the pulmonary parenchyma (Fig. 2 and see Fig. S1 in the supplemental material). The average load of HA and NA RNAs in lung was 300 copies/100 ng of extracted RNA. ISH staining in nonrespiratory tissues was limited to sporadic infection of single cells in intestine, kidney, and lymph node, and the average HA/NA RNA load was five copies/100 ng. These results are consistent with the histological observation that the main site of viral replication is the respiratory tract. Cellular morphology and terminal deoxynucleotidyltransferase-mediated dUTP-biotin nick end labeling (TUNEL) consistent with apoptosis was observed in virus-infected pulmonary epithelial cells (Fig. 3). TUNEL staining also revealed the widespread presence of apoptotic cells in areas where no virus was observed but not in negative-control tissue, suggesting an additional host-mediated response to the infection.

Full-genome sequencing was completed following PCR cloning of all eight influenza genome segments directly from infected tissue. Sequences were submitted to GenBank and assigned accession numbers JQ433879 to JQ433882. Phylogenetic analyses of these nucleotide sequences with avian, canine, and equine H3N8 influenza virus genomes demonstrated the closest relationship to a virus identified in North American waterfowl in all 8 segments (Fig. 4). These data are consistent with the recent transmission of the H3N8 virus from wild birds to seals. The closest avian relative, A/blue-winged teal/Ohio/926/2002, had an overall 96.07% nucleotide sequence identity across the genome (Hamming distance),

with no individual segment having less than 94% identity. This level of similarity across all segments with an isolate separated by a span of 10 years suggests that this virus has been circulating in the aquatic bird populations since at least 2002.

A total of 37 amino acid substitutions separate the seal H3N8 and avian H3N8 viruses, which are summarized in Table 1. The corresponding amino acids found in other seal influenza viruses, in the canine and equine H3N8 viruses, and in selected human influenza viruses are included for comparison. Of these, mutations PB2-701N and HA-260M are shared exclusively by the seal and mammalian (canine/equine) H3N8 viruses, while mutations NA-399R, PB2-382V, and PA-184N are shared by the seal H3N8 and human H3N2 viruses, all of which suggests adaptation to mammalian hosts. Mutations PB2-60N, PB2-376R, PB1-174I, PB1-309G, PB1-359G, PB1-376V, PB1-377G, PB1-464E, NP-63V, NP-128G, and NP-296H are all exclusively found in the seal H3N8 virus (Table 1). Future studies will be required to assess the functional significance of many of these mutations, especially in seal H3N8 PB1, where a significant number of exclusive mutations were observed. Given the importance of PB1 in viral replication, it is probable that these mutations represent adaptive selection to accommodate host-specific differences in intracellular replication.

The seal H3N8 genome was interrogated for any genetic features that might contribute to enhanced transmissibility and virulence in seals. Expression of a second peptide (PB1-F2) from segment 2 has been associated with an increase in pathogenicity by inducing apoptosis and increasing both inflammation and secondary bacterial pneumonia (9, 10). The seal H3N8 virus contains an intact open reading frame for the pathogenic version of this accessory protein, which includes a serine at amino acid position 66 (9). All five seals had evidence of apoptosis and secondary bacterial pneumonia.

Glycosylation can also affect pathogenicity in influenza viruses (11-14). Six potential glycosylation sites were detected in the seal H3N8 HA, based on the sequence $X_{-2}X_{-1}NX(S/T)X_{+1}$, at amino acid positions 24, 38, 54, 181, 301, and 499. None had features

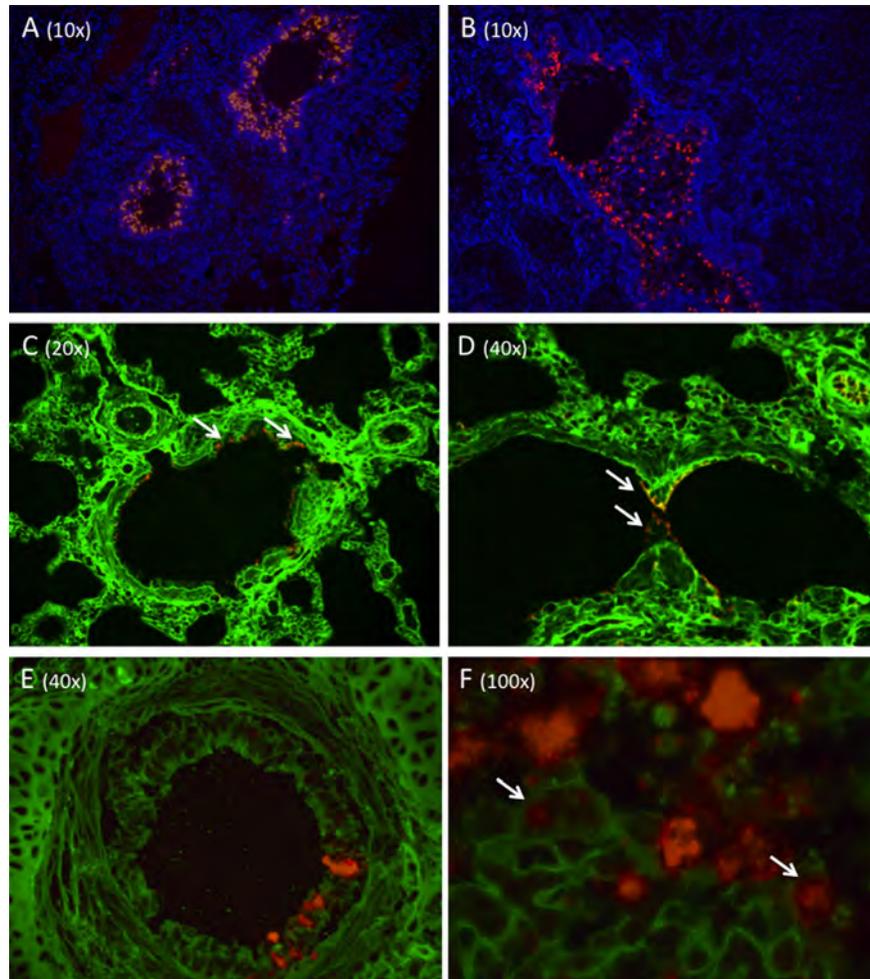

FIG 2 (A and B) Fluorescent *in situ* hybridization (ISH) of H3N8 virus-infected seal cells with DAPI counterstaining. A probe targeting the viral hemagglutinin demonstrates diffuse infection of the bronchial mucosal epithelium. ISH was also performed using probes for the matrix gene. Staining was identical to that shown here for HA. (C and D) Lectin staining to demonstrate the distribution of SA α -2,3 and SA α -2,6 in seal pulmonary parenchyma. The SA α -2,6 (green) was detected using fluorescein-labeled *Sambucus nigra* agglutinin (SNA) lectin, while SA α -2,3 (red) was detected using *Maackia amurensis* II (MAL II) lectin. Both infected and uninfected control tissues were stained, and the results were consistent for both. High levels of SA α -2,6 are observed on bronchiole and alveolar epithelial cells and on endothelial cells. The images in panels C and D were selected because they show staining for both sialic acids; however, the expression of SA α -2,3 was rarely observed (arrows) and limited to bronchiole luminal (C) and occasional alveolar (D) epithelia. (E and F) Costaining of SA α -2,6 and H3N8 HA. SA α -2,6 (green) is expressed on the respiratory epithelium of an intrapulmonary bronchus (E). H3N8 virus-infected cells (red) are present. A serial section was also stained for SA α -2,3, and none was detected. A high-magnification image of infected mucosa clearly shows H3N8 virus infection of cells expressing SA α -2,6 (arrows). All composite images are presented separately (single stains) in Fig. S1 to S3.

suggestive of inactivity or reduced efficiency, as was previously demonstrated for H5N2 (12). Many H5N1 viruses have an additional glycosylation site at positions 158 to 160, and previous work demonstrated that the deletion of this site is critical for H5N1 viruses to bind to human-SA α 2,6-like receptors and to transmit between mammals (15). This glycosylation site is missing in the seal H3N8 HA.

In order to investigate the specificity of sialic acid binding, the seal virus was compared to avian H5 and swine H9, both of which bind to the sialyloligosaccharide SA α 2,3 ligand in a structural-homology model (Fig. 5). All structures confirmed the presence of a highly conserved serine at position 152 (corresponding to S136 by H3 numbering [16, 17]), which lies in a binding pocket, where its hydroxyl group contacts the axial carboxylate of sialic acid (17). While the seal virus contains the same conserved S152, it also harbors a neighboring G151E mutation (Table 1), which intro-

duces a large residue capable of both donating and receiving hydrogen bonds with residues in close proximity to the ligand-binding pocket. Rotamer hydrogen bond analysis of the modeled seal structure indicates that HA's altered conformation results in reduced hydrogen bonding between the conserved serine and SA α 2,3 compared to that of H5 and H9 influenza viruses. Such changes in sialic acid binding play important roles in novel host adaptation (18).

Mutations at positions 226 and 228 (H3 numbering) in the H3 HA can also affect receptor-binding preferences and can either completely abrogate (Q226L) or reduce (G228S) affinity for the avian-preferred SA α -2,3 interaction (18, 19). Seal H3N8 virus maintains the avian phenotype at positions 226 (Q) and 228 (G), which correlates with a continued ability to use SA α -2,3. Together, these findings suggest that the seal virus may still be able to use SA α 2,3, but perhaps with less efficiency than in its original

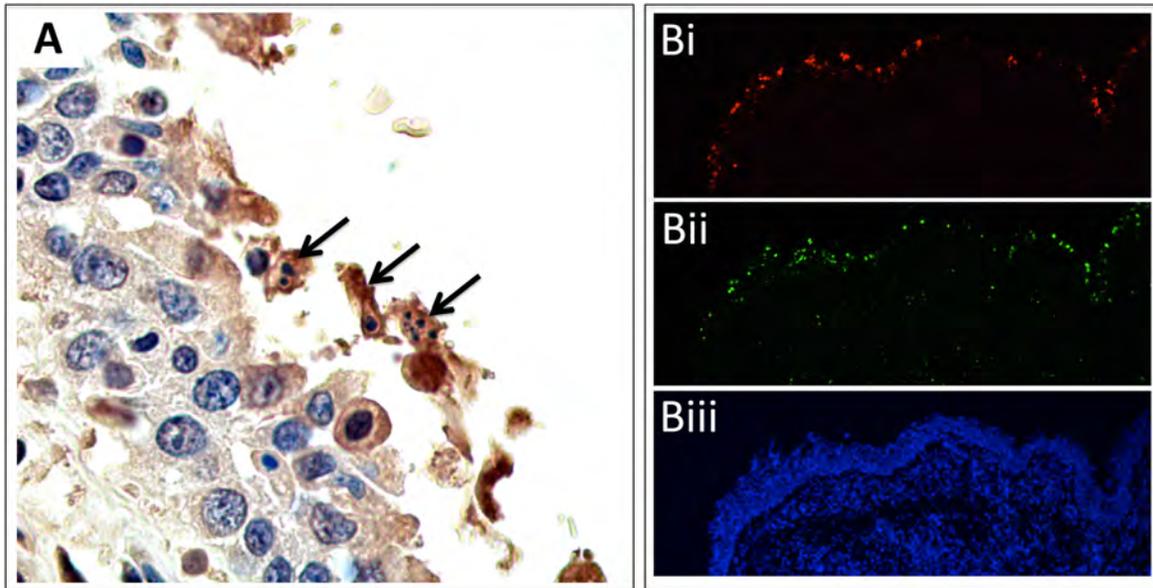

FIG 3 (A) Immunohistochemistry (IHC) of seal bronchus. Polyclonal antibodies were raised against H3N8 virus-specific HA antigen. Brown staining (DAB reporter system) indicates the presence of viral antigen. There is irregularity of the mucosal surface, with sloughed epithelium. IHC demonstrates the presence of viral antigen, pyknosis, and apoptosis (arrows). No viral antigen or apoptosis was seen on negative-control tissue. (Bi) ISH staining of H3N8 virus in lung epithelium (HA probe). (Bii) TUNEL staining (green) in the same region (serial section) of the lung, showing the presence of apoptotic cells. Comparison of virus and TUNEL staining shows localization of apoptosis to virally infected cells. (Biii) DAPI (with dihydrochloride) staining for cell nuclei.

avian host. Given this, we investigated whether seal H3N8 may have adapted and acquired an additional or increased affinity for the SA α -2,6 receptors that are more prevalent in mammalian respiratory tissue (20-23).

The pulmonary distribution of SA α -2,3 and SA α -2,6 influenza receptors was investigated using the receptor-specific lectins *Sambucus nigra* agglutinin (SNA) for SA α -2,6 and *Maackia amurensis* lectin II (MAL II) for SA α -2,3. SA α -2,6 was widely expressed in both infected and noninfected pulmonary parenchyma, with the highest concentration seen on endothelial cells, followed by alveolar/bronchiole epithelia (Fig. 2 and see Fig. S2 in the supplemental material). SA α -2,3 was also observed, but less frequently, and was generally limited to the luminal surfaces of epithelial cells of the bronchioles. This broadly agrees with the expression of these SA saccharides in humans and pigs (20-23) and demonstrates that seals do express receptors that would allow avian viruses to initiate infection. This observation is supported by the H3N3 seal virus from the 1991 epizootic (4), which was shown to preferentially bind SA α -2,3 *in vitro* (19). However, the limited prevalence of SA α -2,3 in the lower lung suggests that the process of infection is inefficient and may help to explain why epizootics of avian influenza occur but are infrequent in harbor seals.

Importantly, the rare expression of SA α -2,3 is insufficient to explain the diffuse infection seen throughout the pulmonary parenchyma (Fig. 2). In contrast, the wide distribution of SA α -2,6 is far more consistent with the level of infection observed. Costaining of infected lung with viral HA and SA α -2,3 or SA α -2,6 demonstrated clear infection of SA α -2,6-positive cells, in which no SA α -2,3 was seen (Fig. 2 and S3).

Hemagglutination assays were also performed to confirm sialic acid binding preferences. Seal H3N8 isolates were first sequenced to confirm that passage in eggs had not altered the HA phenotype detected in the infected tissues, and the viruses were then tested for

their ability to agglutinate erythrocytes that preferentially express SA α -2,3 (horse) or SA α -2,6 (guinea pig, pig) (24, 25), relative to several avian H3N8 viruses (Fig. 6). Average agglutination titers for seal H3N8 virus with horse erythrocytes (1:48) show that the virus can still bind to SA α -2,3. However, titers were appreciably higher with guinea pig (1:192) and pig (1:144) erythrocytes, demonstrating a preference for SA α -2,6. These findings show that seal H3N8 can use both avian and mammalian receptors and add to previous studies that have demonstrated changes in receptor preferences following a host switch event (26). The patterns of SA α -2,3 and SA α -2,6 binding to seal H3N8 virus also agree with the patterns observed for H3 avian viruses adapting to humans (18).

A further mutation was observed in HA, this time at position 110 (Table 1). In avian H3 viruses, phenylalanine (Phe/F) is consistently seen, while seal H3N8 uses Ser (F110S). The significance of this (if any) is currently unknown; however, previous work has suggested that this amino acid (position 110) is a critical component of the influenza fusion peptide (27), and given the essential role of fusion in viral replication and the host-specific differences that presumably exist in this process, the F110S substitution may well represent further adaptation of this virus to mammalian replication.

The ability of avian influenza viruses to adapt to SA α -2,6-mediated cell entry and replication is regarded as a significant driving force in the emergence of global pandemics (19, 28-30), especially for viruses with phenotypes that confer increased virulence. Such phenotypes are often, though not exclusively, dictated by mutations in segment 1 (PB2), which is an important determinant of host range for influenza viruses. Previous studies have experimentally demonstrated the effect of various PB2 substitutions on virulence and transmissibility in mammalian hosts (15, 31-38), including the modification of the aspartic acid (D) avian phenotype to an asparagine (N) mammalian phenotype at amino

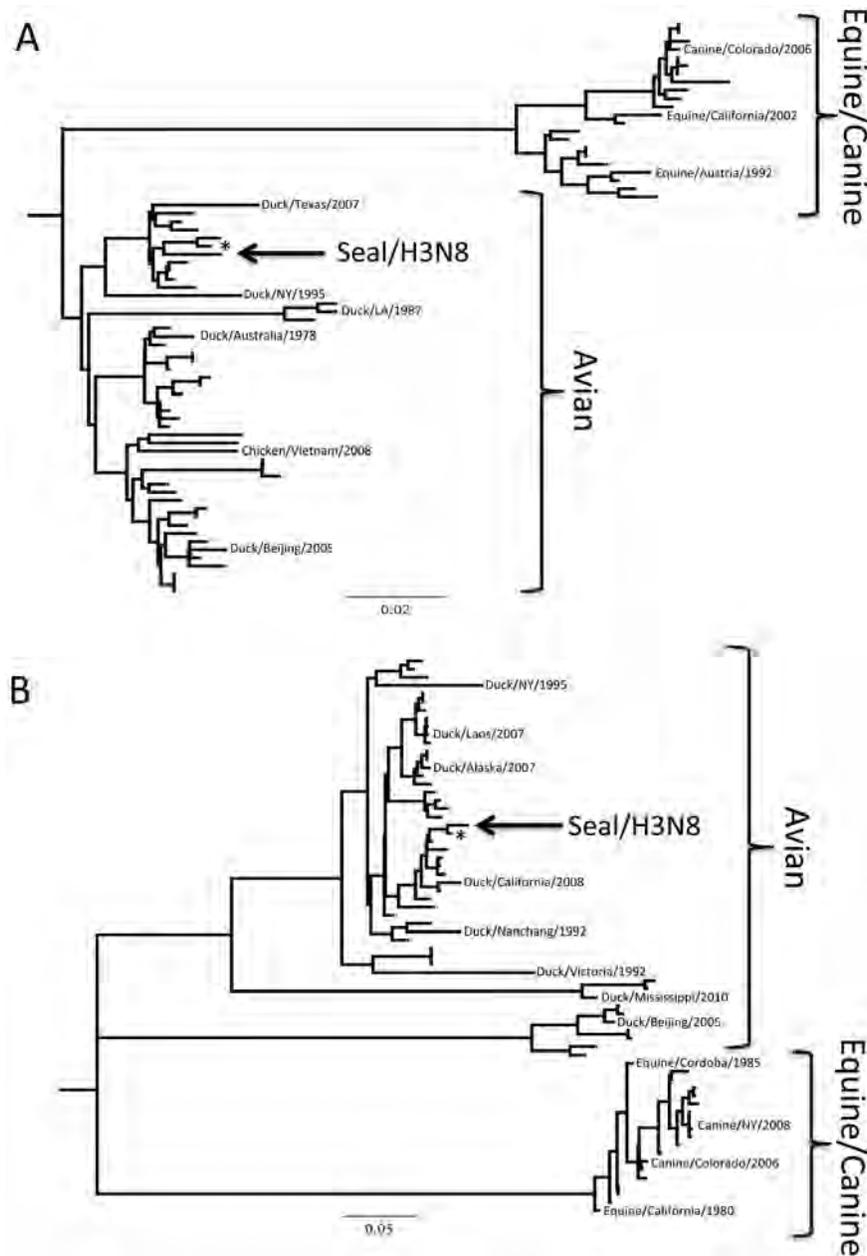

FIG 4 Phylogenetic trees of representative influenza H3N8 genome segments. Nucleotide sequence alignments for all genome segments were created using ClustalW, and trees were produced using neighbor-joining, maximum-likelihood, and Bayesian algorithms. Models of evolution were selected using ModelTest, and a tree was selected based on a consensus of the results of the three algorithms. Only the trees for HA and NA are shown; however, all eight segments showed strong association with sequences of avian origin. Trees are constructed with H3N8 viruses only, and published sequences were selected to represent variation in the year, host, and location of isolation. *, A/blue-winged teal/Ohio/926/2002; NY, New York; LA, Louisiana.

acid 701 (15, 31, 32, 36, 39, 40). This D701N mutation has been experimentally introduced into an adapted version of the H7N7 seal influenza virus isolated in 1982 (1, 2) and was shown to increase the pathogenicity of the virus to mice (32).

The seal H3N8 virus from the 2011 outbreak has naturally acquired this D701N substitution (Table 1), which was confirmed by clonal sequencing directly from infected tissue (50 clones/animal) to be the only phenotype present in all five animals. None of the previous outbreaks of influenza in seals showed this 701N phenotype, but it is consistently found in H3N8 viruses from

horses and dogs, demonstrating further adaptation to replication in mammalian hosts. These observations raise significant concern about the virulence and transmission of this virus between mammals. Interestingly, analysis of HA sequences over the course of the outbreak show the introduction and maintenance of two nucleotide polymorphisms (Table 2), and while this is insufficient to convincingly demonstrate seal-to-seal transmission, it leads us to postulate that mammalian spread might already have occurred.

Together, the adaptations observed in A/harbor seal/Massachusetts/1/11 suggest that it may be able to persist within the seal

TABLE 1 List of amino acid substitutions between seal H3N8 and avian H3N8 viruses^a

^a A total of 40 amino acid substitutions were observed in a comparison of seal H3N8 virus with avian H3N8 virus. Sequences of other seal influenza viruses, canine and equine H3N8 viruses, and selected human influenza viruses were included for comparison. Amino acid positions presented in parentheses represent corresponding H3 numbering. None, no sequence available for comparison; nt, nucleotide; aa, amino acid.

population and evolve into a new clade within the H3N8 group, as happened with the canine and equine viruses. An additional concern is the potential zoonotic threat that this virus poses, as it has already acquired mutations in both PB2 and HA that are often, though perhaps not exclusively, regarded as prerequisites for pandemic spread (19-23, 28, 30, 37) and it is uncertain how any persistence of the virus in mammals may continue to alter its phenotype. A comparison of A/harbor seal/Massachusetts/1/11 with human H3N2 viruses revealed three substitutions that are already common to both seal H3N8 and human H3N2 viruses. These are NA-W399R, PB2-I382V, and PA-S184N (Table 1). In all cases, these substitutions are shared by the seal H3N8 and human H3N2 viruses but are not found in influenza viruses isolated previously from seals, in avian, equine, or canine H3N8 viruses, or in either seasonal or pandemic H1N1 viruses. Further studies will be required to establish the functional significance of these substitutions; however, the natural epizootic emergence at this time of a

pathogenic virus that can transmit between mammals, found in a species that can become infected with multiple influenza virus subtypes, must be considered a significant threat to both wildlife and public health.

MATERIALS AND METHODS

Extractions, PCR, and sequencing. RNA was extracted from all tissues using Trizol reagent, and cDNA was synthesized using Superscript III (Invitrogen) according to the manufacturer's instructions. PCR for the detection of influenza A virus was performed using primers FLUAV-M-U44 (GTCTTCTAACCAGGTCGAAACG) and FLUAV-M-L287 (GCA TTTTGGACAAAAGCGTCTACG), to produce a 243-bp product of segment 7 (coding for matrix protein). For full-genome sequencing, full-length cDNAs were amplified for all eight influenza segments. Primers were designed to target terminal sequences for each segment, based on alignments of avian, canine, and equine H3N8 sequences from the Influenza Research Database (<http://www.fludb.org>). All PCRs were performed using fast-cycling chemistry (Qiagen), according to the manufac-

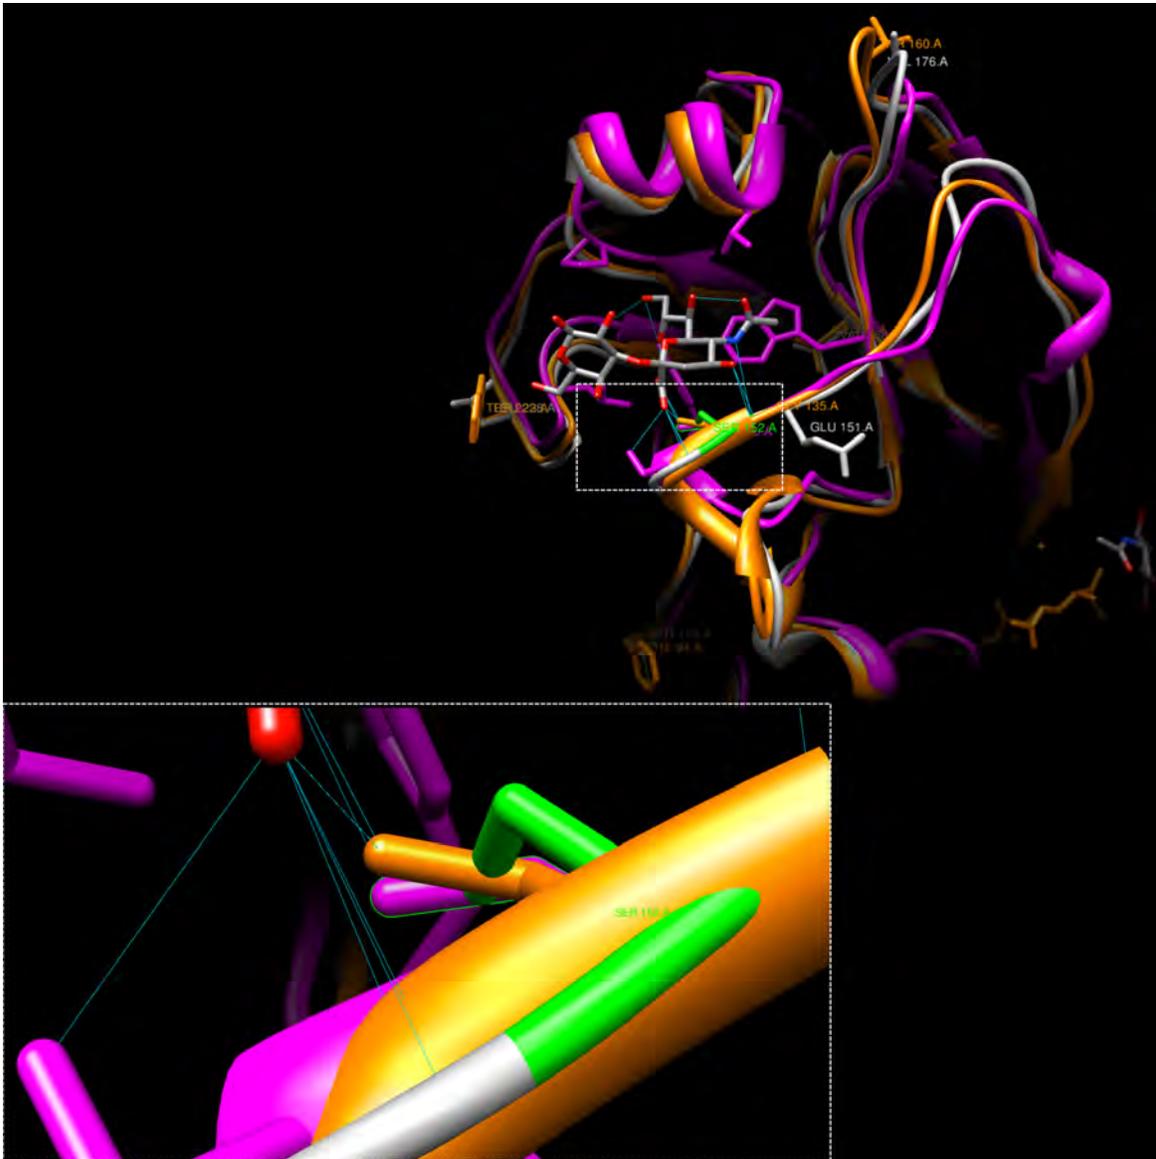

FIG 5 Structural-homology model showing the interaction of influenza HA with the SA α 2,3 ligand. Seal H3 (gray), avian H5 (orange) (Protein Data Bank [PDB] accession number 1J5O), and swine H9 (pink) (PDB accession number 1JSH) were compared. The mutation G151E causes a conformational shift and interrupts H bonding between seal H3 S152 and SA α 2,3, which suggests a reduction in SA α 2,3 binding efficiency. A lost H bond in seal H3 is depicted in green.

turer's instructions. Amplified products were cloned into the pGEM T-easy vector (Promega) and sent for commercial sequencing.

