

ATTACHMENT A: Scope of Work Year 4

Project Description/Summary: Southeast Asia is one of the world's highest-risk EID hotspots, the origin of the SARS pandemic, Nipah virus, and repeated outbreaks of influenza. This is driven by high diversity of wildlife and rapidly expanding demography that brings human and wildlife populations closer. This proposal will launch the Emerging Infectious Diseases - South East Asia Research Collaboration Hub (EID-SEARCH), a collaboration among leaders in emerging disease research in the USA, Thailand, Singapore and the 3 major Malaysian administrative regions. These researchers have networks that span >50 clinics, laboratories and research institutions across almost all SE Asian countries and will use the EID-SEARCH as an early warning system for outbreaks involving exchange of information, reagents, samples and technology, and a collaborative power-house for fundamental and translational research. The EID-SEARCH will also act as a significant asset to scale-up and deploy resources in the case of an outbreak in the region. This EIDRC will conduct research to: 1) Identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife, by analyzing previously-archived wildlife samples, conducting targeted wildlife surveillance, and using serology & PCR assays to identify novel viruses. These will be characterized to assess risk of spillover to people, and a series of in vitro (receptor binding, cell culture) and in vivo (humanized mouse and collaborative cross models) assays used to assess their potential to infect people and cause disease; 2) Collect samples and questionnaire data from human communities that live in EID hotspots and have high cultural and behavioral risk of animal exposure (e.g. wildlife hunting, bat guano collection). These will be tested with serological assays to identify evidence of novel virus spillover, and analyzed against metadata to identify key risk pathways for transmission; 3) Identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts. We will conduct syndromic surveillance at clinics serving the populations in Aim 2, enroll patients with undiagnosed illness and symptoms consistent with emerging viral pathogens, and test samples with molecular and follow-up serological assays to identify causal links between these syndromes and novel viruses.

This research will advance our understanding of the risk of novel viral emergence in a uniquely important region. It will also strengthen in-country research capacity by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. The large body of high impact collaborative research from this EIDRC leadership team provides proof-of-concept that EID-SEARCH has the background, collaborative network, experience, and skillset to act as a unique early warning system for novel EIDs of any etiology threatening to emerge in this hottest of the EID hotspots.

Under this contract, supervised and coordinated by the co-Investigators Dr. Supaporn Wacharapluesadee and Dr. Opass Puthachoen, the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University will:

1. Project coordination, management and training

- 1.1 Increase the number of samples from human community, and hospital syndromic study. Either by new enrolment, or archived samples.
- 1.2 Work with EID-SEARCH global team to update protocols and questionnaires for community and hospital syndromic surveillance.
- 1.3 Facilitate and coordinate training on project data management and analysis (e.g., Airtable, serology result interpretation), biosafety, human subject research (CITI training) and complete relevant assessments.
- 1.4 Collaborating with project partner for training and analysis on bioinformatics (bioinformatics analysis and RBD/spike glycoprotein design), MMIA technique (bead design, coupling, optimization and data analysis), Field Biosafety training.
- 1.5 Maintain all research approval documents in Thailand, including Animal Care and Use Protocol (CU-ACUP) for animal investigations; Institutional Review Board (IRB) approval for human subject research; Institutional Biosafety Committee (IBC) approval for lab work; and other local permissions as needed.

2. Fieldwork

- 2.1 Enroll additional human participants from **community sites** in Thailand human-wildlife contact is common – to aim for a total of 500 people. – **To add new study site in Chanthaburi province, where there are human-wildlife interfaces e.g., bat capture and bat consumption**
129 people from Ratchaburi were enrolled.
Need 371 people.
- Chanthaburi (eating bat): 120
 - Ratchaburi (bat guano collectors and Mojiang-positive villagers): $70 \times 2 = 140$
 - Chonburi (villagers from Nipah positive flying foxes): 120
- 2.2 Enroll additional participants at selected **hospital/clinic sites** for syndromic surveillance to aim for a total of 500 people. – **To add a new hospital/clinic site in Surathani province**
140 patients from 4 sites were enrolled, including 59 from the diarrhea outbreak.
Need 360 people.
- Ratchaburi clinic to continue enrolling the Flu system patients: $n=50$
 - Mukdaharn to enroll severe flu-like illness, encephalitis, non-dengue hemorrhagic fever: $n=100$
 - Surat Thani to enroll severe flu-like illness, encephalitis, non-dengue hemorrhagic fever: $n=100$
 - Unidentified Flu-like illness and encephalitis patients from DDC Lab surveillance: $n=100$
 - Archived samples from Bacteria and Virus infection project, $n=250$; only serum samples are available. Test for serology only, if it is positive, PCR will be performed on a specific family.
 $a+b+c+d+e=600$
- 2.3 Identify archived samples that would also fit the criteria for 2.1 and 2.2 – **We could use samples from other projects that fit criteria for this study??**
2.1 Could we use PREDICT samples (>400) because we tested them?
If yes, we do not need to do 2.1b and 2.1c. However, we want to continue the human study at Ratchaburi.
- 2.4 **Collect PBMCs from individuals with detectable antibodies against the Mojiang-related viruses for further characterization.**
Collect PBMCs from 5 positive Moj and 5 control.
- 2.5 Conduct specimen collection from **bats from different colonies** to those already sampled ($n=200$), rodents/shrews (150 rodents, 150 shrews), and macaques (100 from diverse locations) at the selected sites, with increased sampling efforts for rodents/tree shrews and non-human primates. **(TOTAL animals=600)**– 500 macaques archived specimens from DNP, which we will use for screening by MMIA and/or sVNT
– adding a new study site, Khlong Saeng Wildlife Sanctuary in Surathani province, where there are flying foxes and other insectivore bats (waiting for more information about bat species from Nutthinee) and the viruses in bats at this study site have not been extensively studied
- Bat at Surat Thani: colony 1=100
 - Bat at Petchaburi (archived samples from DNP): $n=100$
 - Rodents and shrew from Surat Thani: $n=100$
 - Rodents and livestock at Moj positive village: $n=120$ (3 times collection, $40 \times 3 = 120$)
 - Macaques: archived samples from DNP: $n=500$, only 100 for PCR
- TOTAL animals: $a+b+c+d+e = 920$ (520 for PCR)**
- 2.6 Targeted investigation to identify the animal hosts and transmission of Mojiang-related viruses.
- Collect neighboring villagers' blood for serology testing (2.1 b)
 - Collect rodents from Moj-positive house and working places bimonthly to test for antibodies and Moj PCR (2.5d).

Commented [SN1]: Yellow highlight = what we also planned to do

Blue text = adding more details from what we brainstormed in the last weekly meeting

Commented [SW2R1]: Red= detail of works

c. Investigate other pet/farm animals at the Moj positive lady, collect specimens for testing.

3. Laboratory analysis

- 3.1 Conduct viral family-level molecular screening of collected or archived wildlife samples for coronaviruses and paramyxoviruses. (*Filoviruses testing is suspended due to low detection rate in swabs*)
No. of animals = 520 * feces sample* 2 families = 1,040 PCRs
- 3.2 Improve primers to better identify diverse paramyxoviruses (e.g. Langya, other Mojiang-related viruses).
Primers and positive control design and synthesis
- 3.3 Conduct DNA barcoding to confirm field animal species identification as necessary on a subset of the specimens.
10% positive, n=104 samples
- 3.4 Conduct deep sequencing of the Spike protein of identified novel coronaviruses. – we might need to be more specific e.g., only do sequencing on sarbecovirus positive specimens
Need the protocol for Spike deep sequencing for all CoV genus.
- 3.5 Perform whole genome sequencing of identified CoVs from humans and animals.
 - a. Perform bat CoV WGS using pan-CoV enrichment kit
 - b. Perform human CoV WGS using RVOP enrichment kit.
 - c. Perform metagenomic (whole genome) sequencing of identified PMV using Oxford Nanopore Technologies
- 3.6 Perform family PCR testing of coronaviruses, filoviruses, and paramyxoviruses with swabs collected from humans enrolled at clinic/hospital-based and community sites.
No. of patients (2.2a-d) = 350*3 specimens (rectal, oral, and blood)*3 families = 3,150 PCRs
- 3.7 Perform serology testing on collected and archived wildlife and human samples.
 - Perform serological testing with optimized multiplex assays for Coronaviruses, Filoviruses, and Henipaviruses.
Animals No. total= 2,170 (animals: bat= 856+200, rodents=214+200, macaque=200+500), 100 rodents and 100 macaque samples were tested; 1,970 will be performed in year 4
Humans= No. n= 739 (patients); n= 380 (community)
 - Perform serological characterization of Sarbecovirus-positive samples using surrogate virus neutralization test (sVNT) RBD-based assay.
All bats n = 1,056
- 3.8 Collaborate with EID-SEARCH partner for the validation of newly developed serological assays.
???
- 3.9 Collaborate with EID-SEARCH partner for further characterization of novel viruses including virus isolation, human cell infection experiments, and animal modeling for viral pathogenesis studies.
OK

4. Results and data sharing and analysis

- 4.1 Share or update sample collection, lab testing, questionnaire, notes, lab notebooks, or all other relevant data and results to the project central database in a timely manner.
- 4.2 Sharing of specimens will ONLY be possible for diagnostic purposes when capacity is not available in Thailand or when it's part of the capacity building and training program.

- 4.3 Participate in the CREID Working Group discussions and work with EID-SEARCH global team to develop data management and sharing policies.
- 4.4 Maintain current contacts with in-country government ministries responsible for human health, livestock/agriculture, and wildlife for project results debriefs.
- 4.5 Collaborate with the EID-SEARCH partners for data cleaning, analysis, interpretation, and contributing to scientific publications as agreed.
- 4.6 The subrecipient will adhere to the applicable elements of resource and data management from the approved project proposal as described in Resource Sharing Plan in **ATTACHMENT D**.
- 4.7 Complete the following programmatic and financial reporting by requested deadlines:
 - Quarterly reporting to EcoHealth Alliance on programmatic activities
 - Semi-annual and annual reports to NIH/NIAID.
 - Annual reports to the CREID Network and other reports requested by NIAID.
 - Invoices and financial reports to EcoHealth Alliance every two months, including 1-page or longer programmatic update, copies of receipts and/or other supporting document, and breakdown of the costs in each item as showed in **ATTACHMENT B** Project Budget.
 - Submit to the requirements of the Federal Funding Accountability and Transparency Act (FFATA) included as **ATTACHMENT C**, with the signed contract.
- 4.8 Reach out to communities and present appropriately available findings and public health information. – **One Health Committee**
- 4.9 ~~Reach out to communities and present appropriately available findings and public health information.~~

5. Communication and reporting

- 5.1 Participate in monthly meetings with the EID-SEARCH global team and EcoHealth Alliance.
- 5.2 Participate in monthly meetings with all EID-SEARCH partners.
- 5.3 Participate in lab biosafety evaluation and regular research facilities inspection.
- 5.4 Represent EID-SEARCH on planning and other relevant meetings.
- 5.5 Complete the following programmatic and financial reporting by the requested deadlines:
 - Semi-annual and annual reports to NIH/NIAID.
 - Invoices and financial reports at least quarterly, including copies of receipts and/or other supporting documents, and a breakdown of the costs in each item as shown in Attachment C. A summary of programmatic updates accompanying all invoices or financial reports is required.
 - Other reports requested by the CREID Network and NIH/NIAID.

6. Project Timeline

ACTIVITIES	YEAR 1				YEAR 2				YEAR 3				YEAR 4				YEAR 5			
	Q1	Q2	Q3	Q4

3.5 sample testing																				
3.6 risk characterization																				
annual meeting																				

ATTACHMENT B: Project Budget

The project budget must correspond to the funder-approved proposal budget. Any and all modifications must be approved by EcoHealth Alliance before this contract is signed.

Items	Year 3
1. Personnel	\$ 63,600.00
2. Fieldwork	
2.1 Human specimens sampling	\$ 14,748.67
2.2 Animal specimens sampling	\$ 20,500.00
3. Diagnosis	
3.1 Family PCR	\$ 55,100.00
3.2 Barcoding PCR	\$ 2,500.00
3.3 Spike gene and Next-generation sequencing	\$ 15,000.00
3.4 Specific real-time PCR	\$ 15,000.00
3.5 MMIA in human and animal samples	\$ 3,500.00
3.6 Equipment maintenance	\$ 5,000.00
4. Equipment (laptop and portable printer)	\$ 5,000.00
Total direct cost	199,948.67
Indirect cost (8%)	\$15,995.89
Total	\$215,944.56

Items	Proposed Year 4	Year 3
1. Personnel	\$ 63,600.00	\$ 63,600.00
2. Fieldwork		
2.1 Human specimens sampling	\$ 47,074.17	\$ 14,748.67
2.2 Animal specimens sampling	\$ 26,347.00	\$ 20,500.00
3. Diagnosis		
3.1 Family PCR (3.1+3.6)	\$ 127,750.00	\$ 55,100.00
3.2 Improve Paramyxovirus primers	\$ 1,500.00	0
3.3 Barcoding PCR	\$ 3,120.00	\$ 2,500.00
3.4 Spike gene and Next-generation sequencing	0	\$ 15,000.00
3.4 Specific real-time PCR	\$ 37,500.00	\$ 15,000.00
3.5 MMIA in human and animal samples	\$ 14,507.50	\$ 3,500.00
3.6 Equipment maintenance	\$ 5,000.00	\$ 5,000.00
4. Equipment (camera trap)	\$ 5,000.00	\$ 5,000.00
Total direct cost	\$ 331,398.67	199,948.67
Indirect cost (8%)	\$ 26,511.89	\$15,995.89
Total	\$ 357,910.56	\$215,944.56

ATTACHMENT C: Federal Funding Accountability and Transparency Act (FFATA)

The Federal Funding Accountability and Transparency Act (FFATA) was signed on September 26, 2006 and requires information on federal awards (federal financial assistance and expenditures) be made available to the public via a single, searchable website, which is www.USASpending.gov. All contractors receiving funds from EHA are required to provide the following information as a condition of receiving funds.

Please answer the following questions Yes or No.

a. In the previous tax year, was your company's gross income from all sources above \$300,000?

Yes No

b. In Subrecipient's business or organization's preceding completed fiscal year, did its business or organization (the legal entity to which the UEI number it provided belongs) receive (1) 80 percent or more of its annual gross revenues in U.S. federal contracts, subcontracts, loans, grants, subgrants, and/or cooperative contracts; **and** (2) \$30,000 or more in annual gross revenues from U.S. federal contracts, subcontracts, loans, grants, subgrants, and/or cooperative contracts?

Yes No

c. Does the public have access to information about the compensation of the executives in Subrecipient's business or organization (the legal entity to which the UEI number it provided belongs) through periodic reports filed under section 13(a) or 15(d) of the Securities Exchange Act of 1934 (15 U.S.C. 78m(a), 78o(d)) or section 6104 of the Internal Revenue Code of 1986?

Yes No

d. Does your business or organization maintain an active registration in the System for Award Management (www.SAM.gov)?

Yes No

ATTACHMENT D: Resource Sharing Plan

To share resources with the academic research community, we will use the uniform Material Transfer Agreement (MTA), which acknowledges that the materials are proprietary to Institutions of the Cooperative Agreement and permitting their use in a manner that is consistent with the Bayh-Dole Act and NIH funding requirements. NIH research grants require that research be made available to the scientific community and public. The primary method of data sharing is through peer-reviewed publications in scientific journals and by presentation at scientific meetings. In addition, data and results created from NIH supported research will be submitted to NIH in annual progress reports per the terms and conditions of this award. Recombinant viruses, transgenic mouse models and experimental recombinant protein constructs will be made available upon request following a standard procedure (below). Several viruses isolated and studied in this program are select agents so these viruses will not be shipped unless appropriate documentation demonstrates the existence of approved BSL3/4 facilities, select agent licenses, and shipment using approved CDC and Department of Commerce procedures.

We already have established MTAs between most of our EID-SEARCH, consortium partners and will ensure these agreements are up to date and agreed upon by our consortium at the start of our project and then reviewed annually. Having these agreements in place will further reduce the time needed to share reagents and other resources in the event of an outbreak when time-sensitive sharing of biological resources and diagnostic reagents is most critical. **At the start of the project, we will work with the EIDRC – Coordinating Center to ensure these agreements and resource sharing plans are compliant and aligned with plans created for NIH’s other EIDRCs.**

Data Sharing Plan

EcoHealth Alliance (EHA) will house the Data Management and Analysis (DMA) team for EIDRC SEARCH. EHA has served as the data and analysis hub for numerous multi-institutional, multi-sectoral, international disease research groups, including acting as the Modeling and Analytics lead institution for the USAID-PREDICT project, the Western Asia Bat Research Network lead by co-I Olival (1) and EHA’s Rift Valley Fever Consortium (2). We will leverage our experience and infrastructure from those projects.

Project Database: We will create a dedicated, centralized EIDRC database to ingest, store, link, and provide for analysis all data associated with the proposed study and other expanded projects associated with the research network. The database will be SQL-based and use encrypted, secure cloud hosting services and enable export to archival and platform-independent formats. It will ensure data and metadata compatibility between project components, track data versioning and annotations. The system will be designed to work with both **with both** paper- and tablet-based field data entry and with laboratory information management systems in place in individual partner labs. We will design and engineer the systems to be compatible with other NIAID approved data management systems, including those utilized by the EIDRC-CC, by designing secure APIs, and matching data fields and data standards. The database will use existing metadata standards, including NCBI standards for genetic and molecular data and Ecological Metadata Language (EML) for field and wildlife data, as well as other standards and formats designated by the EIDRC CC. This will enable rapid publication and deposition of data. Granular security and privacy controls will be applied so that specific expansion projects undertaken in the network may be managed while maintaining data confidentiality as needed.

Commented [HL3]: Copied pasted from submitted proposal, modified one place to remove previous co-workers’ names, the project name also changed from EIDRC SEARCH to EID-SEARCH

Data Identification and Privacy: For human clinical data and questionnaires, data will be identified by a unique identification code assigned to each individual and only this, de-identified code will be accessible in the project database. All questionnaire data and biological samples will be labeled with a unique alphanumeric identification code, assigned to each enrolled, sampled individual that does not identify the individual from whom data are collected. Participants' names and codes, along with other records with identifying information such as informed consent forms, will be stored in a separately secure system accessible to only essential project staff. If participants agree during the consent process, they may be contacted about having their samples or questionnaire data used for future separate studies about new animal infections discovered in the future, and factors that may affect their chances of getting these animal infections. No data will be released for other purposes without full consent from participants. Upon completion of the project, personal identifying information will be destroyed unless this protocol is extended.

Training: Members of the DMA team will **team will** develop documentation and provide training for field and laboratory teams at all partner institutions in data management, metadata standards and data hygiene best practices. The DMA team will act as trainers and consultants for partner institutions in experimental design, power analysis, data analysis, and computational and reproducibility issues. DMA trainers will visit each partner institution and/or field team base for training workshops and analysis consultations, and partner institution researchers and students will spend extended time at EHA for collaborative analysis, a model that has been successful in building and maintaining analytical capacity under our NSF EcoHealthNet and PREDICT programs.

Computing Resources: EHA operates a cluster of high-performance servers (System76 20- and 36-core Linux servers with NVIDIA deep-learning GPUs), for data analysis activities, as well as infrastructure to launch cloud-based computing environments of virtual machine with identical software infrastructure. Our servers provide a web-based analysis environment with all necessary software for statistical and bioinformatics work that is available to the DMA and partners anywhere in the world. We use a mixture of cloud services (AWS, Azure, Backblaze, GitHub) to provide redundancy, backup, version control, and rapid post-disaster recovery. The cluster is available to all project partners and can be used for both high-performance and training-level work (under isolated environments for security and performance).