Virus isolation and intravenous pathogenicity index test. Homogenates from PCR-positive tissues were inoculated into SPF embryonated chicken eggs, and virus growth was determined by PCR. Tissue homogenates were also used to infect the Vero and MDCK cell lines in the presence of trypsin. Virus isolates were sent to the National Veterinary Services Laboratory (Ames, IA), where the chicken intravenous pathogenicity index test was performed according to the OIE manual (41).

Molecular pathology. Fluorescent *in situ* hybridization (FISH) was performed using the Quantigene ViewRNA ISH tissue assay (Affymetrix), according to the manufacturer's instructions. FISH conditions were optimized to include a 10-min boiling and 20-min protease treatment. Oligonucleotide probes were designed commercially by Affymetrix using sequences of HA and M (accession numbers JQ433879 and JQ433882, respectively). Immunohistochemistry (IHC) was performed by pretreating deparaffinized tissue sections with a 1:10 dilution of antigen retrieval

solution (DAKO) for 20 min in a steamer. Samples were then washed three times in distilled water (dH₂O), incubated in 3% hydrogen peroxide (in phosphate-buffered saline [PBS]) for 10 min, washed again twice in dH₂O and once in PBS, and then blocked (10% normal goat serum, 0.1% bovine serum albumin [BSA]) for 20 min. Sections were treated with HA polyclonal H3N8 antibody (Novus Biologicals; catalogue number NBP1-46796) at a 1:250 dilution for 2 h at room temperature. Following three washes in PBS, sections were incubated in Signal Stain Boost IHC reagent (Cell Signaling; catalogue number 8112) for 30 min at room temperature. Sections were again washed three times in PBS, stained with 3,3'-diaminobenzidine (DAB; Dako), and counterstained with hematoxylin. TUNEL staining was performed using the *in situ* cell death detection kit and fluorescein (Roche) with deparaffinization and protease treatment as described for the FISH protocol.

Simultaneous detection of SA α -2,3 and SA α -2,6 glycans. Deparaffinized tissue sections (5 μ M) were blocked with 1 \times Carbo-Free solution (Vector Laboratories; catalogue number SP-5040) for 1 h at room tem-

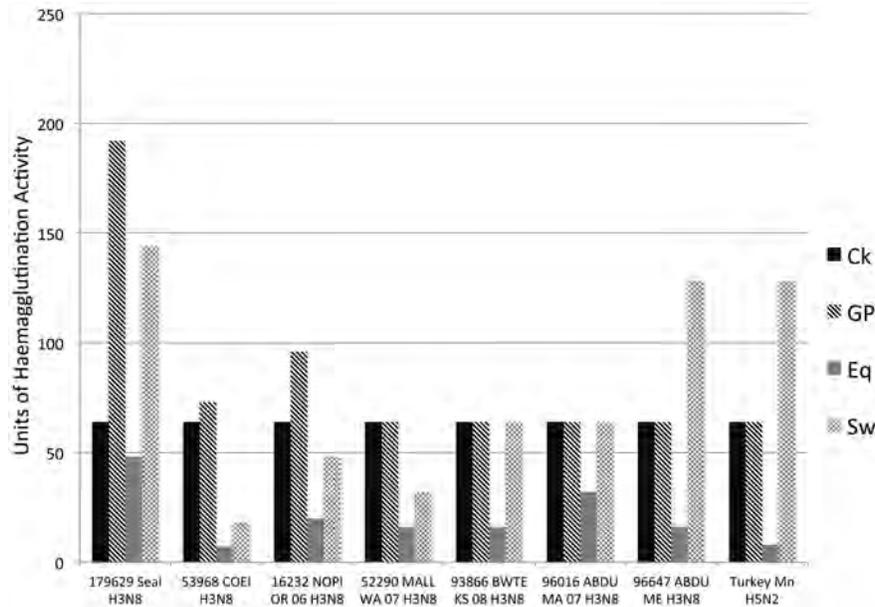

FIG 6 Hemagglutination assays were performed on an isolate of the H3N8 seal virus (A/harbor seal/New Hampshire/179629/2011) to confirm sialic acid binding preferences. Viruses were tested for their ability to agglutinate erythrocytes that preferentially express SA α -2,3 (horse) or SA α -2,6 (guinea pig, pig). Average agglutination titers for seal H3N8 with horse erythrocytes (1:48) show that the virus can still bind to SA α -2,3, though weakly. Titers were appreciably higher with guinea pig (1:192) and pig (1:144) erythrocytes, demonstrating a preference for SA α -2,6. Given that horse erythrocytes express SA α -2,3, it is interesting that the avian H3N8 viruses did not agglutinate with horse RBCs (red blood cells) efficiently, even following repeated attempts. Ito et al. (25) showed that avian H3N8 viruses from Asia in the early 1980s could bind to horse RBCs, while Wiriyarat et al. (43) gave examples of avian viruses (albeit not H3 viruses) that did not bind to horse RBCs. It is not known whether the avian viruses included here simply have a preference for the N-acetyl (NeuAc) sialic acid species, which is not found on horse RBCs, while the seal virus uses N-glycolyl (NeuGc) SA α -2,3. Ck, chicken; GP, guinea pig; Eq, equine; Sw, swine; 179629 Seal H3N8, A/harbor seal/New Hampshire/179629/2011; 53968 COEI H3N8, A/common eider/Massachusetts/20507-001/2007 (H3N8) virus; 16232 NOPI OR 06 H3N8, A/northern pintail/Oregon/44249-547/2006 (H3N8) virus; 52290 MALL WA 07 H3N8, A/mallard/Washington/44338-052/2007 (H3N8) virus; 93866 BWTE KS 08 H3N8, A/blue-winged teal/Kansas/44440-003/2008 (H3N8) virus; 96016 ABDU MA 07 H3N8, A/American black duck/Maine/44411-174/2008 (H3N8) virus; 96647 ABDU ME H3N8, A/American black duck/Maine/44411-532/2008 (H3N8) virus; Turkey Mn H5N2, A/turkey/Minnesota/3689-1551/1981 (H5N2) virus.

perature. Sections were then stained for SA α -2,6 using fluorescein SNA (Vector Laboratories; catalogue number FL-1301) at 10 μ g/ml for 30 min at room temperature, and rinsed twice for 3 min each time in PBS. Sections were then reblocked in 1 \times Carbo-Free solution for 30 min, before being stained for SA α -2,3 with 10 μ g/ml of biotinylated MAL II (Vector Laboratories; catalogue number B-1265) for 30 min at room temperature. The MAL II was poured off, and Texas Red streptavidin (Vector Labora-

tories; catalogue number SA-5006) was laid over the sections at 10 μ g/ml for a further 30 min. Sections were rinsed twice for 3 min each time in PBS and mounted with Vectashield hard-set mounting solution with DAPI (4',6-diamidino-2-phenylindole) counterstaining.

TABLE 2 Sequence analysis of the HA genes isolated from various tissues^a

^a Two polymorphisms were observed in HA at positions 1347 and 1499, relative to avian H3N8 sequence CY041887. Isolates from animals earlier in the outbreak showed C at position 1347 and C at position 1499. The variations C1347T and C1499A were observed in animal 295-Pv, in addition to the wild-type sequence. Animal 294-Pv showed only the variant genotype.

Hemagglutination assays. Hemagglutination assays were performed according to the WHO diagnostic manual (42). Briefly, red blood cells (RBCs) from rooster chicken, guinea pig, horse, and pig were obtained from Lampire Biological Laboratories (Ottsville, PA). The RBCs were washed in PBS and resuspended to 0.5% (chicken) or 0.75% (guinea pig and pig). Equine RBCs were resuspended to 1% in PBS with 0.5% BSA (43). Viruses were diluted to 64 HA units using chicken red blood cells. Serial dilutions were then made, added to equal volumes of washed RBCs of each species, and incubated in U-bottom plates, with the exception of chicken RBCs, which were incubated in V-bottom plates. Reaction mixtures were incubated at room temperature for 1 h, with the exception of those with chicken RBCs, which were incubated for 30 min. The HA titer endpoint is the reciprocal of the highest dilution which causes complete hemagglutination. The seal H3N8 virus was compared with several avian H3N8 isolates, including A/common eider/Massachusetts/20507-001/2007 (H3N8), A/northern pintail/Oregon/44249-547/2006 (H3N8), A/mallard/Washington/44338-052/2007 (H3N8), A/blue-winged teal/Kansas/44440-003/2008 (H3N8), A/American black duck/Maine/44411-174/2008 (H3N8), and A/American black duck/Maine/44411-532/2008 (H3N8). An H5N2 virus was also included: A/turkey/Minnesota/3689-1551/1981 (H5N2) virus.

Sequence analysis. Nucleotide sequences were aligned using ClustalW. Phylogenetic trees were constructed using neighbor-joining, maximum-likelihood, and Bayesian algorithms. Models of evolution were selected using ModelTest, and a representative tree was selected based on

a consensus of the results of the three algorithms. Published H3N8 sequences included in the analyses were selected to represent the diversity of year, host, and location of isolation.

Structural modeling. To create a homology model of the seal 2012 outbreak HA sequence, 10 template models were selected based on their super-secondary structures, with use of the LOMETS meta-threading approach (44, 45). Continuous fragments excised from these templates were then reassembled into full-length models by replica exchange Monte Carlo simulations (44). *Ab initio* modeling of threaded unaligned regions was then used to complete the structure. Low free-energy states were subsequently identified through clustering of simulation decoys by the SPICKER near-native model selection algorithm (46). Chimera was utilized for structural analysis and visualization (47). Hydrogen bonding analysis was based on geometric criteria established through survey of small-molecule crystal systems and Dunbrack rotamer libraries (48, 49).

Nucleotide sequence accession numbers.

The sequences of all eight influenza genome segments were submitted to GenBank and assigned accession numbers JQ433879 to JQ433882.

Attachments: [PREDICTII Consensus PCR Lab Protocols Mar 2017 - Priority Viral Families.pdf](#)

Hi Eric,

No problem! The strategy is super simple - there are standardized consensus PCR protocols targeting <700nt of the RdRp gene that were used by all of the PREDICT labs (attached) for each virus family. Recently there was a new paper that came out that suggested that the CoV consensus PCR assay we are all using misses Sars-CoV-2 and some other newly described viruses, and updated the primers. These are the ones we were talking about testing and potentially switching over to: <https://www.mdpi.com/1999-4915/13/4/599>

Most of the PREDICT work used these cPCR assays and kind of stopped there so we have quite a large number of viruses that were detected and ID'd as being something novel based on short RdRp sequences, but no further genomic characterization was done.

Let me know if you have any other questions or want to chat further about any of this :)

Best wishes,

Cadhla

Specific Aims

An important and frequently asked scientific question is whether bats are better hosts for lethal viruses than other mammals. There are a number of zoonotic viruses that cause high mortality in humans and originate in bats: SARS coronaviruses (SARS-CoV and SARS-CoV-2), Ebola virus, Marburg virus, Nipah virus, Hendra virus, and Middle East respiratory syndrome coronavirus (MERS-CoV). Further, there is increasing evidence that many other human viruses may have originated in bats, including measles, mumps and hepatitis C viruses. However, there is a lack the bat animal models necessary to study basic bat immunology and to conduct controlled and sophisticated viral infection studies. **These studies are invaluable to answering why bats appear to host viruses lethal to humans without any apparent outward disease.** Additionally, given the ability of bats to tolerate viral infections, studies elucidating the mechanisms behind these unusual traits could lead to new clinical approaches and therapeutics for humans affected by bat-borne viral diseases. Finally, the order chiroptera is diverse, comprising of over 1,300 species. A comprehensive understanding of bat immunology and physiology, as related to viral infection, will require bat animal models from multiple species.

We propose to establish sustainable breeding colonies of intermediate horseshoe bats (*Rhinolophus affinis*) and Indian flying foxes (*Pteropus medius*) in the United States that will facilitate research requiring live bats and bat-derived reagents, such as cell lines. In this project, we will import and establish breeding colonies of these species, creating two novel bat models that represent natural reservoirs of SARS-related coronaviruses and henipaviruses. This will create unprecedented opportunities to study host susceptibility and tolerance to high consequence pathogens such as SARS-CoV, SARS-CoV-2, and Nipah virus. Hundreds of SARS-CoV-like viruses have been detected in rhinolophid bats, thus susceptibility testing will allow us to identify susceptible species but only a few have been isolated and none have been used to challenge rhinolophid bats. While the exact host species of SARS-CoV and SARS-CoV-2 are currently unknown, multiple species of bats within the genus *Rhinolophus* have been associated with SARS-related coronaviruses, making any representative bat of this genus a high-value model for studying coronaviruses. Nipah virus is an emerging zoonotic virus with pandemic potential that causes near-annual outbreaks of fatal encephalitis in humans. The Indian flying fox is the natural reservoir of Nipah virus in South Asia, and is also host to more than 50 other viruses, including uncharacterized coronaviruses, paramyxoviruses, and filoviruses. This species is robust and readily colonized

Aim 1. To establish colonies of horseshoe bats and Indian flying foxes for the study of coronavirus and henipavirus infections. Bats will be captured and quarantined in Bangladesh and tested for coronaviruses, henipaviruses and filoviruses and lyssaviruses. Those that are negative will be housed in free-flight holding pens for adaptation to captivity. Offspring of these bats will be imported to Colorado State University for establishment of breeding colonies that will be provided to investigators performing infectious disease research.

Aim 2. To develop cell lines, reagents and methodologies for the study of viral infections in horseshoe bats and Indian flying foxes. Primary bat cells will be isolated from bats for viral susceptibility testing, and stocks of primary cells will be generated for the research community. Susceptible cells will be immortalized to provide indefinite propagation. Organoids of virus targets, such as intestines, will also be generated for virus studies. Recombinant proteins, including cytokines and soluble cell surface antigens, will be generated for in vitro and in vivo use. Monoclonal antibodies to these proteins will also be generated so that investigators can perform in vitro testing and generation of primary cells that require such growth factors, such as antigen-specific T cells, and for the in vivo neutralization of cytokines upon challenge with viruses. Methodologies for transcriptomic, metabolomic and proteomic studies will also be developed.

Aim 3. To perform experimental infections of bats with SARS-CoV-2, bat RaTG13-CoV and Nipah virus to develop laboratory models of bat reservoir hosts. Bats will be challenged with viruses under controlled laboratory conditions to perform kinetic and temporal studies of how these viruses behave in bats, and how the bats control infections without developing disease. We will also perform studies to assess durability of immunity in bats to determine whether immunity wanes and leads to repeated susceptibility to infection.

Commented [MK1]: Added this because we want to do proteomics and metabolomics. Also because my current understanding leads me to believe that bat physiology and flight are connected to bat immunology.

Commented [MK2]: I don't quite understand what this means.

Commented [S3R2]: Hopefully, this is clearer.

Commented [MK4]: Should we expand upon this a bit more – adding something about what goes in to developing these colonies and how we are prepared to do it.

Commented [MK5]: T-cells specifically mentioned here - I would add BM derived monocytes – those also require specific stimulatory cytokines and there is precedent for their successful isolation/development (Zhou et al., 2016). Facts I know you are aware of, I just thought they could be alluded to here.

Commented [S6R5]: We typically ship fresh or frozen bone marrow to others who then make macrophages and dendritic cells. I'll go into detail in the grant.

Commented [MK7]: To make this we require sequence information, correct? This can be synthesized?

Commented [S8R7]: The IFF genome is done. Getting cytokine sequences is very easy – we did it for *Artibeus* by culturing splenocytes overnight with concanavalin A and pokeweed mitogen, then did RNA-Seq. This led to dozens of full-length cytokine sequences (Kingfisher is making some of these for us now).

Commented [MK9]: Maybe something about single-cell sequencing (– I know everyone is doing it). We will have a bevy of different cell types and can pin point what is and isn't activated upon infection of susceptible cells. This could be critical for understanding viral maintenance.

Sort of an aside, but I think the possibility of trained immunity is quite interesting in relation to bats. (If this is a naïve/bad idea – feel free to ignore! I am an immunology novice.) IF there is any epigenetic or chromatin-remodeling that influences the innate immune response, single cell seq technologies that combine looking at chromatin changes or methylation, particularly for myeloid progenitors, could be revealing.

Commented [S10R9]: Lin-fa is designing those studies so if something needs to go in this Aim page we need to wait to see what he writes.

Research Strategy (must address sustainability of projects and resources)

A. Significance

Bats are found on every continent other than Antarctica and [they](#) are reservoirs or suspected reservoirs of many viruses, including coronaviruses, paramyxoviruses, filoviruses and lyssaviruses. In recent years, several bat-borne viruses have emerged that have caused substantial morbidity and mortality among humans. The COVID-19 pandemic is caused by severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2), a virus that [likely](#) originated in horseshoe bats (*Rhinolophus* species) commonly found in Asia. Frequent outbreaks of Nipah virus, hosted by *Pteropus* species bats, also occur in southern Asia, causing encephalitis that is usually fatal. In each of these virus/reservoir host relationships, virtually no disease occurs in the bats. Although numerous studies have been conducted on bats and viruses, many critical questions, such as the role of bats in maintaining and spreading potential zoonotic viruses and how bat immune responses control infections without disease, remain poorly defined. There is an urgent need to study these emerging zoonotic pathogens in their natural hosts to better understand their threats to humans. Unfortunately, there currently are few natural reservoir host models for the study of bat-borne viruses that are highly consequential to humans. This project aims to address this deficiency.

A.1. Bats as reservoir hosts of zoonotic viruses.

Generally, in zoonotic virus/reservoir host relationships, which have been best-studied in rodents and primates, each virus is hosted by one or a few [related](#) species [{Kitchen, 2011 #44}](#). Viruses, like all other biological entities, are subject to evolutionary pressures and are likely genetically and biochemically “optimized” to circulate within their reservoir host populations. [The process of “optimization” or co-evolution often results in persistent infection \(for the life of the host\) or replication and shedding of virus that allows for continual transmission to other susceptible hosts {Mandl, 2015 #43}. In both cases, the virus does not cause substantial disease within the reservoir host population. This is unsurprising, as a robust immune response in the reservoir could lead to viral clearance or immunopathology. When spillover of pathogenic viruses occurs, such viruses are not biochemically optimized for human hosts, which can have unexpected outcomes. In some cases, viral infection leads to disease and death, or alternatively, immune clearance. Because of the occurrence of severe human diseases caused by some of the bat-borne viruses, an important question is: how do bats host these viruses without becoming diseased? The answer to this question is likely complicated and will vary between species of bats and species of viruses. Each of these viruses encodes immune modulating proteins that often target the innate antiviral responses of infected cells of the host. It is thought that these proteins are contributory factors of human disease \(“virulence factors”\). However, because they evolved in their bat reservoirs \(i.e., “optimized”\), their impacts on the orthologous target proteins of humans must somehow be different, otherwise there would not be differential outcomes in bats \(no disease\) and humans \(disease\). \[Although bats share many immunological features with other mammals, little research into their immune systems and responses during infection with these viruses has been conducted. This is necessary to clarify why the response to viral infection differs between humans and bats.\]\(#\)](#)

Commented [MK11]: I like the gist of this section, but the first part could really apply to any reservoir host. The idea of unexpected outcomes is one I like, and I want to keep that, but maybe we can add more specifics about the unique immunological features of bats?

A.2. Coronaviruses. Historically, coronavirus infections of humans have been associated with mild colds that are typically resolved within several days. Unlike most other viral infections, coronaviruses fail to induce durable immunity, thus repeated infections of common cold coronaviruses can occur. However, since 2002, three novel coronaviruses have emerged from bats that have caused significant impacts on humans: SARS-CoV, MERS-CoV and SARS-CoV-2. SARS-CoV emerged in 2002 and caused a significant disease with high mortality in humans [\(11% case fatality rate - WHO\)](#); however, because most patients exhibited signs of disease prior to virus shedding, it was controlled quickly and ended within two years. In 2012, MERS-CoV emerged in the Middle East and causes a disease in humans similar to SARS-CoV but with a higher mortality rate [\(35% case fatality rate - WHO\)](#). Unlike SARS-CoV, MERS-CoV established in a secondary reservoir host, dromedary camels, in North Africa prior to its spillover into humans. Consequently, MERS outbreaks occur many times each year and nearly all outbreaks can be traced to contact with dromedary camels. SARS-CoV-2 emerged in late 2019 and is the etiologic agent of the ongoing COVID-19 pandemic. Both SARS-CoV and SARS-CoV-2 use ACE2 as cellular

Commented [MK12]: This goes from immunity straight to co-evolution, making it a bit abrupt. It doesn't quite connect the dots until the end. So, I rearranged it. You can obviously ignore what I did, and put it back, but I will stand by my comment about needing a better transition from immunity to co-evolution.

Commented [MK13]: I know this is a “lame” sentence.

entry receptors, and SARS-CoV-2 has been shown to infect many species. It is now evident that thousands of distinct coronaviruses circulate in bats throughout the world, and that hundreds of these are SARS-related CoV (SARSr-CoV) that circulate in rhinolophid bats. There are 78 known species of bats within the genus *Rhinolophus* and they are found throughout Asia and Europe. Recombination frequently occurs among coronaviruses, and this has likely contributed to the diverse pool of coronaviruses circulating in rhinolophid bats. Only a few bat coronaviruses have been isolated; nearly all are represented by sequences detected in bats. One bat coronavirus, RaTG13, shares a high degree of sequence similarity to SARS-CoV-2 (32015507). Its sequences have been detected in several intermediate horseshoe bats (*R. affinis*) that are found throughout southern Asia, including Bangladesh. Although there are no isolates of RaTG13, its complete genome has been determined (GenBank [MN996532](#)). Examination of ACE2 sequences from various rhinolophid species suggests intermediate horseshoe bats have the most "human-like" ACE2 for spike binding to the 20 ACE2 residues that are thought to be important (32239522, 31996437). Because of these features, we will focus our efforts on colonizing intermediate horseshoe bats.

A.3. Nipah virus (Jon).

A.4. Sustainability of the resource.

B. Innovation

B1. This project will be the first to establish bat breeding colonies for the infectious disease research community with species relevant to SARS coronaviruses and henipaviruses.

B2. We will determine basic clinical attributes of these bats to provide baseline readings, including body temperatures, hematology, serum chemistry and metabolic profiles.

B3. We will establish bat primary cells and immortalized cell lines for distribution to the research community.

B4. We will develop recombinant bat cytokines for the derivation of primary cell cultures, including endothelial cells, dendritic cells and T cells, and to use these cytokines for in vivo studies to manipulate immune responses during infection.

B5. We will generate monoclonal antibodies for the detection of cytokines, cell surface antigens and for in vivo cytokine neutralization and cellular depletion studies

B6. We will

C. Approach

C1. Preliminary Studies

C1.1. *Fruit bat colony at Colorado State University.* Dr. Schountz established a breeding colony of Jamaican fruit bats (*Artibeus jamaicensis*) in 2006 with previous NIH support (AI25489, AI089419) (Fig 1). This species is found in northern South America, the Caribbean Islands, Central America, and the Florida Keys. Adult bats have an average weight of 42 gm, a wingspan of 45 cm and body length of about 10 cm. Mature females produce two offspring per year, carry pups for about 40 days after birth, and can live up to 15 years in captivity. There are about 400 bats currently in the colony and about 100 to 150 new pups are born at 6-month intervals. Colorado State University has extensive animal expertise by virtue of its College of Veterinary Medicine and Biomedical Sciences, including veterinarians with experience with bats. **Thus, we have extensive investigator and institutional experience with bat husbandry and colony management.**

C1.2. *Candidate SARS-like coronavirus reservoirs.* Receptor incompatibility can pose a potent barrier to infection, preventing a virus from gaining access to the cell; a necessary step to initiate the replication cycle. There is ample evidence that one or a few amino acid substitutions at critical sites of interaction in cellular receptors can affect viral entry (Demogines, 2013 #45; Kaelber, 2012 #47; Ng, 2015 #42; Yan, 2010 #46). Angiotensin converting enzyme 2 (ACE2) is the reported receptor for SARS-CoV and SARS-CoV-2. Therefore, to initially assess the potential of rhinolophid bats as a reservoir for SARS-like coronaviruses we performed a

Fig. 1. Jamaican fruit bats in the CSU colony.

Commented [MK14]: Is this more about finding a bat model that will support SARS-CoV and SARS-CoV-2 infections?

Commented [MK15]: There is a paper that looks at polymorphisms within *R. sinicus* ACE2 and their effect on susceptibility to SARS-rCoV strains (Guo, 2020, JVI). The data is ok, and I believe it, but they do a wildly inappropriate evolution analysis (it's meant for between species and they do it on a within species set, which violates all the assumptions). The virology data is ok, their 0 timepoint of their qPCR is high (start with a lot of genomes) but they increase nicely over time, so it's alright. I sort of don't want to cite it because of the aforementioned issues, but it supports the idea that variation at the receptor can change susceptibility to a SARS-rCoV. Does anyone know of any other papers that do something similar with regards to bat ACE2?

Table 1. ACE2 amino acid identity amongst Rhinolophid bats and hosts supporting SARS-CoV-2.

Species name	Common name	Amino Acid in ACE2																				Amino Acid Identity
		24	27	28	30	31	34	35	37	38	41	42	45	82	83	330	353	354	355	357	393

alignment of all nine *Rhinolophus* species ACE2 sequences available in GenBank with Human ACE2 and ACE2 of known susceptible mammalian species. We specifically compared amino acid identities at 20 sites involved in spike binding (Table 1). Where available, sequences from multiple individuals were included.

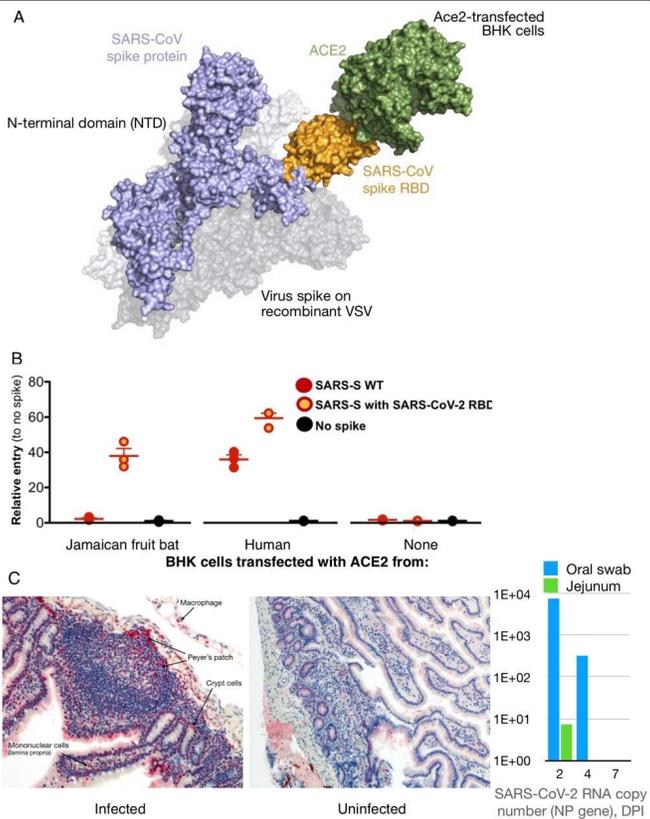

Strikingly, for those species where multiple ACE2 haplotypes are reported (*R. sinicus*, *R. pearsonii*, and *R. affinis*), multiple different amino acid identities are encoded at sites important for ACE2 binding (Table 1). In cases where there are multiple amino acids possible (e.g. Table 1, site 34), occasionally one amino acid matches the residue(s) encoded by humans. This apparent genetic variation reveals two important implications: 1) certain bat individuals may encode ACE2 receptors that are permissive to coronaviruses infecting humans while others of the same species do not, and 2) certain bat individuals may be more likely to harbor a SARS-CoV strain able to infect humans. We can capitalize on this naturally occurring variation through widespread capture, genotyping at loci of importance for coronavirus infection, and selective breeding to develop a colony of bats ideally poised for controlled viral infection and immunology studies.

Based on current ACE2 sequence data, the intermediate horseshoe bat and Pearson's horseshoe bat (*R. pearsonii*) encode the same amino acids as human at 16 of the 20 residues important for ACE2 binding. The Least horseshoe bat (*R. pusillus*) has 14 matching residues. These three species are found in Bangladesh (Table 1). While no bat species encodes the same 20 residues as human, both domestic cats (16 matches) and ferrets (14 matches) are susceptible to SARS-CoV-2, suggesting that all three Bangladeshi species may harbor permissive ACE2 receptors. Intermediate horseshoe bats (16 matches) are widely distributed in southern Asia, including Bangladesh as well as southern China where most of the SARS-CoV sequences have been detected in rhinolophid bats. For this reason, we believe this is the most logical species to capture for susceptibility testing and model development. However, because there are 78 rhinolophid species, we will also capture the other species that are found in Bangladesh (*R. lepidus*, *R. malayanus*, *R. monoceros*, *R. humanus*, *R. luctus*, *R. subbadius*) for importation and SARS-CoV-2 susceptibility testing at CSU.

Commented [MK16]: Maybe a figure showing the species ranges and our proposed site of the Bangladeshi bat colonies?

C1.3. Experimental bat coronavirus infections. Drs. Munster and Schountz have extensive experience with experimental infection models of bats, including with MERS-CoV, SARS-CoV-2, H18N11 bat influenza virus, Zika virus and Tacaribe virus. Challenge of Egyptian fruit bats with an infectious clone of WIV-CoV showed limited susceptibility, despite the ability of its spike protein to bind to Egyptian fruit bat ACE2 (30572566). Recent work by our groups has shown that Jamaican fruit bat ACE2 is bound by SARS-CoV-2 (but not SARS-CoV) spike protein expressed by a VSV pseudotype virus and that challenge of Jamaican fruit bats with SARS-CoV-2 leads to a limited infection that is confined to the small intestine, particularly mononuclear cells of the Peyer's patches and lamina propria, and crypt cells (Fig 2). Viral RNA was detected in oral swabs for 4 days and low

Fig. 2. Infection of Jamaican fruit bats with SARS-CoV-2. Model of SARS-CoV-2/ACE2 receptor (A). BHK cells transfected with Jamaican fruit bat ACE2 cDNA are susceptible to pseudotyped VSV expressing SARS-CoV-2 spike protein (B). Experimental challenge of Jamaican fruit bats with SARS-CoV-2 showed abundant viral antigen in mononuclear cells of the Peyer's patches and lamina propria that are likely macrophages, as well as intestinal epithelial cells and crypt cells, with detectable vRNA for up to 4 days in oral swabs (C).

levels in the small intestine on day 2. However, no neutralizing antibody or nucleoprotein antibody (ELISA) was detected, suggesting abortive infection or robust control of the virus by the innate immune response.

C1.4. Proteomic detection of bat cytokines. We used mass spectrometry to detect several cytokines in trypsinized supernatants of Jamaican fruit bat spleen cells incubated overnight with concanavalin A, including IL-4, IFN γ , IL-2, IL-6, IL-10 and TNF. Assays were conducted on the Acquity UPLC (M class) coupled to a Xevo TQ-S (Waters) MS (housed in the Proteomics and Metabolomics Facility at CSU). The results (Fig. 3.) demonstrate our ability to identify 5 peptides from 4 cytokines in a single experiment and proof of feasibility for the work proposed herein.

C1.5. Detection of NK cells in Jamaican fruit bats. We have screened more than two dozen monoclonal antibodies for cross reactivity to bat cells and have identified only a few. One of these recognizes NK1.1 on bat spleen cells (Fig 4) and this clone has been used to deplete NK cells in mice (9570522). If this antibody also depletes NK cells in bats, it will allow us to scrutinize the role of NK cells during infection. Of particular interest, bats have a substantially higher number of NK activation and repression genes relative to other mammals, suggesting they may play a more important role in bat immunology than in other species (29706541).

C2. Specific Aims

Outreach. We will alert potentially-interested investigators about the resources established by this R24 by personal communications with those publishing in coronavirus/henipavirus research, announcements at conferences, and establish a web site that provides information about the colonies. For security reasons, the web site will be restricted to investigators who request access and will be password protected. **Need more here**

C2.1 Aim 1. To establish colonies of horseshoe bats and Indian flying foxes for the study of coronavirus and henipavirus infections. Bats will be captured and quarantined in Bangladesh and tested for coronaviruses, henipaviruses, filoviruses and lyssaviruses. Those that are negative will be imported to Colorado State University for establishment of breeding colonies.

Formatted: Highlight

Formatted: Font: Not Bold

C2.1.1. Establishment of captive breeding colony of *Pteropus medius* in Bangladesh.

We will establish a captive breeding colony of *Pteropus medius* in Bangladesh. Temporary holding cages used for quarantine prior to shipment to the US will be erected at the Sheikh Kamal Wildlife Center (SKWC) Purabari, adjacent to Bhawal National Park, Gazipur, north of Dhaka. The land is managed by the Forest Department under the direction of the Conservator of Forests (see Kabir letter of support) Ministry of Environment (Govt of Bangladesh). The bats will be cared for and maintained by Forest Department staff. Staging bats in Bangladesh prior to shipment to the US will occur in X phases.

Phase 1: Holding cage development. We will build four temporary holding cages [octagonal shape, approx. 6m diameter and 6ft tall] that are large enough to allow bats to fly, and low enough that project personnel can easily repeatedly catch bats for testing during the screening process. Each cage will be built to hold 30 bats, with a heavy retractable curtain subdividing each cage in half, which will allow us to separate bats into smaller groups. One of the cages will be left empty to allow for isolation of bats that test positive for Nipah virus on PCR during the course of quarantine. Each cage will be made from a metal frame with rubber-coated mesh screening enclosing the cage. An outer cage will be built around each cage, with 6" of space between the fencing to exclude bats inside from contact with bats outside. A solid roof will be built over each cage to prevent excreta from wild bats from entering the cage area and potentially exposing captive bats to henipaviruses. Each cage will also have a door and an anti-chamber to allow staff to safely enter and exit, don and doff PPE, and then enter the flight cage without bats being able to escape.

Facilities at the wildlife park where the bats will be held will include a food preparation station, PPE storage, first aid and disinfection supplies, and a mobile veterinary lab that includes electricity, a portable gas anesthesia machine, and supplies for collecting biological specimens from the bats.

Phase 2: Bat capture. We will capture wild bats from colonies located in Gazipur. Our goal is to capture a total of 81 bats: 6 males and 75 females comprising three groups of 25 females and 2 males - all Nipah virus negative (by PCR and Luminex). We will capture bats 20 at a time. With each group of 20 bats, we will transport them to the cages from the field site, with each bat held in an individual cotton bag suspended from a post in the back of a vehicle. The driver will be wearing PPE, including an N95 respirator, and all vehicle windows will be open during transport. A plastic sheet will line the floor of the vehicle under the bats to allow for disinfection following transport. Bats will be sampled in the vet lab and then immediately transferred into a holding cage and blood samples and swabs collected. Samples will be screened that day for IgG antibodies using a Luminex, and swabs will be screened for Nipah virus RNA using a qRT-PCR assay at icddr. Seropositive and or PCR positive individuals will be released at the park. Seronegative and PCR negative individuals will be moved into a second staging cage, where they will be held for 21 days, with a second and third round of testing on day 10 and 21 post capture. Any bats subsequently testing positive will be released. Negative bats will be retained.

Phase 3: Breeding colony. We will maintain separate groups of 27 bats in the three flight cages. *Pteropus medius* is a synchronous seasonal breeder, with a 6-month gestation period. We will aim to capture bats during the third trimester of pregnancy (January/February) and allow them to give birth in captivity. Pups will be weaned at 3 months and placed

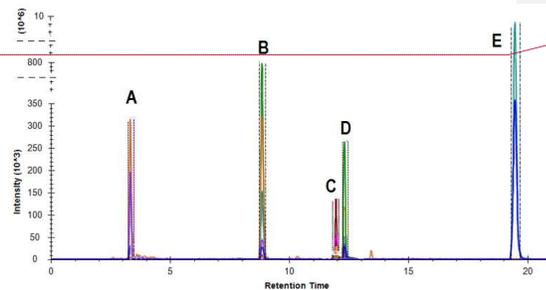

Fig. 4. Detection of bat cytokines using unrefined targeted MS assay. The following peptides were detected in bat cell supernatant after mitogen-stimulation: A. IL-10: FLPCENK, B. IL-4: SLSGLAGQNT, C. IL-6: RDGCFQSGFNEK, D. IFN- γ : AINELIRVMHELTGPNLR, E. IL-10: AAFSMVK.

Commented [MK17]: I assume the holding cages will be different for the rhinolophid bats, but the capture methods will be the same?

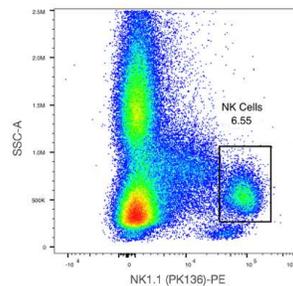

Fig. 3. Detection of NK cells in Jamaican fruit bats. Anti-mouse NK1.1 (clone PK136) was used to stain Jamaican fruit bat splenocytes and allows identification of NK cells in bats. In mice, this antibody depletes NK cells, thus it may be useful for depleted bat NK cells to allow examination of their roles in viral infections.

into a fourth cage, where they will be maintained until 1 year of age. Pups will be screened every 2 weeks for Nipah virus and antibodies. Maternal antibodies are expected to wane at around 6-7 months of age. By isolating the pups, born to seronegative, Nipah-negative dams, we will create an SPF (specific-pathogen free) colony that will be used to found the colony at CSU. We will also allow the bats in Bangladesh to breed, creating an F1 generation that will be maintained in captivity and used to support the US-based colony.

C2.1.2. Experimental challenge of rhinolophid bats. We will determine whether Ace2 sequences from various *Rhinolophus* species bats render BHK cells susceptible to SARS-CoV and SARS-CoV-2 using our VSV pseudotype system (Fig XX). Rhinolophid species will be captured and quarantined in Bangladesh and tested for evidence of SARS-like CoV infection (PCR of rectal swabs and serology). Naïve bats will be shipped to Colorado State University for challenge with SARS-CoV and SARS-CoV-2 to determine susceptibility. Those species that are susceptible will be collected in Bangladesh and after quarantine and testing, up to 50 founders will be shipped to CSU to establish breeding colonies. In the event that more than one species is susceptible, we will determine which is most suitable based upon infection kinetics of each virus.

Upon receipt, bats will be immediately examined by veterinary staff at CSU and manually fed meal worms.

C2.2 Aim 2. To develop cell lines, reagents and methodologies for the study of viral infections in horseshoe bats and Indian flying foxes. Primary bat cells will be isolated from bats for susceptibility testing, and stocks of primary cells will be generated for the research community. Susceptible cells will be immortalized to provide indefinite propagation. Organoids of virus targets, such as intestines, will also be generated for virus studies. Recombinant proteins, including cytokines and soluble cell surface antigens, will be generated for in vitro and in vivo use. Monoclonal antibodies to these proteins will also be generated so that investigators can perform in vitro testing and generation of primary cells that require such growth factors, such as antigen-specific T cells, and for the in vivo neutralization of cytokines upon challenge with viruses. Methodologies for transcriptomic, metabolomic and proteomic studies will also be developed.

C2.2.1. Establishment of primary and immortalized bat cell lines. We will generate primary cells from (Tony)

C2.2.2. Production of recombinant bat cytokines and monoclonal antibodies. Recombinant horseshoe bat and Indian flying fox cytokines will be generated. Codon optimized genes will be designed from bat genomic sequences and available splicing data and synthesized by Genscript and sequence verified by Genewiz. Cytokine genes will be produced in *E. coli*, baculovirus infected SF9 cells or human 293-Freestyle cells, depending on existing literature from other systems. For example, soluble active human CD4 has been successfully produced in *E. coli* (2187501), providing a starting point for production of bat CD4. Recombinant his-tagged human CD20 is commercially available from *E. coli* and human 293T cells (Sinobiologicals), indicating that bat CD20 may be producible in a similar fashion. Cytokine genes will be cloned into appropriate expression vectors (pET28a for bacteria, pFastBac for baculovirus expression, pcDNA3.1 for mammalian expression) with purification tags (6xHis/GST) and fusion partners (thioredoxin/Sumo) to aid folding as necessary. Proteins will be expressed in appropriate cell types (e.g. BL21 pLysS *E. coli*, SF9 insect cells for baculovirus expression, 293Freestyle for mammalian expression). Expressed protein will be purified on AKTA Start FPLC systems using appropriate affinity chromatography columns including nickel columns, ion/anion exchange columns, or glutathione columns. Affinity purified proteins will be further purified using Superdex 200 size exclusion chromatography to select for monomers or dimers of the recombinant protein as needed. Following purification, proteins will be tested for activity and storage/stability of each protein will be optimized to maximize activity and protein life-span. The identity of purified proteins will also be verified by Orbitrap mass spectrometry at the CSU ARC-Bio proteomics core facility.

We will also produce soluble versions of CD4, CD8 β and CD20 proteins for both bat species; these will be used to generate monoclonal antibodies as described below so to provide reagents for detection of helper T cells, cytotoxic T cells and B cells, respectively, by flow cytometry on splenocytes. We will also screen these antibodies for the abilities to deplete these subsets in vivo so that examination of the role of these cells can be performed.

Monoclonal antibodies will be generated as we previously described (32908982). Briefly, recombinant cytokines and soluble CD antigens will be emulsified in Sigma Adjuvant System and used to immunize female BALB/c mice using the CSU Veterinary Service Core. After biweekly boosting and determination of high antibody

titers by ELISA (cytokines) and flow cytometry (CD antigens), mice will be given a final dose of respective antigens in PBS, then euthanized 4 days later for fusion to Sp2/0 Ag14 myeloma cells using the ClonaCell™-HY Hybridoma Kit (Stem Cell Sciences). Cells are plated on methylcellulose containing HAT medium, which allows concurrent selection and cloning during 2 weeks of incubation. Clones will be picked and screened for production of antibodies specific to cytokines (ELISA) and CD antigens (flow cytometry). For cytokine-specific antibodies, we will identify suitable pairs of monoclonal antibodies that can be used for capture ELISA (pg/ml sensitivity) and neutralization (for in vitro and in vivo use). Antibodies to CD antigens will be tested in live bats for their abilities to deplete CD4+ helper T cells, CD8β+ cytotoxic T cells, and CD20+ B cells.

C2.2.3. Development of metabolomic profiles. ([Lin-fa and Rushika](#))

C2.2.4. Development of proteomic profiles. ([Lin-fa and Rushika](#))

C2.3 Aim 3. To perform experimental infections of bats with SARS-CoV-2, bat RaTG13-CoV and Nipah virus to develop laboratory models of bat reservoir hosts. Bats will be challenged with viruses under controlled laboratory conditions to perform kinetic and temporal studies of how these viruses behave in bats, and how the bats control infections without developing disease. We will also perform studies to assess durability of immunity in bats to determine whether immunity wanes and leads to repeated susceptibility to infection.

C2.3.1. Experimental infection of horseshoe bats with SARS-CoV-2. We have previously performed MERS-CoV and SARS-CoV-2 infection experiments with Jamaican fruit bats (26899616) (Fig XX). In year 1, we will capture rhinolophid bats in Bangladesh for quarantine, testing for evidence of coronavirus infection, and identification of coronaviruses that might be harbored by the bats. Those that are uninfected and seronegative will be shipped to CSU for immediate challenge with SARS-CoV-2 to determine species susceptibility and inform species of interest for colonization. Only one reference genome for a *Rhinolophus* species is available (*R. ferremuquium*); however, it is likely that most genes will be of high enough similarity for use with the species that we expect to capture in Bangladesh.

Six bats of each species will be challenged with SARS-CoV-2, whereas three bats of each species will be held as negative controls. At two-day intervals, rectal and oral swabs will be collected in virus transport medium from each bat for RNA extraction and virus isolation. At seven-day intervals, 100 ul of blood will be collected from the wing vein for serological analysis using a microbead flow cytometric assay we have developed for SARS-CoV-2 (33083807). Bats will be euthanized at day 21 for necropsy, thus providing 4 serological time points per bat (days 0, 7, 14, 21). We previously determined that MERS-CoV replicates in the lungs, liver, spleen and intestines of Jamaican fruit bats, and that SARS-CoV-2 replicates in the intestines only (Fig XX). We will extract RNA from each tissue for detection of vRNA and attempt virus isolation from those tissues that possess vRNA.

Based upon this preliminary study, we will assess the susceptibility of each species to SARS-CoV-2 and use the information from this study to determine which species is most likely a suitable model for the study of SARS-CoV-2 reservoir host. This species will be used to establish the breeding colony as a resource for the coronavirus research community. We will also assess host immunity on bats by using immunosuppressants that target the type I IFN response (fludarabine), T cell response (cyclosporine A) and general immunosuppression (dexamethasone).

In years 3-5, challenge studies will be performed to determine target cells of SARS-CoV-2 infection and immunosuppress bats during SARS-CoV-2 challenge. It is evident that coronaviruses replicate in the intestines of bats; however, it is unknown which cells are targets. Thus, it will be necessary to perform single cell RNA-Seq of infected cells to identify the gene expression profiles of target cells, which will clarify susceptible cells. Once target organs are identified in the Year 2 study described above, we will infect bats and collect targeted tissues and organs to prepare single cell suspensions as we describe with SARS-CoV-2 challenged African green monkeys (33431511). Briefly, target organs will be minced and digested with DNase and Liberase TM, subjected to AKC RBC lysis, and filtered for individual cells for use with 10X Genomics Chromium platform (10,000 cells per sample). The RNA Seq data will be processed through the cellRanger pipeline for gene expression analysis and cell identification with the FindMarkers component of Seurat R package (31178118).

We will use dexamethasone (Dex), fludarabine and cyclosporine A (CyA) to immunosuppress bats and challenge with SARS-CoV-2. (Our experience is that a combination of Dex and cyclophosphamide leads to pathological expansion of the microbiota and compromises the health of bats.) Dex is a general immunosuppressant that acts upon a variety of immune cells, including all T cell subsets, B cells and impairment of macrophage maturation; fludarabine is a STAT1 inhibitor that suppresses type I IFN receptor signaling; and cyclosporine A disrupts T cell activation. We will use these immunosuppressants to assess how they influence SARS-CoV-2 infection, with an expectation that they will each lead to increased virus replication and shedding and, perhaps, a disease phenotype. Samples will be collected to assess infection kinetics and host responses during infection.

We will also perform challenge studies with the rescued RaTG13 virus described below. Because this virus genome was discovered in *R. affinis* bats, a species commonly found in Bangladesh, we are confident that this species will be susceptible upon experimental challenge. Importantly, with the development of an infectious clone, we will solicit R01 funding to develop this project independently of the R24 once we have demonstrated susceptibility.

Caveats and Extensions. The principal concern is that none of the bat species are susceptible to SARS-CoV-2. We think this is unlikely, given the high similarity of the important ACE2 residues (Table 1) that mediate spike binding. As extensions, we can also challenge the bats with SARS-CoV (Dr. Schountz's lab staff and BSL-3 are Tier 1 Select Agent approved) and MERS-CoV.

C2.3.2. Experimental infections of Indian flying foxes with Nipah virus. In year 1, pregnant Indian flying foxes bats will be captured and held in Bangladesh to verify they are not infected to Nipah virus (as described above). Pups born in captivity will be shipped to RML for use in initial infection studies in Year 2 of the grant. This work will be supervised by Dr. Munster. After baseline infection kinetics have been determined, we will perform subsequent challenge studies to better assess virus distribution using mCherry-labeled virus (which retains fluorescence after fixation, 26781134), to identify specific target cells by single-cell sequencing (24023909) and impact of immunosuppression on the response to Nipah virus. An annotated [reference genome](#) for the Indian flying fox is available (32849415) and will be used for transcript identification.

We will follow our previous experimental strategies for experimental infection of bats (31527796, 30716104, 26899616, 22379103, 31682727). The first experimental challenge of Indian flying foxes will occur in year 2. Bats born in captivity at the Bangladesh holding facility will be shipped directly to RML, which has animal BSL-4 capacity. For this initial study, 18 bats of both sexes will be used. Bats will be housed in cages specifically designed for BSL-4 use at RML. They will be anesthetized and inoculated intranasally with 10^5 TCID₅₀ of a Bangladesh isolate of NiV that is maintained as a stock at RML. Bats will be recumbently positioned during inoculation to ensure delivery of virus to the trachea and esophagus (i.e., lung and GI delivery). Three unchallenged bats will be cohoused with inoculated bats beginning 2 days after challenge (contact transmission study) and three bats will be held as uninfected negative controls. At 2 day intervals, oral and rectal swabs, and urine samples will be collected for virus detection. On days 2, 6, 10 and 20, three bats will be euthanized for necropsy, and the contact and negative control bats will be euthanized on day 21. At euthanasia, whole blood and serum will be collected for hematology, serum chemistry and serology studies. Tissues will be partitioned, with some flash-frozen in liquid nitrogen for virus isolation and RNA extraction, and others in buffered formalin for immunohistochemistry, RNA-Scope for vRNA and histopathology.

As described above, we will also assess the role of the immune response with use of immunosuppressants to determine if viral loads are elevated and whether clinical signs of disease occur.

Caveats and Extensions.

C2.3.3. Generation of bat RaTG13-CoV infectious clone. Reverse genetics have been used as a powerful tool to generate infectious clones of SARS-CoV, SARS-CoV-2 and MERS-CoV (32526206, 28377531, 24043791, 32978313, 32289263). To rescue recombinant RaTG13 we will follow methods previously described to generate SARS/MERS-CoV full-length genome cDNA (24043791, 14569023, 12368349, 18818320, 19036930). Six contiguous RaTG12 cDNA fragments will be synthesized and the contiguous cDNA fragments will then be ligated

into a full-length cDNA using a subcloning strategy with *Bgl*I class II restriction endonuclease sites. The ligated cDNA product under T7 promoter control will then be electroporated into a co-culture of mammalian cell lines (Vero, BSR-T7) along with T7 RNA polymerase and a nucleoprotein expressing vector to enhance replication efficiency. To construct neonGreen fluorescent protein (GFP) and red fluorescent protein (RFP) reporter viruses, the ORF7a/7b sequence will be replaced with GFP or RFP sequences as previously described (16306622, 32289263). The same simultaneous ligation strategy will be employed to generate the full-length cDNA of RaTG13 GFP/RFP variants. Cytopathic effects and plaques will be monitored for 24 – 72 hours post-transfections; duplicate wells will be a) stained with anti-SARS-CoV nucleoprotein secondary antibodies for intracellular detection of RaTG13 infectious clone replication and b) lysed and cells/cell-culture supernatant will be passaged to fresh Vero cells for amplification of the virus stock. Replication kinetics and titers of infectious clone RaTG13 and reporter virus variants will be monitored by standard plaque assays and/or measurement of fluorescent plaques. Recombinant RaTG13 infectious clones will be sequenced with at least 2X coverage to ensure fidelity after passaging on Vero cells. A mammalian cell line will be transfected with human and bat ACE-2 orthologues to allow functional characterization of infectious clones of RaTG13 receptor-usage for cellular entry. Virus genome sequencing will be performed after passage to verify sequence integrity, as we have previously described (32793912).

Caveats and Extensions. In the event a novel SARS-CoV sequence is discovered in quarantined rhinolophid bats in Bangladesh, the virus will be considered as a candidate for infectious clone development, especially if it is commonly found in a particular species of *Rhinolophus* bat (i.e., putative reservoir host/virus model).

C2.3.4. Detection of virus specific antibodies in experimentally-challenged flying foxes and horseshoe bats.

Whether bats develop long-lasting adaptive immune responses to viruses remains unknown. Egyptian fruit bats, natural hosts of Marburg virus and Ravn virus (19649327), challenged with Marburg virus seroreverted to undetectable levels three months after infection (28821722). Virus-specific antibody responses are surrogates of predictive protection or correlates of protection for nearly all vaccines. Here, we will establish primary and secondary humoral responses to virus infections in two virus-host models: NiV-flying foxes, RaTG13-horseshoe bats. Utilizing multiplex serology strategies that our groups have developed for NiV and coronaviruses (32034942, 31671094, 33083807) we will capture bat immunoglobulin (Ig) G and IgM with virus envelope/spike glycoprotein antigen-based assays. The kinetics, magnitude and duration of virus-specific flying fox and horseshoe IgG/IgM will be monitored longitudinally for seroconversion, seroreversion and anamnestic boosting after secondary infection. Population-level biosurveillance of NiV and other emerging zoonotic viruses relies on susceptible-infected-recovered models to understand the spread of these viruses among wildlife hosts. Experimental establishment of longevity of virus-specific bat IgG-responses will provide valuable information for ongoing biosurveillance projects focused on the transmission/spillover dynamics of emerging zoonotic viruses in wildlife host populations and communities.

Caveats and Extensions.

Vertebrate Animals

Description of Procedures:

Housing of Bats at Colorado State University

Indian flying foxes. During year 1 of the grant, CSU will renovate a building at the Foothills Campus to house the flying foxes. This building is approximately 300 meters from the Center for Vector-borne Infectious Diseases, where Drs. Schountz and Perera laboratories are located. It has approximately 2500 ft² and will include an anteroom where a sink, food prep area, refrigerator and freezer will be used for food preparation. The diet for the bats will be composed of apples, bananas, cantaloupe pear, grapes, carrots, sweet potato and kale, sprinkled with HMS Bat Supplement, which contains essential vitamins and minerals. This dietary formulation has been provided to by Brian Pope at the Lube Bat Conservancy in Gainesville, FL who will also provide expert guidance for maintaining the breeding colony (letter of support provided). Free-choice salt licks will be provided. Enrichment, including artificial tree branches, landscape fabric, skewers for hanging fruit (i.e., stimulation of foraging behavior) will be included. The facility will have 4 meter ceilings to permit free-flight, with a capacity to house 25 bats for the breeding colony, with room for an additional 20 bats for short-term holding. This will allow us to import additional bats that will not be used for breeding, but instead for acclimation and veterinary health check after importation, and prior to shipment from CSU to other investigators that will require bats for their research projects (e.g., RML, UTMB, NEIDL, etc.).

For breeding purposes, we will have 5 males and 20 females. Flying foxes produce one offspring per year and these offspring will be distributed to the research community for experimental work. When breeders are retired, offspring will be used to replenish the breeding colony.

Horseshoe bats. Horseshoe bats are insectivorous and usually require dietary adjustments to maintain in breeding colonies. Elizabeth Falendysz, a veterinarian with the US Geological Survey in Madison, WI, will provide guidance for colonizing horseshoe bats (letter of support provided). She has maintained a breeding colony of insectivorous big brown bats (*Myotis lucifugus*) for several years as part of the USGS's white nose syndrome research. Bats will be maintained in a free-flight room at the Center for Vector-borne Infectious Diseases at CSU. This facility was constructed in 2020 and includes three rooms dedicated for bat research. Similar to our Jamaican fruit bat colony room, the horseshoe bat room has approximately 240 ft² of space with 8 ft ceilings. We will provide enrichment, including landscape fabric (for hiding) draped on walls and hanging from rope lines across the room. Live meal worms will be provided daily as a food source and water provided ad libitum.