Data and Code Sharing: Data will be available to the public and researchers without cost or registration, and be released under a CC0 license, as soon as related publications are in press. Data will be deposited for in long-term public scientific repositories. All sequence data will be made publicly available via GenBank. Additional ecological data collected in wildlife sampling will be deposited to the Knowledge Network for Biodiversity, and other data will be deposited in appropriate topic-specific or general repositories. Computer code for modeling and statistical analysis will be made available on a code-hosting site (GitHub), and archived in the Zenodo repository under an open-source, unrestrictive MIT license. Limited human survey and clinical data will be released following anonymization and aggregation per IRB requirements. Publications will be released as open-access via deposition to PubMed commons.

Sharing Model Organisms

Within the program, we will utilize standard laboratory mice as well as different Collaborative Cross mouse strains as well as various transgenic mouse strains, several of which are already available at the NIH-supported Mutant Mouse Regional Resource Center (MMMRC) at UNC. The Collaborative Cross mice are already publicly available from the UNC Systems Genetics Core Facility and the Jackson laboratories, and as such available to the scientific community. All genotyping information generated on these populations will be deposited in the appropriate public repositories (e.g. GEO, ImmPort, ENA). Similarly, all phenotypic data generated within this program from studies with mice will be deposited in the Mouse Phenome Database upon publication, as well as ImmPort to ensure dissemination to the community at large.

In accordance with the NIH/NIAID data sharing and release guidelines, we will coordinate the rapid and unrestricted sharing of all data generated as part of this project.

1. Genotypes generated on the MUGA mouse array, including raw x- and y- intensity data and derived genotype calls will be made available for download from the Mutant Mouse Regional Resource Center at UNC's website (<https://www.med.unc.edu/mmrc/genotypes/publications>) and at Zenodo (<https://zenodo.org/>).

Reagent Sharing

For all other reagents/requests, we have established a consistent process for evaluating requests for samples and reagents from outside scientists. In order of priority, these include: 1) requests for reagents that have been published in peer-reviewed journals; 2) requests which enhance/promote a specific agenda of the program projects and faculty; 3) requests that promote scientifically valid collaborations between project faculty and outside scientists; and 4) overall research and public health needs. The general format involves: a) establishing a working knowledge of the research agenda and credentials of the requestor, b) group discussion and agreement, 3) MTA agreement with the appropriate institution, or license agreement with a commercial entity, and 4) inventory checking and sending out of reagents. We will work closely with the appropriate institutional Technology Transfer Office and individuals involved in these transactions. The goal will be to provide reagents within a few months of receiving a request for traditional research purposes. In the event of an outbreak or emergency situation, we will communicate with the NIH and EIDRC-CC, and rapidly speed up resource sharing among our EID-SEARCH core partners and our extended network. As documented in the Research Strategy, EHA has successfully provided rapid technical assistance for testing and reagent needs during outbreaks under the USAID-PREDICT project, and has strong existing relationships and existing MTAs with our core EID-SEARCH partners to facilitate this. If needed, we will also acquire appropriate letters from the recipient institutions environmental health and safety officers and help coordinate CDC and/or USDA and Department of Commerce permits. The program faculty will not send reagents to individuals or institutions that do not have appropriate documentation of appropriate containment for the materials, might harbor ill-intentions, or are conducting irresponsible research.

Genomic Data Sharing

We will ensure compliance with NIH's Genomic Data Sharing plans for all viral sequence data generated in this project. We anticipate obtaining genetic sequence data for 100s of novel virus genotypes, including RNA-dependent RNA polymerase (RdRp) sequences for all strains/genotypes and sequences of viral

attachment glycoproteins. We will generate full viral genomes for a subset of the viruses and human virus strains that we identify. We will also generate host genetic sequence data for relevant cellular receptor genes of wildlife species. We will deposit all genetic sequences in the NIH data bank, NCBI GenBank as soon as possible after data are generated (including assurance of quality control), and no later than 6 months, so that they are readily available to the scientific community. We will ensure that all meta-data associated with these sequences, including collection locality lat/long, species-level host identification, date of collection, and sequencing protocols will also be submitted. We anticipate sequence generation will occur over the 5 year proposed project period.

All datasets and associated meta-data will be additionally submitted to Virus Pathogen Resource (ViPR, <http://www.viprbrc.org>). All computational models of biological processes will be made available on the BioModels Database (<http://www.ebi.ac.uk/biomodels-main/>).

Intellectual Property

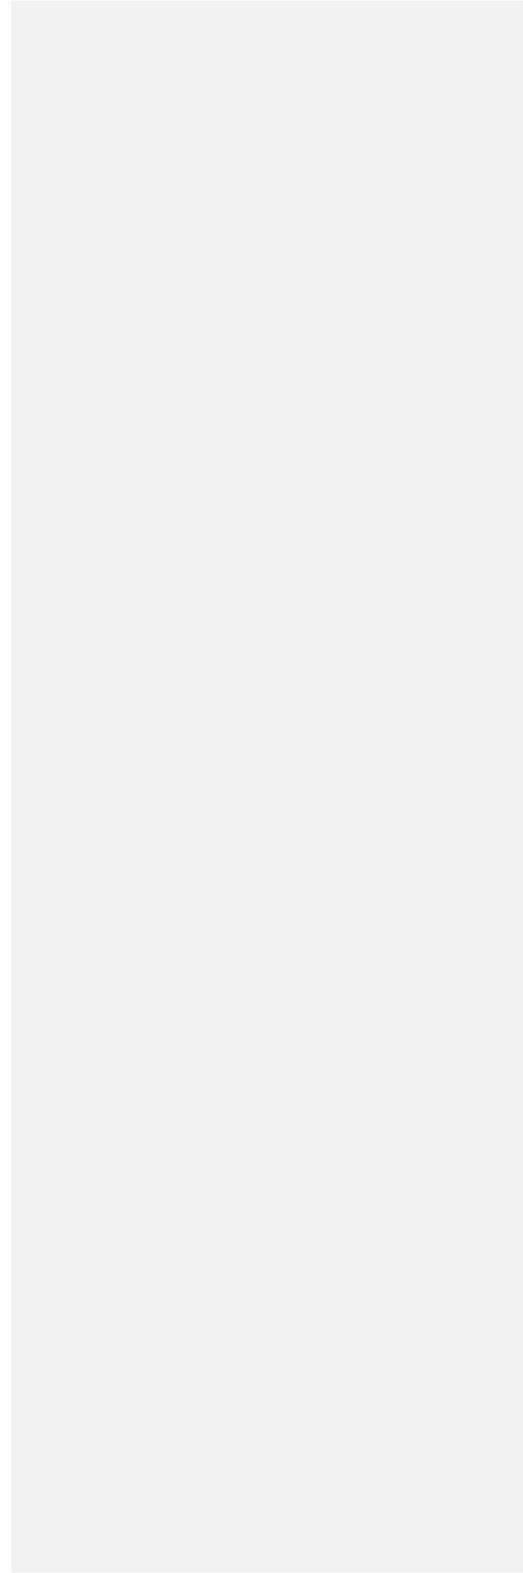

Intellectual property agreements, identified during the course of this project, will be accomplished by negotiation in good faith among the institutions and inventors. We will work with the inventors in the production of the necessary documents, working with the particular institutions, legal firms and commercial interests. It is anticipated that companies and institutions will have access to these reagents and viruses by MTA (for research purposes) or by a license agreement to be negotiated in good faith with a company.

Subject: Thailand EID-SEARCH Meeting this week August 2/3
Date: Monday, July 31, 2023 9:28:36 AM
Attachments: [Thailand Y4 Scope of Work v02_SN_SW.docx](#)

Dear All,

This is a reminder of the Thailand EID-SEARCH Meeting **this Wednesday (9 PM NYC) and Thursday (8 AM BKK)** when we'll discuss the Y4 Scope of Work and check on a few items:

- Year 4 project Scope of Work in Thailand (please see the attached Word document with edits from both EHA and TRC-EIDCC teams)
- Update on the Mpox concept notes (budget)
- Update on papers
- Others

Look forward to the discussion.

Dear Dr. Supaporn - Thank you for sharing the edits. I didn't include the PPT slides in the email since there is budget information that you may want to present from your side at the meeting.

All the best,
Hongying

Next Steps: Visit https://grants.nih.gov/grants/next_steps.htm
Human Subjects: X4-Human subjects involved - Exemption #4 designated
Animal Subjects: 30-Vertebrate animals involved - no SRG concerns noted

Project Year	Direct Costs Requested
1	492,733
2	489,677
3	499,863
4	498,388
5	499,507
<hr/> TOTAL	<hr/> 2,480,168

++NOTE TO APPLICANT: Members of the Scientific Review Group (SRG) were asked to identify those applications with the highest scientific merit, generally the top half. Written comments, criterion scores, and preliminary impact scores were submitted by the assigned reviewers prior to the SRG meeting. At the meeting, the more meritorious applications were discussed and given final impact scores; by concurrence of the full SRG, the remaining applications, including this application, were not discussed or scored. The reviewers' comments (largely unedited by NIH staff) and criterion scores for this application are provided below. Because applications deemed by the SRG to have the highest scientific merit generally are considered for funding first, it is highly unlikely that an application with an ND recommendation will be funded. Each applicant should read the written critiques carefully and, if there are questions about the review or future options for the project, discuss them with the Program Contact listed above.

ADMINISTRATIVE NOTE
BIOHAZARD
NEW INVESTIGATOR

ROSS, N

1R01AI179865-01 Ross, Noam**BIOHAZARD COMMENT
NEW INVESTIGATOR
SCIENTIFIC REVIEW OFFICER'S NOTES**

DESCRIPTION (provided by applicant): Serology remains under-utilized as a reliable surveillance tool for the detection of emerging zoonotic viruses. Detection and estimation of Ebola virus spillovers is dependent on outbreak scale and thus may not be caught through early warning systems. The geographies at-risk for Nipah virus, and bat-borne and rodent-borne henipaviruses spill over across sub-Saharan Africa, Asia and Oceania remain under-surveyed. Limitations of serosurveillance in addressing virus emergence can be found at both the front-end in serological assay design and development, and back-end in the statistical frameworks used to analyze data. Both need to be adapted to the unique challenges associated with known emergent viruses and novel unknown viruses not yet genetically characterized. These challenges include cross-reactivity of antigens and antibodies and complex immune responses. The major goal of this proposal is to dramatically improve the utility of antigen-based serosurveillance for new viral discovery and epidemiology of emerging zoonotic viruses by addressing the challenges of cross-reaction and statistical rigor. We will create discovery panels - qualified and optimized panels of multiplexed immunoassays designed to identify and characterize previously unknown viruses only detected through the serologically profiling wildlife and human hosts. We will develop new statistical approaches to extract the signals of novel viruses from those of known viruses or mixtures of virus-specific antibodies from complex histories multiple previous viral exposures, as well as integrate these into models into population-scale epidemiological models. Finally, we will partner with international viral surveillance projects to apply these techniques to identifying and characterizing filoviruses and henipaviruses in bat populations in South Africa and workers at-risk for exposure to wildlife viruses in Thailand, and to modeling immune-epidemiological dynamics of Nipah virus circulation in bats and people in Bangladesh.

PUBLIC HEALTH RELEVANCE: This project develops new methods to identify emerging and zoonotic viruses by analyzing the virus-induced antibodies present in wildlife and human populations in contact with wildlife. It will create both new laboratory techniques to test for those antibodies as markers of infection and new mathematical models to analyze data to identify the trace of those viruses. It will test these methods in partnership with international virus surveillance projects in Bangladesh, Thailand, and South Africa.

CRITIQUE 1

Significance: 6
Investigator(s): 5
Innovation: 4
Approach: 8
Environment: 4

Overall Impact: The project seeks to develop a novel serological platform to identify emerging and zoonotic viruses by analyzing the virus-induced antibody profiles present in wildlife and human populations at risk. The measurable outcomes would include new laboratory techniques for serodiagnostics and new mathematical models to analyze the seroprevalence data to for previously characterized and emerging viruses. Although investigative team is remarkably strong with a track record of independent and collaborative success, this specific project builds on a relatively weak

ROSS, N

scientific premise that serological methods (as described in the proposal) can be applied to detect novel/emerging, previously uncharacterized viruses. This seems fundamentally wrong, because even current state-of-the-art serological techniques can only target KNOWN antigens. Another important issue is that the PI failed to emphasize the advantage and significance of the proposed approach compared with sequence based or comprehensive techniques for virus discovery/characterization. Further, the proposal refers to multiple limitations of the current serological techniques but fails to describe how those will be addressed. The diversity and complexity of the immune response in the target wildlife species (including bats) is poorly acknowledged. Preliminary data do not seem to be compelling. The model organism chosen for experimental studies (rabbit) does not seem appropriate, as it's not representative of the biology/immunology of wildlife reservoir species of the target viruses. The grant is written poorly and there is a lack of clarity in details throughout. There are other issues that will be detailed in individual sections. Overall enthusiasm for this proposal is very low.

1. Significance:

Strengths

- Ebola and Nipah viruses are a significant public health threat, and tools for their real-time monitoring/detection of new variant emergence are of high significance

Weaknesses

- The approach selected decreases the overall study significance
- The use of serology vs. molecular/sequence-based methods is not justified (other than it was mentioned that it's underutilized). Does not seem feasible or necessary
- The team acknowledged the challenges associated with serological methods that include cross-reactivity and complex/diverse immune responses. The team does not propose feasible strategies to circumvent those. Additionally, they do not acknowledge other issues associated with serological detection of viruses – you can only target known antigens/antibodies. Sensitivity of serological detection is way lower than that of molecular diagnostic methods. Duration and magnitude of immune responses vary per host and per virus, etc.
- The approach to identify shadow viruses by subtracting signals to known viruses does not seem feasible. Proof-of-concept experiments were not done, or results were not presented.
- Although, the PI states that the proposed approach will identify and CHARACTERIZE novel pathogens, the CHARACTERIZE component is not explain well, while the ability to identify novel pathogens using it is highly questionable.

2. Investigator(s):

Strengths

- A very strong team with highly complementary expertise. The team includes a mathematical and statistical disease ecologist, 2 virologists, 2 infectious disease epidemiologists/specialists, and 2 virologist-ecologists experienced with a variety of emerging and zoonotic viral diseases.
- Established collaborations are also beneficial.

Weaknesses

- No immunologist on the team shows in the lack of in-depth understanding of multiple challenges associated with species-specific immune responses, their diversity, complexity, etc.
- No wildlife (specifically bat) specialist on the team is also detrimental.

ROSS, N

3. Innovation:

Strengths

- Using serology for virus discovery/characterization.

Weaknesses

- The use of microsphere-based multiplex immunoassay platforms is not particularly innovative.

4. Approach:

Strengths

- None noted.

Weaknesses

- The Approach has countless deficiencies including the main ones: flawed scientific premise, rabbit model to develop assays for bats and humans, extremely vague description of the proposed immunological experiments, the lack of a clearly presented rationale for detection of antibodies to unknown pathogens using specific reagents derived from previously characterized pathogens, and many others.
- Specifically, rabbits are highly immuno-reactive animals, they lack serological background against the target viruses. Neither they are the natural hosts of these viruses, which will affect the immune response characteristics. Targeted antibody isotypes (that vary between different hosts) are not mentioned.
- Immunization regimen is poorly and vaguely described. Not clear how the antigens will be derived, purified, processed. Not specified numbers of immunizations, timing between each, the time of antiserum harvest, etc.
- The team does not take in the account the immunological phenomena including antigenic sin, whereby exposure to the primary related antigen/pathogen affects subsequent immune responses against related antigens/pathogens.
- Preliminary data needed to prove feasibility of the proposed approach are not provided. At this point, the team should have had a proof that it is possible to detect a signal against an unknown (shadow) virus by simply subtracting the signal against known related viruses. The available preliminary data are not very compelling.
- The proposed statistical models do not seem to account for way too numerous biological variables across different species, pathogens, etc.
- Another factor that would greatly impact feasibility of the proposed research is the variable and sometimes unknown duration of antibody response against the target viruses. While it appears that in experimental rabbits the exposure to different antigens will be time-matched, and the magnitudes of the responses to the non-replicating antigens will be comparable, it is not the case in bats or humans, where time post-infection will vary greatly, and the magnitude/characteristics of the antibody response will be greatly affected by this and the fact.
- Besides the fact that bats are capable of reducing pro-inflammatory response, some studies reported that their antibody response to various test antigens may be lower compared to what is seen in conventional laboratory animals.
- While the team acknowledges that sex and age are important biological variables affecting antibody responses, they do not seem to account for it in their rabbit immunization experiments.

ROSS, N

- At the genomic level, bats seem to possess a much larger repertoire of germline genes encoding immunoglobulin variable (V), diversity (D) and joining (J) segments than humans or rabbits, which may provide a much larger number of antigen specificities in their naive B cell receptor (BCR) repertoire. This suggests that antibody detection discovery matrix would not work for bats as it would work for rabbits or humans (even if it's possible for the latter species).

5. Environment:

Strengths

- The environment seems to be suitable for the proposed research with access to computer/bioinformatics and experimental lab resources.

Weaknesses

- Access to an advanced immunological lab focusing on human and bat adaptive immune responses is needed.

Study Timeline:

Strengths

- Sufficient time seem to be provided for Aim 2.

Weaknesses

- May be not feasible for the proposed experimental (Aim 1) and surveillance (Aim 3) studies.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

- The study will only access previously collected samples

Inclusion Plans:

- Sex/Gender: Distribution justified scientifically
- The sex is acknowledged as a biological variable throughout

Vertebrate Animals:

YES, all criteria addressed

Biohazards:

Unacceptable

- Not described, while it is perceivable that viruses will be used at some point to generate antigens for rabbit immunization

Applications from Foreign Organizations:

Justified

ROSS, N

Select Agents:

Unacceptable

- Not discussed

Resource Sharing Plans:

Unacceptable

- Seems to be missing, while referred to multiple times.

Authentication of Key Biological and/or Chemical Resources:

Unacceptable

- Not sufficient detail regarding the sources of the antigens

Budget and Period of Support:

Recommend as Requested

CRITIQUE 2

Significance: 5

Investigator(s): 1

Innovation: 1

Approach: 5

Environment: 1

Overall Impact: This R01 proposal addresses questions related to serological cross reactivity between filoviruses and henipaviruses, which has confounded serosurveillance, virus discovery, and efforts to incriminate reservoir hosts for these viruses. The investigators propose to create innovative multiplex serological panels that are optimized for virus discovery and combine these with novel statistical methods to solve the cross-reactivity problem. As a result, this is a highly innovative approach from both a technical and conceptual standpoint. In addition, the investigative team is outstanding, and a major strength of the proposal is the ability to leverage several different disease surveillance networks to ground-truth the development of their assay and statistical approaches. However, there were some issues with the experimental design and presentation of the scientific premise that lowered my overall enthusiasm. One major weakness was that it is unclear how these tools would be used to identify putative reservoir hosts, when multiple animal species might be exposed and seroconvert. The other major weakness was the ambitious nature of the proposal which only provided limited depth to each study component. In addition, critical preliminary data were not included in the proposal. This made it difficult to evaluate everything that was being proposed. In conclusion, despite there being laudable aspects related to virus discovery and pandemic preparedness, the potential overall impact of this proposal is only moderate.

1. Significance:**Strengths**

ROSS, N

- It has been long recognized that cross-reactivity between closely related, antigenically variable viruses is a problem for serosurveillance. This has confounded diagnostics and has made it difficult to incriminate zoonotic reservoirs for emerging viruses.
- Incriminating zoonotic reservoirs for emerging viruses is important for prediction, prevention, and control efforts to mitigate the risk posed by these viruses.
- Improved serological assays have utility in diagnostics as well as for virus discovery, and if successful this approach would be useful for other virus families where serological cross-reactivity is a known problem.

Weaknesses

- It is unclear—even with improved serological approaches—how these data would be used to incriminate an animal species as a putative reservoir host without molecular (or some other) evidence of infection. Many animals that come into close contact with the reservoir may have abortive or asymptomatic infection where virus is not shed but still result in seroconversion. This does not mean that these animals are responsible for maintenance of the virus in nature.

2. Investigator(s):

Strengths

- The assembled team has a unique combination of laboratory, analytic, and field expertise and a history of successful collaboration in zoonotic disease surveillance.
- The mPI is very comprehensive.

Weaknesses

- None noted.

3. Innovation:

Strengths

- The approach to detect signatures of “shadow viruses” is conceptually and technically innovative. The use of discovery panels is an improvement on traditional serosurveillance techniques that rely on virus-specificity.
- Identifying putative reservoir hosts for some of these high consequence pathogens would represent a considerable shift in mitigation and prevention efforts for these viruses.
- The proposal has the added benefit on contributing to better understanding basic immune system responses to these viruses during sequential infections.

Weaknesses

- None noted.

4. Approach:

Strengths

- The ability to leverage specimens and infrastructure from the CREID network in Thailand, a DTRA program in South Africa, and a NIAD program in Bangladesh is a strength of the study.
- Preliminary data demonstrate feasibility of the approach.

ROSS, N

- The combination of laboratory, field, and modeling studies addresses the hypotheses posed in complimentary but independent approaches. In addition, there is synergy amongst the aims.
- Aims 1 and 2 are developmental and Aim 3 provides proof-of-concept for the approach.

Weaknesses

- The primary weakness is that the proposal is expansive in scope, so only limited depth was provided for each study component. This made it difficult to evaluate the veracity of what is being proposed.
- Aim 1 references unpublished data on filovirus immunoreactivity in populations of hammer-headed fruit bats. These data need to be shown otherwise it is difficult to evaluate the rigor of the approach.
- For the immunization experiments in Aim 1, n=3 rabbits are not justified statistically or by some other method.
- In addition, better justification for the use of rabbits is warranted given the ultimate target will likely be bats and other wildlife species. Rabbits are highly immune-reactive compared to other species.

5. Environment:

Strengths

- The environments at all of the partner institutions are sufficient for the proposed work with the requisite infrastructure to conduct studies of this nature.

Weaknesses

- None noted.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

- Exempt under #4

Vertebrate Animals:

YES, all criteria addressed

- No concerns noted.

Biohazards:

Unacceptable

- Not described

Select Agents:

Unacceptable

- The investigators will not use authentic viruses but at a minimum there should be some description about how samples that might contain select agents are handled.

ROSS, N

Resource Sharing Plans:

Unacceptable

- This was not included. They mention in the research strategy that they want to share their assay. This a critical resource that could be shared with the community.

Authentication of Key Biological and/or Chemical Resources:

Acceptable

Budget and Period of Support:

Recommend as Requested

CRITIQUE 3

Significance: 2

Investigator(s): 3

Innovation: 2

Approach: 5

Environment: 2

Overall Impact: This project aims to develop an ambitious and novel approach to viral discovery based on multiplexed serological panels. Such developments would have high significance for viral discovery and pandemic preparedness. The investigator team and environment is extremely strong. However, there are some concerns about the ultimate ability to resolve the identity of novel/shadow viruses and the lingering difficulties associated with poor detectability of viral sequence even when the target host species is known or highly suspected. Additionally, the data requirements and the intractability of the novel statistical methodology are likely extreme, and simulation studies that could characterize the potential pitfalls are needed. Overall, this project is high-risk, high-reward and has potentially critical methodological challenges.

1. Significance:**Strengths**

- There is high potential for multiplex serological panels to enable definitive characterization of novel pathogens.
- The project is aimed squarely at a key bottleneck in viral discovery – the poor detection and characterization of novel pathogens.

Weaknesses

- Proposed viral identities based on multiplex serological panels would be able to yield a rough taxonomic identification of a “shadow virus,” but would not be paired with sequence information or any other capability of definitive identification. Definitive identification would remain hampered by its current plaguing issues, poor detectability of viral sequence.

2. Investigator(s):

ROSS, N

Strengths

- The investigator team possesses a high degree of expertise across multiple disciplines relevant to achieve the proposed project.

Weaknesses

- None noted

3. Innovation:**Strengths**

- Adapting methods from image processing to multivariate serological signatures is a novel approach to disambiguate sample identification

Weaknesses

- While the combination of multiple antigens can cover antigenic space, this coverage rests on the assumption that known/suspected space encompasses unknown space. It seems plausible that the identification of novel shadow viruses that extend antigenic space would require continuous updating of key estimated parameters, such as the reaction/cross reaction matrix.

4. Approach:**Strengths**

- The discovery panel approach overcomes substantial limitations of prior serological approaches.

Weaknesses

- It is unclear if reaction/cross reaction is stable enough across age, exposure history, and other traits for an estimated cross reaction matrix to hold reliable and/or meaningful information to be used in disambiguating viral identity.
- Experiments in Aim 1 use extremely small sample size, n=3 per treatment, which may leave low power, high sensitivity to individual variation, and poor replicability.
- The methods developed in Aim 2 require large quantities of high-resolution data to parameterize. However, no simulation studies to establish the feasibility or data requirements of this approach are presented.

5. Environment:**Strengths**

- The environment is highly supportive of this project's goals.

Weaknesses

- None

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

NIH has modified its policy regarding the receipt of resubmissions (amended applications). See Guide Notice NOT-OD-18-197 at <https://grants.nih.gov/grants/guide/notice-files/NOT-OD-18-197.html>. The impact/priority score is calculated after discussion of an application by averaging the overall scores (1-9) given by all voting reviewers on the committee and multiplying by 10. The criterion scores are submitted prior to the meeting by the individual reviewers assigned to an application, and are not discussed specifically at the review meeting or calculated into the overall impact score. Some applications also receive a percentile ranking. For details on the review process, see http://grants.nih.gov/grants/peer_review_process.htm#scoring.

ROSS, N

1R01AI179865-01 Ross, Noam**BIOHAZARD COMMENT
NEW INVESTIGATOR
SCIENTIFIC REVIEW OFFICER'S NOTES**

DESCRIPTION (provided by applicant): Serology remains under-utilized as a reliable surveillance tool for the detection of emerging zoonotic viruses. Detection and estimation of Ebola virus spillovers is dependent on outbreak scale and thus may not be caught through early warning systems. The geographies at-risk for Nipah virus, and bat-borne and rodent-borne henipaviruses spill over across sub-Saharan Africa, Asia and Oceania remain under-surveyed. Limitations of serosurveillance in addressing virus emergence can be found at both the front-end in serological assay design and development, and back-end in the statistical frameworks used to analyze data. Both need to be adapted to the unique challenges associated with known emergent viruses and novel unknown viruses not yet genetically characterized. These challenges include cross-reactivity of antigens and antibodies and complex immune responses. The major goal of this proposal is to dramatically improve the utility of antigen-based serosurveillance for new viral discovery and epidemiology of emerging zoonotic viruses by addressing the challenges of cross-reaction and statistical rigor. We will create discovery panels - qualified and optimized panels of multiplexed immunoassays designed to identify and characterize previously unknown viruses only detected through the serologically profiling wildlife and human hosts. We will develop new statistical approaches to extract the signals of novel viruses from those of known viruses or mixtures of virus-specific antibodies from complex histories multiple previous viral exposures, as well as integrate these into models into population-scale epidemiological models. Finally, we will partner with international viral surveillance projects to apply these techniques to identifying and characterizing filoviruses and henipaviruses in bat populations in South Africa and workers at-risk for exposure to wildlife viruses in Thailand, and to modeling immune-epidemiological dynamics of Nipah virus circulation in bats and people in Bangladesh.

PUBLIC HEALTH RELEVANCE: This project develops new methods to identify emerging and zoonotic viruses by analyzing the virus-induced antibodies present in wildlife and human populations in contact with wildlife. It will create both new laboratory techniques to test for those antibodies as markers of infection and new mathematical models to analyze data to identify the trace of those viruses. It will test these methods in partnership with international virus surveillance projects in Bangladesh, Thailand, and South Africa.

CRITIQUE 1

Significance: 6
Investigator(s): 5
Innovation: 4
Approach: 8
Environment: 4

Overall Impact: The project seeks to develop a novel serological platform to identify emerging and zoonotic viruses by analyzing the virus-induced antibody profiles present in wildlife and human populations at risk. The measurable outcomes would include new laboratory techniques for serodiagnostics and new mathematical models to analyze the seroprevalence data to for previously characterized and emerging viruses. Although investigative team is remarkably strong with a track record of independent and collaborative success, this specific project builds on a relatively weak

ROSS, N

scientific premise that serological methods (as described in the proposal) can be applied to detect novel/emerging, previously uncharacterized viruses. This seems fundamentally wrong, because even current state-of-the-art serological techniques can only target KNOWN antigens. Another important issue is that the PI failed to emphasize the advantage and significance of the proposed approach compared with sequence based or comprehensive techniques for virus discovery/characterization. Further, the proposal refers to multiple limitations of the current serological techniques but fails to describe how those will be addressed. The diversity and complexity of the immune response in the target wildlife species (including bats) is poorly acknowledged. Preliminary data do not seem to be compelling. The model organism chosen for experimental studies (rabbit) does not seem appropriate, as it's not representative of the biology/immunology of wildlife reservoir species of the target viruses. The grant is written poorly and there is a lack of clarity in details throughout. There are other issues that will be detailed in individual sections. Overall enthusiasm for this proposal is very low.

1. Significance:

Strengths

- Ebola and Nipah viruses are a significant public health threat, and tools for their real-time monitoring/detection of new variant emergence are of high significance

Weaknesses

- The approach selected decreases the overall study significance
- The use of serology vs. molecular/sequence-based methods is not justified (other than it was mentioned that it's underutilized). Does not seem feasible or necessary
- The team acknowledged the challenges associated with serological methods that include cross-reactivity and complex/diverse immune responses. The team does not propose feasible strategies to circumvent those. Additionally, they do not acknowledge other issues associated with serological detection of viruses – you can only target known antigens/antibodies. Sensitivity of serological detection is way lower than that of molecular diagnostic methods. Duration and magnitude of immune responses vary per host and per virus, etc.
- The approach to identify shadow viruses by subtracting signals to known viruses does not seem feasible. Proof-of-concept experiments were not done, or results were not presented.
- Although, the PI states that the proposed approach will identify and CHARACTERIZE novel pathogens, the CHARACTERIZE component is not explain well, while the ability to identify novel pathogens using it is highly questionable.

2. Investigator(s):

Strengths

- A very strong team with highly complementary expertise. The team includes a mathematical and statistical disease ecologist, 2 virologists, 2 infectious disease epidemiologists/specialists, and 2 virologist-ecologists experienced with a variety of emerging and zoonotic viral diseases.
- Established collaborations are also beneficial.

Weaknesses

- No immunologist on the team shows in the lack of in-depth understanding of multiple challenges associated with species-specific immune responses, their diversity, complexity, etc.
- No wildlife (specifically bat) specialist on the team is also detrimental.

ROSS, N

3. Innovation:

Strengths

- Using serology for virus discovery/characterization.

Weaknesses

- The use of microsphere-based multiplex immunoassay platforms is not particularly innovative.

4. Approach:

Strengths

- None noted.

Weaknesses

- The Approach has countless deficiencies including the main ones: flawed scientific premise, rabbit model to develop assays for bats and humans, extremely vague description of the proposed immunological experiments, the lack of a clearly presented rationale for detection of antibodies to unknown pathogens using specific reagents derived from previously characterized pathogens, and many others.
- Specifically, rabbits are highly immuno-reactive animals, they lack serological background against the target viruses. Neither they are the natural hosts of these viruses, which will affect the immune response characteristics. Targeted antibody isotypes (that vary between different hosts) are not mentioned.
- Immunization regimen is poorly and vaguely described. Not clear how the antigens will be derived, purified, processed. Not specified numbers of immunizations, timing between each, the time of antiserum harvest, etc.
- The team does not take in the account the immunological phenomena including antigenic sin, whereby exposure to the primary related antigen/pathogen affects subsequent immune responses against related antigens/pathogens.
- Preliminary data needed to prove feasibility of the proposed approach are not provided. At this point, the team should have had a proof that it is possible to detect a signal against an unknown (shadow) virus by simply subtracting the signal against known related viruses. The available preliminary data are not very compelling.
- The proposed statistical models do not seem to account for way too numerous biological variables across different species, pathogens, etc.
- Another factor that would greatly impact feasibility of the proposed research is the variable and sometimes unknown duration of antibody response against the target viruses. While it appears that in experimental rabbits the exposure to different antigens will be time-matched, and the magnitudes of the responses to the non-replicating antigens will be comparable, it is not the case in bats or humans, where time post-infection will vary greatly, and the magnitude/characteristics of the antibody response will be greatly affected by this and the fact.
- Besides the fact that bats are capable of reducing pro-inflammatory response, some studies reported that their antibody response to various test antigens may be lower compared to what is seen in conventional laboratory animals.
- While the team acknowledges that sex and age are important biological variables affecting antibody responses, they do not seem to account for it in their rabbit immunization experiments.

ROSS, N

- At the genomic level, bats seem to possess a much larger repertoire of germline genes encoding immunoglobulin variable (V), diversity (D) and joining (J) segments than humans or rabbits, which may provide a much larger number of antigen specificities in their naive B cell receptor (BCR) repertoire. This suggests that antibody detection discovery matrix would not work for bats as it would work for rabbits or humans (even if it's possible for the latter species).

5. Environment:

Strengths

- The environment seems to be suitable for the proposed research with access to computer/bioinformatics and experimental lab resources.

Weaknesses

- Access to an advanced immunological lab focusing on human and bat adaptive immune responses is needed.

Study Timeline:

Strengths

- Sufficient time seem to be provided for Aim 2.

Weaknesses

- May be not feasible for the proposed experimental (Aim 1) and surveillance (Aim 3) studies.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

- The study will only access previously collected samples

Inclusion Plans:

- Sex/Gender: Distribution justified scientifically
- The sex is acknowledged as a biological variable throughout

Vertebrate Animals:

YES, all criteria addressed

Biohazards:

Unacceptable

- Not described, while it is perceivable that viruses will be used at some point to generate antigens for rabbit immunization

Applications from Foreign Organizations:

Justified

ROSS, N

Select Agents:

Unacceptable

- Not discussed

Resource Sharing Plans:

Unacceptable

- Seems to be missing, while referred to multiple times.

Authentication of Key Biological and/or Chemical Resources:

Unacceptable

- Not sufficient detail regarding the sources of the antigens

Budget and Period of Support:

Recommend as Requested

CRITIQUE 2

Significance: 5

Investigator(s): 1

Innovation: 1

Approach: 5

Environment: 1

Overall Impact: This R01 proposal addresses questions related to serological cross reactivity between filoviruses and henipaviruses, which has confounded serosurveillance, virus discovery, and efforts to incriminate reservoir hosts for these viruses. The investigators propose to create innovative multiplex serological panels that are optimized for virus discovery and combine these with novel statistical methods to solve the cross-reactivity problem. As a result, this is a highly innovative approach from both a technical and conceptual standpoint. In addition, the investigative team is outstanding, and a major strength of the proposal is the ability to leverage several different disease surveillance networks to ground-truth the development of their assay and statistical approaches. However, there were some issues with the experimental design and presentation of the scientific premise that lowered my overall enthusiasm. One major weakness was that it is unclear how these tools would be used to identify putative reservoir hosts, when multiple animal species might be exposed and seroconvert. The other major weakness was the ambitious nature of the proposal which only provided limited depth to each study component. In addition, critical preliminary data were not included in the proposal. This made it difficult to evaluate everything that was being proposed. In conclusion, despite there being laudable aspects related to virus discovery and pandemic preparedness, the potential overall impact of this proposal is only moderate.

1. Significance:**Strengths**

ROSS, N

- It has been long recognized that cross-reactivity between closely related, antigenically variable viruses is a problem for serosurveillance. This has confounded diagnostics and has made it difficult to incriminate zoonotic reservoirs for emerging viruses.
- Incriminating zoonotic reservoirs for emerging viruses is important for prediction, prevention, and control efforts to mitigate the risk posed by these viruses.
- Improved serological assays have utility in diagnostics as well as for virus discovery, and if successful this approach would be useful for other virus families where serological cross-reactivity is a known problem.

Weaknesses

- It is unclear—even with improved serological approaches—how these data would be used to incriminate an animal species as a putative reservoir host without molecular (or some other) evidence of infection. Many animals that come into close contact with the reservoir may have abortive or asymptomatic infection where virus is not shed but still result in seroconversion. This does not mean that these animals are responsible for maintenance of the virus in nature.

2. Investigator(s):

Strengths

- The assembled team has a unique combination of laboratory, analytic, and field expertise and a history of successful collaboration in zoonotic disease surveillance.
- The mPI is very comprehensive.

Weaknesses

- None noted.

3. Innovation:

Strengths

- The approach to detect signatures of “shadow viruses” is conceptually and technically innovative. The use of discovery panels is an improvement on traditional serosurveillance techniques that rely on virus-specificity.
- Identifying putative reservoir hosts for some of these high consequence pathogens would represent a considerable shift in mitigation and prevention efforts for these viruses.
- The proposal has the added benefit on contributing to better understanding basic immune system responses to these viruses during sequential infections.

Weaknesses

- None noted.

4. Approach:

Strengths

- The ability to leverage specimens and infrastructure from the CREID network in Thailand, a DTRA program in South Africa, and a NIAD program in Bangladesh is a strength of the study.
- Preliminary data demonstrate feasibility of the approach.

ROSS, N

- The combination of laboratory, field, and modeling studies addresses the hypotheses posed in complimentary but independent approaches. In addition, there is synergy amongst the aims.
- Aims 1 and 2 are developmental and Aim 3 provides proof-of-concept for the approach.

Weaknesses

- The primary weakness is that the proposal is expansive in scope, so only limited depth was provided for each study component. This made it difficult to evaluate the veracity of what is being proposed.
- Aim 1 references unpublished data on filovirus immunoreactivity in populations of hammer-headed fruit bats. These data need to be shown otherwise it is difficult to evaluate the rigor of the approach.
- For the immunization experiments in Aim 1, n=3 rabbits are not justified statistically or by some other method.
- In addition, better justification for the use of rabbits is warranted given the ultimate target will likely be bats and other wildlife species. Rabbits are highly immune-reactive compared to other species.

5. Environment:

Strengths

- The environments at all of the partner institutions are sufficient for the proposed work with the requisite infrastructure to conduct studies of this nature.

Weaknesses

- None noted.

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

- Exempt under #4

Vertebrate Animals:

YES, all criteria addressed

- No concerns noted.

Biohazards:

Unacceptable

- Not described

Select Agents:

Unacceptable

- The investigators will not use authentic viruses but at a minimum there should be some description about how samples that might contain select agents are handled.

ROSS, N

Resource Sharing Plans:

Unacceptable

- This was not included. They mention in the research strategy that they want to share their assay. This a critical resource that could be shared with the community.

Authentication of Key Biological and/or Chemical Resources:

Acceptable

Budget and Period of Support:

Recommend as Requested

CRITIQUE 3

Significance: 2

Investigator(s): 3

Innovation: 2

Approach: 5

Environment: 2

Overall Impact: This project aims to develop an ambitious and novel approach to viral discovery based on multiplexed serological panels. Such developments would have high significance for viral discovery and pandemic preparedness. The investigator team and environment is extremely strong. However, there are some concerns about the ultimate ability to resolve the identity of novel/shadow viruses and the lingering difficulties associated with poor detectability of viral sequence even when the target host species is known or highly suspected. Additionally, the data requirements and the intractability of the novel statistical methodology are likely extreme, and simulation studies that could characterize the potential pitfalls are needed. Overall, this project is high-risk, high-reward and has potentially critical methodological challenges.

1. Significance:

Strengths

- There is high potential for multiplex serological panels to enable definitive characterization of novel pathogens.
- The project is aimed squarely at a key bottleneck in viral discovery – the poor detection and characterization of novel pathogens.

Weaknesses

- Proposed viral identities based on multiplex serological panels would be able to yield a rough taxonomic identification of a “shadow virus,” but would not be paired with sequence information or any other capability of definitive identification. Definitive identification would remain hampered by its current plaguing issues, poor detectability of viral sequence.