Although little is known about horseshoe bat reproduction, females typically become reproductive by age 2. For species found in temperate climates, gestation is tied hibernation. However, the species found in Bangladesh typically do not hibernate because of the nation's tropical and subtropical climates. Therefore, females may give birth every 4 to 6 months (similar to the Jamaican fruit bats in the CSU colony). Because of this low fecundity, we will typically use more males than females for experiments and distribution to the research community.

Justifications:

Indian flying foxes are a natural reservoir host of Nipah virus. More than 100 SARS-related coronaviruses have been detected in horseshoe bats and are, thus, likely reservoir hosts SARSr-CoV. For these reasons, we will colonize these species.

Minimization of Pain and Distress:

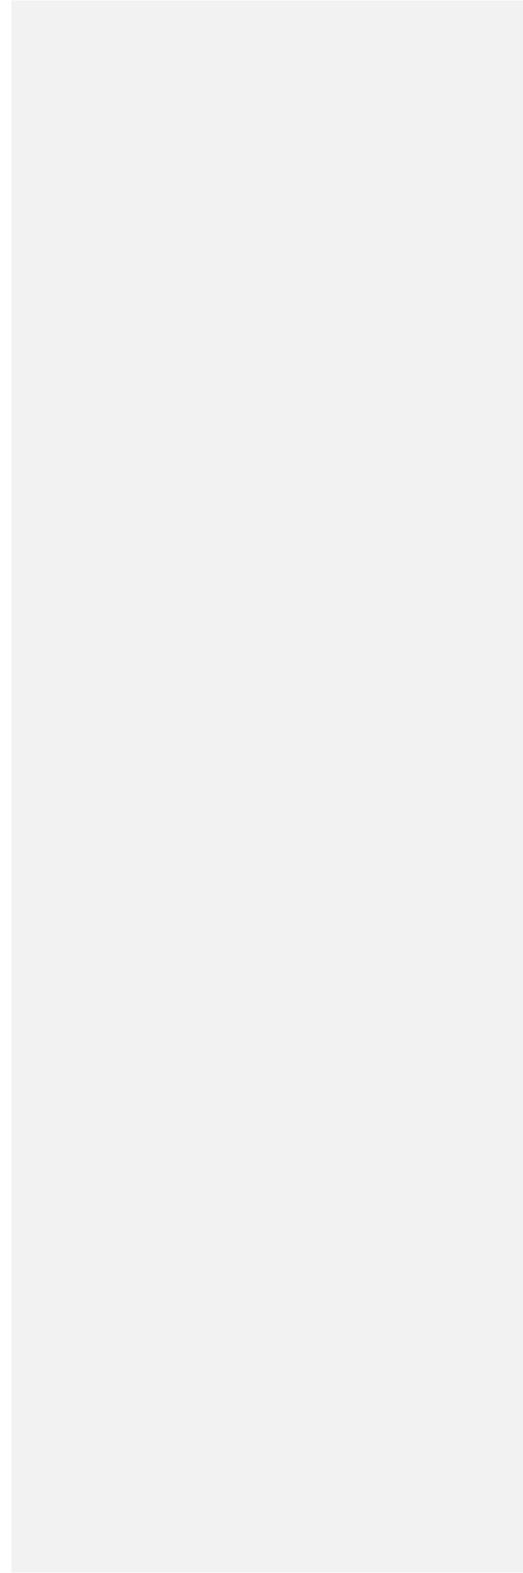

Housing of bats at CSU (Aim 1). Bats will be provided free-flight rooms at CSU, similar to how we have housed Jamaican fruit bats since 2006 (for details, see 25494448). No procedures involving pain will be employed, other than temporary pain associated with minor procedures, such as blood collection for hematology and serum chemistry studies. To minimize distress, bats are provided enrichment, including landscape fabric dangling from

the ceiling for horseshoe bats (social gathering and sequestration), and horizontal ropes attached to the ceiling for flying fox roosts. Handling of bats will be minimized and limited to collection for basic health studies (e.g., hematology and serum chemistry), training of personnel, veterinary care that may arise, and for removal from the colony (e.g., euthanasia for generation of cell lines in Aim 2, infection studies in Aim 3, shipment to other investigators in the USA). As per standard CSU veterinary care, bats will be monitored and fed daily, and rooms will be sanitized twice weekly by CSU Laboratory Animal Resources staff. We will abide by the US Animal Welfare Act for providing care and handling of all bats.

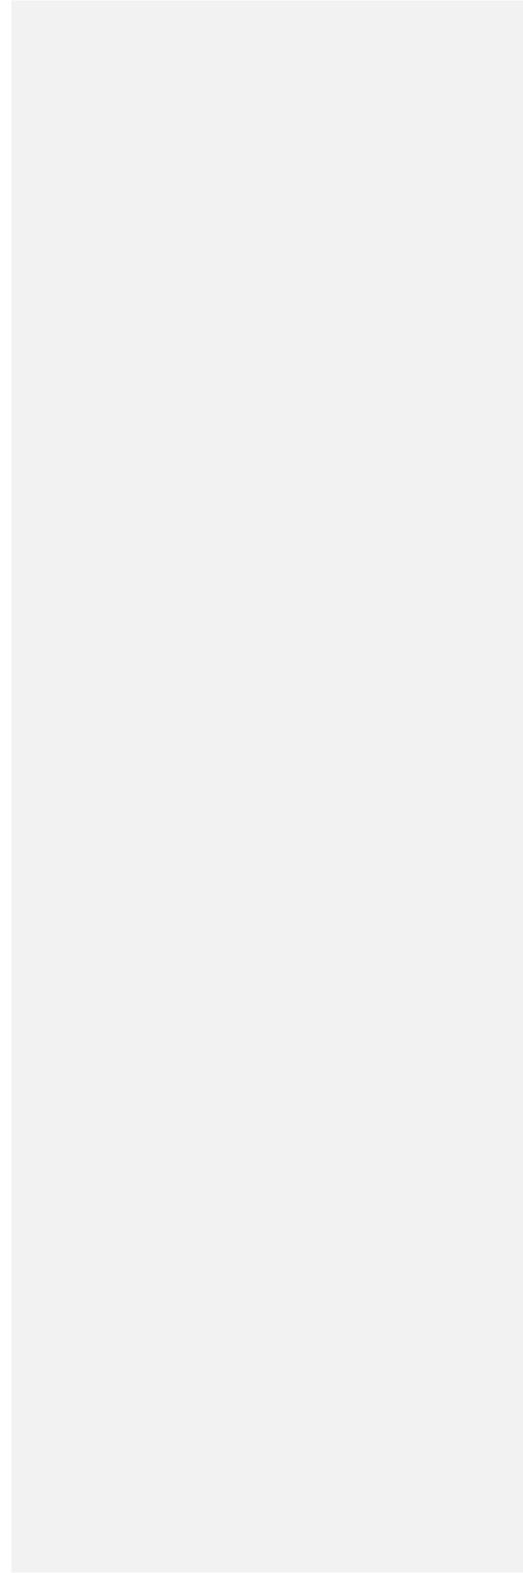

Select Agent Research

Coronaviruses are not select agents, other than the original SARS-CoV. Nipah virus is also a select agent and requires BSL-4 containment. Both CSU and RML are Tier 1 select agent facilities and Dr. Schountz's laboratory staff have select agent approvals for work at CSU. Dr. Schountz also has approval to work in the BSL-4 at RML should it become necessary for him to work there for Nipah virus infection experiments. Dr. Munster is the Director of the Virus Ecology laboratory at RML and has extensive experience with BSL-4 work with henipaviruses, including Nipah virus.

Hi Maria and Eric,

I think I have incorporated the changes but please check on the attached. This is the current snap-shot of the proposal, but it has a ways to go, yet.

Thanks,

Tony

Hi Maria,

Nice to meet you. Thanks for the ORF5/ORF7 catch. I changed that and added the correct citations. Will you pass this along to Tony? He has probably updated the GFP text to neonGreen.

<R24_Edl_mekQuestions-edl.docx>

Specific Aims

An important and frequently asked scientific question is whether bats are better hosts for lethal viruses than other mammals. There are a number of zoonotic viruses that cause high mortality in humans and originate in bats: SARS coronaviruses (SARS-CoV and SARS-CoV-2), Ebola virus, Marburg virus, Nipah virus, Hendra virus, and Middle East respiratory syndrome coronavirus (MERS-CoV). Further, there is increasing evidence that many other human viruses may have originated in bats, including measles, mumps and hepatitis C viruses. However, there is a lack the bat animal models necessary to study basic bat immunology and to conduct controlled and sophisticated viral infection studies. These studies are invaluable to answering why bats appear to host viruses lethal to humans without any apparent outward disease. Additionally, given the ability of bats to tolerate viral infections, studies elucidating the mechanisms behind these unusual traits could lead to new clinical approaches and therapeutics for humans affected by bat-borne viral diseases. Finally, the order chiroptera is diverse, comprising of over 1,300 species. A comprehensive understanding of bat immunology and physiology, as related to viral infection, will require bat animal models from multiple species.

We propose to establish sustainable breeding colonies of intermediate horseshoe bats (*Rhinolophus affinis*) and Indian flying foxes (*Pteropus medius*) in the United States that will facilitate research requiring live bats and bat-derived reagents, such as cell lines. In this project, we will import and establish breeding colonies of these species, creating two novel bat models that represent natural reservoirs of SARS-related coronaviruses and henipaviruses. This will create unprecedented opportunities to study host susceptibility and tolerance to high consequence pathogens such as SARS-CoV, SARS-CoV-2, and Nipah virus. Hundreds of SARS-CoV-like viruses have been detected in rhinolophid bats, thus susceptibility testing will allow us to identify susceptible species but only a few have been isolated and none have been used to challenge rhinolophid bats. While the exact host species of SARS-CoV and SARS-CoV-2 are currently unknown, multiple species of bats within the genus *Rhinolophus* have been associated with SARS-related coronaviruses, making any representative bat of this genus a high-value model for studying coronaviruses. Nipah virus is an emerging zoonotic virus with pandemic potential that causes near-annual outbreaks of fatal encephalitis in humans. The Indian flying fox is the natural reservoir of Nipah virus in South Asia, and is also host to more than 50 other viruses, including uncharacterized coronaviruses, paramyxoviruses, and filoviruses. This species is robust and readily colonized

Aim 1. To establish colonies of horseshoe bats and Indian flying foxes for the study of coronavirus and henipavirus infections. Bats will be captured and quarantined in Bangladesh and tested for coronaviruses, henipaviruses and filoviruses and lyssaviruses. Those that are negative will be housed in free-flight holding pens for adaptation to captivity. Offspring of these bats will be imported to Colorado State University for establishment of breeding colonies that will be provided to investigators performing infectious disease research.

Aim 2. To develop cell lines, reagents and methodologies for the study of viral infections in horseshoe bats and Indian flying foxes. Primary bat cells will be isolated from bats for viral susceptibility testing, and stocks of primary cells will be generated for the research community. Susceptible cells will be immortalized to provide indefinite propagation. Organoids of virus targets, such as intestines, will also be generated for virus studies. Recombinant proteins, including cytokines and soluble cell surface antigens, will be generated for in vitro and in vivo use. Monoclonal antibodies to these proteins will also be generated so that investigators can perform in vitro testing and generation of primary cells that require such growth factors, such as antigen-specific T cells, and for the in vivo neutralization of cytokines upon challenge with viruses. Methodologies for transcriptomic, metabolomic and proteomic studies will also be developed.

Aim 3. To perform experimental infections of bats with SARS-CoV-2, bat RaTG13-CoV and Nipah virus to develop laboratory models of bat reservoir hosts. Bats will be challenged with viruses under controlled laboratory conditions to perform kinetic and temporal studies of how these viruses behave in bats, and how the bats control infections without developing disease. We will also perform studies to assess durability of immunity in bats to determine whether immunity wanes and leads to repeated susceptibility to infection.

Commented [MK1]: Added this because we want to do proteomics and metabolomics. Also because my current understanding leads me to believe that bat physiology and flight are connected to bat immunology.

Commented [MK2]: I don't quite understand what this means.

Commented [S3R2]: Hopefully, this is clearer.

Commented [MK4]: Should we expand upon this a bit more – adding something about what goes in to developing these colonies and how we are prepared to do it.

Commented [MK5]: T-cells specifically mentioned here - I would add BM derived monocytes – those also require specific stimulatory cytokines and there is precedent for their successful isolation/development (Zhou et al., 2016). Facts I know you are aware of, I just thought they could be alluded to here.

Commented [S6R5]: We typically ship fresh or frozen bone marrow to others who then make macrophages and dendritic cells. I'll go into detail in the grant.

Commented [MK7]: To make this we require sequence information, correct? This can be synthesized?

Commented [S8R7]: The IFF genome is done. Getting cytokine sequences is very easy – we did it for *Artibeus* by culturing splenocytes overnight with concanavalin A and pokeweed mitogen, then did RNA-Seq. This led to dozens of full-length cytokine sequences (Kingfisher is making some of these for us now).

Commented [MK9]: Maybe something about single-cell sequencing (– I know everyone is doing it). We will have a bevy of different cell types and can pin point what is and isn't activated upon infection of susceptible cells. This could be critical for understanding viral maintenance.

Sort of an aside, but I think the possibility of trained immunity is quite interesting in relation to bats. (If this is a naïve/bad idea – feel free to ignore! I am an immunology novice.) IF there is any epigenetic or chromatin-remodeling that influences the innate immune response, single cell seq technologies that combine looking at chromatin changes or methylation, particularly for myeloid progenitors, could be revealing.

Commented [S10R9]: Lin-fa is designing those studies so if something needs to go in this Aim page we need to wait to see what he writes.

Research Strategy (must address sustainability of projects and resources)

A. Significance

Bats are found on every continent other than Antarctica and [they](#) are reservoirs or suspected reservoirs of many viruses, including coronaviruses, paramyxoviruses, filoviruses and lyssaviruses. In recent years, several bat-borne viruses have emerged that have caused substantial morbidity and mortality among humans. The COVID-19 pandemic is caused by severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2), a virus that [likely](#) originated in horseshoe bats (*Rhinolophus* species) commonly found in Asia. Frequent outbreaks of Nipah virus, hosted by *Pteropus* species bats, also occur in southern Asia, causing encephalitis that is usually fatal. In each of these virus/reservoir host relationships, virtually no disease occurs in the bats. Although numerous studies have been conducted on bats and viruses, many critical questions, such as the role of bats in maintaining and spreading potential zoonotic viruses and how bat immune responses control infections without disease, remain poorly defined. There is an urgent need to study these emerging zoonotic pathogens in their natural hosts to better understand their threats to humans. Unfortunately, there currently are few natural reservoir host models for the study of bat-borne viruses that are highly consequential to humans. This project aims to address this deficiency.

A.1. Bats as reservoir hosts of zoonotic viruses.

Generally, in zoonotic virus/reservoir host relationships, which have been best-studied in rodents and primates, each virus is hosted by one or a few [related](#) species {Kitchen, 2011 #44}. Viruses, like all other biological entities, are subject to evolutionary pressures and are likely genetically and biochemically “optimized” to circulate within their reservoir host populations. [The process of “optimization” or co-evolution often results in persistent infection \(for the life of the host\) or replication and shedding of virus that allows for continual transmission to other susceptible hosts \(Mandl, 2015 #43\). In both cases, the virus does not cause substantial disease within the reservoir host population. This is unsurprising, as a robust immune response in the reservoir could lead to viral clearance or immunopathology. When spillover of pathogenic viruses occurs, such viruses are not biochemically optimized for human hosts, which can have unexpected outcomes. In some cases, viral infection leads to disease and death, or alternatively, immune clearance. Because of the occurrence of severe human diseases caused by some of the bat-borne viruses, an important question is: how do bats host these viruses without becoming diseased?](#) The answer to this question is likely complicated and will vary between species of bats and species of viruses. Each of these viruses encodes immune modulating proteins that often target the innate antiviral responses of infected cells of the host. It is thought that these proteins are contributory factors of human disease (“virulence factors”). However, because they evolved in their bat reservoirs (i.e., “optimized”), their impacts on the orthologous target proteins of humans must somehow be different, otherwise there would not be differential outcomes in bats (no disease) and humans (disease).

[Although bats share many immunological features with other mammals, little research into their immune systems and responses during infection with these viruses has been conducted. This is necessary to clarify why the response to viral infection differs between humans and bats.](#)

A.2. Coronaviruses. Historically, [seasonal](#) coronavirus infections of humans have been associated with mild colds that are typically resolved within several days. [Most humans have been infected with seasonal coronaviruses, yet the frequency of re-infections with these coronaviruses has created a perception that immunity is short-lived. Unlike most other viral infections, coronaviruses fail to induce durable immunity, thus repeated infections of common cold coronaviruses can occur.](#) However, since 2002, three novel coronaviruses have emerged from bats that have caused significant impacts on humans: SARS-CoV, MERS-CoV and SARS-CoV-2. SARS-CoV emerged in 2002 and caused a significant disease with high mortality in humans ([11% case fatality rate - WHO](#)); however, because most patients exhibited signs of disease prior to virus shedding, [the pandemic](#) was controlled quickly and ended within two years. In 2012, MERS-CoV emerged in [the Middle East Saudi Arabia](#) and causes a disease in humans similar to SARS-CoV but with a higher mortality rate ([35% case fatality rate - WHO](#)). Unlike SARS-CoV, MERS-CoV established in a secondary reservoir host, dromedary camels, in North Africa prior to its spillover into humans. Consequently, MERS outbreaks occur many times each

Commented [MK11]: I like the gist of this section, but the first part could really apply to any reservoir host. The idea of unexpected outcomes is one I like, and I want to keep that, but maybe we can add more specifics about the unique immunological features of bats?

Commented [MK12]: This goes from immunity straight to co-evolution, making it a bit abrupt. It doesn't quite connect the dots until the end. So, I rearranged it. You can obviously ignore what I did, and put it back, but I will stand by my comment about needing a better transition from immunity to co-evolution.

Commented [MK13]: I know this is a “lame” sentence.

Commented [EL14]: I tried to rework this, but in general over the last year I've found previous HCoV literature lacking. There's no evidence that seasonal fluctuations in HCoV-specific Ab result in loss of immunity; most of the HCoV surveillance papers did not really show that waning Ab to one HCoV resulted in symptomatic “re-infection” with a homologous or heterologous HCoV.

year and nearly all outbreaks can be traced to contact with dromedary camels. SARS-CoV-2 emerged in late 2019 and is the etiologic agent of the ongoing COVID-19 pandemic. Both SARS-CoV and SARS-CoV-2 utilize human ACE2 as cellular entry receptors, and SARS-CoV-2 has been shown to infect many species demonstrating broad host tropism. It is now evident that thousands of distinct coronaviruses circulate in bats throughout the world, and that hundreds of these are SARS-related CoV (SARSr-CoV) that circulate in rhinolophid bats. There are 78 known species of bats within the genus *Rhinolophus* and they are found throughout Asia and Europe. Recombination frequently occurs among coronaviruses, and this has likely contributed to the diverse pool of coronaviruses circulating in rhinolophid bats. Although, only a few bat coronaviruses have been isolated; nearly all are represented by sequences detected in bats. One bat coronavirus, RaTG13, shares a high degree of sequence similarity to SARS-CoV-2 (32015507). Its sequences have been detected in several intermediate horseshoe bats (*R. affinis*) that are found throughout southern Asia, including Bangladesh. Although ~~no isolates of RaTG13 have been made?~~ RaTG13 has not been isolated, its complete genome has been determined (GenBank [MN996532](#)). Examination of ACE2 sequences from various rhinolophid species suggests intermediate horseshoe bats have the most "human-like" ACE2 orthologue for spike binding to the 20 ACE2 residues that are thought to be important for receptor-binding interactions (32239522, 31996437). Because of these features, we will focus our efforts on colonizing intermediate horseshoe bats.

A.3. Nipah virus (Jon).

A.4.

B. Innovation

B1. This project will be the first to establish bat breeding colonies for the infectious disease research community with species relevant to SARS coronaviruses and henipaviruses.

B2. We will determine basic clinical attributes of these bats to provide baseline readings, including body temperatures, hematology, serum chemistry and metabolic profiles.

B3. We will establish bat primary cells and immortalized cell lines for distribution to the research community.

B4. We will develop recombinant bat cytokines for the derivation of primary cell cultures, including endothelial cells, dendritic cells and T cells, and to use these cytokines for in vivo studies to manipulate immune responses during infection.

B5. We will generate monoclonal antibodies for the detection of cytokines, cell surface antigens and for in vivo cytokine neutralization and cellular depletion studies

B6. We will

C. Approach

C1. Preliminary Studies

C.1.1. Fruit bat colony at Colorado State University. Dr. Schountz established a breeding colony of Jamaican fruit bats (*Artibeus jamaicensis*) in 2006 with previous NIH support (AI25489, AI089419) (Fig 1). These bats are found in northern South America, the Caribbean Islands, Central America, and the Florida Keys. Adult bats have an average weight of 42 gm, a wingspan of 45 cm and body length of about 10 cm. Mature females produce two offspring per year and carry pups for about 40 days after birth. This species can live up to 15 years in captivity. There are about 400 bats currently in the colony and about 100 to 150 new pups are born at 6-month intervals. Colorado State University has extensive animal expertise by virtue of its College of Veterinary Medicine and Biomedical Sciences, including veterinarians with experience with bats. **Thus, we have extensive investigator and institutional experience with bat husbandry and colony management.**

Fig. 1. Jamaican fruit bats in the CSU colony.

C.1.2. Candidate SARS-like coronavirus reservoirs. Receptor incompatibility can pose a potent barrier to infection, preventing a virus from gaining access to the cell; a necessary step to initiate the replication cycle. There is ample evidence that one or a few amino acid substitutions at critical sites of interaction in cellular receptors can affect viral entry (Demogines, 2013 #45; Kaelber, 2012 #47; Ng, 2015 #42; Yan, 2010 #46). **Angiotensin-2 or ACE2 is the reported receptor for SARS-CoV and SARS-CoV-2.**

Therefore, to initially assess the potential of rhinolophid bats as a reservoir for SARS-like coronaviruses, we performed an alignment of all nine *Rhinolophus* species ACE2 sequences available in GenBank with Human ACE2 and ACE2 of known susceptible mammalian species. We specifically compared amino acid identities at 20 sites involved in spike binding (Table 1). Where available, sequences from multiple individuals were included.

Strikingly, for those species where multiple ACE2 haplotypes are reported (*R.sinicus*, *R.pearsonii*, and *R.affinis*) multiple different amino acid identities are encoded at sites important for ACE2 binding (Table 1). In cases where there are multiple amino acids possible (e.g. Table 1, site 34), occasionally one amino acid matches the residue(s) encoded by humans. This apparent genetic variation reveals two important implications: 1) certain bat individuals may encode ACE2 receptors that are permissive to coronaviruses infecting humans while others of the same species do not, and 2) certain bat individuals may be more likely to harbor a SARS-CoV strain able to infect humans. We can capitalize on this naturally occurring variation through widespread capture, genotyping at loci of importance for coronavirus infection, and selective breeding to develop a colony of bats ideally poised for controlled viral infection and immunology studies.

Based on current ACE2 sequence data, the intermediate horseshoe bat and Pearson's horseshoe bat (*R.pearsonii*) encode the same amino acids as human at 16 of the 20 residues important for ACE2 binding. The Least horseshoe bat (*R. pusillus*) has 14 matching residues. These three species are found in Bangladesh (Table 1). While no bat species encodes the same 20 residues as human, both domestic cats (16 matches) and ferrets (14 matches) are susceptible to SARS-CoV-2, suggesting that all three Bangladeshi species may harbor permissive ACE2 receptors. Intermediate horseshoe bats (16 matches) are widely distributed in southern Asia, including Bangladesh as well as southern China where most of the SARS-CoV sequences have been detected in rhinolophid bats. For this reason, we believe this is the most logical species to capture for susceptibility testing and model development. However, because there are 78 rhinolophid species, we will also capture the other species that are found in Bangladesh (*R. lepidus*, *R. malayanus*, *R. monoceros*, *R. humanus*, *R. luctus*, *R. subbadius*) for importation and SARS-CoV-2 susceptibility testing at CSU.

Table 1. ACE2 amino acid identity amongst Rhinolophid bats and hosts supporting SARS-CoV-2

Commented [MK15]: Is this more about finding a bat model that will support SARS-CoV and SARS-CoV-2 infections?

Commented [MK16]: There is a paper that looks at polymorphisms within *R.sinicus* ACE2 and their effect on susceptibility to SARS-rCoV strains (Guo, 2020, JVI). The data is ok, and I believe it, but they do a wildly inappropriate evolution analysis (it's meant for between species and they do it on a within species set, which violates all the assumptions). The virology data is ok, their 0 timepoint of their qPCR is high (start with a lot of genomes) but they increase nicely over time, so it's alright. I sort of don't want to cite it because of the aforementioned issues, but it supports the idea that variation at the receptor can change susceptibility to a SARS-rCoV. Does anyone know of any other papers that do something similar with regards to bat ACE2?

Commented [EL17R16]: •Also this article in PLoS Pathogen from 2017. PLoS Path 2017 Nov 30;13(11):e1006698.

•Michael and Vincent's Cell Report DPP4 paper is a good example of this for MERS-CoV. PMID: 30110630

Commented [MK18]: Maybe a figure showing the species ranges and our proposed site of the Bangladeshi bat colonies?

Species name	Common name	Amino Acid in ACE2																			
		24	27	28	30	31	34	35	37	38	41	42	45	82	83	330	353	354		355	357
<i>Homo sapiens</i>	Human (dbSNP)	Q	T/A	F	D	K	H	E/D/K	E	D	Y	Q	L	M/I	Y	N	K	G	D/N	R	R

<i>Felis catus</i>	Domestic cat (N=1)	L	T	F	E	K	H	E	E	E	Y	Q	L	T	Y	N	K	G	D	R	R
<i>Rhinolophus affinis</i>	Intermediate horseshoe bat (N=23)	R	I	F	D	N	H/R	E	E	E/D	Y	Q	L	N	Y/H	N	K	G	D	R	R
<i>Rhinolophus pearsonii</i>	Pearson's horseshoe bat (N=2)	R/Q	T/I	F	D	K	H/R	E	E	D	H	E	L	D	Y	N	K	D	D	R	R
<i>Mustela putorius</i>	Ferret (N=1)	L	T	F	E	K	Y	E	E	E	Y	Q	L	T	Y	N	K	R	D	R	R
<i>Rhinolophus pusillus</i>	Least horseshoe bat (N=1)	K	K	F	N	D	S	E	E	D	Y	Q	L	N	Y	N	K	G	D	R	R
<i>Rhinolophus macrotis</i>	Big-eared horseshoe bat (N=1)	E	K	F	D	K	S	K	E	D	Y	E	L	N	Y	K	K	G	D	R	R
<i>Rhinolophus landeri</i>	Lander's horseshoe bat (N=1)	L	T	F	D	D	S	A	E	N	Y	Q	L	N	F	N	K	G	D	R	R

Commented [MK19]: Since viruses move through populations, I thought collecting all available complete ACE2 sequences on ncbi (skipped uniprot, but I can add, if necessary) for each of the species listed would be more representative. Also, I edited the text to reflect these changes.