2. Investigator(s):

ROSS, N

Strengths

- The investigator team possesses a high degree of expertise across multiple disciplines relevant to achieve the proposed project.

Weaknesses

- None noted

3. Innovation:**Strengths**

- Adapting methods from image processing to multivariate serological signatures is a novel approach to disambiguate sample identification

Weaknesses

- While the combination of multiple antigens can cover antigenic space, this coverage rests on the assumption that known/suspected space encompasses unknown space. It seems plausible that the identification of novel shadow viruses that extend antigenic space would require continuous updating of key estimated parameters, such as the reaction/cross reaction matrix.

4. Approach:**Strengths**

- The discovery panel approach overcomes substantial limitations of prior serological approaches.

Weaknesses

- It is unclear if reaction/cross reaction is stable enough across age, exposure history, and other traits for an estimated cross reaction matrix to hold reliable and/or meaningful information to be used in disambiguating viral identity.
- Experiments in Aim 1 use extremely small sample size, n=3 per treatment, which may leave low power, high sensitivity to individual variation, and poor replicability.
- The methods developed in Aim 2 require large quantities of high-resolution data to parameterize. However, no simulation studies to establish the feasibility or data requirements of this approach are presented.

5. Environment:**Strengths**

- The environment is highly supportive of this project's goals.

Weaknesses

- None

Protections for Human Subjects:

Acceptable Risks and/or Adequate Protections

Vertebrate Animals:

THE FOLLOWING SECTIONS WERE PREPARED BY THE SCIENTIFIC REVIEW OFFICER TO SUMMARIZE THE OUTCOME OF DISCUSSIONS OF THE REVIEW COMMITTEE, OR REVIEWERS' WRITTEN CRITIQUES, ON THE FOLLOWING ISSUES:

BIOHAZARD COMMENT:

From Critique 1:

- Not described, while it is perceivable that viruses will be used at some point to generate antigens for rabbit immunization

From Critique 2:

- Not described

SCIENTIFIC REVIEW OFFICER'S NOTES:

From Critique 1, regarding resource sharing plan:

- Seems to be missing, while referred to multiple times.

From Critique 2, regarding resource sharing plan:

- This was not included. They mention in the research strategy that they want to share their assay. This a critical resource that could be shared with the community.

From Critique 1, regarding authentication plan:

- Not sufficient detail regarding the sources of the antigens

From Critique 1, regarding select agents:

- Not discussed

From Critique 2, regarding select agents:

- The investigators will not use authentic viruses but at a minimum there should be some description about how samples that might contain select agents are handled.

NIH has modified its policy regarding the receipt of resubmissions (amended applications). See Guide Notice NOT-OD-18-197 at <https://grants.nih.gov/grants/guide/notice-files/NOT-OD-18-197.html>. The impact/priority score is calculated after discussion of an application by averaging the overall scores (1-9) given by all voting reviewers on the committee and multiplying by 10. The criterion scores are submitted prior to the meeting by the individual reviewers assigned to an application, and are not discussed specifically at the review meeting or calculated into the overall impact score. Some applications also receive a percentile ranking. For details on the review process, see http://grants.nih.gov/grants/peer_review_process.htm#scoring.

Subject: R01 summary responses and follow-up
Date: Monday, July 17, 2023 11:36:02 AM
Attachments: [1R01AI179865-01.pdf](#)
[1R01AI179865-01.pdf](#)

Hi Eric,

I have the summary response to R01 submission (attached). I'm not sure if you got it. I'm still processing it. One reviewer really hated it. I think the other critiques are addressable but fundamentally I think we need to be able to demonstrate the feasibility with a preliminary version and figure out how carve out the time in current/smaller projects to do so.

I have a very busy rest of the month, but propose that we regroup in August to think about plans for next steps/resubmission.

A couple of other things:

- On August 1 at 4PM, we have the team from NIH ImmPort giving a talk at EHA's regular "methods and models" meeting. I'll send along an invite if you or any of your lab are interested in attending.

- I'm also considering submitting a proposal to this NIH software development call: <https://grants.nih.gov/grants/guide/rfa-files/RFA-AI-23-038.html>, for creating R packages that would implement the both current and in-development serology analysis methods. It says "No wet-lab technologies or new data collection will be supported," but I'd include you and your team in it for data/testing/consultation.

Best,
Noam

Chapter 3

FILOVIRUSES AND HENIPAVIRUSES AT THE HUMAN-LIVESTOCK-WILDLIFE INTERFACE IN FOREST FRINGE CATTLE FARMS IN SELECTED STATES OF PENINSULAR MALAYSIA

3.1 Introduction

Filoviruses and henipaviruses are high consequence emerging zoonotic pathogens that have caused severe outbreaks in many parts of the world leading to high mortality and morbidity and grave economic losses in both human and animal health sectors (Knust et al., 2017; Looi & Chua, 2007). The economic losses due to Ebola has been estimated to be USD2.8 billion in the 2014 Ebola outbreak and USD446 million in 1998 Nipah outbreak (FAO and APHCA, 2002; World Bank, 2016).

The viruses within the family Filoviridae; Ebola (EBOV) and Marburg virus (MARV) cause haemorrhagic fever outbreaks in Africa, Germany and isolated cases in other parts of the world like Spain, United States of America, United Kingdom, Philippines, Italy, and Russia (CDC, 2018; C. E. Smith et al., 1967; WHO, 2014). The mortality from Ebola disease in Africa was 50-90% in humans and almost 100% mortality in non-human primates (Bowen et al., 1978; Jaax et al., 1996; Jahrling et al., 1996; K. M. Johnson, 1978; Simpson, 1978). While *Henipavirus*; Hendra virus (HeV) and Nipah virus (NiV) have cause respiratory and neurological signs in humans, pigs and horses in Malaysia, Australia, Bangladesh and

India (Chadha et al., 2006; Chua et al., 1999; Hsu et al., 2004; Nor, Gan, Ong, et al., 2000; O'Sullivan et al., 1997). The mortality from Nipah virus infection was 40-70% in humans in Malaysia and Bangladesh; and of 1-5% in adult pigs and 40% in suckling pigs in Malaysia (Chua et al., 2000; Goh et al., 2000; Hsu et al., 2004; Luby et al., 2009; Nor, Gan, & Ong, 2000).

With an exception of Nipah virus which emerged in 1998 (Fikri et al., 2011; Rahman et al., 2013a; Sohayati et al., 2011), limited information is available on both filoviruses and henipaviruses in Malaysia. The investigative work on Nipah has led to numerous works on bat ecology and bat-borne microbial agents. It is now understood that bats have co-evolved with multiple viruses that may be of public health significance such as Nipah (Hayman, 2016). Filoviruses have been detected in bats in Singapore, Bangladesh, China, and the Philippines (Laing et al., 2018; Olival et al., 2013; Taniguchi et al., 2011; Yuan et al., 2012). While henipaviruses widely circulate in bats in Malaysia, India, Vietnam, Cambodia, Indonesia and Australia (Breed et al., 2013; Epstein et al., 2008; Hasebe et al., 2012; Rahman et al., 2013a; Reynes et al., 2005; Sendow et al., 2006). Besides bats, filoviruses and henipaviruses can infect a broad range of mammals such as human primates, rodents, shrews, guinea pigs, bats, dogs, pigs, cattle, donkey, chicken; and rodents, horse, cats, pigs, dogs, goats, respectively (Chua et al., 2000; Edson et al., 2015; Gonzalez et al., 2005; Leroy et al., 2004; Morvan et al., 1999; Wu et al., 2014).

Commented [A1]: I would not use the Laing et al 2019 conference poster abstract as a reference for NIV emergence or really anywhere else.

Despite the apparently wide distribution and reported prevalence of these pathogens amongst the reservoir hosts in Southeast Asia, outbreak has been rare in both humans and domestic animals. Following the Nipah outbreak in 1998-1999 in Malaysia, no further cases have been reported in both humans and animals to date (Fikri et al., 2011; Muniandy et al., 2001; Naama et al., 2013; Sohayati et al., 2016). There has also been no human outbreaks in Cambodia despite serological and molecular evidence widely found in Cambodian bats (Olson et al., 2002; Reynes et al., 2005). However, the SEA region is considered a hotspot for emerging pathogens because several localized emerging zoonosis have occurred in the past two decades and because multiple factors that drives emerging infectious diseases are highly prevalent. For example, wide circulation and abundance of reservoir hosts, topographical or landscape changes and intensified systems of agriculture and animal production may increase contact opportunities for viral transmission at the wildlife-livestock-human interfaces (Breed et al., 2013; Horby et al., 2013; Jung & Threlfall, 2016; I. Smith & Wang, 2013). In addition, the global climatological changes may impact distribution and concentration of disease vectors which subsequently facilitates spatiotemporal changes of filovirus and henipavirus viral spillover events (Martin et al., 2018; McFarlane et al., 2011; Schmidt et al., 2017).

The one health approach of managing complex emerging diseases requires the understanding of all actors that take part at the environment-animal-human interface. For example, food animals may become infected with pathogens from wildlife that can then be transmitted to human such as Nipah, Highly Pathogenic Avian Influenza H5N1,

Pandemic Influenza H1N1 (2009) amongst others. Many livestock farms in this region are located in the rural or peri-urban areas bordering primary or secondary forests. In Malaysia, livestock especially cattle are commonly managed extensively or semi-intensively at forest fringes thus may have higher probability of contact with infectious materials from infected wildlife or domestic animals. Beef cattle are most commonly raised using the aforementioned systems where animals are let out to graze in a field, plantations or in a village located at forest fringes where wildlife and peri-domestic animals are plentiful. Such setting improves the chance and frequency for pathogen spillover events to livestock or humans (Hassell et al., 2017). The spillover occurrences varies given available drivers and rarely result in an epidemic, however frequent spillover events will increase the chance of an outbreak (Clayton et al., 2013; Hayman et al., 2011; Parrish et al., 2008; Plowright et al., 2017).

In this chapter, we targeted cattle farms located at forest fringe areas with high contact risk and probability of pathogen spillover events. We hypothesise that cattle, other domestic animals, wild animals and farmers are seropositive for filoviruses and henipaviruses. The objectives of this study are: 1) To determine the serological evidence of filoviruses and/or henipaviruses in cattle, farmers, and other domestic animals and wildlife in and at close proximity to the targeted cattle farm; 2) To determine risk factors of virus infection in those species.

3.2 Materials and Methods

3.2.1 Ethics statement

All human and animal samples from cattle farms were collected in accordance to an established USAID Emerging Pandemic Threats PREDICT Operating Procedures with permission from the local institutional and ministerial Institutional Animal Care and Use Committee from UPM (AUP-R064/2018), UC Davis (#19300) and Tufts (G2021-131) and the Institutional Review Board from the Medical Research and Ethics committee (MERC) from National Medical Research Register (NMRR), Malaysia (NMRR-17-3356-37135, IIR) and UC Davis (#804522) in collaboration with Ministry of Health (MOH), Malaysia, Department of Veterinary Services (DVS), Malaysia, and the Department of Wildlife and National Parks (PERHILITAN). The work performed for this project is part of a larger project in collaboration with the EcoHealth Alliance.

3.2.2 Study design and study sites

A cross-sectional survey was performed in 3 semi-intensive, 2 integrated and 1 intensive cattle farm. These farms were selected based on a defined selection criteria which include, 1) located in districts with existing NMRR and IRB approval for human study, 2) located 5 km from periphery of forests as approved by the Department of Veterinary Services, Putrajaya, 3) a minimum of 30 cattle in farm, and 4) has other domestic animals and wildlife in or around farm. The approved districts were Kuala Kangsar in the state of Perak, Gua Musang in Kelantan and Kuala Lipis in Pahang. In these districts, the district

health officers had worked with EcoHealth Alliance on previous projects and have agreed to assist the human sampling aspects in this project.

The identification of the cattle farms consisted of several steps as in **Figure 3.1**. The details of the steps in identifying location and farms are further described in **Appendix X**.

All animals sampled in this study were within 5 km radius of a primary forest.

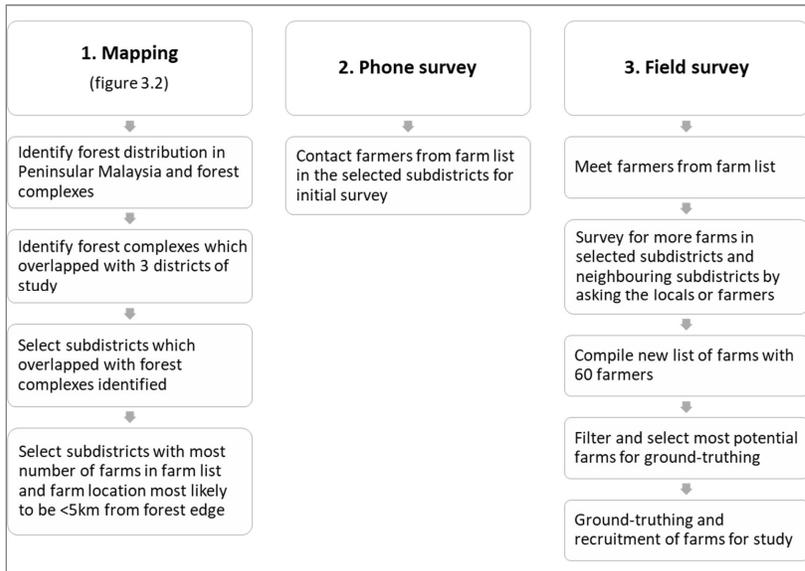

Figure 3. 1 Identification of forest-fringed cattle farm for the study on filovirus and henipavirus exposure at the wildlife-livestock-human interface

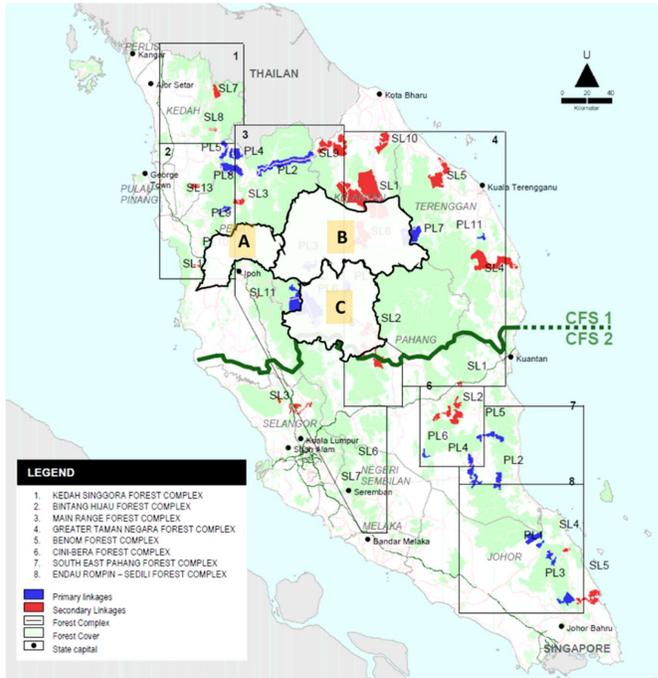

Figure 3. 2 Map of forest complexes in Peninsular Malaysia and the overlapping targeted districts in our study marked by A: Kuala Kangsar, B: Gua Musang, C: Lipis. (Source: Regional Planning Division, Department of Town and Country Planning, Peninsular Malaysia, 2009)

3.2.3 Sample size

Four cattle farms from Kuala Kangsar district, Perak and two cattle farms from Gua Musang district, Kelantan within 5 km radius of forests were sampled beginning 2019.

Targeted sample size for each animal species per farm were 30 cattle from participating target farms, 30 other domestic animals (eg, goat, sheep, dog, etc) and 60 wildlife (eg, bats and rodents). The sample size (n) for this study (Table 3.1) was determined using

the Open-Epi Version 3 calculator. The software program applies the formula of $n = \frac{DEFF * N * p * (1-p)}{[(d/2)^2 * (N-1) + p * (1-p)]}$, where N = population size, p = prevalence, d = confidence limits = 10%, and DEFF = design effect for cluster surveys = 1. The estimated prevalence used in the current study was 5% based on prevalence studies of filoviruses and henipaviruses in the region which reported seroprevalence of 0-79% in domestic animals and 1-33% in bats (Table). Other domestic animals and wildlife were opportunistically captured and sampled with priority given to animals in and closest to the participating target farms.

Commented [A2]:

Commented [A3R2]: Citation for these?

Commented [A4R2]: This table will be in the literature review. Kindly see attached document for the table.

Table 3. 1 Sample size calculation for the sero-detection of filovirus and henipavirus in cattle, other domestic animals and wildlife in participating cattle farms located at the forest fringe in Perak and Kelantan, Malaysia

	Estimated Population Size, N per farm	Estimated Prevalence, p (% +/-5) ^a	Sample size, n per Farm	No. of farms	Total
Cattle : (Semi-intensive (n=3), Integrated oil palm (n=2), Intensive farm(n=1)	50	5	30	6	180
Other domestic animals : Goat, sheep, dog, etc.	50	5	30	6	180
Wildlife : Bat, rodent, other small mammal	1249 per roost for bats	5	70 (max of 60) ^c	6	360

^aPrevalence of 5% was decided based on prevalence studies of filoviruses and henipaviruses in the region (see Table ???).

^bEstimated population size for bats is based on the average roost size of bats. Total number of bats calculated is an overestimation as it will be highly dependent on the bats captured in nets and number of days the nets are placed in a location.

^cTotal number of wildlife are set to the maximum of 60 due to logistical and financial limitations.

3.2.4 Sampling of cattle and other domestic animals

Cattle and other domestic animals such as goat, sheep, dog and rabbit were conducted with the team from the EcoHealth Alliance in accordance to USAID Emerging Pandemic Threats PREDICT Operating Procedures (PREDICT One Health Consortium, 2016b, 2016e).

All domestic animals were manually restrained for the sampling procedures (Appendix B). Blood samples were obtained from the appropriate venepuncture sites according to species. In cattle, goat, and sheep, the jugular vein or coccygeal vein was used (Figure 3.3). In dogs, blood was collected from the cephalic vein, jugular vein, femoral vein, lateral or medial saphenous vein. In rabbits, blood was collected from the lateral saphenous vein. Three to five mL of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube.

A basic physical examination was performed by veterinarian to assess the health status and identify the age and sex of the animal. Photographs of sampled animal was taken from the sides and front, including dentition, or presence of any lesions, abnormalities or identifying marks or characteristics for future reference.

All blood tubes were labelled appropriately and placed in cooler boxes and transported back to sampling processing base. Blood in BD Vacutainer® serum tubes were left to clot

for serum collection within 1 hour. After clot is form, serum tubes were centrifuged at 1300 r.p.m for 15 minutes and 1 mL of serum was transferred into 0.5 mL cryovial tubes to produce at least two aliquots. Cryovial tubes were labelled appropriately. Samples were then placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at - 80 °C freezer in the lab according to proper cold chain methods.

Figure 3. 3 Locating the jugular vein in the jugular groove for blood sampling

3.2.5 Sampling of wildlife

Permission was obtained from the local authorities or landowners before bat and rodent trapping and sampling begun. Selected sites were first surveyed with priorities given to potential trapping locations in the farm and nearest to farm within 5 km radius. All personnel handling trapping and sampling of wildlife had to be immunized against rabies

virus, Japanese encephalitis virus, hepatitis B virus, tetanus and negative sputum tests for tuberculosis.

3.2.5.1 Sampling of bat

Bats were captured using mist nets suitable for capturing bats in open spaces as described by FAO Manual for Investigating the Role of Bats in Emerging Zoonoses (Food and Agriculture Organisation of the United Nations, 2011). Further description on the sampling procedure is in Appendix X. Briefly, bats were captured using mist nets placed at anticipated bat flyways in the farm, village and in nearby plantations such as across streams or trails. The nets were also positioned near roosting or feeding sites such as near flowering banana trees and flowering durian trees (Figure 3.4).

Figure 3. 4 A bat trapping site with banana and durian plantation in a village near a participating cattle farm.

The mist nets were raised around sunset at 7.30pm and remained opened until 12:00am for trapping to occur (Figure 3.5) and closed neatly after trapping period (Figure 3.6). Bat nets were repositioned to new locations when recapture rates were high, or captures were absent. The GPS coordinates for each mist nets were recorded.

Figure 3. 5 Extended mist nets for capture of bats at sunset.

Figure 3. 6 Retracted mist nets that is secured after trapping period

Mist nets were checked for bats every 30 minutes to an hour. Captured bats were extracted from the nets carefully using leather gloves and forceps or a small stick to move the netting or bat mandibles. Bats are then placed into a porous cotton bag with a draw-string mouth and taken to a sampling processing site where sampling was performed immediately (Figure 3.7). Approximately 20-30 bats were sampled in a night. No bats should be kept for more than 6 hours.

Commented [A5]: Check whether you've been using min or minutes, then be consistent throughout (same with hour or hr).

Commented [A6R5]: Corrected

Commented [A7]: This is a lengthy. I suggest rewriting/rewording into 2 sentences.

Commented [A8R7]: Corrected. Tq

Figure 3. 7 Bags containing bats hung in draw-string cloth bags on a raffia string between two pillars

Bats were sampled and identified according to the USAID Emerging Pandemic Threats PREDICT Operating Procedures with some modifications (Hoffmann et al., 2010; PREDICT One Health Consortium, 2016a; C. Smith et al., 2010). A bat was removed from the cloth bag and manually restrained for sampling using leather gloves. In bats that were > 100 g, a non-heparinised syringe was used to collect blood from the cephalic vein, brachial vein or saphenous vein. Blood was then placed in a serum vacutainer tube containing serum-clotting factor and centrifuge. Extracted serum was placed into 2 cryovials of a minimum of 60 μ L if volume. If bats were < 100 g, the tip of a sterile 25G needle was used to puncture the brachial or propatagial vein (C. Smith et al., 2010).

A 1:10 serum dilution (10 μ L blood into 90 μ L PBS) was centrifuged, and the supernatant was transferred into a new cryovial tube. Cryovial tubes were labelled appropriately and placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80 °C freezer in the lab according to proper cold chain methods.

Figure 3. 8 Blood sampling from the cephalic vein of a bat by aspirating the drop of blood using a pipette.

Morphometric measurements and photographs of each bat were taken during the sampling procedure for the purpose of species identification. Identification of bat species was performed by an experienced rangers and field veterinarian based on the morphology and biometric measurements. Guide books were used for identification of bats in the field (Francis, 2008; Kingston et al., 2006; Payne et al., 1985; Phillipps & Phillipps, 2016).

Sexual characteristics and size were used to classify the age of bats as adult, subadult and juvenile. Males with descended testis and relative body size were considered adults while those with unfused epiphyses and undescended testis were considered subadults. Relative body size, prominent nipples, pregnant or lactating, and complete fusion of the phalangeal symphysis were morphological features used to classify female bats as adult. Whereas female bats that were fully grown with unfused epiphyses were considered subadults. Pregnancy status was identified by gently palpating the abdomen, and lactating status was identified by attempted milk expression from the teats. Female and male bats that were small, clinging to dam, and suckling were considered juveniles.

Typically, sampling per bat took less than 15 minutes with one person handling and performing the morphometric measurements, while a second person focused on the sampling. Bats nails were painted with a red nail polish as identification in case of recapture. Frugivorous or nectivorous bats were fed with approximately 1 mL of 100% fruit juice or honey water prior to release. Bats were released after sampling.

3.2.5.2 Sampling of rodent and other small mammal

Rodents and other small mammals were trapped and sampled according to the USAID Emerging Pandemic Threats PREDICT Operating Procedures with some modifications (Aplin et al., 2003; Hoffmann et al., 2010; Mills et al., 1995; PREDICT One Health Consortium, 2016d, 2016e). Further description on the sampling technique is in

Appendix X. A total of 100 traps were used to trap rodents, including 45 Sherman traps, 45 small Tomahawk for smaller mammals such as mice, rats, tree shrews, and 10 large Tomahawk traps for larger mammals, such as civets (Figure 3.9).

Figure 3. 9 Sorting of 100 rodent traps according to transect lines before deployment

Sites for traps were first surveyed and divided between inside farm or nearby plantation or forest. Transect lines were used for placement of traps as opposed to grid to reduce overlapping and increase sampling area coverage and increase chance of capturing more species through coverage of small mammal home ranges and microhabitats (Pearson et al., 2003).

Traps containing appropriate baits were placed at strategic pathways for rodents (Figure 3.10). Oil palm fruit was the preferred option as it does not attract insects. Traps were placed at the same sites for a minimum of three consecutive nights from 6:00pm to 8:00am the next day. If adverse weather such as heavy rain was expected, traps would not be opened for that night.

Figure 3. 10 Placement of rodent trap by the fences in a farm

Commented [A9]: Typically, 0-9 are written, and 10 and above are numbered. Ex: five, eight, nine, 10, 15, 38.

Commented [A10R9]: Does this include the numbers between 0-9 in the results too?

Commented [A11]: Double check for consistency, I think above you used: 12:00am.

Commented [A12R11]: 12:00am was the closing of mist nets for bats. Whereas this line is for rodents

Figure 3. 11 Roasting of oil palm fruits that were used as baits for rodents

Trapped small mammal were gently transferred into a draw-string cloth bag by covering the bag over the opening of the trap and slightly tilting the trap downwards. Animals that were too stressed were released, while animals found to be injured or weak were brought back to sampling processing base for veterinary treatment.

Smaller rodents were removed from the bag gently and placed in a modified container for anaesthetic induction. Whereas, in small mammal species like civets, a gas mask was used for induction without completely removing animal out from the bag to reduce stress (Figure 3.12). Once an animal was motionless and unresponsive, it was taken out

Commented [A13]: Check the spacing format of this Picture Heading and the paragraph below.

Commented [A14]: Was there a standard way to measure this?

Commented [A15R14]: This was only through behavioral observation, eg if animal were pacing or have risk of injuring self from intense movement in the cage. Do you recommend that I remove this?

Commented [A16]: Check your tense agreement.

and placed on the table with an appropriate fitting face mask for continue induction or maintenance of anaesthesia. Monitoring of animal was performed by a veterinarian throughout during procedure along with a basic physical examination to access health status.

Figure 3. 12 Induction of general anesthesia using isoflurane in a small Indian civet (*Viverricula indica*)

Blood samples were collected from the lateral tail vein, ventral tail artery or lateral saphenous vein or lateral saphenous vein in rodents and other small mammals (Hem et al., 1998; G. Lee & Goosens, 2015; Mills et al., 1995; Office of the University Veterinarian, 2017a; PREDICT One Health Consortium, 2016d). In smaller rodents, approximately 1 mL of blood was collected, and in larger small mammals (~200 g), 3-5 mL of blood was collected. Whole blood was diluted 1:10 in PBS, left to stand for a minimum of 30 minutes

and centrifuged to remove red blood cells. Sera was collected and subsequent steps in processing and storage are as mentioned in 3.2.5.1.

Commented [A17]: How an incubation period of coagulation prior to centrifugation?

Commented [A18R17]: Added duration of time

After blood collection, fluid volume replacement was given subcutaneously using Lactated Ringer's or 0.9% NaCl solution to avoid hypovolemic shock. Markings on sampled rodents or small mammals was done by clipping 3-5 mm of hair at the right ventral thigh. Morphometric measurements and photographs of each animal were taken during the sampling procedure for the purpose of species identification.

Secondary sexual characteristics and size were used to classify animal ages as adult, subadult and juvenile. Adults were considered fully grown with adult pelage and sexually mature. Subadults were not fully grown, were developing pelage and were or were not sexually mature. Juveniles were smaller than subadults and not sexually mature with grey and soft pelage (Hoffmann et al., 2010). Animals were monitored in a small cage until fully recovered from anaesthesia before release at place of capture.

3.2.5.3 Sampling of Wild boar

Wild boar were sampled according to established protocols (Office of the University Veterinarian, 2017b, 2017c; PREDICT One Health Consortium, 2016b). Further description on the sampling technique is in Appendix X. Wild boar were trapped according to trapping protocol described for rodent and other small mammals, and transported in a cage to sampling processing base for sampling (Figure 3.13).

Commented [A19]: unclear

Commented [A20R19]: Changed sampling base to sampling processing base

Figure 3. 13 A subadult wild boar in a Tomahawk trap from an oil palm plantation

Wild boar were sedated with by creating an anaesthetic chamber for induction and maintained with a gas mask. Monitoring of anaesthesia was performed by a veterinarian throughout during procedure. Blood samples were collected from the anterior vena cava and is distributed equally in a BD Vacutainer® serum tube and an EDTA tube. Processing of blood for serum extraction and storage were similar to previously mentioned in 3.2.4. After blood collection, fluid volume replacement was given subcutaneously using Lactated Ringer's or 0.9% NaCL solution. A basic physical examination was performed by veterinarian to assess health status. Morphometric measurements and photographs of each animal were taken during the sampling procedure for the purpose of species identification.

Commented [A21]: Plural

Commented [A22R21]: Thank you.

Wild boar were classified into adult, subadult and juvenile based on secondary sexual characteristics and size. Adults were considered fully grown with adult pelage and is sexually mature. Subadults are-were not fully grown, were-with developing pelage and may-or-maywere or were not be sexually mature. Juveniles are-were smaller than subadults and not sexually mature with grey and soft pelage (Hoffmann et al., 2010).

Commented [A23]: Tense agreement

Commented [A24R23]: Corrected

3.2.5.4 Sampling of Non-human primate

Non-human primates (NHP) were kept as pets hence trapping was not required. NHP were anaesthetized and sampled upon the agreement of its owner according to established protocols (Hoffmann et al., 2010; PREDICT One Health Consortium, 2016c). Further description on the sampling technique is in **Appendix X**. Briefly, aesthesia drug used to sedate animals were the combination of: 1) 4mg/kg Ketamine and 0.15mg/kg Xylazine with Yohimbine 1:1 as reversal agent for Xylazine, or 2) Tiletamine-Zolazepam, Zoletil® 3-5mg/kg in more aggressive primates. A dart syringe and blowpipe were used to deliver anaesthetic drug intra-muscularly by an experienced and trained ranger. Anaesthetic monitoring was performed by a veterinarian. After immobilization, basic physical examination was performed. A sterile lubricant is placed into animal's eyes to prevent corneal drying or scratches during sedation.

NHP were placed in a supine position. Blood was withdrawn from femoral vein located in the inguinal region lateral and parallel to the femoral artery (**Figure 3.14**). Three to five

Commented [A25]: Singular vs plural agreement

Commented [A26R25]: Apologies for the mistake

mL of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube. Processing of blood for serum extraction and storage are similar to previously mentioned in 3.2.4.

Figure 3. 14 Sampling of an anaesthetized pig-tailed macaque (*Macaca nemestrina*)

Photographs of the anterior and ventral view of the full body, anterior and lateral face, upper and lower dentition and genitalia were taken for future reference. Age was classified to 7 age class according to the PREDICT Operating Procedures for Non-Human Primates. Neonates are animals that show signs of being born within few days; infants are young that were still suckling and clinging on to mother; juveniles are mostly independent from mother, sexually immature and have not developed into adult size; immature primates are individual that have not sexually mature, subadults are fully independent, appears sexually mature but has not fully grown into adult size; adults are fully grown size with sexually mature sexual characteristics; old adults are adults with

signs of age degeneration. Monitoring is done from a safe distance until NHP is fully awake and ambulatory.

3.2.6 Sampling of Human

Human samples were collected from farmers in participating cattle farms. Sample size was limited to 10 farmers per farm due to logistical and budget constraints. Individuals were recruited based on their willingness to participate, were above 18 years old and have worked or assisted with handling of animals in participating farms. Individuals were recruited based on recommendations from the farm owner.

Human sampling was conducted by district health officers from Ministry of Health, Malaysia and staffs of EcoHealth Alliance in accordance to USAID Emerging Pandemic Threats PREDICT Operating Procedures (Huppenthal, 2009; C. K. Johnson & Saylor, 2016). A written informed consent from the participant was obtained for biological sampling collection and questionnaire. Participants were explained about the study objectives and that the biological testing was for **research** and not diagnostic for their health, the types of question asked, duration of questionnaire and potential risks of their participation. They were also informed that the study was voluntary and anonymous in nature.

Commented [A27]: Was 'exploratory' used as the word, "research" is also an appropriate term.

Commented [A28R27]: Agree that 'research' is a better term

Biological sampling and questionnaire were conducted in a convenient, comfortable and private environment. Further description on the sampling is in Appendix X. Briefly, blood was taken from the median cubital vein on the upper limb or metacarpal plexus or the dorsal venous arch on the dorsal surface of the hand. Three mL of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube. Processing of blood for serum extraction and storage were similar to previously mentioned in 3.2.4.

3.2.7 Data collection

Following biological sampling, interviews with farmers were conducted using questionnaire designed to gauge exposure or behavioural risks to zoonotic spillover events. The questionnaire has been approved for used by the Institutional Review Board for studies on human research subjects and has been verified in previous studies (Kamau et al., 2021; Li et al., 2019; The PREDICT Consortium, 2021). The questionnaire was designed into several parts to gather information on participants' demographics, exposure to different species of domestic animal and wildlife, forms of exposure to domestic animal and wildlife, reported unusual illnesses within the past year. The questionnaire took less than 30 minutes to be completed and were administered by trained EcoHealth Alliance staffs in Malay language.

Data for livestock, other domestic animals and wildlife were recorded accordingly during the sampling process as described above (Table 3.2).

Table 3. 2 Types of data collected during sampling of animals and human from participating cattle farms located at the forest fringe in Perak and Kelantan, Malaysia

Species	Data collected
Livestock/Dogs	Date of sampling, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal classification (domestic, feral domestic, captive wild, wild), species scientific name, species' English name, breed, farm location GPS coordinates, husbandry, ecological setting, other animals at site, tag number, sex, pregnancy status, lactating status, descended testes, age class, age, age in captivity, health condition during sampling, presence of ectoparasite, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, GPS coordinates of sampling base
Rodent/Small mammal/Non-human primates/Wild boar	Date of capture, time of trap check, trap ID and type, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal taxa, species scientific name, species' English name, sex, pregnancy status, lactating status, descended testes, age class, health condition during sampling, presence of ectoparasite, morphometric measurements (body length, right ear height, right hind foot, tail length), recapture marking, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, GPS coordinates of traps, GPS coordinates of sampling base
Bats	Date of capture, time of capture, GPS coordinate of net, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal taxa, species scientific name, species' English name, sex, pregnancy status, lactating status, descended testes, age class, health condition during sampling, presence of ectoparasite, morphometric measurements (forearm or radius length, body length, ear length, hind foot length, tail length), recapture marking, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, volume of serum dilution, of traps, GPS coordinates of sampling base
Human	Participant ID, site location, GPS coordinates, date of sampling, body temperature, blood pressure, pulse, weight, height, obvious signs of illness, age, sex, ethnicity, education level, years of residence in village, frequency of entering forest, exposure to different species of domestic animal and wildlife (primate, bat, rodent, small mammal, wild boar, wild bird, swine, cattle, dog, cat, goat, chicken, others), forms of exposure to domestic animal and wildlife (1. General exposure: lived with pet, handled live animals, raised animals, share water source with animals, seen faeces in or near food, animal entered house, eaten food that were touched, disturbed or damaged by animal, scratched or bitten by animal; and 2. Exposure to wildlife: cook or handle recently slaughtered meat, offal or blood of wildlife, eaten raw or undercooked meat, offal or blood of wildlife, eaten wildlife of unknown health status, eaten or shared dead wildlife, collect and sell dead wildlife, slaughter or butcher wildlife), reported unusual illnesses within the past year (fever with headaches and lethargy @ encephalitis, haemorrhagic fever and rash, severe acute respiratory infection (SARI), Influenza-like illnesses (ILI), fever with diarrhoea and vomiting, fever with skin rash), interviewer's name

3.2.8 Multiplex Serology

Serum samples from all species of wildlife and domestic animals, and humans were analysed using an antigen-based multiplex microsphere immunoassay (MMIA) (Bossart et al., 2007). This antigen-based MMIA utilizes Luminex xMAP (xMAP = multianalyte profile) technology based on flow-cytometry principles which allows high-throughput, multiplex and simultaneous detection of up to 500 analytes in a 96-well microtiter plate. Since its invention in the late 1990s, this technology has been extensively used for detection of viral, bacterial, parasitological and fungal agents (Reslova et al., 2017). It has also been used increasingly for seroprevalence study of filoviruses and henipaviruses globally (Chowdhury et al., 2014; Dovih et al., 2019; Hayman et al., 2008; Laing et al., 2018; Peel et al., 2013b).

Filovirus envelope attachment glycoproteins (GP) and henipavirus envelope receptor-binding proteins (G) were designed as structurally native-like ectodomains for recombinant production, expressed in a mammalian cell-culture system, and purified by size exclusion and affinity chromatography (Bossart et al., 2005; Chan et al., 2009). Purified protein antigens were coupled to 5.6 µm diameter polystyrene magnetic beads for antigen-antibody binding. The list of filoviruses and henipaviruses tested are shown in [Table 3.3](#).

Table 3. 3 Filovirus and henipavirus envelope glycoprotein antigen conjugated magnetic beads used in multiplex assay for antibody detection.

Filoviruses (GP)	Henipaviruses (G)
EBOV, Ebola virus	HeV, Hendra virus
BDBV, Bundibugyo virus	NiV, Nipah virus
BOMV, Bombali virus	CedV, Cedar virus
SUDV, Sudan virus	MojV, Mojjang virus
MLAV, Mengla virus	GhV, Ghana virus.
RESTVm, Reston virus monkey isolate	
RESTVp, Reston virus pig isolate	
LLOV, Lloviu virus	
MARV, Marburg virus	
RAVV, Ravn virus	

Prior to testing, individual serum samples were diluted 1:100 in phosphate-buffered saline (PBS) in 1.5 mL Eppendorf tube and vortexed briefly to mix followed by heat inactivation at 56 °C for 30 minutes. Duplicates of 100 µl diluted sera were added into 96-wells plate containing 100 µL of bead master mix containing specific GP- and G-coated beads. Mixture is covered with plastic shield and aluminium foil and incubated on a shaker for 1200 r.p.m for 1 minute followed by 900 r.p.m for 45 minutes. Samples were washed to remove unbound antibodies three times and incubated at room temperature maintaining plate shaker agitation with 100 µL of 1:1 mixture of biotinylated-Protein A and biotinylated Protein G (Thermo Fisher Scientific, Waltham, MA, USA) diluted in 1:1000 in PBS-Tween 20 (0.05%). Mixture was washed three times and lastly incubated on a shaker with 100 µL 1:1000 streptavidin-phycoerythrin (PE) in into each well and agitated for 30 minutes. Antigen-antibody complexes were measured by a Bio-Rad Bio-

Commented [A29]: Check previous use of PBS in preceding pages

Plex 200 HTF multiplexing system with at least 50 antigen-bead results per spectral region and antigen-bound IgG levels were reported as median fluorescence intensities (MFI). Cut-off values in the first round of testing at dilutions 1:100 were determined by outlier-based detection (3*Sigma, 3-fold change of the mean of adjusted MFI values or above the mean plus 3 standard deviations) (Dovih et al., 2019).

Positive samples in the first round were rerun at the optimum dilutions of 1:400 and 1:500 with additional positive and negative controls. [Sera from EBOV infected bats-GP positive rabbit polyclonal sera](#) at dilutions of 1:6400 were used as positive controls for EBOV which resulted in an average MFI value of 20359. [Negative rabbit polysera and PBS](#) were used as negative controls with a maximum MFI value of 1629 and 1851 respectively. Naïve livestock sera (N=46) comprising of cattle, goat, sheep and pigs tested with filovirus and henipavirus antigens by collaborators in Uniformed Services University of the Health Sciences, USA yield a maximum MFI value of less than 900. Antigen-antibody binding were measured and read using a Bio-Plex 200 system. Data were transformed to adjusted MFI values by taking the mean MFI values duplicates of each sample and subtracting average blank-PBS MFI per plate.