C1.3. Experimental bat coronavirus infections. Drs. Munster and Schountz have extensive experience with experimental infection models of bats, including with MERS-CoV, SARS-CoV-2, H18N11 bat influenza virus, Zika virus and Tacaribe virus. Challenge of Egyptian fruit bats with an infectious clone of WIV-CoV showed limited susceptibility, despite the ability of its spike protein to bind to Egyptian fruit bat ACE2 (30572566). Recent work by our groups has shown that Jamaican fruit bat ACE2 is bound by SARS-CoV-2 (but not SARS-CoV) spike protein expressed by a VSV pseudotype virus and that challenge of Jamaican fruit bats with SARS-CoV-2 leads to a limited infection that is confined to the small intestine, particularly mononuclear cells of the Peyer's patches and lamina propria, and crypt cells (Fig 2). Viral RNA was detected in oral swabs for 4 days and low levels in the small intestine on day 2. However, no neutralizing antibody or nucleoprotein antibody (ELISA) was detected, suggesting abortive infection or robust control of the virus by the innate immune response.

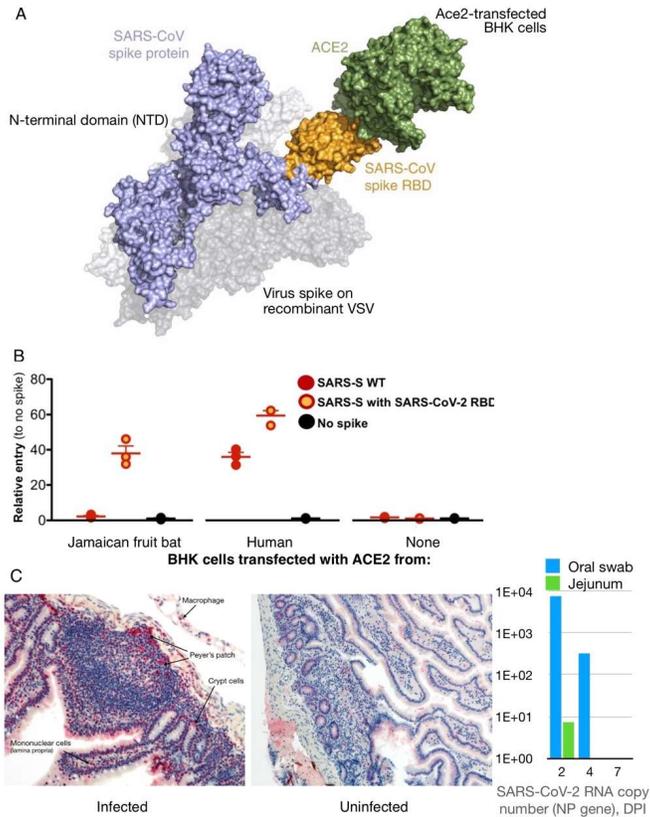

C1.4.

C2. Specific Aims

C2.1 Aim 1. To establish colonies of horseshoe bats and Indian flying foxes for the study of coronavirus and henipavirus infections. Bats will be captured and quarantined in Bangladesh and tested for coronaviruses, henipaviruses, filoviruses and lyssaviruses. Those that are negative will be imported to Colorado State University for establishment of breeding colonies.

C2.1.1. Establishment of captive breeding colony of *Pteropus medius* in Bangladesh. We will establish a captive breeding colony of *Pteropus medius* in Bangladesh. Temporary holding cages used for quarantine prior to shipment to the US will be erected at the Sheikh Kamal Wildlife Center (SKWC) Purabari, adjacent to Bhawal National Park, Gazipur, north of Dhaka. The land is managed by the Forest Department under the direction of

Commented [MK20]: I assume the holding cages will be different for the rhinolophid bats, but the capture methods will be the same?

the Conservator of Forests (see Kabir letter of support) Ministry of Environment (Govt of Bangladesh). The bats will be cared for and maintained by Forest Department staff. Staging bats in Bangladesh prior to shipment to the US will occur in X phases.

Phase 1: Holding cage development. We will build four temporary holding cages [octagonal shape, approx. 6m diameter and 6ft tall] that are large enough to allow bats to fly, and low enough that project personnel can easily repeatedly catch bats for testing during the screening process. Each cage will be built to hold 30 bats, with a heavy retractable curtain subdividing each cage in half, which will allow us to separate bats into smaller groups. One of the cages will be left empty to allow for isolation of bats that test positive for Nipah virus on PCR during the course of quarantine. Each cage will be made from a metal frame with rubber-coated mesh screening enclosing the cage. An outer cage will be built around each cage, with 6" of space between the fencing to exclude bats inside from contact with bats outside. A solid roof will be built over each cage to prevent excreta from wild bats from entering the cage area and potentially exposing captive bats to henipaviruses. Each cage will also have a door and an anti-chamber to allow staff to

safely enter and exit, don and doff PPE, and then enter the flight cage without bats being able to escape.

Facilities at the wildlife park where the bats will be held will include a food preparation station, PPE storage, first aid and disinfection supplies, and a mobile veterinary lab that includes electricity, a portable gas anesthesia machine, and supplies for collecting biological specimens from the bats.

Phase 2: Bat capture. We will capture wild bats from colonies located in Gazipur. Our goal is to capture a total of 81 bats: 6 males and 75 females comprising three groups of 25 females and 2 males - all Nipah virus negative (by PCR and Luminex). We will capture bats 20 at a time. With each group of 20 bats, we will transport them to the cages from the field site, with each bat held in an individual cotton bag suspended from a post in the back of a vehicle. The driver will be wearing PPE, including an N95 respirator, and all vehicle windows will be open during transport. A plastic sheet will line the floor of the vehicle under the bats to allow for disinfection following transport. Bats will be sampled in the vet lab and then immediately transferred into a holding cage and blood samples and swabs collected. Samples will be screened that day for IgG antibodies using a Luminex, and swabs will be screened for Nipah virus RNA using a qRT-PCR assay at icddr, b. Seropositive and or PCR positive individuals will be released at the park. Seronegative and PCR negative individuals will be moved into a second staging cage, where they will be held for 21 days, with a second and third round of testing on day 10 and 21 post capture. Any bats subsequently testing positive will be released. Negative bats will be retained.

Phase 3: Breeding colony. We will maintain separate groups of 27 bats in the three flight cages. Pteropus medius is a synchronous seasonal breeder, with a 6-month gestation period. We will aim to capture bats during the third

trimester of pregnancy (January/February) and allow them to give birth in captivity. Pups will be weaned at 3 months and placed into a fourth cage, where they will be maintained until 1 year of age. Pups will be screened every 2 weeks for Nipah virus and antibodies. Maternal antibodies are expected to wane at around 6-7 months of age. By isolating the pups, born to seronegative, Nipah-negative dams, we will create an SPF (specific-pathogen free) colony that will be used to found the colony at CSU. We will also allow the bats in Bangladesh to breed, creating an F1 generation that will be maintained in captivity and used to support the US-based colony.

C2.1.2. Experimental challenge of rhinolophid bats. We will determine whether Ace2 sequences from various *Rhinolophus* species bats render BHK cells susceptible to SARS-CoV and SARS-CoV-2 using our VSV pseudotype system (Fig XX). Rhinolophid species will be captured and quarantined in Bangladesh and tested for evidence of SARS-like CoV infection (PCR of rectal swabs and serology). Naïve bats will be shipped to Colorado State University for challenge with SARS-CoV and SARS-CoV-2 to determine susceptibility. Those species that are susceptible will be collected in Bangladesh and after quarantine and testing, up to 50 founders will be shipped to CSU to establish breeding colonies. In the event that more than one species is susceptible, we will determine which is most suitable based upon infection kinetics of each virus.

Upon receipt, bats will be immediately examined by veterinary staff at CSU and manually fed meal worms.

C2.2 Aim 2. To develop cell lines, reagents and methodologies for the study of viral infections in horseshoe bats and Indian flying foxes. Primary bat cells will be isolated from bats for susceptibility testing, and stocks of primary cells will be generated for the research community. Susceptible cells will be immortalized to provide indefinite propagation. Organoids of virus targets, such as intestines, will also be generated for virus studies. Recombinant proteins, including cytokines and soluble cell surface antigens, will be generated for in vitro and in vivo use. Monoclonal antibodies to these proteins will also be generated so that investigators can perform in vitro testing and generation of primary cells that require such growth factors, such as antigen-specific T cells, and for the in vivo neutralization of cytokines upon challenge with viruses. Methodologies for transcriptomic, metabolomic and proteomic studies will also be developed.

C2.2.1. Establishment of primary and immortalized bat cell lines. ([Tony](#))

C2.2.2. Production of recombinant bat cytokines and monoclonal antibodies. ([Brian cytokines](#), [Tony Mab](#))

C2.2.3. Development of metabolomic profiles. ([Lin-fa and Rushika](#))

C2.2.4. Development of proteomic profiles. ([Lin-fa and Rushika](#))

C2.3 Aim 3. To perform experimental infections of bats with SARS-CoV-2, bat RaTG13-CoV and Nipah virus to develop laboratory models of bat reservoir hosts. Bats will be challenged with viruses under controlled laboratory conditions to perform kinetic and temporal studies of how these viruses behave in bats, and how the bats control infections without developing disease. We will also perform studies to assess durability of immunity in bats to determine whether immunity wanes and leads to repeated susceptibility to infection.

C2.3.1. Experimental infection of horseshoe bats with SARS-CoV-2. ([Tony](#), [Lin-fa](#), [Vincent](#))

C2.3.2. Experimental infections of Indian flying foxes with Nipah virus. ([Tony](#), [Lin-fa](#), [Vincent](#))

C2.3.3. Generation of bat RaTG13-CoV infectious clone. ([Eric](#)) Reverse genetics have been used as a powerful tool to generate infectious clones of SARS-CoV and MERS-CoV (32526206, 28377531, 24043791, 32978313). To rescue recombinant RaTG13 we will follow methods previously described to generate SARS/MERS-CoV full length genome cDNA (24043791, 14569023, 12368349, 18818320, 19036930). Six contiguous RaTG12 cDNA fragments will be synthesized and the contiguous cDNA fragments will then be ligated into a full-length cDNA using a subcloning strategy with Bgl1 class II restriction endonuclease sites. The ligated cDNA product under T7 promoter control will then be electroporated into a co-culture of mammalian cell lines (Vero, BSR-T7) along with T7 RNA polymerase and a nucleoprotein expressing vector to enhance replication efficiency. To construct green fluorescent protein (GFP) and red fluorescent protein (RFP) reporter viruses, the ORF5 sequence will be replaced with GFP or RFP sequences. The same simultaneous ligation strategy will be employed to generate

[the full-length cDNA of RaTG13 GFP/RFP variants](#). Cytopathic effects and plaques will be monitored for 24 – 72 hours post-transfections; duplicate wells will be a) stained with anti-SARS-CoV nucleoprotein secondary antibodies for intracellular detection of RaTG13 infectious clone replication and b) lysed and cells/cell-culture supernatant will be passaged to fresh Vero cells for amplification of the virus stock. Replication kinetics and titers of infectious clone RaTG13 and reporter virus variants will be monitored by standard plaque assays and/or measurement of fluorescent plaques. Mammalian cell line will be transfected with human and bat ACE-2 orthologues to allow functional characterization of infectious clones of RaTG13 receptor-usage for cellular entry.

C2.3.4. Detection of virus specific antibodies in experimentally-challenged flying foxes and horseshoe bats.

Whether bats develop long-lasting adaptive immune responses to viruses remains unknown. Egyptian fruit bats, natural hosts of Marburg virus and Ravn virus (19649327), challenged with Marburg virus seroreverted to undetectable levels three months after infection (28821722). Virus-specific antibody responses are surrogate of predictive protection or correlates of protection for nearly all vaccines. Here, we will establish primary and secondary humoral responses to virus infections in two virus-host models: NiV-flying foxes, RaTG13-horseshoe bats. Utilizing multiplex serology strategies that our groups have developed for NiV and coronaviruses (32034942, 31671094, 33083807) we will capture bat immunoglobulin (Ig) G and IgM with virus envelope/spike glycoprotein antigen-based assays. The kinetics, magnitude and duration of virus-specific flying fox and horseshoe IgG/IgM will be monitored longitudinally for seroconversion, seroreversion and anamnestic boosting after secondary infection. Population-level biosurveillance of NiV and other emerging zoonotic viruses relies on susceptible-infected-recovered models to understand the spread of these viruses among wildlife hosts. Experimental establishment of longevity of virus-specific bat IgG-responses will provide valuable information for ongoing biosurveillance projects focused on the transmission/spillover dynamics of emerging zoonotic viruses in wildlife host populations and communities.

Commented [EL21]: Jon do you have a reference for the most recent NiV seasonal transmission study (PNAS)?

Commented [EL22]: Just threw these in here

Specific Aims

An important and frequently asked scientific question is whether bats are better hosts for lethal viruses than other mammals. There are a number of zoonotic viruses that cause high mortality in humans and originate in bats: SARS coronaviruses (SARS-CoV and SARS-CoV-2), Ebola virus, Marburg virus, Nipah virus, Hendra virus, and Middle East respiratory syndrome coronavirus (MERS-CoV). Further, there is increasing evidence that many other human viruses may have originated in bats, including measles, mumps and hepatitis C viruses. However, there is a lack the bat animal models necessary to study basic bat immunology and to conduct controlled and sophisticated viral infection studies. These studies are invaluable to answering why bats appear to host viruses lethal to humans without any apparent outward disease. Additionally, given the ability of bats to tolerate viral infections, studies elucidating the mechanisms behind these unusual traits could lead to new clinical approaches and therapeutics for humans affected by bat-borne viral diseases. Finally, the order chiroptera is diverse, comprising of over 1,300 species. A comprehensive understanding of bat immunology and physiology, as related to viral infection, will require bat animal models from multiple species.

We propose to establish sustainable breeding colonies of intermediate horseshoe bats (*Rhinolophus affinis*) and Indian flying foxes (*Pteropus medius*) in the United States that will facilitate research requiring live bats and bat-derived reagents, such as cell lines. In this project, we will import and establish breeding colonies of these species, creating two novel bat models that represent natural reservoirs of SARS-related coronaviruses and henipaviruses. This will create unprecedented opportunities to study host susceptibility and tolerance to high consequence pathogens such as SARS-CoV, SARS-CoV-2, and Nipah virus. Hundreds of SARS-CoV-like viruses have been detected in rhinolophid bats, thus susceptibility testing will allow us to identify susceptible species but only a few have been isolated and none have been used to challenge rhinolophid bats. While the exact host species of SARS-CoV and SARS-CoV-2 are currently unknown, multiple species of bats within the genus *Rhinolophus* have been associated with SARS-related coronaviruses, making any representative bat of this genus a high-value model for studying coronaviruses. Nipah virus is an emerging zoonotic virus with pandemic potential that causes near-annual outbreaks of fatal encephalitis in humans. The Indian flying fox is the natural reservoir of Nipah virus in South Asia, and is also host to more than 50 other viruses, including uncharacterized coronaviruses, paramyxoviruses, and filoviruses. This species is robust and readily colonized

Aim 1. To establish colonies of horseshoe bats and Indian flying foxes for the study of coronavirus and henipavirus infections. Bats will be captured and quarantined in Bangladesh and tested for coronaviruses, henipaviruses and filoviruses and lyssaviruses. Those that are negative will be housed in free-flight holding pens for adaptation to captivity. Offspring of these bats will be imported to Colorado State University for establishment of breeding colonies that will be provided to investigators performing infectious disease research.

Aim 2. To develop cell lines, reagents and methodologies for the study of viral infections in horseshoe bats and Indian flying foxes. Primary bat cells will be isolated from bats for viral susceptibility testing, and stocks of primary cells will be generated for the research community. Susceptible cells will be immortalized to provide indefinite propagation. Organoids of virus targets, such as intestines, will also be generated for virus studies. Recombinant proteins, including cytokines and soluble cell surface antigens, will be generated for in vitro and in vivo use. Monoclonal antibodies to these proteins will also be generated so that investigators can perform in vitro testing and generation of primary cells that require such growth factors, such as antigen-specific T cells, and for the in vivo neutralization of cytokines upon challenge with viruses. Methodologies for transcriptomic, metabolomic and proteomic studies will also be developed.

Aim 3. To perform experimental infections of bats with SARS-CoV-2, bat RaTG13-CoV and Nipah virus to develop laboratory models of bat reservoir hosts. Bats will be challenged with viruses under controlled laboratory conditions to perform kinetic and temporal studies of how these viruses behave in bats, and how the bats control infections without developing disease. We will also perform studies to assess durability of immunity in bats to determine whether immunity wanes and leads to repeated susceptibility to infection.

Commented [MK1]: Added this because we want to do proteomics and metabolomics. Also because my current understanding leads me to believe that bat physiology and flight are connected to bat immunology.

Commented [MK2]: I don't quite understand what this means.

Commented [S3R2]: Hopefully, this is clearer.

Commented [MK4]: Should we expand upon this a bit more – adding something about what goes in to developing these colonies and how we are prepared to do it.

Commented [MK5]: T-cells specifically mentioned here - I would add BM derived monocytes – those also require specific stimulatory cytokines and there is precedent for their successful isolation/development (Zhou et al., 2016). Facts I know you are aware of, I just thought they could be alluded to here.

Commented [S6R5]: We typically ship fresh or frozen bone marrow to others who then make macrophages and dendritic cells. I'll go into detail in the grant.

Commented [MK7]: To make this we require sequence information, correct? These can be synthesized?

Commented [S8R7]: The IFF genome is done. Getting cytokine sequences is very easy – we did it for Artibeus by culturing splenocytes overnight with concanavalin A and pokeweed mitogen, then did RNA-Seq. This led to dozens of full-length cytokine sequences (Kingfisher is making some of these for us now).

Commented [MK9]: Maybe something about single-cell sequencing (– I know everyone is doing it). We will have a bevy of different cell types and can pin point what is and isn't activated upon infection of susceptible cells. This could be critical for understanding viral maintenance.

Sort of an aside, but I think the possibility of trained immunity is quite interesting in relation to bats. (If this is a naïve/bad idea – feel free to ignore! I am an immunology novice.) IF there is any epigenetic or chromatin-remodeling that influences the innate immune response, single cell seq technologies that combine looking at chromatin changes or methylation, particularly for myeloid progenitors, could be revealing.

Commented [S10R9]: Lin-fa is designing those studies so if something needs to go in this Aim page we need to wait to see what he writes.

Research Strategy (must address sustainability of projects and resources)

A. Significance

Bats are found on every continent other than Antarctica and [they](#) are reservoirs or suspected reservoirs of many viruses, including coronaviruses, paramyxoviruses, filoviruses and lyssaviruses. In recent years, several bat-borne viruses have emerged that have caused substantial morbidity and mortality among humans. The COVID-19 pandemic is caused by severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2), a virus that [likely](#) originated in horseshoe bats (*Rhinolophus* species) commonly found in Asia. Frequent outbreaks of Nipah virus, hosted by *Pteropus* species bats, also occur in southern Asia, causing encephalitis that is usually fatal. In each of these virus/reservoir host relationships, virtually no disease occurs in the bats. Although numerous studies have been conducted on bats and viruses, many critical questions, such as the role of bats in maintaining and spreading potential zoonotic viruses and how bat immune responses control infections without disease, remain poorly defined. There is an urgent need to study these emerging zoonotic pathogens in their natural hosts to better understand their threats to humans. Unfortunately, there currently are few natural reservoir host models for the study of bat-borne viruses that are highly consequential to humans. This project aims to address this deficiency.

A.1. Bats as reservoir hosts of zoonotic viruses.

Generally, in zoonotic virus/reservoir host relationships, which have been best-studied in rodents and primates, each virus is hosted by one or a few [related](#) species {Kitchen, 2011 #44}. Viruses, like all other biological entities, are subject to evolutionary pressures and are likely genetically and biochemically “optimized” to circulate within their reservoir host populations. [The process of “optimization” or co-evolution often results in persistent infection \(for the life of the host\) or replication and shedding of virus that allows for continual transmission to other susceptible hosts \(Mandl, 2015 #43\). In both cases, the virus does not cause](#) substantial disease within the [reservoir host](#) population. [This is unsurprising, as a](#) robust immune response in the reservoir could lead to viral clearance or immunopathology. When spillover of pathogenic viruses occurs, such viruses are not biochemically optimized for human hosts, which can [have unexpected outcomes. In some cases, viral infection leads](#) to disease and death, or [alternatively](#), immune clearance. Because of the occurrence of severe human diseases caused by some of the bat-borne viruses, an important question is: *how do bats host these viruses without becoming diseased?* The answer to this question is likely complicated and will vary between species of bats and species of viruses. Each of these viruses encodes immune modulating proteins that often target the innate antiviral responses of infected cells of the host. It is thought that these proteins are contributory factors of human disease (“virulence factors”). However, because they evolved in their bat reservoirs (i.e., “optimized”), their impacts on the orthologous target proteins of humans must somehow be different, otherwise there would not be differential outcomes in bats (no disease) and humans (disease).

[Although bats share many immunological features with other mammals, little research into their immune systems and responses during infection with these viruses has been conducted. This is necessary to clarify why the response to viral infection differs between humans and bats.](#)

A.2. Coronaviruses. Historically, coronavirus infections of humans have been associated with mild colds that are typically resolved within several days. Unlike most other viral infections, coronaviruses fail to induce durable immunity, thus repeated infections of common cold coronaviruses can occur. However, since 2002, three novel coronaviruses have emerged from bats that have caused significant impacts on humans: SARS-CoV, MERS-CoV and SARS-CoV-2. SARS-CoV emerged in 2002 and caused a significant disease with high mortality in humans ([11% case fatality rate - WHO](#)); however, because most patients exhibited signs of disease prior to virus shedding, it was controlled quickly and ended within two years. In 2012, MERS-CoV emerged in the Middle East and causes a disease in humans similar to SARS-CoV but with a higher mortality rate ([35% case fatality rate - WHO](#)). Unlike SARS-CoV, MERS-CoV established in a secondary reservoir host, dromedary camels, in North Africa prior to its spillover into humans. Consequently, MERS outbreaks occur many times each year and nearly all outbreaks can be traced to contact with dromedary camels. SARS-CoV-2 emerged in late 2019 and is the etiologic agent of the ongoing COVID-19 pandemic. Both SARS-CoV and SARS-CoV-2 use ACE2 as cellular

Commented [MK11]: I like the gist of this section, but the first part could really apply to any reservoir host. The idea of unexpected outcomes is one I like, and I want to keep that, but maybe we can add more specifics about the unique immunological features of bats?

Commented [MK12]: This goes from immunity straight to co-evolution, making it a bit abrupt. It doesn't quite connect the dots until the end. So, I rearranged it. You can obviously ignore what I did, and put it back, but I will stand by my comment about needing a better transition from immunity to co-evolution.

Commented [MK13]: I know this is a “lame” sentence.

entry receptors, and SARS-CoV-2 has been shown to infect many species. It is now evident that thousands of distinct coronaviruses circulate in bats throughout the world, and that hundreds of these are SARS-related CoV (SARS-CoV) that circulate in rhinolophid bats. There are 78 known species of bats within the genus *Rhinolophus* and they are found throughout Asia and Europe. Recombination frequently occurs among coronaviruses, and this has likely contributed to the diverse pool of coronaviruses circulating in rhinolophid bats. Only a few bat coronaviruses have been isolated; nearly all are represented by sequences detected in bats. One bat coronavirus, RaTG13, shares a high degree of sequence similarity to SARS-CoV-2 (32015507). Its sequences have been detected in several intermediate horseshoe bats (*R. affinis*) that are found throughout southern Asia, including Bangladesh. Although no isolates of RaTG13 have been made², its complete genome has been determined (GenBank [MN996532](#)). Examination of ACE2 sequences from various rhinolophid species suggests intermediate horseshoe bats have the most "human-like" ACE2 for spike binding to the 20 ACE2 residues that are thought to be important (32239522, 31996437). Because of these features, we will focus our efforts on colonizing intermediate horseshoe bats.

A.3. Nipah virus (Jon).

A.4.

B. Innovation

B1. This project will be the first to establish bat breeding colonies for the infectious disease research community with species relevant to SARS coronaviruses and henipaviruses.

B2. We will determine basic clinical attributes of these bats to provide baseline readings, including body temperatures, hematology, serum chemistry and metabolic profiles.

B3. We will establish bat primary cells and immortalized cell lines for distribution to the research community.

B4. We will develop recombinant bat cytokines for the derivation of primary cell cultures, including endothelial cells, dendritic cells and T cells, and to use these cytokines for in vivo studies to manipulate immune responses during infection.

B5. We will generate monoclonal antibodies for the detection of cytokines, cell surface antigens and for in vivo cytokine neutralization and cellular depletion studies

B6. We will

C. Approach

C1. Preliminary Studies

C1.1. *Fruit bat colony at Colorado State University.* Dr. Schountz established a breeding colony of Jamaican fruit bats (*Artibeus jamaicensis*) in 2006 with previous NIH support (AI25489, AI089419) (Fig 1). These bats are found in northern South America, the Caribbean Islands, Central America, and the Florida Keys. Adult bats have an average weight of 42 gm, a wingspan of 45 cm and body length of about 10 cm. Mature females produce two offspring per year and carry pups for about 40 days after birth. This species can live up to 15 years in captivity. There are about 400 bats currently in the colony and about 100 to 150 new pups are born at 6-month intervals. Colorado State University has extensive animal expertise by virtue of its College of Veterinary Medicine and Biomedical Sciences, including veterinarians with experience with bats. **Thus, we have extensive investigator and institutional experience with bat husbandry and colony management.**

C1.2. Candidate SARS-like coronavirus reservoirs. Receptor incompatibility can pose a potent barrier to infection, preventing a virus from gaining access to the cell; a necessary step to initiate the replication cycle. There is ample evidence that one or a few amino acid substitutions at critical sites of interaction in cellular receptors can affect viral entry (Demogines, 2013 #45; Kaelber, 2012 #47; Ng, 2015 #42; Yan, 2010 #46). Angiotensin-2 or ACE2 is the reported receptor for SARS-CoV and SARS-CoV-2. Therefore, to initially assess the potential of rhinolophid bats as a reservoir for SARS-like coronaviruses W

Fig. 1. Jamaican fruit bats in the CSU colony.

Commented [MK14]: Is this more about finding a bat model that will support SARS-CoV and SARS-CoV-2 infections?

Commented [MK15]: There is a paper that looks at polymorphisms within *R. sinicus* ACE2 and their effect on susceptibility to SARS-rCoV strains (Guo, 2020, JVI). The data is ok, and I believe it, but they do a wildly inappropriate evolution analysis (it's meant for between species and they do it on a within species set, which violates all the assumptions). The virology data is ok, their 0 timepoint of their qPCR is high (start with a lot of genomes) but they increase nicely over time, so it's alright. I sort of don't want to cite it because of the aforementioned issues, but it supports the idea that variation at the receptor can change susceptibility to a SARS-rCoV. Does anyone know of any other papers that do something similar with regards to bat ACE2?

performed an alignment of all nine *Rhinolophus* species ACE2 sequences available in GenBank with Human ACE2 and ACE2 of known susceptible mammalian species. We specifically compared amino acid identities at 20 sites involved in spike binding (Table 1). Where available, sequences from multiple individuals were included.

Strikingly, for those species where multiple ACE2 haplotypes are reported (*R. sinicus*, *R. pearsonii*, and *R. affinis*), multiple different amino acid identities are encoded at sites important for ACE2 binding (Table 1). In cases where there are multiple amino acids possible (e.g. Table 1, site 34), occasionally one amino acid matches the residue(s) encoded by humans. This apparent genetic variation reveals two important implications: 1) certain bat individuals may encode ACE2 receptors that are permissive to coronaviruses infecting humans while others of the same species do not, and 2) certain bat individuals may be more likely to harbor a SARS-CoV strain able to infect humans. We can capitalize on this naturally occurring variation through widespread capture, genotyping at loci of importance for coronavirus infection, and selective breeding to develop a colony of bats ideally poised for controlled viral infection and immunology studies.