Cut-off were determined by using 3*Sigma and Latent cluster analysis (LCA). LCA was used in absence of gold standard assays and lack of positive and negative reference samples for the viral and animal species tested (Peel et al., 2013a). To improve cut-off

Commented [A30]: Can you confirm the source of EBOV+ bat sera? We don't have that so this was not provided by us.

Commented [A31R30]: Corrected

Commented [A32]: If this is referring to the positive control from our lab, it's is GP immunized rabbit polyclonal antisera.

Commented [A33R32]: Yes, my notes were rabbit positive controls

determination, MFI values from local samples collected as part of the research programme were combined with this study dataset. Serum samples above the cut-off values were considered seropositive. The 3*Sigma cut-off values for filoviruses and henipaviruses were determined to be 4182 MFI and 4641 MFI respectively. LCA for filoviruses and henipaviruses were attempted but were not possible due to insufficient samples reactive samples, prohibiting the LCA models to converge on specific MFI values for threshold cut-off determination.

3.2.9 Data Analysis

Serodetection of filoviruses and henipavirus for different species were calculated based on the number of seropositive animals over the total number of sample and reported as percentage (%). The association between the serological evidence and determinants from animals (such as, farm, sex, age, age class, species, reproductive status and health status) and humans (such as, farm, husbandry, sex, age range, ethnicity, education level, years of residence in village, frequency of entering forest, exposure to different species of domestic animal and wildlife, forms of exposure to domestic animal and wildlife, reported unusual illnesses within the past year) were analysed for sero-epidemiological data using Pearson Chi-Square test, X^2 or Fisher's exact test (two-tailed), when X^2 is not appropriate (one of expected cell value is less than 5) at significance level $\alpha = 0.05$. Post-hoc test Bonferroni corrections and Bonferroni adjusted p-value were used for multiple comparison. Odds ratio (OR) and OR 95% Confidence intervals (CI) with Haldane-Anscombe correction were applied when contingency table has values of 0. The

Commented [A34]: Serodetection or Seroprevalence

Commented [A35R34]: Prof Latiffah advice to use serodetection since we didn't do random sampling

difference between seropositivity and hypothesized risk factors were tested using Kruskal-Wallis, KW (more than two groups) test at $\alpha=0.05$ and post-hoc Dunn's test was applied if applicable. Variable was excluded from further analysis if data is insufficient or too small ($n<10$). All analysis were conducted using the Statistical Package for Social Sciences (SPSS 27) and Microsoft Excel.

Commented [A36]: Clarify?

Commented [A37R36]: For eg, when values were 0 or 1 in 2x2 table (eg, sheep, dog, bat; table 3.15-3.18). Or when total of a variable was less than 10 (eg, Table 3.20 on exposure to animal species).

3.3 Results

3.3.1 Population characteristics

3.3.1.1 Domestic animals

Six forest-fringed cattle farms were enrolled in the study in 2018 from Kuala Kangsar district, Perak and Gua Musang district, Kelantan. Serum samples were collected from farmers ($n=55$), cattle ($n=156$), goats ($n=158$), sheep ($n=11$), dogs ($n=23$), bats ($n=265$), rodents ($n=36$), civet ($n=1$), wild boar ($n=1$), rabbits ($n=3$) and non-human primates ($n=2$). In total, 709 serum samples were collected.

Cattle were mostly sampled from integrated cattle farms (Table 3.13). Other domestic animals such as goats and sheep were mainly sampled from semi-intensive goat and sheep farms (Table 3.14 and 3.15). Dogs sampled were either tethered or free-roaming in the village or plantation (Table 3.16). Besides these animals, a pet rabbit was also sampled. Majority of the farm animals sampled were adults.

3.3.1.2 Wildlife

A total of 265 bats that were sampled during the study with an average of 44 (25-56) bats sampled per farm. Out of 9 species captured, 6 species were frugivores or nectarivores and 3 species were insectivores. Species that were most sampled were mostly adult male *C. brachyotis* (n=108), *E. spelaea* (n=70) and *C. horsfieldii* (n=52) (Table 3.17).

Table 3. 4 Bats based on sex, age class and species sampled from the surrounding targeted cattle farm at forest fringe

Commented [A38]: Format so this is all on one page.

Other wildlife sampled were pet macaques (n=2), a wild boar (n=1) and a civet, *Viverricula indica* (n=1).

3.3.1.3 Human

A total of 56 farmers from participating cattle farms were enrolled but only 55 samples were obtained. An average of 9 farmers were sampled from each farm. Majority sampled were male, between 20-29 years old, with mean age of 42 (18-68) of the Malay race.

Most have completed secondary school or above and have resided in the village for more than 10 years (51/55, 92.7%) (Table 3.19).

The most common domestic animals that farmers were exposed to within the past one year of sampling were cattle, cat and poultry. Whereas the most common wildlife exposed to were rodents and bats (Table 3.20). Farmers had general exposure to domesticated animals and wildlife in the past one year primarily through handling of live animals, animal entering living quarters and living with pet. Farmers were exposed to wildlife primarily through slaughter, butchering, cooking and handling of recently slaughtered meat, offal or blood of wildlife (Table 3.21).

Out of the 55 farmers, many farmers reported Influenza-like illnesses (ILI), followed by fever with diarrhoea and vomiting, Severe acute respiratory infection (SARI), fever with headaches and lethargy (3/55, 5.5%), and fever with skin rash (1/55, 1.8%) in the past year. No farmers reported haemorrhagic fever (Table 3.22).

3.3.2 Serological result

3.1.1.1 Filovirus

A total of 45 out of 709 (6%) sera/serum samples were reactive to filovirus. (6%, 45/709??). The serological detection for filovirus among species in descending order were goat (15.2%, 95% CI 10-22), sheep (9.1%, 95% CI 0.2-41.3), human (9.1%, 95% CI 3-

Most filovirus reactive samples were reactive to BDBV (29/45) followed by SUDV (16/45) and RESTV (16/45) (Table 3.8). Twenty-three (23/45, 51%) samples were reactive to only one antigen, with the most being BDBV (16/23), followed by EBOV (4/23), RESTVp (2/23) and SUDV (1/23). Whereas twenty-two (22/45, 48.9%) samples were reactive to two to five filovirus antigens which involved BDBV, SUDV, RESTVp the most. Cross-reactivity were observed between EBOV, BDBV, BOMV, SUDV, RESTVm, RESTVp, MARV, and RAVV (Appendix).

3.1.1.2 Henipavirus

A total of 36 out of 709 sera-serum samples were reactive with henipavirus protein antigens. The reactive sera were in detected from goats (13.9%, 95% CI 8.9-20.3), sheep (9.1%, 95% CI 0.2-41.3), humans (7.3%, 95% CI 2-17.6), dogs (4.3%, 95% CI 0.1-21.9), cattle (3.2%, 95% CI 1.0-7.3) and bats (1.1%, 95% CI 0.2-3.3) (Table 3.10 and Figure 3.25-31). Bats seropositive for henipavirus were *C. brachyotis* and *C. horsfieldii* (Table 3.11).

Commented [A51]: Out of 709?

Commented [A52R51]: Yes tq

HeV, Hendra virus; NiV, Nipah virus; CedV, Cedar virus; MojV, Mojiang virus; GhV, Ghana virus.

The range of MFI for henipavirus positive sera was between 4182 and 24689 with the highest being 24689 MFI against GhV in a farmer. There were 39 reactions with an MFI reading of 10000-19999 MFI (HeV, NiV, CedV, and GhV), and 5 reactions of >20000 MFI (HeV, CedV, MojV and GhV). Goat sera displayed many high MFI readings of >10000. In general, almost all henipavirus reactive sera had reactivity with GhV G with many being >10000 MFI. (Table 3.13 and Appendix).

Commented [A59]: Do you mean that these are all cross-reactive, with the highest binding to GhV?

Commented [A60R59]: Yes, 25 sera were cross-reactive to more than 1 antigen. Among them, 23 were cross-reactive to GhV

Commented [A61R59]: This is the breakdown of cross-reaction

3.3.3 Serological evidence and demographic distribution

3.3.3.1 Cattle

The serological evidence of filovirus and henipavirus in cattle were 5.1%, 8/156 (95% CI 2.2-9.9) and 3.2%, 5/156 (95% CI 1.0-7.3) respectively. Among the filovirus positive (8/156) and henipavirus positive (5/156) cattle sera, most were female, adults and apparently healthy and had no observable ectoparasite at the time of sampling. No

significant difference was observed between serological evidence of filovirus or henipavirus with husbandry, sex, age class and health status (Table 3.14).

Table 3. 14 Serological evidence of filovirus and henipavirus in cattle based on farm, sex, age class, reproduction status, health status and presence of ectoparasite

3.3.3.2 Goat

The serological evidence of filovirus and henipavirus in goat were 15.2%, 24/158 (95% CI 10-22) and 13.9%, 22/158 (95% CI 8.9-20.3) respectively. Among the filovirus positive (24/158) and henipavirus positive (22/158) goat sera, most were semi-intensively reared, female, adults and apparently healthy. Subadult goats were 6.3 times less likely to be seropositive for filoviruses as compared to adults (P= 0.028, OR=6.3, 95% CI=1.149, 34.383). No significant difference was observed between serological evidence of henipavirus and the various factors (Table 3.15).

Commented [A64]: Stats significance?

Commented [A65R64]: It was not significant after Bonferroni correction

3.3.4 Sheep

The serological evidence of filovirus and henipavirus in sheep were 9.1%, 1/11 (95% CI 0.2-41.3) for both. Out of 11 sheep sampled, only one sheep was seropositive for filoviruses and henipaviruses. The sheep was a female pregnant and lactating adult that was raised extensively, and apparently healthy (Table 3.16). Further analysis with the variables were not performed due to insufficient or too small data.

3.3.5 Dog

The serological evidence of filovirus and henipavirus in dog were 8.7%, 2/23 (95% CI 1.1-28) and 4.3%, 1/23 (95% CI 0.1-21.9) respectively. Filovirus positive dog (2/23) were adult and subadult tethered males. Whereas henipavirus positive dog was an adult male raised extensively. All filovirus and henipavirus positive dogs were apparently healthy with no observable ectoparasite at time of sampling. Further analysis with the variables were not performed due to insufficient or too small data (Table 3.17).

3.3.6 Bat

The serological evidence of filovirus and henipavirus in bat were 1.9%, 5/265 (95% CI 0.6-4.3) and 1.1%, 3/265 (95% CI 0.2-3.3) respectively. Majority of the filovirus positive (5/265) and henipavirus positive (3/265), bat sera were adult females that were apparently healthy (Table 3.18). Seropositivity was detected in 3 bat species (*C. brachyotis*, *E. spelaea* and *C. horsfieldii*). Further analysis with the variables were not performed due to insufficient or too small data.

3.1.1.1 Human

The serological evidence of filovirus and henipavirus in human were 9.1%, 5/55 (95% CI 3-20) and 7.3%, 4/55 (95% CI 2-17.6) respectively. Humans positive for filovirus (5/55) and henipavirus (4/55) were mostly males of Malay ethnicity, completed secondary level education and have resided in village for more than 10 years. No significant difference was observed between serological evidence of filovirus or henipavirus with the various factors (Table 3.19).

Commented [A66]: Were seropositive humans residing on SI farms, and raising goats?

Commented [A67R66]: Yes, 2 seropositive humans were residing on SI farms. We didn't sample goat owners as they were not part of the study. Although two positive cattle farmer raised goats in the past year (1 extensive system cattle farmer which also had a goats which we sampled).

Filovirus and henipavirus serologically positive humans reported exposure to cat, cattle, poultry, goat, rabbit, rodent, wild bird, bat and deer. One henipavirus positive human had exposure to non-human primates. No significant finding were found between serological evidence of filovirus and henipavirus and exposure to different animal species (Table 3.20).

^aVariable is excluded from further analysis due to insufficient or too small data

A majority (26.7%, 4/15) filovirus seropositive humans have eaten food that were touched, disturbed or damaged by animals. These [animals-humans](#) were 10 times more likely to be seropositive for filovirus compared to those who have not (P=0.017, OR=10.3, 95% CI=1.45, 73.24). For henipavirus, there was no significant association between seropositivity to the different forms of exposure to various animal species. However, there is a meaningful increase of risk for consuming food that were touched, disturbed or damaged by animal (P=0.057) and eating raw or undercooked meat, offal or blood of wildlife (0.097) (Table 3.21).

Commented [A68]: These humans?

Commented [A69R68]: Yes :D

^aVariable is excluded from further analysis due to insufficient or too small data

*Humans that consumed food damaged by animal were more likely to be seropositive for filovirus (P=0.017, OR=10.3, 95% CI=1.45, 73.24).

Most farmers reported have had symptoms of Influenza-like illnesses (ILI) in the past one year. A few filoviruses and henipavirus seropositive farmers also reported other symptoms such as severe acute respiratory infection and fever with diarrhea and vomiting (Table 3.22). However, bivariate analysis between seropositivity and reported symptoms were not performed due to insufficient data for meaningful analysis.

Table 3. 22 Seroprevalence of filovirus and henipavirus in human based on symptoms experienced by farmers in participating cattle farms within the past year

3.4 Discussion

In this study, domestic animals and wildlife in and around forest-fringe cattle farms were tested for exposure to the viruses in family *Filoviridae* and the genus *Henipavirus* using multiplex serology. This technology has been developed and widely used for screening of viruses globally (Chowdhury et al., 2014; Dovich et al., 2019; Hayman et al., 2008, 2011; Laing et al., 2018; Peel et al., 2013b) but is not meant for diagnostic determinations. The findings can be used to target areas of surveillance for emerging pathogens but should not be used for policy decisions such as trade, quarantine or culling (MacNeil et al., 2011; Peel et al., 2013a). Serologically positive samples may indicate positivity to the tested virus or to antigenically related viruses. Antigenically related viruses share similar epitopes on its surface antigenic molecule that confers binding by antibodies or T cell receptor (Frank, 2020). Phylogenetically closely related viruses have higher epitope amino acid sequence similarity and binding to similar antibodies which result in greater degrees of antigenic-similarity and cross-reactivity of antibodies to antigens included in the test (Brangel et al., 2018; Marsh et al., 2012a; Schuh et al., 2019). Further testing and characterization are necessary using virus neutralisation test could improve virus specific interpretation (OIE, 2018).

Filovirus

This study found the highest serological evidence for filoviruses in goats (24/158, 15.2%), sheep (1/11, 9.1%), humans (5/55, 9.1%), cattle (5/156, 5.1%) and lowest in bats (5/265,

1.9%). Seropositivity indicates evidence of past exposure to specific viruses antigenically related to filoviruses. Studies on filoviruses in domestic animals have been scarce. Only dogs and pigs have been demonstrated to be infected with filoviruses (Allela et al., 2005; Chowdhury et al., 2014). In Gabon, 28% of dogs from an Ebola epidemic areas were found to be IgG positive for Ebola virus (Allela et al., 2005). Meanwhile, Reston ebolavirus (RESTV) was identified in a spillover event between pigs and human in the Philippines and later in sick pigs in China (Barrette et al., 2009; Pan et al., 2014). [RESTV infection in humans are rare and occurs when there is close contact through occupational exposure](#) (Barrette et al., 2009; Miranda & Miranda, 2011; Morris, 2009). To our knowledge, this study is the first to report evidence of exposure to filoviruses in cattle, goat and sheep. This is also the first evidence of exposure of filoviruses in dogs beyond Africa.

Highest seropositivity was reported among goats in this study particularly in semi-intensively reared goats which were 4 times more compared to cattle. The reasons for this may need further exploration however we suggest a few reasons for this findings: 1) Goats are known to browse extensively relative to other species (Hofmann, 1989; Rutagwenda et al., 1989) and have the habit of sampling wide ranges of items (edible and non-edible), therefore may increase their risk of exposure to multiple disease agents; 2) Many of the seropositive goats reported in this study were managed semi-intensively to browse freely around village and raised in close proximity where flowering and fruiting trees are abundant which attracts bats such as *C. brachyotis* (V. C. Lim et al., 2017; Tan et al., 1998). Goats are very likely to pick up partially eaten fruits consistent

Commented [A70]: There is a Reston virus paper focused on abattoirs in the Philippines

Commented [A71R70]: Yes, tq. My mistake. The paper which I cited two sentence before reported RESTV seropositive animal handlers

with their feeding behaviour therefore increases risk of contracting multiple disease agents.

Predictive modelling demonstrated that Southeast Asia is a hotspot for filovirus carriers, particularly in Old World fruit bats (family Pteropodidae) (Han et al., 2016). Our study results corroborate with the model and filovirus surveillance in the region. Seropositivity of bats in this study was found to be lower than previous reports of bats in this region. ~~Studies from~~ neighbouring country, Singapore which reported 9.1% (17/186) in *E. spelaea*, 8.5% (13/153) in *C. brachyotis* and 4.3% (3/70) in *P. lucasi*; and in the Philippines which reported 31% (5/16) in *Rousettus amplexicaudatus* bats, all of which belong to family Pteropodidae. Besides *E. spelaea* and *C. brachyotis*, *C. horsfieldii* was seropositive for filoviruses in our study. *Cynopterus sp.* and *E. spelaea* are adaptive species that occupy a range of habitats from orchards, plantations, primary and secondary forests and urban sites (Campbell et al., 2004; Fukuda et al., 2009; Heidenan & Heaney, 1989; Kitchener et al., 1990; V. Lim, 2018; Tan et al., 1998). Livestock farming in rural and sub-rural areas where fruit trees are plenty provides bat roosting and foraging areas (Fukuda et al., 2009). This overlapping spatial distribution of bats and livestock increase risk of viral spillover to livestock and agricultural workers (Mikail et al., 2017). Longitudinal spatial-temporal distribution studies will ascertain the level of such risk (Zhao et al., 2022).

Antibody reactivity to specific filovirus antigen in our study suggests that circulating filoviruses in this region are predominantly more closely related to BDBV, SUDV, EBOV,

Commented [A72]: This is a good reference. They used predictive traits to ID possible ebolavirus bat hosts.
<https://journals.plos.org/plosntds/article?id=10.1371/journal.pntd.0004815>

Commented [A73R72]: Thank you, reference added.

Formatted: Font: Italic

RESTV and less so with BOMV, MARV, and RAVV. Reactivity to filoviruses closely related to EBOV, BDBV and SUDV corresponds to a similar study in Singapore bats (Laing et al., 2018). However, in contrast to that study, we report a considerably high number of reactivity to antigenically related but not identical to RESTV-pig in a *C. brachyotis* and many goats. RESTV is a zoonotic Asiatic filovirus responsible for sporadic cases in non-human primates, pigs and human (Barrette et al., 2009; CDC, 1993; Demetria et al., 2018; Miranda et al., 1999). Bats may be natural reservoirs for RESTV in the Philippines, Bangladesh and China (Jayme et al., 2015; Olival et al., 2013; Taniguchi et al., 2011; Yang et al., 2017). Finding of our study suggests possible transmission of RESTV-related viruses from bats to goat. However, nucleic-acid detection of RESTV genome is necessary to confirm spillover.

Henipavirus

Seropositivity to henipaviruses was highest in goats (13.9%), sheep (9.1%), human (7.3%), dog (4.3%), cattle (3.2%) and bat (1.1%). Seropositivity indicates evidence of past exposure to viruses antigenically related to henipaviruses. Antibody reactivity to specific henipavirus antigen in our study suggests that circulating henipavirus in this region is predominantly more closely related to GhV, HeV, NiV, MojV and less so to CedV. The MFI values for GhV is high with many that cross-reacted with other henipaviruses and several that did not cross-react with other henipaviruses. Presently, little is known about GhV which was first detected in African bats and is the only African henipavirus (Drexler et al., 2009, 2012). GhV is also antigenically closer to ancestral henipaviruses

(Pernet et al., 2014). Thus, reaction to GhV in our study indicates prevalence of an ancestral henipavirus more antigenically related to GhV than the other presently known Asiatic viruses.

A *C. brachyotis* bat and three goats were seropositive for NiV antigenically related viruses. All four reactions cross-reacted with GhV and HeV with MFI difference of less than 3000 between them. Besides that, sera that were seropositive for HeV antigenically related viruses cross-reacted with different combinations of NiV, GhV and CedV. These sera were all from seven goats. Typically, cross-reactivity between NiV and HeV is high while cross-reactivity between NiV/HeV and GhV is low due to the less sequence identity (<30%) between their G protein (B. Lee et al., 2015). Cross-reactivity MFI values generated using positive NiV positive rabbit polyclonal sera in Chapter 4 also supports this finding. Hence, the bats and goats were likely exposed to an unidentified henipavirus most closely related to NiV or NiV and HeV respectively.

Interestingly, our study found two reactions only to MojV with no cross-reactivity in a cattle and dog from the same intensive cattle farm. One MojV reaction in human also cross-reacted with GhV. MojV is a rodent henipavirus discovered in anal specimens of *Rattus flavipectus* in Southern China. This novel virus was identified in the same cave 6 months later where three patients died of respiratory illness of unidentified aetiology. MojV pathogenicity remains to be determined due to the absence of isolate (Wu et al.,

2014). Cattle and dog may have acquired MojV closely related virus through contact with rodent excrement. [Previously, most henipaviruses were fruit-bat associated, such as HeV, NiV, CedV, GhV, including novel Angavokely virus \(AngV\)](#)(Madera et al., 2022). [In the recent years, more rodent-associated henipaviruses have been identified such as MojV, Gamak \(GAKV\), Daeryong viruses \(DARV\) and Langya henipavirus \(LayV\).](#) Rodents are probable reservoir hosts or amplifying host for MojV (Cheliout et al., 2021). [GAKV and DARV were identified Korea \(Lee et al., 2021\), whereas LayV was identified in shrews and rodents during an epidemiological investigation of febrile pneumonia outbreak in patients who were mostly farmers in China, indicative of a spillover event from rodents to humans \(ECDC, 2022; Zhang et al., 2022\).](#) Increasing ~~the surveillance efforts and~~ sample size of rodents to detect [henipavirus](#) antibodies and genome of MojV or MojV-like virus will improve chances of detection and determine its circulation locally.

[Pteropus spp. \(flying foxes\) are reservoirs for NiV, HeV and CedV](#) (Anderson et al., 2019; Boardman et al., 2020; Halpin et al., 2011; Marsh et al., 2012b). Previous survey of bats in Malaysia were mostly focused in the *P. vampyrus* and *P. hypomelanus* species with a reported seroprevalence of 1-33% (Rahman et al., 2013a; Yob et al., 2001). Those studies used indirect ELISA and serum neutralization test to detect the antibodies against Nipah virus in samples. ~~A recent survey using multiplex serological assay in the local *P. hypomelanus* bats samples found 25% reactivity to NiV (Laing et al., 2019). The reported seroprevalence in our study of 1% (2/108) in *C. brachyotis* and *C. horsfieldii* 2% (1/52) is much less than that of Laing et al. (2109) *Pteropus sp.* surveys.~~ Although our study did

Commented [A74]: I suggest adding in Langya virus, and Gamak/Daeryong virus refernces. These are new rodent-associated henipaviruses. It may be worth to mention that HeV/NiV/CedV/GhV/AngV are fruit-bat associated and MojV/LayV/GamV/DarV are rodent-associated.

Commented [A75R74]: Thanks, added

Commented [A76]: I'd mention that flying foxes have been confirmed as the reservoirs of NiV/HeV/CedV. That you did not sample flying foxes, and found little seroprevalence in the fruit bats, cynos/eonycteris, for NiV. Corroborating that flying foxes are the wildlife host.

Commented [A77R76]: Thank you for the suggestion, added them

Commented [A78]: Difference between types of bats – but again, I would not cite the conference abstract from IMED.

Commented [A79R78]: Okay

not sample *Pteropus sp.* bats, we determined that seropositivity in *Cynopterus sp.* and *Eonycteris sp.* bats to be low. This finding is comparable to the seroprevalence of 4% (2/56) in *C. brachyotis* and 5% (2/38) in *E. spelaea* in a separate study in 1999 (Yob et al., 2001) and corroborates that flying foxes are wildlife host for henipavirus.

Surveillance of NiV in human outbreak areas near *Pteropus sp.* bat roosts in Bangladesh using the [a similar antigen-based multiplex test via a Luminex platform](#) found that 6.5% (26/400) of cattle and 4.3% (17/400) of goats were positive for henipavirus (Chowdhury et al., 2014). During the Nipah virus outbreak in Malaysia, dogs sampled near infected pig farms had detectable antibodies for Nipah virus (Mills et al., 2009; Rahman et al., 2013b). Since 2001, NiV have not been reported in domestic animals and wildlife locally using ELISA (Fikri et al., 2011; Naama et al., 2013). This study is the first report that uses Luminex technology of henipavirus infection in dogs since 1999 and in local cattle, goat and sheep. Multiplex serology approach with recently described henipaviruses employed may be more sensitive to capture antibodies against antigenically related henipaviruses, thus, is an advantageous screening tool for epidemiological studies especially in new populations (Brook et al., 2019; Hayman et al., 2008; Peel et al., 2013b).

Reported seropositivity of henipaviruses in goats was high at 13.9% (22/158) particularly in semi-intensively reared goats and was 4 times more as compared to cattle 3.2% (5/156) for hypothetical reasons of risk of exposure to infectious materials as explained before.

Commented [A80]: I suggest reworking this paragraph. Are the henipavirus positive samples, GhV or NiV positive? The work done in Chowdhury et al did not run CedV, GhV, and MojV G so it's similar but needs to be compared and contrasted. I would pull out the NiV discussion and focus on your results, then bring up NiV more generally towards the end of the discussion. Highlighting, the ELISA data from 2001 that you cited, and that the multiplex approach with recently described henipaviruses may be more sensitive to capture antigenically-related henipaviruses.

Commented [A81R80]: Thank you for the suggestion!

Risk Factors

We detected exposure against viruses antigenically related to filoviruses, EBOV, BDBV and RAVV; and henipaviruses HeV, CedV, MojV in humans. Our study found those that consumed food that were touched, disturbed or damaged by animal were more 10 times more likely to be seropositive for filovirus. This is supported by the study by Adjemian et al., which established increased risk of filovirus infection amongst febrile tribesmen presented to healthcare facilities in Uganda that were exposed to activities related to increased risk of filovirus infection was observed in activities such as hunting (37.5 times), touching (5.6 times) or eating wildlife (10.7 times) (Adjemian et al., 2011). Likewise, bushmeat slaughtering or working closely with infected pigs or horse enhanced risk of henipavirus infection (Chua, 2010; Pernet et al., 2014; Rogers et al., 1996). The finding is expected because the both viruses are transmitted via direct contact with body fluids (Amal et al., 2000; Bausch et al., 2007; O'Sullivan et al., 1997; Saéz et al., 2015; Williamson et al., 1998). Therefore, poor hygiene practices or improper personal protective equipment may expose farmers to infectious materials, especially when handling sick or infected animals, animal waste or carcasses.

Approximately half of the humans sampled (21/55) reported Influenza-like illnesses (ILI), fever with diarrhoea and vomiting, fever with headaches and lethargy and severe acute respiratory infection (SARI) symptoms within the past year of survey. Half of the seropositive human for filovirus and/or henipavirus in our study had reported one of the symptoms in the past year, while the other half did not. The symptoms can be due to

Commented [A82]: unclear

Commented [A83R82]: Corrected

several multitude of reasons, unfortunately causal relationship between viral infection and symptoms in our study cannot be ascertain without clinical and longitudinal data. Syndromic surveillance incorporating important pathogens at the family or genus level will improve early detection and appropriate intervention.

The catastrophic Nipah outbreak in 1998 is a turning point for cross-sectoral ministerial integration in managing zoonotic disease and recognition that the country is susceptible to spillover of pathogenic viruses (Chua, 2003). Unfortunately, at present, novel or emerging viral surveillance in animal population is sporadic and scant; usually linked to specific research endeavours. The ecological concerns and agricultural intensification in Malaysia strongly indicate the need for regular monitoring and surveillance of livestock and humans working in close proximity to animals especially those that are located in geographic areas with high potential for wildlife viral spillover events. A better understanding on the interaction and viral transmission between human, livestock, other domestic animals and wildlife will inform disease surveillance and control policy to reduce the risk of transmission and prevent undesirable animal and public health consequences.

Limitations

This study was performed on highly targeted populations to increase the chance of viral detection in high-risk populations at the wildlife-livestock-human interface. Therefore,

the findings should be interpreted in light of the sampling bias, limited sample size, non-random sampling, cross-reactions between antigenically related viruses and the diversity of uncharacterized filoviruses and henipaviruses that is missed from the test panel. Further characterization of filoviruses and henipaviruses in the region, larger data set, improved diagnostic assays and species-specific positive controls will influence cut-off values and reported sero-detection.

Additionally, infection status in bats fluctuates seasonally and are influenced by reproduction phases, nutritional stress, migrations or contacts with infected animals (Amman et al., 2012; Baker et al., 2014; Hayman, 2015; Plowright et al., 2008; Sohayati et al., 2011; Wang et al., 2013). This infection pattern in bats as a reservoir host would subsequently impact degree of spillover to other potential hosts like cattle, goats or humans in our case (Amman et al., 2012; Plowright et al., 2017). Antibody post-infection also wax and wanes over time (Boardman et al., 2020; Diallo et al., 2021). Thus, the sero-detection reported in this cross-sectional study only provides information at the time of sampling which may be an underestimation or overestimation and will differ depending on time of sampling.

In addition, maternal antibodies to NiV can last up to 14 months, hence without longitudinal data, some reactivity in our study may be misrepresented (Sohayati et al., 2011). As a result of lack of longitudinal data, serological findings only demonstrate past

exposure to filoviruses and henipaviruses. Despite these limitations, our study generated valuable information of filoviruses and henipaviruses in the multiple animal host species to inform future studies. Besides that, research on viral diversity characterization in this region will improve the depth of interpreting serological results.

3.5 Conclusion

This study provides the first evidence of exposure to viruses antigenically related to filoviruses and henipaviruses in domestic animals and humans in Malaysia, as well as viruses antigenically related to henipaviruses in previously unreported bat species. Results from our study supports more extensive and longitudinal viral surveillance in these populations to enhance disease preparedness and improve our understanding on the viral distribution, diversity and potential spillover at the human-livestock-wildlife interface.

Table 3. 1 Sero-detection of filovirus and henipavirus from selected references of countries closest to Malaysia

Species	Year	Test used	Seroprevalence*	Location	Reference
Cattle	-	Luminex using NiV and HeV glycoproteins	NiV: 26/400 (6.5%)	Bangladesh	(Chowdhury et al., 2014)
Goat	-	Luminex using NiV and HeV glycoproteins	NiV: 17/400 (4.3%)	Bangladesh	(Chowdhury et al., 2014)
Pig	2009	Luminex with NiV and HeV glycoproteins	NiV: 138/312 (44.2%)	Bangladesh	(Chowdhury et al., 2014)
	2008 & 2010	Immunofluorescence and IgG-ELISA using RESTV-NP and RESTV-GP	RESTV- affected farms: 71-79% Non-RESTV-affected farms: 0-1%	Philippines	(Sayama et al., 2012)
Dog	2001-2013	NiV Indirect ELISA	NiV: 0/2184 (0%)	Malaysia	(Naama et al., 2013)
Bats	2004-2007	NiV serum neutralization test	Cross-sectional study : 82/253 (32.8%) in <i>P. vampyrus</i> : 13/117 (11.1%) in <i>P. hypomelanus</i> Longitudinal study : 64/650 (9.8%) in <i>P. hypomelanus</i> *Fluctuated between 1-20% in the span of 3 years	Malaysia	(Rahman et al., 2013a)
	1999	NiV Indirect ELISA	: 11/35 (31%) in <i>P. hypomelanus</i> : 5/29 (17%) in <i>P. vampyrus</i> : 2/38 (5%) in <i>E. spelaea</i> : 2/4 (4%) in <i>C. brachyotis</i> : 1/33 (3%) in <i>Scotophilus kuhli</i>	Malaysia	(Yob et al., 2001)
	2002-2004	NiV Indirect ELISA	: 82/1,304 (7.8%) from all bats : 4/26 (15.4%) in <i>P. hypomelanus</i> : 76/813 (9.3%) in <i>P. lylei</i> : 1/39 (2.6%) in <i>P. vampyrus</i> : 1/74 (1.3%) in <i>H. larvatus</i>	Thailand	(Wacharapluesa dee et al., 2005)
	2011-2016	Luminex using EBOV, BDBV, SUDV, or TAFV glycoproteins	Filovirus seropositivity : 17/186 (9.1%) in <i>E. spelaea</i> : 13/153 (8.5%) in <i>C. brachyotis</i> : 3/70 (4.3%) in <i>P. lucasi</i>	Singapore	(Laing et al., 2018)
	2011-2013	EBOV ELISA	: 0/699 (0%) in all bats	Thailand	(Wacharapluesa dee et al., 2015)
	2009	Luminex with NiV and HeV glycoproteins	NiV: 29/71 (42%)	Indonesia	(Sendow et al., 2013)
Rodents	1999	NiV Indirect ELISA	: 0/25 (0%) trapped on farms with NiV-infected pigs	Malaysia	(Rahman et al., 2013b)
Non-human primate	2013	EBOV ELISA	: 0/50 (0%) in <i>Macaca fascicularis</i>	Thailand	(Wacharapluesa dee et al., 2015)
	2005-2006	ELISA (ZEBOV, SEBOV, CIEBOV, BEBOV, REBOV, and MARV), Year 2005-2006	: 18.4% (65/353) EBOV : 1.7% (6/353) MARV in <i>Pongo pygmaeus</i>	Indonesia	(Nidom et al., 2012)

*Sero-surveys during non-outbreak periods were prioritized

Chapter 3

FILOVIRUSES AND HENIPAVIRUSES AT THE HUMAN-LIVESTOCK-WILDLIFE INTERFACE IN FOREST FRINGE CATTLE FARMS IN SELECTED STATES OF PENINSULAR MALAYSIA

3.1 Introduction

Filoviruses and henipaviruses are high consequence emerging zoonotic pathogens that have caused severe outbreaks in many parts of the world leading to high mortality and morbidity and grave economic losses in both human and animal health sectors (Knust et al., 2017; Looi & Chua, 2007). The economic losses due to Ebola has been estimated to be USD2.8 billion in the 2014 Ebola outbreak and USD446 million in 1998 Nipah outbreak (FAO and APHCA, 2002; World Bank, 2016).

The viruses within the family Filoviridae; Ebola (EBOV) and Marburg virus (MARV) cause haemorrhagic fever outbreaks in Africa, Germany and isolated cases in other parts of the world like Spain, United States of America, United Kingdom, Philippines, Italy, and Russia (CDC, 2018; C. E. Smith et al., 1967; WHO, 2014). The mortality from Ebola disease in Africa was 50-90% in humans and almost 100% mortality in non-human primates (Bowen et al., 1978; Jaax et al., 1996; Jahrling et al., 1996; K. M. Johnson, 1978; Simpson, 1978). While *Henipavirus*; Hendra virus (HeV) and Nipah virus (NiV) have cause respiratory and neurological signs in humans, pigs and horses in

Malaysia, Australia, Bangladesh and India (Chadha et al., 2006; Chua et al., 1999; Hsu et al., 2004; Nor, Gan, Ong, et al., 2000; O'Sullivan et al., 1997). The mortality from Nipah virus infection was 40-70% in humans in Malaysia and Bangladesh; and of 1-5% in adult pigs and 40% in suckling pigs in Malaysia (Chua et al., 2000; Goh et al., 2000; Hsu et al., 2004; Luby et al., 2009; Nor, Gan, & Ong, 2000).

With an exception of Nipah virus which emerged in 1998 (Fikri et al., 2011; Laing et al., 2019; Rahman et al., 2013; Sohayati et al., 2011), limited information is available on both filoviruses and henipaviruses in Malaysia. The investigative work on Nipah has led to numerous works on bat ecology and bat-borne microbial agents. It is now understood that bats have co-evolved with multiple viruses that may be of public health significance such as Nipah (Hayman, 2016). Filoviruses have been detected in bats in Singapore, Bangladesh, China, and the Philippines (Laing et al., 2018; Olival et al., 2013; Taniguchi et al., 2011; Yuan et al., 2012). While henipaviruses widely circulate in bats in Malaysia, India, Vietnam, Cambodia, Indonesia and Australia (Breed et al., 2013; Epstein et al., 2008; Hasebe et al., 2012; Rahman et al., 2013; Reynes et al., 2005; Sendow et al., 2006). Besides bats, filoviruses' and henipaviruses can infect a broad range of mammals such as human primates, rodents, shrews, guinea pigs, bats, dogs, pigs, cattle, donkey, chicken; and rodents, horse, cats, pigs, dogs, goats respectively (Chua et al., 2000; Edson et al., 2015; Gonzalez et al., 2005; Leroy et al., 2004; Morvan et al., 1999; Wu et al., 2014).

Despite the apparently wide distribution and reported prevalence of these pathogens amongst the reservoir hosts in Southeast Asia, outbreak has been rare in both humans and domestic animals. Following the Nipah outbreak in 1998-1999 in Malaysia, no further cases have been reported in both humans and animals to date (Fikri et al., 2011; Muniandy et al., 2001; Naama et al., 2013; Sohayati et al., 2016). There has also been no human outbreaks in Cambodia despite serological and molecular evidence widely found in Cambodian bats (Olson et al., 2002; Reynes et al., 2005). However, the SEA region is considered a hotspot for emerging pathogens because several localized emerging zoonosis have occurred in the past two decades and because multiple factors that drives emerging infectious diseases are highly prevalent. For example, wide circulation and abundance of reservoir hosts, topographical or landscape changes and intensified systems of agriculture and animal production may increase contact opportunities for viral transmission at the wildlife-livestock-human interfaces (Breed et al., 2013; Horby et al., 2013; Jung & Threlfall, 2016; I. Smith & Wang, 2013). In addition, the global climatological changes may impact distribution and concentration of disease vectors which subsequently facilitates spatiotemporal changes of filovirus and henipavirus viral spillover events (Martin et al., 2018; McFarlane et al., 2011; Schmidt et al., 2017).

The one health approach of managing complex emerging diseases requires the understanding of all actors that take part at the environment-animal-human interface. For example, food animals may become infected with pathogens from wildlife that can

then be transmitted to human such as Nipah, Highly Pathogenic Avian Influenza H5N1, Pandemic Influenza H1N1 (2009) amongst others. Many livestock farms in this region are located in the rural or peri-urban areas bordering primary or secondary forests. In Malaysia, livestock especially cattle are commonly managed extensively or semi-intensively at forest fringes thus may have higher probability of contact with infectious materials from infected wildlife or domestic animals. Beef cattle are most commonly raised using the aforementioned systems where animals are let out to graze in a field, plantations or in a village located at forest fringes where wildlife and peri-domestic animals are plentiful. Such setting improves the chance and frequency for pathogen spillover events to livestock or humans (Hassell et al., 2017). The spillover occurrences varies given available drivers and rarely result in an epidemic, however frequent spillover events will increase the chance of an outbreak (Clayton et al., 2013; Hayman et al., 2011; Parrish et al., 2008; Plowright et al., 2017).