Based on current ACE2 sequence data, the intermediate horseshoe bat and Pearson's horseshoe bat (*R. pearsonii*) encode the same amino acids as human at 16 of the 20 residues important for ACE2 binding. The Least horseshoe bat (*R. pusillus*) has 14 matching residues. These **three** species are found in Bangladesh (Table 1). While no bat species encodes the same 20 residues as human, both domestic cats (16 matches) and ferrets (14 matches) are susceptible to SARS-CoV-2, suggesting that all three Bangladeshi species may harbor permissive ACE2 receptors. Intermediate horseshoe bats (16 matches) are widely distributed in southern Asia, including Bangladesh as well as southern China where most of the SARS-CoV sequences have been detected in rhinolophid bats. For this reason, we believe this is the most logical species to capture for susceptibility testing and model development. However, because there are 78 rhinolophid species, we will also capture the other species that are found in Bangladesh (*R. lepidus*, *R. malayanus*, *R. monoceros*, *R. humanus*, *R. luctus*, *R. subbadius*) for importation and SARS-CoV-2 susceptibility testing at CSU.

Commented [MK16]: Maybe a figure showing the species ranges and our proposed site of the Bangladeshi bat colonies?

Table 1. ACE2 amino acid identity amongst Rhinolophid bats and hosts supporting SARS-CoV-2

Species name	Common name	Amino Acid in ACE2																			
		24	27	28	30	31	34	35	37	38	41	42	45	82	83	330	353	354	355	357	393

<i>Mustela putorius</i>	Ferret (N=1)	L	T	F	E	K	Y	E	E	E	Y	Q	L	T	Y	N	K	R	D	R	R
<i>Rhinolophus pusillus</i>	Least horseshoe bat (N=1)	K	K	F	N	D	S	E	E	D	Y	Q	L	N	Y	N	K	G	D	R	R
<i>Rhinolophus macrotis</i>	Big-eared horseshoe bat (N=1)	E	K	F	D	K	S	K	E	D	Y	E	L	N	Y	K	K	G	D	R	R
<i>Rhinolophus landeri</i>	Lander's horseshoe bat (N=1)	L	T	F	D	D	S	A	E	N	Y	Q	L	N	F	N	K	G	D	R	R

Commented [MK17]: Since viruses move through populations, I thought collecting all available complete ACE2 sequences on ncbi (skipped uniprot, but I can add, if necessary) for each of the species listed would be more representative. Also, I edited the text to reflect these changes.

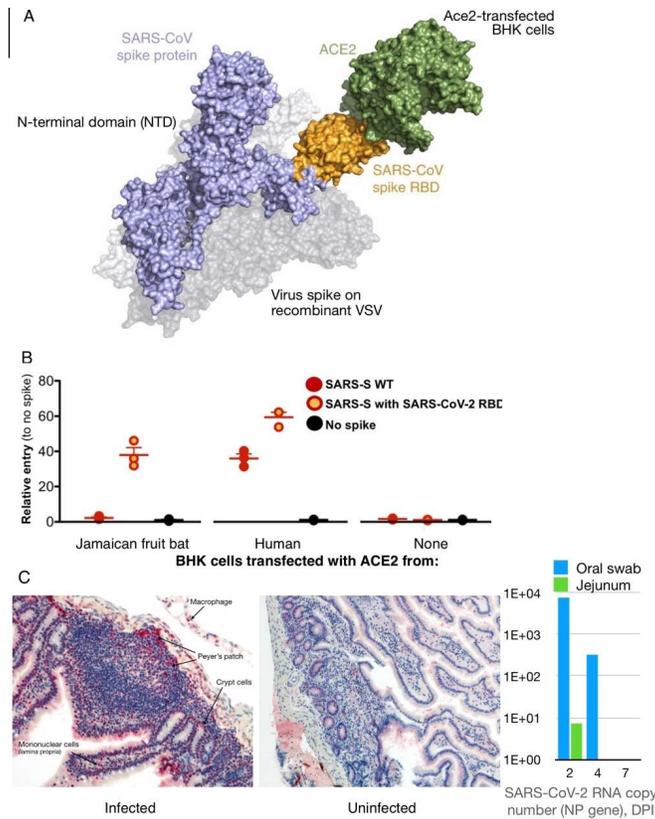

C1.3. Experimental bat coronavirus infections. Drs. Munster and Schountz have extensive experience with experimental infection models of bats, including with MERS-CoV, SARS-CoV-2, H18N11 bat influenza virus, Zika virus and Tacaribe virus. Challenge of Egyptian fruit bats with an infectious clone of WIV-CoV showed limited susceptibility, despite the ability of its spike protein to bind to Egyptian fruit bat ACE2 (30572566). Recent work by our groups has shown that Jamaican fruit bat ACE2 is bound by SARS-CoV-2 (but not SARS-CoV) spike protein expressed by a VSV pseudotype virus and that challenge of Jamaican fruit bats with SARS-CoV-

2 leads to a limited infection that is confined to the small intestine, particularly mononuclear cells of the Peyer's patches and lamina propria, and crypt cells (Fig 2). Viral RNA was detected in oral swabs for 4 days and low levels in the small intestine on day 2. However, no neutralizing antibody or nucleoprotein antibody (ELISA) was detected, suggesting abortive infection or robust control of the virus by the innate immune response.

C1.4.

C2. Specific Aims

C2.1 Aim 1. To establish colonies of horseshoe bats and Indian flying foxes for the study of coronavirus and henipavirus infections. Bats will be captured and quarantined in Bangladesh and tested for coronaviruses, henipaviruses, filoviruses and lyssaviruses. Those that are negative will be imported to Colorado State University for establishment of breeding colonies.

C2.1.1. Establishment of captive breeding colony of *Pteropus medius* in Bangladesh

We will establish a captive breeding colony of *Pteropus medius* in Bangladesh. Temporary holding cages used for quarantine prior to shipment to the US will be erected at the Sheikh Kamal Wildlife Center (SKWC) Purabari, adjacent to Bhawal National Park, Gazipur, north of Dhaka. The land is managed by the Forest Department under the direction of the Conservator of Forests (see Kabir letter of support) Ministry of Environment (Govt of Bangladesh). The bats will be cared for and maintained by Forest Department staff. Staging bats in Bangladesh prior to shipment to the US will occur in X phases. **Phase 1: Holding cage development.** We will build four temporary holding cages [octagonal shape, approx. 6m diameter and 6ft tall] that are large enough to allow bats to fly, and low enough that project personnel can easily repeatedly catch bats for testing during the screening process. Each cage will be built to hold 30 bats, with a heavy retractable curtain subdividing each cage in half, which will allow us to separate bats into smaller groups. One of the cages will be left empty to allow for isolation of bats that test positive for Nipah virus on PCR during the course of quarantine. Each cage will be made from a metal frame with rubber-

Commented [MK18]: I assume the holding cages will be different for the rhinolophid bats, but the capture methods will be the same?

coated mesh screening enclosing the cage. An outer cage will be built around each cage, with 6" of space between the fencing to exclude bats inside from contact with bats outside. A solid roof will be built over each cage to prevent excreta from wild bats from entering the cage area and potentially exposing captive bats to henipaviruses. Each cage will also have a door and an anti-chamber to allow staff to safely enter and exit, don and doff PPE, and then enter the flight cage without bats being able to escape.

Facilities at the wildlife park where the bats will be held will include a food preparation station, PPE storage, first aid and disinfection supplies, and a mobile veterinary lab that includes electricity, a portable gas anesthesia machine, and supplies for collecting biological specimens from the bats.

Phase 2: Bat capture. We will capture wild bats from colonies located in Gazipur. Our goal is to capture a total of 81 bats: 6 males and 75 females comprising three groups of 25 females and 2 males - all Nipah virus negative (by PCR and Luminex). We will capture bats 20 at a time. With each group of 20 bats, we will transport them to the cages from the field site, with each bat held in an individual cotton bag suspended from a post in the back of a vehicle. The driver will be wearing PPE, including an N95 respirator, and all vehicle windows will be open during transport. A plastic sheet will line the floor of the vehicle under the bats to allow for disinfection following transport. Bats will be sampled in the vet lab and then immediately transferred into a holding cage and blood samples and swabs collected. Samples will be screened that day for IgG antibodies using a Luminex, and swabs will be screened for Nipah virus RNA using a qRT-PCR assay at icddr. Seropositive and or PCR positive individuals will be released at the park. Seronegative and PCR negative individuals will be moved into a second staging cage, where they will be held for 21 days, with a second and third round of testing on day 10 and 21 post capture. Any bats subsequently testing positive will be released. Negative bats will be retained.

Phase 3: Breeding colony. We will maintain separate groups of 27 bats in the three flight cages. *Pteropus medius* is a synchronous seasonal breeder, with a 6-month gestation period. We will aim to capture bats during the third trimester of pregnancy (January/February) and allow them to give birth in captivity. Pups will be weaned at 3 months and placed into a fourth cage, where they will be maintained until 1 year of age. Pups will be screened every 2 weeks for Nipah virus and antibodies. Maternal antibodies are expected to wane at around 6-7 months of age. By isolating the pups, born to seronegative, Nipah-negative dams, we will create an SPF (specific-pathogen free) colony that will be used to found the colony at CSU. We will also allow the bats in Bangladesh to breed, creating an F1 generation that will be maintained in captivity and used to support the US-based colony.

C2.1.2. Experimental challenge of rhinolophid bats. We will determine whether Ace2 sequences from various *Rhinolophus* species bats render BHK cells susceptible to SARS-CoV and SARS-CoV-2 using our VSV pseudotype system (Fig XX). Rhinolophid species will be captured and quarantined in Bangladesh and tested for evidence of SARS-like CoV infection (PCR of rectal swabs and serology). Naïve bats will be shipped to Colorado State University for challenge with SARS-CoV and SARS-CoV-2 to determine susceptibility. Those species that are susceptible will be collected in Bangladesh and after quarantine and testing, up to 50 founders will be shipped to CSU to establish breeding colonies. In the event that more than one species is susceptible, we will determine which is most suitable based upon infection kinetics of each virus.

Upon receipt, bats will be immediately examined by veterinary staff at CSU and manually fed meal worms.

C2.2 Aim 2. To develop cell lines, reagents and methodologies for the study of viral infections in horseshoe bats and Indian flying foxes. Primary bat cells will be isolated from bats for susceptibility testing, and stocks of primary cells will be generated for the research community. Susceptible cells will be immortalized to provide indefinite propagation. Organoids of virus targets, such as intestines, will also be generated for virus studies. Recombinant proteins, including cytokines and soluble cell surface antigens, will be generated for in vitro and in vivo use. Monoclonal antibodies to these proteins will also be generated so that investigators can perform in vitro testing and generation of primary cells that require such growth factors, such as antigen-specific T cells, and for the in vivo neutralization of cytokines upon challenge with viruses. Methodologies for transcriptomic, metabolomic and proteomic studies will also be developed.

C2.2.1. Establishment of primary and immortalized bat cell lines. [\(Tony\)](#)

C2.2.2. Production of recombinant bat cytokines and monoclonal antibodies. [\(Brian cytokines, Tony Mab\)](#)

C2.2.3. Development of metabolomic profiles. [\(Lin-fa and Rushika\)](#)

C2.2.4. Development of proteomic profiles. [\(Lin-fa and Rushika\)](#)

C2.3 Aim 3. To perform experimental infections of bats with SARS-CoV-2, bat RaTG13-CoV and Nipah virus to develop laboratory models of bat reservoir hosts. Bats will be challenged with viruses under controlled laboratory conditions to perform kinetic and temporal studies of how these viruses behave in bats, and

how the bats control infections without developing disease. We will also perform studies to assess durability of immunity in bats to determine whether immunity wanes and leads to repeated susceptibility to infection.

C2.3.1. Experimental infection of horseshoe bats with SARS-CoV-2. ([Tony, Lin-fa, Vincent](#))

C2.3.2. Experimental infections of Indian flying foxes with Nipah virus. ([Tony, Lin-fa, Vincent](#))

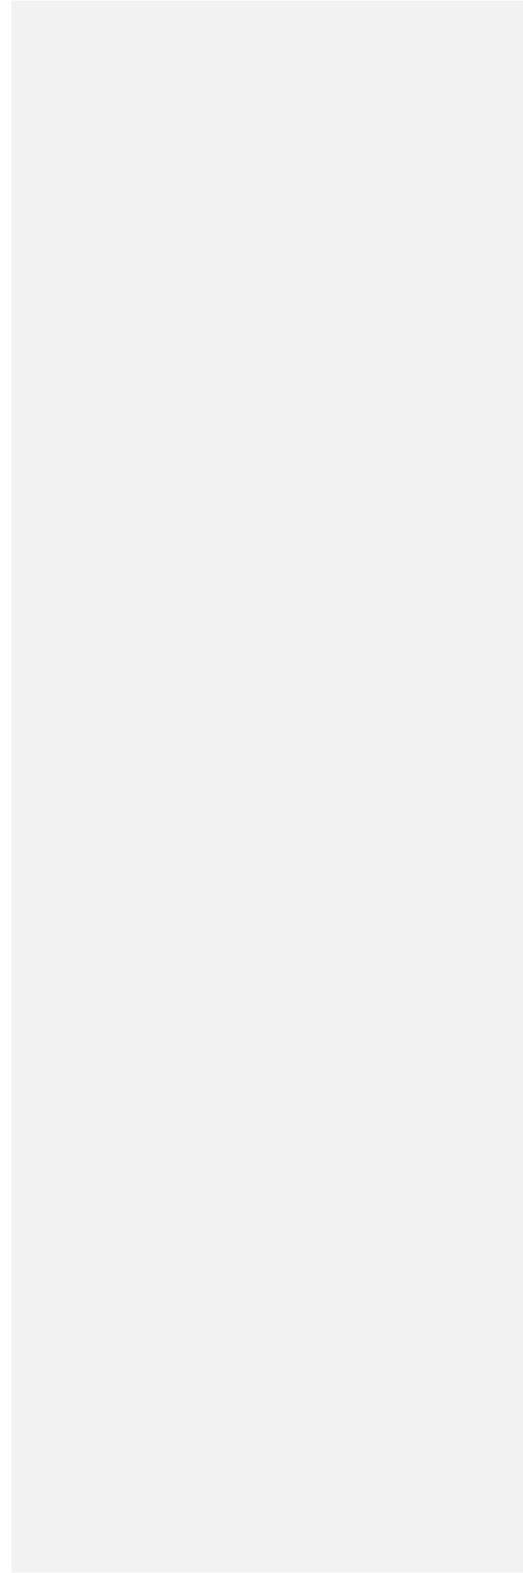

C2.3.3. Generation of bat RaTG13-CoV infectious clone. ([Eric](#))

All, attached is the very rough skeleton of the R24 proposal. I've noted areas for each of you to work on, but of course please feel free to edit any other places you want. It's certainly going to change a bit before the final submission, but Jon and I want to get it to you sooner rather than later. Keep in mind that R24s are not supposed to be hypothesis-driven; they are really about resource development. The NIAID program officers gave us permission to do experimental challenges (Aim 3) so that's the place where we can do some science. We need to keep the Research Strategy to 12 pages (like an R01), so that means that means your sections should be a page to a page and a half. For your references, please just insert the PMID number and I'll get it the references inserted and formatted. It would be great if you could get your edits to us by Friday, but no later than Monday morning so that Jon and I can tidy up the proposal in preparation for submission on January 22.

For R24s, the Resource Sharing plan is critically important since the mechanism is directed to distribution of materials to the greater research community. We haven't started on that but I expect that once the proposal starts to shape up, this section will be mostly self-populating (but of course everyone will get to see it before it is submitted).

Susan Rogers here at CSU is assembling the budgets and I think it will start routing through CSU's internal review process. If there are any problems, I'll be sure to let you know ASAP.

Jon and I have lined up several people who will provide letters of support for the proposal and I will be working on draft letters for each of them today.

Let me know if you have questions.

Thanks,

Tony

Abstract

1. Bats are the second most species-rich Mammalian order and provide a wide range of ecologically important and economically significant ecosystem services. Nipah virus is a zoonotic emerging infectious disease for which pteropodid bats have been identified as a natural reservoir. In Cambodia, Nipah virus circulation has been reported in *Pteropus lylei*, but little is known about the spatial distribution of the species and the associated implications for conservation and public health.
2. We deployed Global Positioning System (GPS) collars on 14 *P. lylei* to study their movements and foraging behavior in Cambodia in 2016. All of the flying foxes were captured from the same roost, and GPS locations were collected for 1 month. The habitats used by each bat were characterized through ground-truthing, and a spatial distribution model was developed of foraging sites.
3. A total of 13,643 valid locations were collected during the study. Our study bats flew approximately 20 km from the roost each night to forage. The maximum distance traveled per night ranged from 6.88–105 km and averaged 28.3 km. Six of the 14 bats visited another roost for at least one night during the study, including one roost located 105 km away.
4. Most foraging locations were in residential areas (53.7%) followed by plantations (26.6%). Our spatial distribution model confirmed that residential areas were the preferred foraging habitat for *P. lylei*, although our results should be interpreted with caution due to the limited number of individuals studied.
5. *Synthesis and applications:* Our findings suggest that the use of residential and agricultural habitats by *P. lylei* may create opportunities for bats to interact with humans and livestock. They also suggest the importance of anthropogenic habitats for conservation of this vulnerable and ecologically important group in Cambodia. Our mapping of the probability of occurrence of foraging sites will help identification of areas where public awareness should be promoted regarding the

1 | INTRODUCTION

Bats are the second most species-rich Mammalian order with over 1,300 species worldwide (Voigt & Kingston, 2016) and provide a wide range of ecologically important and economically significant ecosystem services (Kunz, Torrez, Bauer, Lobo, & Fleming, 2011). They are also recognized as reservoir hosts for highly pathogenic viruses such as Nipah virus (NiV; Calisher, Childs, Field, Holmes, & Schountz, 2006).

Nipah virus was first identified in pigs and people in Malaysia in 1998 (Chua, 2000) and has reemerged annually in Bangladesh since 2001 (Luby et al., 2009). NiV causes lethal encephalitis in people, and bats in the *Pteropus* genus are the reservoir (Epstein, Field, Luby, Pulliam, & Daszak, 2006). Transmission of the virus in Malaysia is presumed to have occurred as a result of pigs consuming bat-contaminated fruits, followed by contamination of humans working with pigs (Chua, 2003). In Bangladesh, direct bat-to-human transmission of the virus occurs through the consumption of date palm sap (Luby et al., 2006). NiV has been isolated or detected in several *Pteropus* species in Southeast Asia, including *P. medius* in Bangladesh, *P. lylei* in Thailand and Cambodia, and *P. vampyrus* and *P. hypomelanus* in Malaysia. However, despite its detection in *P. hypomelanus*, a serological study on Tioman Island did not find the virus in any of the local people (Chong, Tan, Goh, Lam, & Bing, 2003) that the bats live among and regularly interact with (Aziz, Clements, Giam, Forget, & Campos-Arceiz, 2017). Seasonal NiV shedding patterns have been suggested for *P. lylei* in Thailand, with peak shedding occurring in May (Cappelle, Hul, Duong, Tarantola, & Buchy, 2014; Wacharapluesadee et al., 2010).

Understanding the capacity of a reservoir to spread the virus at local and regional levels to humans and domestic animals is fundamental to surveillance and prevention initiatives. Knowledge about the distribution and movement patterns of these bat species is thus required, and telemetry (measurement and transmission of data from remote sources) is a valuable tool to monitor the drivers and characteristics of fruit bat movements (Smith et al., 2011). This can be used to develop appropriate host management strategies that maximize the conservation of bat populations and minimize the risk of disease outbreaks in domestic animals and humans.

Telemetry studies have been undertaken on several *Pteropus* species in Asia and Australia. In Australia, tracking of fourteen *P. poliocephalus* males revealed that these are highly mobile between roosts and regularly travel long distances (Roberts, Catterall, Eby, & Kanowski, 2012). For instance, one *P. alecto* was tracked between

Papua New Guinea and Australia and traveled more than 3,000 km over 11 months (Breed, Field, Smith, Edmonston, & Meers, 2010). In Southeast Asia, the movements of seven *P. vampyrus* males encompassed Malaysia, Indonesia, and Thailand, indicating the need for regional management plans for such species (Epstein et al., 2009). These studies highlight the difference between migratory and non-migratory flying foxes and the need to adapt management strategies to relevant geographic scales.

At a local scale, telemetry studies indicate that *Pteropus* bats make foraging flights on a nightly basis, with distances from the roost ranging from a few kilometers to 20–30 km. Depending on species, foraging sites range from apparently intact forest to cultivated areas. In Bangladesh, the roosting ecology of *P. giganteus* is associated with forest fragmentation, likely because fragmented forests offers more foraging options to the bats, including fruit species cultivated by humans (Hahn et al., 2014). Conversely, in the Philippines, most foraging locations of eight *Acerodon jubatus* were situated in closed forest remote from areas of evident human activity (de Jong et al., 2013). Another study on *A. jubatus* and *P. vampyrus* in the Philippines suggested these species prefer undisturbed forest types and select against disturbed and agricultural areas (Mildenstein, Stier, Nuevo-Diego, & Mills, 2005). Foraging also repeatedly occurred 15–30 km from the roost on average. Similarly, movements of *P. alecto* were very similar between nights with most foraging sites located less than 6 km from roost sites. In Thailand, *P. lylei* also undertakes relatively short foraging movements (2.2–23.6 km) on a nightly basis to fields, plantations, backyards, and mangroves (Weber et al., 2015).

In Cambodia, three flying fox species are thought to occur, large flying fox *P. vampyrus* which is listed as “near threatened” by IUCN, Lyle's flying fox *P. lylei* which is listed as “vulnerable,” and island flying fox *P. hypomelanus*, which is listed as “least concern” (IUCN, 2008; Kingsada et al., 2011). Most of the known flying fox roost sites in Cambodia are located on the grounds of pagodas, where hunting is limited by the presence of the monks (Ravon, Furey, Hul, & Cappelle, 2014). Consequently, these are often located in the middle of villages close to human and domestic animal populations, and available foraging areas mostly comprise anthropogenic landscapes. Flying foxes in Cambodia are likely to interact frequently with humans and to depend on human activities for their subsistence. As a consequence, understanding of their preferred foraging areas is important to inform public health and conservation actions.

The objective of our study was to use telemetry data to determine and characterize foraging locations visited by flying foxes

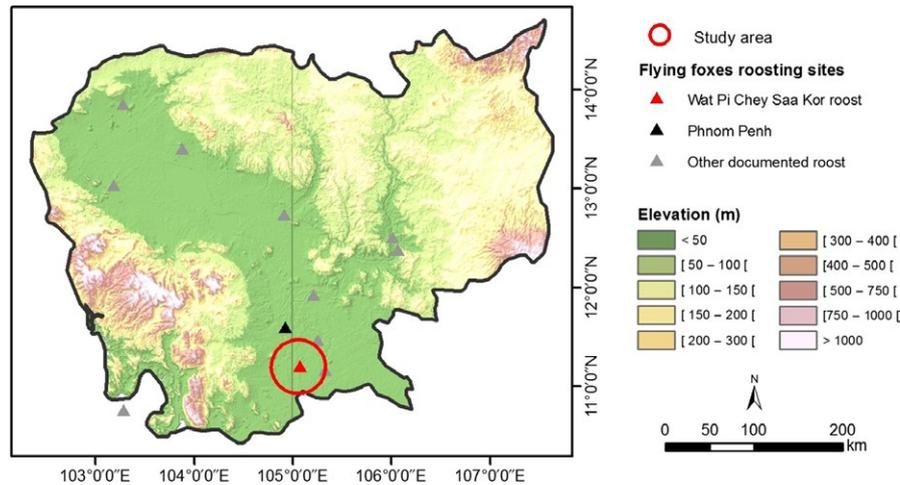

FIGURE 1 Location of the study area and other flying fox roost sites known in Cambodia

inhabiting a *P. lylei* roost in Koh Thom District, Kandal Province, Cambodia.

2 | MATERIALS AND METHODS

2.1 | Study site

The *P. lylei* roost selected for this study was located at Wat Pi Chey Saa Kor (11.200 N, 105.058 E), Kom Pong Kor village, Koh Thom District, Kandal Province (Figure 1). The site comprises a grove of trees on the grounds of a Buddhist pagoda which encompasses 21 roost trees with an estimated population of 4,000 flying foxes (Ravon et al., 2014). The village is bisected by a road with houses on either side and is characterized by a mosaic of agriculture that lacks significant areas of natural vegetation/forest. Land uses in the region include cultivation of rice and other crops, backyards, plantations, and various backyard animal farming activities.

2.2 | Study period

Our study was conducted from April 18, 2016 to May 17, 2016 when shedding of the NiV by *P. lylei* is believed to peak in Cambodia (Cappelle et al., 2014), similar to Thailand (Wacharapluesadee et al., 2010). Nine Global Positioning System (GPS) collars were deployed from April 18, 2016 to April 21, 2016 and five GPS collars from May 3, 2016 to May 6, 2016. Data were collected from these every day for two weeks after each collaring, related to the lifespan of individual collars.

2.3 | Bat collaring

Bats were captured using mist nets between 6 p.m. and 5 a.m. using methods described in (Newman, Field, Epstein, & De Jong, 2011). Weight, forearm length, sex, age, and reproductive status were documented for each bat. Animals were selected for collaring based on weight. Adult males and females without pups weighing at least

400 g were selected so that collars, weighting 20 g, would comprise <5% of body mass (Brigham, 1988). Pregnant and lactating female bats were excluded to avoid adding extra burdens.

Selected bats were anesthetized by injecting medetomidine into the pectoral muscle (Epstein, Zambriski, Rostal, Heard, & Daszak, 2011). GPS devices (FLR V, Telemetry Solutions™, www.telemetrysolutions.com) attached to nylon bands were secured around the neck of each bat using catgut suture (1.0) and three surgical knots (Figure 2), which were presumed to last for at least 30 days. Following collar attachment, atipamezol was injected intramuscularly. Each collared bat was kept in a separate cage during recovery from anesthesia and offered pieces of mango ad libitum prior to release.

We deployed 14 GPS collars on 13 adult males and one adult female (Table 1). Collars 1–5 were programed to transmit one location every 30 min from 5 p.m. to 6 a.m. while collars 6–14 were programed to transmit one location every 30 min for the first night only and one location every 5 min from 5 p.m. to 6 a.m. on following nights. As a consequence, collars 1–5 were expected to last for 1 month and allow observations of foraging behavior across the expected annual excretion peak of NiV. Collars 6–14 were expected to last for 10 days and provide detailed information on *P. lylei* foraging sites, including night roosts. Data were remotely downloaded each morning from active collars with a base station, which automatically connected to the GPS collars when within reading distance (10–20 m).

2.4 | Spatial data and site characterization

Global Positioning System data were transferred each morning to a computer, converted into KML format (QGIS, version 2.14), and mapped to identify foraging locations visited by bats the previous night (Google Earth, version 7.1). Foraging sites were identified based on clusters of two or more locations obtained from individual bats and as many as possible were visited depending on accessibility. Tree species visited by bats and evidence of foraging such as partially

eaten fruits were recorded to facilitate identification of roosting and feeding trees. Nonfruiting trees were also recorded.

2.5 | Habitat use

All locations were classified in three major categories: roost locations (all points less than 30 m from the roost site), foraging locations (a cluster of ≥ 2 two points separated by < 30 m where the bat spent at least 10 min at night (i.e., from 6 p.m. to 6 a.m.)), and commuting locations (isolated points connecting the roost and foraging sites located > 30 m from a foraging or roost location). Based on patterns visible in Google Earth, five habitat types were recognized for foraging locations: plantations (including fruit trees within the plantation and trees around the plantation), residential areas (locations within 50 m of human settlements, including pagodas, backyards, roads),

FIGURE 2 Collared *Pteropus lylei*, southern Cambodia

agricultural lands (any cultivated land not included in “plantations” and “residential areas”), rivers, and uncultivated areas (all locations not included in the preceding categories).

2.6 | Spatial analysis

The home range of an animal illustrates spatial and temporal use of an area and is defined as the area commonly used for normal activities such as foraging for food, breeding, and caring for young (Burt, 1943). We used the kernelUD() function of the Adehabitat package in R software (Version 3.2.3) to estimate the home range for all bats, using the kernel density method (Calenge, 2006). The function computes the different percentage levels of home range estimation, for example the 50% home range identifies the areas where an individual is likely to occur 50% of the time.

We used QGIS to analyze the trajectories of each bat and to generate heatmaps based on kernel density estimation. The density was calculated based on the number of points in a location, with larger numbers of clustered points resulting in larger values. We also used the sp package in R software to calculate the maximum linear distance traveled from the roost per night.

The spatial distribution of foraging sites in the study area was modeled using the GPS data collected, a set of generated background data and land cover data. We created a map which classified habitats according to their expected influence on foraging site selection by the bats. This map was the product of a classification procedure based on Landsat images (30 m spatial resolution) acquired in 2015 and ground-truthing. Details of the classification are provided as Appendix (Supporting information Appendix S1: Table S1), and the result is illustrated by (Supporting information Appendix S1: Figure S1). The eight different habitats identified in this classification were

TABLE 1 Characteristics of *Pteropus lylei* studied and GPS device performance, southern Cambodia. The proportion of valid data corresponds to the proportion of locations recorded with valid geographic coordinates

Bat ID	Sex	Reproductive Status	Weight (g)	Forearm (mm)	Collar lifespan (nights)	Total recorded data	Proportion of valid data (%)

Bat14	Male	Mature	550	152.4	13	1,912	97

speculated to have the following impacts on the distribution of foraging sites. Plantations were expected to be highly attractive to bats because of the high density of fruit available. Tree vegetation was expected to be attractive because of the potential presence of fruit consumed by bats. Water bodies such as rivers were also expected to attract the bats due to the presence of fruit trees on their banks. Residential areas were expected to have mixed effects as a source of disturbance for the bats and a potential source of fruit in backyards. The four remaining habitats in the classification (rice field, bare soil, flooded vegetation, and shrubland) were not expected to attract the bats.

To train and validate the model, we used all GPS locations of foraging sites and generated an equivalent number of background locations in the study area which were used as pseudoabsences by the model. Half of the data were randomly assigned to a training dataset and the other half to a validation dataset. We used a generalized linear model with the training dataset as the response variable with a binomial distribution (1 for presence and 0 for pseudoabsence) and habitat type as an explanatory qualitative variable. To deal with the discrepancy between the spatial resolution of our classification (30 m) and GPS points (1–5 m), we calculated the distances of all data points to the closest habitats with an expected influence on bat habitat selection: plantations, tree vegetation, water bodies, and residential areas. Because of this discrepancy and landscape fragmentation in the study area, GPS locations of bats foraging in attractive habitats could be recorded in an adjacent nonattractive habitat. We therefore generated four explanatory variables (dPlant, dTree, dWater, and dResid) to allow us to capture the spatial structure of the study area. Using the distance to these attractive habitats as explanatory variables in the model would then help take into account the limited spatial resolution of

our habitat classification as well as spatial autocorrelation. As a consequence, no further variable was added to the model to deal with the latter. Finally, distance to the roost (dRoost) was added to the explanatory variables as this should be minimized by the bats to optimize their energy efficiency while foraging. We used the results of the model, which was based on data from 14 individuals, to map the probability of presence of the foraging sites of *P. lylei* in the study area. The validation dataset was used to estimate the performance of the model through the calculation of the area under the ROC curve (AUC).

3 | RESULTS

3.1 | Collar performance

A total of 84 bats were caught, 14 of which were selected for collaring (Table 1). Our GPS devices transmitted from 1 to 26 nights, with an average of 11.8 nights (Table 1). A total of 13,646 valid locations were collected over 27 nights from the 14 collared bats. The proportion of valid data (i.e., data with an actual geographic location provided) varied from 32% to 99% of the data provided by each collar. Overall, 84.6% of the data generated were valid locations ($n = 13,646/16,128$).

3.2 | Habitat use

Tree species identified during visits to foraging sites are listed in Table 2. Partially eaten mango (*Mangifera indica*, $n = 15$) and sapodilla (*Manilkara zapota*, $n = 3$) were found at exact GPS foraging locations (Figure 3). It was not possible to detect whether leaves or flowers were also consumed.

TABLE 2 Tree species identified at foraging sites of 14 GPS-collared *Pteropus lylei*, southern Cambodia

^aDirect means direct evidence from feces or feeding remains, indirect means information based on evidence from location data but with no direct evidence from feces or feeding remains. Based on (Aziz, Clements, Peng et al., 2017; Hahn et al., 2014; Weber et al., 2015; Win & Mya, 2015).

Among the valid data, 29% of the locations ($n = 3,959/13,646$) corresponded to the roost site where the bats were captured, 20.3% ($n = 2,774$) to commuting locations, and 50.7% ($n = 6,913$) to foraging locations and night roosts. Most of the foraging locations were in residential areas: 53.7% ($n = 3,714/6,913$), 26.6% ($n = 1,836$) in plantations, 16.2% ($n = 1,118$) in uncultivated areas, 3.2% ($n = 219$) in agricultural lands, and 0.4% ($n = 26$) on rivers (Table 3). (Supporting information Appendix S1: Figure S2) shows the spatial distribution of the foraging sites in the study area.

3.3 | Movement patterns and flight distances

The maximum distance traveled per bat/night ranged from 6.88 to 105.14 km and averaged 28.3 km (Table 3). All individuals showed fidelity to at least one foraging site, returning on 3–11 nights to the same site (all locations <30 m from the previous one were counted as the same foraging site) during the study period. Thirty-six foraging sites were shared by at least two bats. All bats (excluding bat #9 due to lack of data) shared at least one and as many as eight foraging locations with another bat. Shared foraging locations or night roosts were relatively close to the roost, with an average and maximum distance of 2.85 and 7.75 km, respectively. Eight bats returned to the study roost every night (bats #1–3, #6, #9, #11, #13–14). Of the six remaining bats, four went to a nearby *P. lylei* roost in Prey Veng Province (28 km east, Wat Veal Lbang, Prey Veng, 700 flying foxes), whereas two went to more distant and previously unknown roosting sites: 65 km in one night (site A) and 105 km over two nights (site B) for bat #8 and 50 km during one night (site C) for bat #10 (Figure 4).

3.4 | Spatial analysis

The complete results of the home range estimations for all bats are shown in (Supporting information Table S2). The estimated home ranges were maximal for bats #08 and #10 which went to distant

FIGURE 3 Partially consumed mangoes at a GPS foraging location of *Pteropus lylei*, Kandal Province, southern Cambodia

roosts, with 95% home range of respectively 5,984 and 1,158 km². For the eight bats that did not join another roost, the 95% home range ranged from 29.5 to 316.8 km² with an average 95% home range of 104.5 km² ($SD = 115.5$ km²). The 50% home range of these same eight bats ranged from 4.3 to 41.1 km² with an average 95% home range of 14.9 km² ($SD = 13.4$ km²). Our heatmap of GPS locations showed that most foraging sites and night roosts were located <15 km from the roost (Figure 5). The spatial distribution model showed that foraging locations were significantly negatively correlated with the distance to the roost, residential areas, and water bodies. Conversely, foraging locations were significantly and positively correlated with distance to plantations. Residential areas, trees, and plantations were the main foraging habitats used by the bats (Table 4). Our map of the probability of *P. lylei* foraging sites highlights areas close to the roost but also helps to identify further areas where bat–human interfaces could occur (Figure 6). Model performance was very good with a cross-validated AUC of 0.93.

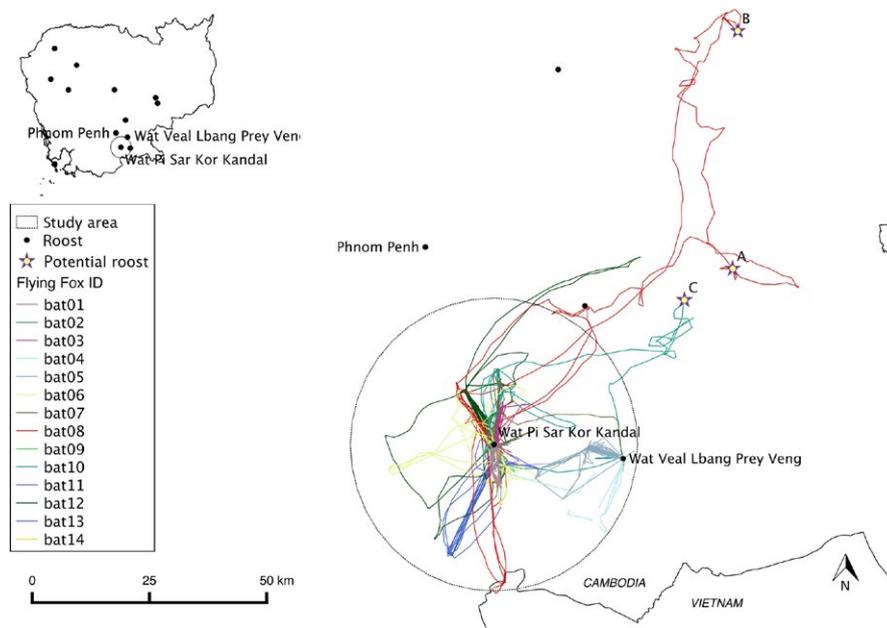

4 | DISCUSSION

Our study yielded two main results. First, our study bats mostly foraged in residential areas (53.7% of foraging locations) rather than in plantations (25.6%) and our spatial model indicated that residential areas were the preferred foraging habitat (Table 4). While other studies have shown that *P. lylei* and *P. giganteus* can primarily forage in anthropogenic landscapes (Hahn et al., 2014; Luskin, 2010; Weber et al., 2015), our data indicate a particularly strong interface through residential backyards where the potential for contact between bats and humans would be higher due to continuous human presence. This could potentially facilitate NiV transmission to humans and domestic animals and two transmission routes have been documented in previous outbreaks of NiV. The first is directly from bats to humans due to consumption of raw palm sap contaminated by flying foxes, which has led to recurrent outbreaks in Bangladesh (Luby et al., 2009). The second route was suggested for the Malaysian outbreak where pigs were likely infected after consuming fruit contaminated by flying foxes (Chua, 2003) and supported by isolation of the virus from fruit partially eaten by bats in Malaysia (Chua et al., 2002). Consistent with this second route, a direct bat-to-human transmission via ingestion of fruit has been suggested for another paramyxovirus in Malaysia (Yaiw et al., 2007). Thus, by frequently foraging in residential areas, *P. lylei* could contaminate fruit where humans and domestic animals live, increasing the chance of indirect contact. As such, further information on the use by local residents of fruit partially eaten by bats would help to characterize transmission risks and inform preventative actions including promotion of public awareness. Similarly, palm sap collectors in the study area reported seeing flying foxes on palm trees and urine and feces on collection containers. As our data also indicate that *P. lylei* visits these trees (Table 2), research on palm sap collection in the area is needed to assess the risk associated with this potential transmission route.

**FIGURE 4** Movements of 14 GPS-collared *Pteropus lylei* during the study period in southern Cambodia

Our finding that *P. lylei* mostly forages in residential areas—which mostly correspond to backyards—rather than in plantations was unexpected because human disturbance would likely be higher in the former and food availability greater in the latter. Since our data indicate that *P. lylei* feeds on a variety of fruit in April–May, the greater diversity of fruit typically found in backyards compared to plantations could possibly explain this. More generally, the link between flying fox foraging behavior and the greater diversity of fruits in anthropogenic versus natural environments has been reported elsewhere (Hahn et al., 2014; Luskin, 2010; Weber et al., 2015). All

foraging sites in our study were located in anthropogenic landscapes and all individuals showed fidelity to foraging areas, indicating repeated utilization once a food resource was located. This is presumably more energy-efficient than random foraging and is consistent with studies of *A. jubatus* in the Philippines (de Jong et al., 2013) and *P. alecto* in Australia (Palmer & Woinarski, 1999). From an epidemiological standpoint, an infectious flying fox repeatedly shedding virus in the same area could facilitate site contamination and increase the risk of transmission to humans or animals. Indeed, all of our 14 bats shared at least one foraging site during the study. Repeated shedding

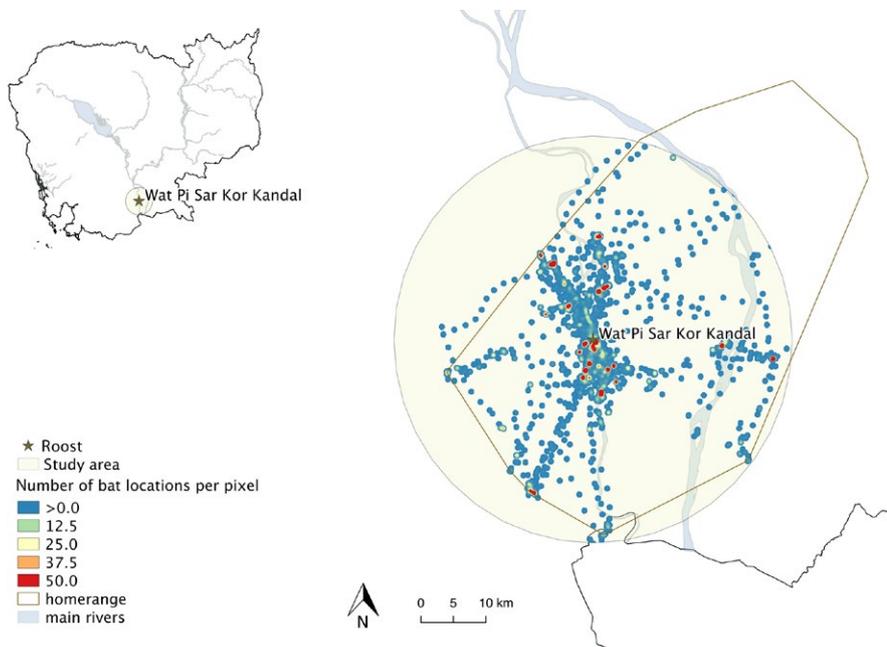

FIGURE 5 Heatmap of *Pteropus lylei* movements and home range (minimum convex polygon) in southern Cambodia

at a shared foraging site or night roost could also increase pathogen transmission in the bat population through fruit contamination. In future analyses, we will use a hidden Markov model to determine different phases of nightly movements and attempt to differentiate foraging sites from night roosts.

From a conservation perspective, the apparent preference for backyards and plantations suggest that our *P. lylei* population is highly dependent on human activities for foraging. As such, understanding of community knowledge, attitudes, and practices regarding bats will be important to develop appropriate conservation and public awareness strategies and is now underway. Nevertheless, that residential backyards were the most strongly selected foraging habitat suggests that conflict with humans may be limited in our study area. This is consistent with the fact that other patches of trees were also attractive to our study bats ("Tree vegetation" in Table 4), albeit less than backyards and plantations. Were major bat–human conflicts to occur in our study area, the few attractive non-human-dominated habitats present could possibly become overselected by the bats. However, our results must of course be interpreted with caution as only 14 bats in the same population were studied.

Second, because six of our 14 study bats visited at least one other roost during our 28-day study, it would appear that movements to other roost sites are relatively frequent. However, these movements were limited in time and the fidelity shown to the day roost by all of our study bats is consistent with the non-nomadic ecology attributed to *P. lylei*. Similar to observations for *P. vampyrus* (Epstein et al., 2009) and *P. medius* (Epstein, unpublished), visits to four other roosts including one 105 km from the study site were observed. These frequent exchanges between roosts are consistent with a regional circulation of different NiV strains in Southeast Asia suggested in previous studies (Epstein, 2017; Wacharapluesadee et al., 2016). From a conservation perspective, they also suggest that *P. lylei* in Cambodia is likely a metapopulation and that conservation

strategies should be planned on a regional scale. This is consistent with the results of another telemetry study on the migratory *P. vampyrus*, calling for a comprehensive protection by regional management plans across their international range (Epstein et al., 2009).

The main limitation of our research is the small number of individuals we could study. With only 14 nonrandomly selected individuals tracked out of an estimated 4,000–6,000, our data are unlikely to be representative of the roost population as a whole. Additionally, because foraging behavior is highly dependent on local environments, our results should not be extrapolated to all *P. lylei* colonies in Cambodia. Furthermore, our study group had a strong male bias, with only one female tagged with the GPS device. Though

TABLE 4 Results of generalized linear model. Significant explanatory variables with a p -value $<10^{-3}$ are given in bold

Variable	Coefficient (SE)	p -Value
Intercept	2.844 (0.355)	$1.10 \cdot 10^{-15}$

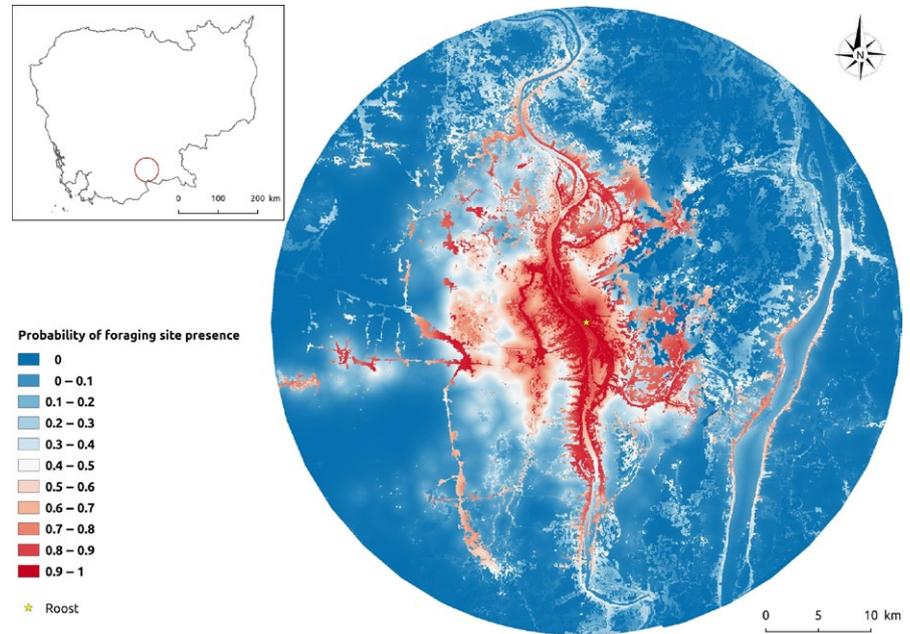

FIGURE 6 Probability of occurrence of *Pteropus lylei* foraging sites based on spatial distribution modeling, southern Cambodia. The model was trained and validated with GPS locations from 14 tracked individuals

other females were caught, these were excluded as they were pregnant or lactating and because limited data are available for female *P. lylei*, it remains unclear if the sexes differ in their foraging behavior. For instance, while female and male *P. poliocephalus* are similar in their movement patterns (Roberts et al., 2012; Tidemann & Nelson, 2004), lactating females of *P. alecto* travel greater distances between roosts and foraging sites than males (Palmer & Woinarski, 1999; Roberts et al., 2012). Nine of the 14 GPS collars we deployed lasted for at least 10 nights (average 11.8 nights), and 80% of the data were valid. Three other collars provided relatively few valid locations, and only one failed to transmit meaningful data. This performance rate was probably influenced by extended battery life due to high temperatures during the study period, while the open agricultural landscape of our study area probably facilitated the acquisition of GPS locations, saving further battery power. We deployed GPS devices on a limited number of individuals, preventing us from any generalization of the observed patterns at the population level. However, the results were consistent between the different individuals and provided useful information on the movement and foraging ecology of *P. lylei* in Cambodia. The GPS devices we used were battery-powered, and the size of the battery was limited by the body weight of the flying foxes. By programming five GPS devices to record locations every 30 min instead of 5 min for the nine other devices, we expected them to last for a month. However, data for only two of these bats were collected for more than 20 days, limiting our capacity to observe any change in foraging patterns over this period. Further studies should then be implemented to assess any variability of foraging patterns over time.

While our data represent a brief snapshot in time, they nonetheless illustrate the potential for foraging behavior to potentially facilitate NiV transmission to humans and domestic animals. To date, no transmission from *P. lylei* to human or animals has been recorded despite the circulation of NiV in this species in Cambodia and Thailand (Cappelle

et al., 2014; Reynes et al., 2005; Wacharapluesadee et al., 2010). The presence of a hazard such as the NiV in a reservoir population does not necessarily lead to an emergence (Hosseini et al., 2017). Indeed, despite NiV being detected in *P. hypomelanus* on Tioman Island, no outbreak has occurred there, and no evidence of the virus has been found in people on the island (Chong et al., 2003). As such, close and frequent interfaces between bats and humans, including bats roosting in the middle of villages and feeding on cultivated fruit in residential backyards and orchards (Aziz, Clements, Giam et al., 2017) may not be sufficient to lead to an emergence. Other factors such as cultural and agricultural practices must be taken into account.

Different agricultural practices may lead to different levels of exposure in the countries of Southeast and South Asia. Conditions specific to intensive pig farming in Malaysia or palm sap collection in Bangladesh may explain why the virus emerged in these countries. Nevertheless, understanding the ecology of *P. lylei* may significantly improve our ability to target limited resources for interventions, and educational campaigns that discuss the risks of NiV to people and their domestic animals (Nahar et al., 2014; Parveen et al., 2016). In particular, while based on only 14 individuals, our mapping of the probability of occurrence of foraging sites for the *P. lylei* will help targeting prevention measures to areas where contact between flying foxes and humans can be expected.

ACKNOWLEDGMENTS

For their help in the field, we thank Pring Long and Yen Sroy. Particular gratitude is due to Dr Keo Omaliss of the Forestry Administration of the Cambodia Ministry of Agriculture, Forest and Fisheries for arranging study approval and permissions by the national authorities of Cambodia. This study was supported by the European Commission Innovate program (ComAcross project, grant no. DCI-ASIE/2013/315-047) and the French "Centre National

d'Etudes Spatiales" (TeleNipah project, DAR 4800000780). USAID's Emerging Pandemic Threats, PREDICT program (Epstein).

CONFLICT OF INTEREST

None declared.

AUTHOR CONTRIBUTIONS

JC and AT conceived the study and designed methodology; JC and TH coordinated the capture of the bats with the help of KC, SR, NF, VH, and CN; JHE coordinated the deployment of the GPS collars; AT, MG, and AJ collected environmental data and produced the land cover map of the study area; KC and SR collected the GPS data from the collars; KC and SR analyzed the data and led the writing of the manuscript. KC, SR, and JC drafted the first version of the manuscript and all authors contributed critically to the drafts and gave final approval for publication.

DATA ACCESSIBILITY

The data used in this study are available on Movebank (movebank.org, study name "Foraging movements of Lyle's flying foxes in Cambodia (data from Choden et al. 2019)") and are published in the Movebank Data Repository (Choden et al., 2019). <https://doi.org/10.5441/001/1.j25661td>.

1st Annual BOHRN RESEARCH WORKSHOP

Workshop Overview

Executive Summary

The Bat/One Health Research Network (BOHRN) convened its 1st Annual Research Workshop in Vienna, Austria, 7-8 November 2018, in advance of the International Meeting on Emerging Diseases and Surveillance (IMED). This two-day workshop was organized and hosted by the Defense Threat Reduction Agency, Cooperative Threat Reduction Directorate, Biological Threat Reduction Program (BTRP) in its capacity as a sponsor of life-sciences research-based Threat Reduction Networks (TRNs). This event provided an opportunity to advance BOHRN's core agenda of enabling interdisciplinary collaboration at the interface of biological threat reduction, research, and conservation.

The BOHRN initiative was organized at a side-meeting of the 2nd International Symposium on Infectious Diseases of Bats in Fort Collins, CO on 29 June 2017. During this meeting participants established a Steering Committee and began preliminary actions to build a multi-disciplined, self-sustainable network to better characterize global threats of bat-borne pathogens and formalize community standards and conservation-conscious practices for One Health disease research. During a series of follow-on meetings, members of the BOHRN Steering Committee identified objectives and developed a research strategy to prioritize and target common needs. The BOHRN 1st Annual Research Workshop in Vienna provided an opportunity to validate its research strategy with a wider audience.

The workshop began with a series of introductory presentations from Dr. Martha Stokes, DTRA BTRP, who provided background on her organization and the BOHRN effort. There were also a series of presentations from other subject matter experts who provided short lectures on areas were identified as knowledge gaps by members of the Steering Committee at previous BOHRN meetings (note: the full agenda may be found [here](#)). Next, workshop attendees participated in two breakout sessions. The first session focused on the research focus areas within the four (4) BOHRN Working Groups and aimed to solicit feed-back in real time on the short and long-term objectives within each network working group.

The second breakout session was initiated by an interactive exercise, facilitated by Dr. Tigga Kingston (Texas Tech University) and Dr. Jon Epstein (EcoHealth Alliance), mapping the intersection of ecological and epidemiological research questions. Participants were then divided into regional groups with diverse and varying levels of expertise to sketch out hypothesis-driven research projects that mapped to BOHRN working group focus areas. Members of the BOHRN Steering Committee and other experts were on-hand to provide mentorship and guidance. At the end of the workshop, each project was presented orally by a member of the project team in a mock peer review session for feed-back and discussion.

The output and recommendations gathered from the small-group sessions will inform BOHRN next steps, which Dr. Stokes described at the conclusion of the workshop as a series of special grant awards for project proposals under BOHRN. She described the process as 'still under construction' but affirmed her leadership's commitment to maintain the network's initial momentum. While the exact mechanism and criteria for award are still being discussed, all interested parties may anticipate a call for proposals via the BOHRN website at some point in the spring of 2019.

1st Annual BOHRN RESEARCH WORKSHOP

There are a number of factors that make bats unique disease reservoirs, including their social behavior, distinct physiology and metabolism, ability to travel long distance, nocturnal activity, species diversity, and long life-span. BTRP anticipates that by taking a lead in funding bat-associated pathogen research, their organization can play a significant role in better characterizing the role of bats in global zoonotic disease ecology, coupled with assessing the impact of human-mediated interactions and environmental changes, to better understand threat reduction value of surveillance and intervention efforts.

Previous BOHRN Events

BOHRN Kick-off Meeting

- Concurrent with 2nd International Symposium on EID
- Sponsored by BTRP
- Took place in Fort Collins, CO – 29 June 2017
- **Outcomes:** (1) established a steering committee; (2) drafted terms of reference; (3) identified research areas of interest

BOHRN Steering Committee Strategy Mapping Meeting – 1

- Concurrent with Prince Mahidol Award Ceremony
- Sponsored by BTRP
- Took place in Bangkok, Thailand – 30 January 2018
- **Outcomes:** (1) prioritized research focus areas; (2) developed targeted action plans; (3) drafted associated workplans and timelines

BOHRN Steering Committee Strategy Mapping Meeting – 2

- Concurrent with International One Health Congress
- Sponsored by BTRP
- Took place in Saskatoon, Canada – 20-21 June 2018
- **Outcomes:** (1) completed workplans and timelines for research focus areas; (2) established BOHRN branding and website; (3) drafted communication and outreach strategy

BOHRN Biological Threat Characterization Discussion

- Concurrent with Western Asia Bat Network (WABNet) Kickoff Meeting
- Sponsored by BTRP, organized by EcoHealth Alliance
- Took place in Tbilisi, Georgia – 20 September 2018
- **Outcomes:** (1) identified and characterized regionally-focused gaps and needs (2) activated communication and outreach strategy;

Workshop Outcomes

Presentation Summaries

The following subject matter experts were invited to present on areas that were identified as knowledge gaps in BOHRN. Event participants received a pdf copy of each presenter's slides.

Dr. Jon Epstein

Dr. Jon Epstein, EcoHealth Alliance, presented on *Understanding the Ecology of Emerging Zoonoses*. His presentation focused on the three stages of disease emergence to help understand the complexities of spillover. Starting with the first stage, wildlife and domestic animal interactions, Dr. Epstein explained the movement of microbes into domestic animals. Human's increasing interactions with domestic animals leads to the second stage where the microbe has spilled over into the human population causing widespread outbreaks. The third and final stage of disease emergence is the outbreak reaching pandemic levels. Dr. Epstein proceeded to present two cases Nipah Virus spillover from Pteropid Bats and Nipah Virus spillover from date palm sap harvesting. Both cases were used to support evidence that the driver of spillover is human activity. However, as Dr. Epstein explained, this does not account for why human infections occur a small areas of these bat's known habitats. Therefore, it is important to understand why spillover is only occurring in these small areas, whether it is a rare event or there is a need for more broad spread surveillance.

Dr. Jonathan Towner

Dr. Jonathan Towner, from the Center for Disease Control and Prevention, presented on *Filovirus Maintenance in Nature: Potential Lessons Learned from Studying Marburg Virus*. Dr. Towner's presentation focused on the persistence of Marburg Virus (MARV) in nature supported by the recent study findings that Egyptian Rousette bats are identified as a natural reservoir for MARV. The study looked at bats during birthing and breeding seasons in the Python Cave of Uganda and focused on the impact seasonal pluses have on human spillover. From this study, Dr. Towner presented on the need for messaging to miners and the community to emphasize the importance of bats to the ecosystem and the effects of culling the bats in Python Cave. In addition, the presentation focused on discussing virus transmission from bat to bat, long-term immunity in bats, and the potential to recreate the study with Ebola Virus.

Dr. Brian Bird

Dr. Brian Bird, from the University of California-Davis, presented on *Synergies Between the Bench and the Field for Virus Discovery and Capacity Building*. Dr. Bird's focused on the work of the USAID PREDICT program and the Ebola Host Project. Dr. Bird began his presentation by explaining the challenges of targeted, risk-based surveillance the PREDICT program focuses on. He led into a discussion on virus discovery and detection from identifying viruses by consensus polymerase chain reaction (PCR) supplemented by high-throughput screening (HTS) to performing experiments to understand and rank the potential risk of the virus. Dr. Bird then explained the process PREDICT uses to strengthening laboratory efforts and used the Ebola Host Project in Sierra Leone as an example of

1st Annual BOHRN RESEARCH WORKSHOP

these efforts. The Ebola Host project has led to the training of numerous local scientists and the development of community outreach materials. Dr. Bird's presentation summarized the efforts in Sierra Leone to focus on Filoviruses which has led to identifying new Ebola viruses in insect eating bats before known human or animal sickness.

Dr. Susan Tsang

Dr. Susan Tsang presented on *Flying Foxes as Bushmeat in Sulawesi Indonesia, Building Community Outreach Initiatives Based on Novel Understanding of Who, Where, and Why*. Dr. Tsang began by identifying the common challenges in institutional capacity, identification of stakeholders, interagency coordination, and funding. Her presentation then focused on the flying foxes as bushmeat and the cultural understanding of the drivers for how and why bats are hunted. Dr. Tsang used the outreach initiatives in Sulawesi, Indonesia to emphasize that outreach must include regional level coordination to allow for national level communication at both the front and tail end of any project. In addition, outreach should be designed for the community and the importance of assessing effective ways to disseminate information. Dr. Tsang explained potential resolutions to the common challenges could include providing training on outreach, incorporating voices from all levels of policy, and demonstrating the value to other sectors for interdisciplinary funding.

Breakout Session 1 Overview

In advance of the first breakout session, Dr. Jon Epstein (EcoHealth Alliance) and Dr. Tigga Kingston (Texas Tech University) provided an update from the Steering Committee, summarizing a year's worth of Steering Committee Strategy Sessions. They presented two - three slides per Working Group, summarizing the group's mission, focus areas, objectives, measurements of success, challenges, and timelines. The new participants, who had not been part of previous BOHRN strategy sessions, were able to discuss the slides as a large group, before breaking out into smaller groups to provide constructive feedback and guidance based on their knowledge and experiences. Breakout session discussions led to the development of cross-cutting recommendations on capacity for in region repositories and curation of voucher material and the implementation of a data-sharing culture. The outcome of these suggested recommendations will ultimately build an additional working group.

Steering Committee Presentations

BOHRN planners collated and drafted the following material from the BOHRN strategy sessions, to provide a visual tool to solicit feedback from a group of new stakeholders. This information was presented in slide-form as an introduction to the large-group discussions and break-out group sessions.

Working Group 1: researching host-pathogen biology and interactions

MISSION: EXPLAIN THE DETERMINANTS OF PATHOGEN TOLERANCE, TRANSMISSION, AND SPILLOVER FROM BATS AT INDIVIDUAL AND POPULATION LEVELS

Established Working Group 1 Research Focus Areas

Bat physiology and immunology	Distributions of pathogen amongst species	Bat pathogen community biology	Modeling approaches for host dynamics and epidemiology
-------------------------------	-------------------------------------------	--------------------------------	--------------------------------------------------------

1st Annual BOHRN RESEARCH WORKSHOP

Objective		Outcomes
Complete a systematic review of knowledge gaps on model systems	➔	Publish a systematic review of modeling systems and knowledge gaps that were defined
Identify modeling systems that are representatives of all geographic and phylogenetic areas	➔	Modeling systems are defined, characterized, and validated
Evaluate the transmission risks and spillover pathogens to another animal host	➔	Intrinsic and extrinsic risk factors are identified for major diseases and geographic areas

Overall Challenges: (1) Objectives require multidisciplinary team: (2) consortia would be needed for modeling systems review and validation

Established Working Group 1 Research Projects and Activities Priority Timeline

Short-term project / activity pipeline 6 -12 months	Long-term project / activity pipeline 12 months +
Map funding landscape ➔ Identify funders ➔ Host a funders meeting	Conduct long-term lab and field studies ➔ Develop cell lines and bat animal models ➔ IgM immunoassay ➔ Develop methods for determining the age of bats ➔ Determine the timing of viral shedding and the effects of environmental stresses ➔ Determine co-infection in bat species ➔ Determine temperate versus tropical variables associated with infection (hibernation periods / viral replication) ➔ Understand climate change with respect to physiology ➔ Develop heat stable preservatives ➔ Develop smaller telemetry and physiology sensors

Working Group 2: researching pathogen surveillance, diagnostic capacity and epidemiology

MISSION: FORM REGIONAL NETWORKS TO ESTABLISH A COMMON METHODOLOGY FOR SURVEILLANCE OF HUMAN AND ANIMAL HEALTH; BETTER UNDERSTAND SPILLOVER RISKS AND EPIDEMIOLOGY OF BAT PATHOGENS

Established Working Group 2 Research Focus Areas

1st Annual BOHRN RESEARCH WORKSHOP

Objective		Outcomes
Conduct a gap analysis of existing diagnostic tools	➔	Publish review of epidemiology of known bat-borne pathogens
Conduct outreach to various groups of researchers and build awareness amongst public and science community	➔	Established and linked regional networks of practice and expertise
Establish a common methodology for surveillance	➔	A better understanding of the risks associated with spillover and established standards for surveillance and reporting

Overall Challenges: (1) The logistics and bureaucracy of creating a multidisciplinary team of international experts; (2) funding to support and sustain efforts to standardize surveillance

Established Working Group 2 Research Projects and Activities Priority Timeline

Short-term project / activity pipeline 6 -12 months	Long-term project / activity pipeline 12 months +
Conduct a gap analysis of diagnostic tools <ul style="list-style-type: none"> ➔ Identify list of labs and contacts ➔ Create a list for priority interventions / assistance ➔ Analyze return data; publish resource lists 	Conduct surveillance platform assessment <ul style="list-style-type: none"> ➔ Conduct a literature review of previous surveillance platform assessments ➔ Identify most beneficial platform for animal and human health data information sharing ➔ Identify most logical platform for low resource settings ➔ Identify the best field-forward platforms

Working Group 3: researching ecology (bat, domesticated animals and wildlife interface)

MISSION: DEFINE HOW AND TO WHAT EXTENT THE ECOLOGICAL CONTEXT OF BATS, AND THE HUMAN INFLUENCE ON THAT CONTEXT, INFLUENCE PATHOGEN DYNAMICS AND SPILLOVER THREATS

Established Working Group 3 Research Focus Areas

Bat behavior, distribution and movement	Effect of anthropogenic disturbance and modification on pathogen dynamics	Domesticated animals and wildlife behavior, distribution, and movement impact on interaction with bats
-----------------------------------------	---------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------

1st Annual BOHRN RESEARCH WORKSHOP

Objective		Outcomes
Engage the ecological community to define system uniqueness and interdependencies	➔	Pathogen research community acknowledges and integrates ecological systems and interdependencies
Advocate for ecological design and analysis frameworks to pathogen research	➔	BOHRN research projects are designed using a framework for well-balanced outcomes
Build capacity for disease researchers to gather ecological data to provide context for their studies	➔	More funded studies return ecological data
Define emerging ecological principles that could inform spillover threats	➔	Emerging ecological principles become widely accepted governing principles for practice
Establish key messages and conduct efforts to promote a culture of conservation amongst One Health researchers, practitioners, and stakeholders	➔	BOHRN establishes itself as a consistent and unbiased perspective from the community and its statements are widely accepted and distributed

Overall Challenges: (1) Science communities have polarized and insular view of bats and diseases; (2) lack of collaboration and communication efforts

Established Working Group 3 Research Projects and Activities Priority Timeline

Short-term project / activity pipeline 6 -12 months	Long-term project / activity pipeline 12 months +
Conduct conservation / One Health literature review <ul style="list-style-type: none"> ⇒ Establish parameters ⇒ Conduct literature review ⇒ Quantify interdisciplinary relationships w/ assessment of numbers of publications ⇒ Publish results Establish ecology tool / training aid kits <ul style="list-style-type: none"> ⇒ Identify and source materials 	N/A ⇒ N/A

1st Annual BOHRN RESEARCH WORKSHOP

- ⇒ Collect and build case-control studies for training
- ⇒ Develop training plans
- ⇒ Distribute through BOHRN

Working Group 4: researching human-bat interactions

MISSION: FULLY DEVELOP, UNDERSTAND, AND COMMUNICATE THE BAT AND HUMAN INTERFACE TO KEY STAKEHOLDERS AND COMMUNITIES

Established Working Group 4 Research Focus Areas

Hunting and commodity chain	Human behavioral risk characterization	Interactions in human dwellings	Ecotourism
-----------------------------	----------------------------------------	---------------------------------	------------

Objective		Outcomes
Develop and test policy interventions for specific human-bat interfaces	⇒	Policy interventions for human-bat interfaces are developed and put into place
Communicate key findings to stakeholders	⇒	Effectively communicate and publish findings of studies
Develop global risk maps to assess existing data and validate risk maps	⇒	Publish global risk maps highlighting geographic areas of risk
Identify high-risk groups and develop education platforms to measure knowledge, attitude and practices	⇒	Getting community buy-in and understanding of concepts

Overall Challenges: (1) Truthful responses in behavior research on bat-human interactions; (2) accuracy of risk map and models; (3) cultural barriers and beliefs

Established Working Group 4 Research Projects and Activities Priority Timeline

Short-term project / activity pipeline 6 -12 months	Long-term project / activity pipeline 12 months +
<ul style="list-style-type: none"> ⇒ Develop global risk maps ⇒ Survey high-risk groups for their KAP 	Conduct research studies / support for ecology <ul style="list-style-type: none"> ⇒ Develop and validate education platforms ⇒ Research to measure changes in KAP ⇒ Validate ground-truth risk maps

1st Annual BOHRN RESEARCH WORKSHOP

- ⇒ Adapt education platforms / materials

Recommendations

BOHRN organizers invited many researchers from diverse backgrounds at varying levels of professional experience to the Vienna workshop. This approach facilitated lively discussions and prompted the Steering Committee to consider new objectives, priorities, and perspectives within their previously established Working Group bounds. The following recommendations were captured by note-takers, observers, and other members of the Steering Committee, and will be marked for further discussion and adjudication during BOHRN's next Steering Committee meeting which will be held at International Bat Research Conference (IBRC) in Phuket, Thailand 2019.

Working Group 1: researching host-pathogen biology and interactions

Breakout Session Recommendations: members of the breakout group accepted the overall mission and objectives that Working Group 1 had established and proposed adding two additional research focus areas: (1) the role of bat taxonomy in host-pathogen coevolution and (2) host specificity in bat-borne pathogens. Members of the breakout group also proposed the following additions to the priority timeline:

- ⇒ Establish species identification consensus tools and techniques – such as the role of bar coding and other methods
- ⇒ Host or link to public-facing databases (e.g., Vertnet, National Science Foundation digitized database)
- ⇒ Identify regional resource repositories for voucher materials
- ⇒ Establish sustainable freezer network
- ⇒ Develop funding models for in-country collection curation capacity building / field sample collection transfer (business plans, logistics, maintenance, training)
- ⇒ Establish a database of reagents
- ⇒ Establish a list of international regulatory experts for transport of select agent materials (e.g., Bombali ebolavirus discovery and the issues they had with reporting and transfer)

Working Group 2: researching pathogen surveillance, diagnostic capacity and epidemiology

Breakout Session Recommendations: members of this breakout group generally accepted the mission and objectives that Working Group 2 had established. They proposed amending the research focus area for “Molecular Epidemiology” to include “Molecular and Serological Epidemiology”. They also proposed the following additions to the priority timeline:

- ⇒ Establish a set of common research questions and topics related to biosurveillance data-type (syndromic, diagnostic, environmental) associated with bat-borne pathogen threats
- ⇒ Establish a catalog of surveillance models
- ⇒ Develop a sera and antibody collection with a standardized pool of collection
- ⇒ Conduct studies that integrate bat ecology and pathogen research (One Health research team that collects virology and ecological data at the same time)

1st Annual BOHRN RESEARCH WORKSHOP

- ⇒ Establish a list of minimum biosecurity / biosafety protocols for research (lab / field) and recommended sample sets / study
- ⇒ Establish a list of laboratories with bat sample repositories (by region and country)
- ⇒ Establish a registry of “Bat Experts” by region and country
- ⇒ Identify diagnostic capabilities (person / institution)
- ⇒ Develop a hypothesis map
- ⇒ Outline funding mechanisms for other BOHRN stakeholders

The breakout group also recommended that any efforts to seek “standardization” (surveillance platforms) should use the phrase “common framework” as methods and implementation will vary in different countries and regions.

Working Group 3: researching ecology (bat, domesticated animals and wildlife interface)

Breakout Sessions Recommendations: during the breakout session, members of this group did not have any substantial modifications to the Working Group’s mission, focus areas, or objectives. They did provide several ideas long-term timeline priorities, which included:

- ⇒ Conduct ecological and taxonomic studies that support disease research (and threat reduction), this will create a demand for ecologists to collect samples and will ultimately capacity for ecology through training and networking
- ⇒ Identify ecological and taxonomic gaps at local levels

Since much of Working Group 3’s approach was built around the development of training modules, the group discussed training and the importance of tailoring existing projects / programs. They talked about sustainability in bat research programs and mechanisms for incentivization, offering ideas such as scholarships at the end of a short research project or using a training workshop as a research candidate selection opportunity.

Working Group 4: researching human-bat interactions

Breakout Sessions Recommendations: members of this breakout group did not have any major changes to the Working Group’s mission, focus areas, or objectives. They did, however, want to emphasize the importance determining *where* human behavioral risks are the highest and *what* drives specific human bat interactions and the need to map these interactions accordingly. With regard to the timeline priorities, they made the following recommendations:

- ⇒ Characterize the risk map with priorities
 - DTRA (BTRP) priority pathogens, USG priority pathogen threats, WHO regional threats
 - Chart recent pandemics with drivers (e.g., bush meat markets overlaid with outbreaks)
- ⇒ For database define the approach to obtain data; Bat Conservation International (example), Bat-Plant.com for ecology interactions

1st Annual BOHRN RESEARCH WORKSHOP

Breakout Session 2 Overview

The first breakout session provided a foundation for the second breakout session during which participants formed into regional teams to craft research projects within the bounds of the BOHRN Working Group research focus areas. BTRP intends to fund several high priority threat reduction projects in FY19-FY20 and developed this exercise to test the viability of the network's strategy thus far. The

1st Annual BOHRN RESEARCH WORKSHOP

projects that were developed will not be summarized in this report, as they may be part of future project proposal; however, the images below show the work, collaboration, and collegial spirit of this session.

1st Annual BOHRN RESEARCH WORKSHOP

Participant Feedback

After the BOHRN Workshop participants were sent an anonymous feedback survey via SurveyMonkey. The participants were asked the following six questions:

1. What did you like about this Workshop?
2. Do you think the objectives for the BOHRN Workshop were achieved? Please explain your answer.
3. What do you wish we did differently?
4. What does success of this network look like to you, for your field of study?
5. What do you think was the most important aspect of this Workshop?
6. Any other comments or suggestions?

Overall, the participants responded positively to the efforts accomplished at the first annual BOHRN Workshop. An appreciation for the multidisciplinary networking opportunities, the potential opportunities the network presents, and the alignment of breakout group work with the Workshop presentations was conveyed by all participants. One participant's comment reflects this in saying "the multidisciplinary networking opportunities for engaging the ecological context of emerging infectious disease and breakout sessions were a nice complement to the big group discussions." Participant feedback indicated that the BOHRN Workshop objectives were achieved but there was a need for further information on next steps and more opportunity for discussion after the final small group session. Suggestions for change were to extend the workshop for two whole days and provide more focus on funding the discussed research.

BOHRN Path Forward

As a result of this workshop, BTRP intends to release an announcement for research project funding in the early part of 2019. The official announcement will be released on the BOHRN website (www.BOHRN.net) and emailed to anyone who has participated in a BOHRN activity.

At the conclusion of the workshop, Dr. Martha Stokes presented draft criteria for project award consideration, which included:

- Performed in BTRP engagement countries
- Demonstrated commitment to capacity building in BTRP mission areas (biosafety and biosecurity, and biosurveillance)
- Demonstrated commitment to open science
 - Transparent sharing of knowledge and information
 - Should include a data curation plan and broad statement on information access
 - Sample sharing not required, but strongly encouraged and preferred
- Demonstrated commitment to One Health
 - Inter-disciplinary research teams
 - Local engagement plans or educational outreach

1st Annual BOHRN RESEARCH WORKSHOP

- Include early to mid-career project investigators
- Address cross-cutting themes of BOHRN
 - Projects should be tied to no less than two working groups
 - Projects should be tied to no less than one focus area within each working group
- Include mentorship from member of steering committee or a Steering Committee/Executive Committee-approved designee (correlates to respective working group(s))

These factors are still under consideration and BTRP may change any or all. The only information regarding “Criteria for Eligibility” for a BOHRN grant/project award will be released on BOHRN.net. The timeline for award will also be released on BOHRN.net.

1st Annual BOHRN RESEARCH WORKSHOP

Annex 1: Agenda

Day 1

Time	Session	Objectives
0700 – 0800	Closed-door Steering Committee Meeting	
0730 – 0810	Photo Registration (for non-steering committee members)	
0810 – 0845	Welcome and Introductions Marty Stokes <i>Biological Threat Reduction Program (BTRP)</i>	Welcome all participants, provide four slides about BTRP and TRNs All participants go around the room and introduce name and organization
0845 – 0900	BOHRN Overview Marty Stokes <i>Biological Threat Reduction Program (BTRP)</i>	Provide an overview about BOHRN, its mission and objectives; make sure to discuss (1) the funding opportunity; (2) the principles of capacity building / mentorship
0900 – 0910	BOHRN Workshop Agenda, Objectives, and Housekeeping Katie Leahy <i>Global Systems Engineering</i>	Provide overview of meeting objectives, scheme of maneuver, and other housekeeping items
Session 1: BOHRN Focus Group Progress and Work		
0910 – 0930	Understanding the Ecology of Viruses Jon Epstein <i>EcoHealth Alliance</i>	Discuss the challenges and understanding of the ecology of viruses such as Nipah and Ebola
0930 – 0950	Host/Pathogen Interaction Jon Towner <i>CDC- Division of High-Consequence Pathogens and Pathology</i>	Present on work focusing on viruses in the national reservoir hosts and determine the mechanisms by which the viruses are maintained in nature
0950 – 1010	Laboratory Response Brian Bird <i>UC Davis, School of Veterinary Medicine</i>	Synergies between the Bench and the Field: Rift Valley Fever and Ebola
1010 – 1030	Building Policy and Community Outreach Initiatives Based on a Novel Understanding of Who, What, and Why Susan Tsang <i>American Museum of Natural History and National Museum of the Philippines</i>	Discuss efforts to bridge policy gaps between local, national, regional, and international efforts
1030 – 1110	Focus Area Research Mentor Progress Reports	A representative or mentor from each group will present their Focus Area

1st Annual BOHRN RESEARCH WORKSHOP

		<p>objectives, its long / short-term goals schedule, and progress</p> <p>Group 1: 10 min Group 2: 10 min Group 3: 10 min Group 4: 10 min</p>
1110 – 1215	Breakout Groups	<p>Participants will be broken into the focus area groups; their placement will be pre-arranged by decision of the steering committee and they will have a sticker on the back of their name card; they will be asked to listen in on the focus area group discussion, see if they could contribute to the group's direction</p>
1215 – 1320	Working Lunch	
1320 – 1400	Breakout Group Open Discussion	<p>Each group will present any changes to their schedules or objectives</p> <p>Group 1: 10 min Group 2: 10 min Group 3: 10 min Group 4: 10 min</p>
Session 2: BOHRN Project Development Work		
1400 – 1430	<p>Doing Business with BTRP: Pathways to Contracts, Objectives for BOHRN and Beyond</p> <p>Dr. Martha Stokes <i>BTRP</i></p>	<p>20 Minute presentation of slides that Lance gave in Georgia, plus 1-2 developed with Scott V., plus 10 minutes for questions from the audience; this presentation will queue funding project development for focus area-specific RFPs</p>
1430 – 1600	Interactive Illustration Hypothesis Mapping Exercise	<p>Dr. Kingston and Dr. Epstein will facilitate an interactive hypothesis mapping session for the group</p>
1600 – 1715	Breakout Groups	<p>Breakout into blended project development groups. These groups will be based on seating arrangement (e.g., tables 1 and 2 will work together) to ensure that we have multi-disciplinary efforts.</p>
1715 – 1730	Close-out Day 1 and Review Day 2	
1830 – 2000	Dinner / Social Event Quad Chart / Poster Presentations	

1st Annual BOHRN RESEARCH WORKSHOP

Day 2

Time	Session	Objectives
0900 – 1130	Small Group Project Development Work	Groups will come back to the main room to continue work in the smaller group project development
1000 – 1030	Working Tea Break	
1130 – 1300	Working Lunch Break / Small Group Brief-outs	
1300 – 1315	Close-out / Group Discussion	
TBD	Steering Committee Meeting	

1st Annual BOHRN RESEARCH WORKSHOP

Annex 2: Participant list

Name	Country	Organization
Abel Wade	Cameroon	National Veterinary Laboratory, Cameroon
Wanda Markotter	South Africa	University of Pretoria, Dept of Microbiology and Plant Pathology
Benneth Obitte	Nigeria	Texas Tech University
Iroro Tanshi	Nigeria	Texas Tech University
Joram Buza	Tanzania	Nelson Mandela African Institute of Science and Technology
Robert Kityo	Uganda	Makerere University, Kampala
Julian Lutwama	Uganda	Uganda Virus Research Institute
Astghik Ghazaryn	Armenia	Yerevan State University
Ioseb Natradze	Georgia	Ilia State University
Keti Sidamonidze	Georgia	National Center for Disease Control and Public Health -Georgia
Lela Urushadze	Georgia	National Center for Disease Control and Public Health - Georgia
Nesreen Alhmoud	Jordan	Royal Scientific Society
Meryem Lemrani	Jordan	Pasteur Institute in Morocco
Ehab Abu-Basha	Jordan	Jordan University of Science and Technology
Shusmita Dutta	Bangladesh	University of North Bengal
Ariful Islam	Bangladesh	EcoHealth Alliance
Shahanaj Shano	Bangladesh	Jahangirnagar Univeristy
Pilot Dovih	India	National Centre for Biological Sciences
Juliana Senawi	Malaysia	University of Kebangsaan Malaysia
Philip Alviola	Philippines	University of the Philippines-Los Banos
Catalino Demetria	Philippines	Research Institute for Tropical Medicine
Benjamin Lee	Singapore	Duke-NUS, Singapore
Sara Bumrungsri	Thailand	Prince of Songkla University
Pipat Soisook	Thailand	Princess Maha Chakri Sirindhorn Natural History Museum
Supaporn Wacharapluesadee	Thailand	WHO CC for Research and Training in Viral Zoonoses, King Chulalongkorn Memorial Hospital, Thailand
Vu Dinh Thong	Vietnam	Institute of Ecology and Biological Resources
Patrick Ayscue	United States	Metabiota
Brian Bird	United States	University of California- Davis
Bradford Brooks	United States	Metabiota
Jon Epstein	United States	EcoHealth Alliance
Jason Farlow	United States	Metabiotia
Tracey Goldstein	United States	University of California- Davis
Andreas Handel	United States	University of Georgia

1st Annual BOHRN RESEARCH WORKSHOP

Rebekah Kading	United States	Colorado State University
Tigga Kingston	United States	Texas Tech University
Eric Laing	United States	Uniformed Services Health Service University
Kendra Phelps	United States	EcoHealth Alliance
Mariano Sanchez-Lockhart	United States	United States Army Medical Research Institute for Infectious Diseases - Genomic Center
Jonathan Towner	United States	Center for Disease Control and Prevention, Viral Special Pathogens Branch
Susan Tsang	United States	Royal Scientific Society
Marty Stokes	United States	DTRA Biological Threat Reduction Program
Steve Becker	United States	DTRA A&AS
Katie Leahy	United States	Global Systems Engineering
Chris Russell	United States	Global Systems Engineering
Jason Hudson	United States	Global Systems Engineering
Megan Hudson	United States	Global Systems Engineering

Dear all,

On behalf of Dr. Marty Stokes, please find the final report for the BOHRN Workshop in Vienna.

As discussed in Vienna, there are several action items for the BOHRN network. In order to move forward on several of these items, we ask that you take a few moments to answer the following questionnaire. This survey will help us to identify BOHRN's efforts and progress towards its overarching goals and evaluate the networks threat reduction efforts. Please follow the link and complete the survey no later than 28 February: <https://www.surveymonkey.com/r/6FQPQR3>

Additionally, please use the following Drop Box link for access to the [BOHRN Workshop participant list with pictures and the quad charts](#) submitted by all participants. You may also access the video of the BOHRN Workshop [here](#).

We had hoped to make a more formal announcement regarding solicitation for BOHRN special projects around this time; however, BTRP is internally still reviewing necessary criteria for award and will not be ready to make a more formal announcement until the April / May timeframe. The announcement will be released via the www.bohrn.net website.

Please let us know if you have any questions or concerns.

Kind Regards,

Megan