In this chapter, we targeted cattle farms located at forest fringe areas with high contact risk and probability of pathogen spillover events. We hypothesise that cattle, other domestic animals, wild animals and farmers are seropositive for filoviruses and henipaviruses. The objectives of this study are: 1) To determine the serological evidence of filoviruses and/or henipaviruses in cattle, farmers, and other domestic animals and wildlife in and at close proximity to the targeted cattle farm; 2) To determine risk factors of virus infection in those species.

3.2 Materials and Methods

3.2.1 Ethics statement

All human and animal samples from cattle farms were collected in accordance to an established USAID Emerging Pandemic Threats PREDICT Operating Procedures with permission from the local institutional and ministerial Institutional Animal Care and Use Committee from UPM (AUP-R064/2018), UC Davis (#19300) and Tufts (G2021-131) and the Institutional Review Board from the Medical Research and Ethics committee (MERC) from National Medical Research Register (NMRR), Malaysia (NMRR-17-3356-37135, IIR) and UC Davis (#804522) in collaboration with Ministry of Health (MOH), Malaysia, Department of Veterinary Services (DVS), Malaysia, and the Department of Wildlife and National Parks (PERHILITAN). The work performed for this project is part of a larger project in collaboration with the EcoHealth Alliance.

3.2.2 Study design and study sites

A cross-sectional survey was performed in 3 semi-intensive, 2 integrated and 1 intensive cattle farm. These farms were selected based on a defined selection criteria which include, 1) located in districts with existing NMRR and IRB approval for human study, 2) located 5km from periphery of forests as approved by the Department of Veterinary Services, Putrajaya, 3) a minimum of 30 cattle in farm, and 4) has other domestic animals and wildlife in or around farm. The approved districts were Kuala Kangsar in the state of Perak, Gua Musang in Kelantan and Kuala Lipis in Pahang. In

these districts, the district health officers had worked with EcoHealth Alliance on previous projects and have agreed to assist the human sampling aspects in this project.

The identification of the cattle farms consisted of several steps as in **Figure 3.1**. The details of the steps in identifying location and farms are further described in **Appendix**

X. All animals sampled in this study were within 5km radius of a primary forest.

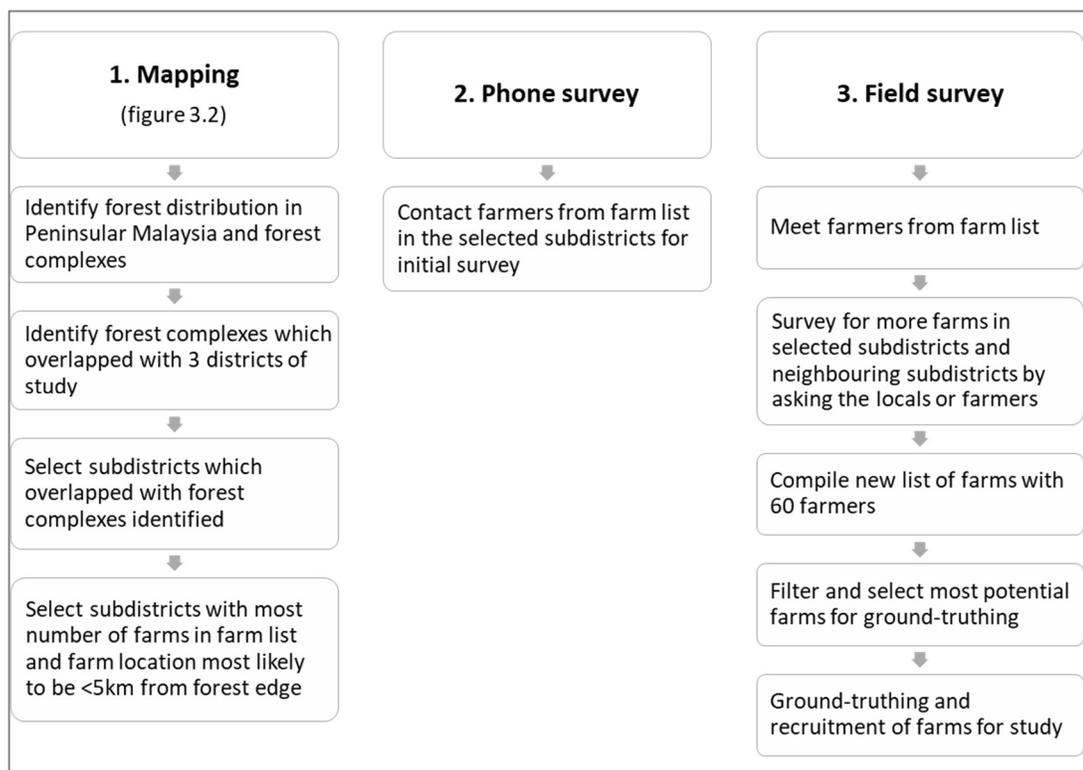

Figure 3. 1 Identification of forest-fringed cattle farm for the study on filovirus and henipavirus at the wildlife-livestock-human interface

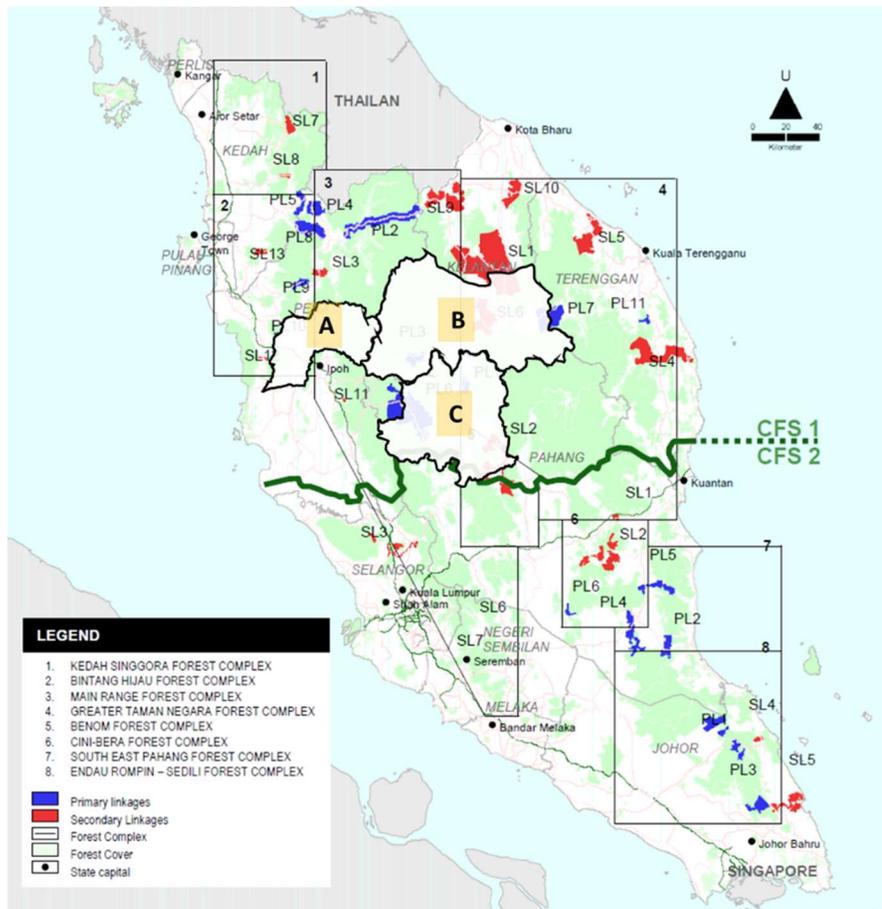

Figure 3. 2 Map of forest complexes in Peninsular Malaysia and the overlapping targeted districts in our study marked by A: Kuala Kangsar, B: Gua Musang, C: Lipis. (Source: Regional Planning Division, Department of Town and Country Planning, Peninsular Malaysia, 2009)

3.2.3 Sample size

Four cattle farms from Kuala Kangsar district, Perak and two cattle farms from Gua Musang district, Kelantan within 5km radius of forests were sampled beginning 2019.

Targeted sample size for each animal species per farm were 30 cattle from participating target farms, 30 other domestic animals (eg, goat, sheep, dog, etc) and 60 wildlife (eg, bats and rodents). The sample size (n) for this study (Table 3.1) was determined using

the Open-Epi Version 3 calculator. The software program applies the formula of $n = \frac{DEFF * N * p * (1-p)}{[(d/2) - Z_{1-\alpha/2} * \sqrt{p * (1-p)}]}$, where N = population size, p = prevalence, d = confidence limits = 10%, and DEFF = design effect for cluster surveys = 1. The estimated prevalence used in the current study was 5% based on prevalence studies of filoviruses and henipaviruses in the region which reported seroprevalence of 0-6.5% in domestic animals and 1-20% in bats (Table). Other domestic animals and wildlife were opportunistically captured and sampled with priority given to animals in and closest to the participating target farms.

Table 3. 1 Sample size calculation for the sero-detection of filovirus and henipavirus in cattle, other domestic animals and wildlife in participating cattle farms located at the forest fringe in Perak and Kelantan, Malaysia

	Estimated Population Size, N per farm	Estimated Prevalence, p (% +/-5) ^a	Sample size, n per Farm	No. of farms	Total
Cattle : (Semi-intensive (n=3), Integrated oil palm (n=2), Intensive farm(n=1)	50	5	30	6	180
Other domestic animals : Goat, sheep, dog, etc.	50	5	30	6	180
Wildlife : Bat, rodent, other small mammal	1249 per roost for bats	5	70 (max of 60) ^c	6	360

^aPrevalence of 5% was decided based on prevalence studies of filoviruses and henipaviruses in the region (see Table ???).

^bEstimated population size for bats is based on the average roost size of bats. Total number of bats calculated is an overestimation as it will be highly dependent on the bats captured in nets and number of days the nets are placed in a location.

^cTotal number of wildlife are set to the maximum of 60 due to logistical and financial limitations.

3.2.4 Sampling of cattle and other domestic animals

Cattle and other domestic animals such as goat, sheep, dogs and rabbit were conducted with the team from the EcoHealth Alliance in accordance to USAID Emerging Pandemic Threats PREDICT Operating Procedures (PREDICT One Health Consortium, 2016b, 2016e).

All domestic animals were manually restraint for the sampling procedures (Appendix B). Blood samples were obtained from the appropriate venepuncture sites according to species. In cattle, goat, and sheep, the jugular vein or coccygeal vein was used (Figure 3.3). In dogs, blood was collected from the cephalic vein, jugular vein, femoral vein, lateral or medial saphenous vein. In rabbits, blood was collected from the lateral saphenous vein. Three to five ml of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube.

A basic physical examination was performed by veterinarian to assess the health status and identify the age and sex of the animal. Photographs of sampled animal was taken from the sides and front, including dentition, or presence of any lesions, abnormalities or identifying marks or characteristics for future reference.

All blood tubes were labelled appropriately and placed in cooler boxes and transported back to sampling processing base. Blood in BD Vacutainer® serum tubes were left to

clot for serum collection within 1 hour. After clot is form, serum tubes were centrifuged at 1300 r.p.m for 15 minutes and 1 ml of serum was transferred into 0.5ml cryovial tubes to produce at least two aliquots. Cryovial tubes were labelled appropriately. Samples were then placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to proper cold chain methods.

Figure 3. 3 Locating the jugular vein in the jugular groove for blood sampling

3.2.5 Sampling of wildlife

Permission was obtained from the local authorities or landowners before bat and rodent trapping and sampling begun. Selected sites were first surveyed with priorities given to potential trapping locations in the farm and nearest to farm within 5 km radius. All personnel handling trapping and sampling of wildlife had to be immunized

against rabies, Japanese Encephalitis, Hepatitis B, tetanus and negative sputum tests for Tuberculosis.

3.2.5.1 Sampling of bat

Bats were captured using mist nets suitable for capturing bats in open spaces as described by FAO Manual for Investigating the Role of Bats in Emerging Zoonoses (Food and Agriculture Organisation of the United Nations, 2011). Further description on the sampling procedure is in [Appendix X](#). Briefly, bats were captured using mist nets placed at anticipated bat flyways in the farm, village and in nearby plantations such as across streams or trails. The nets were also positioned near roosting or feeding sites such as near flowering banana trees and flowering durian trees ([Figure 3.4](#)).

Figure 3. 4 A bat trapping site with banana and durian plantation in a village near a participating cattle farm.

The mist nets were raised at 7.30pm at sunset and left opened until 12am for trapping to occur (Figure 3.5) and closed neatly after trapping period (Figure 3.6). Bat nets were repositioned to new locations when recapture rates were high, or captures were absent. The GPS coordinates for each mist nets were recorded.

Figure 3. 5 Extended mist nets for capture of bats at sunset.

Figure 3. 6 Retracted mist nets that is secured after trapping period

Mist nets were checked for bats every 30 mins to an hour. Captured bats were extracted from the nets carefully using at least one leather gloves on one hand and with the use of forceps or small stick to move the netting or bat mandibles then placed into a porous cotton bag with a draw-string mouth and taken to a sampling processing site where sampling was performed immediately (Figure 3.7). Approximately 20-30 bats were sampled in a night. No bats should be kept for more than 6 hours.

Figure 3. 7 Bags containing bats hung in draw-string cloth bags on a raffia string between two pillars

Bats were sampled and identified according to the USAID Emerging Pandemic Threats PREDICT Operating Procedures with some modifications (Hoffmann et al., 2010; PREDICT One Health Consortium, 2016a; C. Smith et al., 2010). Bat was removed from the cloth bag and manually restrained for sampling using leather gloves. In bats that were >100g, a non-heparinised syringe was used to collect blood from the cephalic vein, brachial vein or saphenous vein. Blood was then placed in a serum vacutainer tube containing serum-clotting factor and centrifuge. Extracted serum was placed into 2 cryovials of a minimum of 60 μ l if volume. If bats were <100g, the tip of a sterile 25G needle was used to puncture the brachial or propatagial vein (C. Smith et al., 2010).

A 1:10 serum dilution (10µl blood into 90µl PBS) was centrifuged, and the supernatant was transferred into a new cryovial tube. Cryovial tubes was labelled appropriately and placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to proper cold chain methods.

Figure 3. 8 Blood sampling from the cephalic vein of a bat by aspirating the drop of blood using a pipette.

Morphometric measurements and photographs of each bat were taken during the sampling procedure for the purpose of species identification. Identification of bat species was performed by an experienced rangers and field veterinarian based on the morphology and biometric measurements. Guide books were used for identification of bats on the field (Francis, 2008; Kingston et al., 2006; Payne et al., 1985; Phillipps & Phillipps, 2016).

Age of bats were classified according to adult, subadult and juvenile based on sexual characteristics and size. Males with descended testis and relative body size were considered adults while those with unfused epiphyses and undescended testis were considered subadults. Female bats with prominent nipples, were pregnant or lactating, relative body size and complete fusion of the phalangeal symphysis are classified as adult while those that were fully grown with unfused epiphyses were considered subadults. Pregnancy status was identified by gently palpating the abdomen and lactating status were identified by attempting to express milk from the teats. Bats that were small, clinging to dam and suckling were considered juveniles.

Typically, sampling per bat took less than 15 minutes with one person handling and performing the morphometric measurements, while the other person focused on the sampling. Bats nails were painted with a red nail polish as identification in case of recapture. Frugivorous or nectivorous bats were fed with approximately 1ml of 100% fruit juice or honey water prior to release. Bats were released after sampling.

3.2.5.2 Sampling of rodent and other small mammal

Rodents and other small mammals were trapped and sampled according to the USAID Emerging Pandemic Threats PREDICT Operating Procedures with some modifications (Aplin et al., 2003; Hoffmann et al., 2010; Mills et al., 1995; PREDICT One Health Consortium, 2016d, 2016e). Further description on the sampling technique is in

Appendix X. A total of 100 traps were used to trap rodents which encompasses 45 Sherman traps, 45 small Tomahawk for smaller mammals such as mice, rats, tree shrews and 10 large Tomahawk traps for larger mammals, such as civet (**Figure 3.9**).

Figure 3. 9 Sorting of 100 rodent traps according to transect lines before deployment

Sites for traps were first surveyed and divided between inside farm or nearby plantation or forest. Transect lines were used for placement of traps as opposed to grid to reduce overlapping and increase sampling area coverage and increase chance of capturing more species through coverage of small mammal home ranges and microhabitats (Pearson et al., 2003).

Traps containing appropriate baits were placed at strategic pathways for rodents (Figure 3.10). Oil palm fruit was the preferred option as it does not attract insects. Traps were placed at the same sites for a minimum of 3 consecutive nights from 6pm to 8am the next day. If adverse weather such as heavy rain is expected, traps will not be opened for that night.

Figure 3. 10 Placement of rodent trap by the fences in a farm

Figure 3. 11 Roasting of oil palm fruits that were used as baits for rodents

Trapped small mammal were gently transferred into a draw-string cloth bag by covering the bag over the opening of the trap and slightly tilting the trap downwards. Animals that were too stressed will be released, while animals found to be injured or weak will be brought back to sampling base for veterinary treatment.

Smaller rodents were removed from the bag gently and placed in a modified container for anaesthetic induction. Whereas, in small mammal species like civets, a gas mask was used for induction without completely removing animal out from the bag to reduce stress (Figure 3.12). Once animal is motionless and unresponsive, it is taken out and placed on the table with an appropriate fitting face mask for continue induction or

maintenance of anaesthesia. Monitoring of animal was performed by a veterinarian throughout during procedure along with a basic physical examination to access health status.

Figure 3. 12 Induction of general anesthesia using isoflurane in a small Indian civet (*Viverricula indica*)

Blood samples were collected from the lateral tail vein, ventral tail artery or lateral saphenous vein or lateral saphenous vein in rodents and other small mammals (Hem et al., 1998; Lee & Goosens, 2015; Mills et al., 1995; Office of the University Veterinarian, 2017a; PREDICT One Health Consortium, 2016d). In smaller rodents, approximately 1ml of blood was collected, and in larger small mammals (~200g), 3-5ml of blood was collected. Blood collected was placed into 1:10 PBS and spin to collect serum. Subsequent steps in processing and storage are as mentioned in 3.2.5.1.

After blood collection, fluid volume replacement was given subcutaneously using Lactated Ringer's or 0.9% NaCl solution to avoid hypovolemic shock. Marking on sampled rodent or small mammal is done by clipping 3-5mm of hair at the right ventral thigh. Morphometric measurements and photographs of each animal were taken during the sampling procedure for the purpose of species identification.

Age was classified into adult, subadult and juvenile based on secondary sexual characteristics and size. Adults are fully grown with adult pelage and is sexually mature. Subadults are not fully grown with developing pelage and may or may not be sexually mature. Juveniles are smaller than subadults and not sexually mature with grey and soft pelage (Hoffmann et al., 2010). Animals were monitored in a small cage until fully recovered from anaesthesia before release at place of capture.

3.2.5.3 Sampling of Wild boar

Wild boar were sampled according to established protocols (Office of the University Veterinarian, 2017b, 2017c; PREDICT One Health Consortium, 2016b). Further description on the sampling technique is in **Appendix X**. Wild boar was trapped according to trapping protocol described for rodent and other small mammals. It is transported to sampling base in the cage for sampling (**Figure 3.13**).

Figure 3. 13 A subadult wild boar in a Tomahawk trap from an oil palm plantation

Wild boar is sedated with by creating an anaesthetic chamber for induction and maintained with a gas mask. Monitoring of anaesthesia was performed by a veterinarian throughout during procedure. Blood samples were collected from the anterior vena cava and is distributed equally in a BD Vacutainer® serum tube and an EDTA tube. Processing of blood for serum extraction and storage were similar to previously mentioned in 3.2.4. After blood collection, fluid volume replacement was given subcutaneously using Lactated Ringer's or 0.9% NaCL solution. A basic physical examination was performed by veterinarian to access health status. Morphometric measurements and photographs of each animal were taken during the sampling procedure for the purpose of species identification.

Wild boar was classified into adult, subadult and juvenile based on secondary sexual characteristics and size. Adults are fully grown with adult pelage and is sexually mature. Subadults are not fully grown with developing pelage and may or may not be sexually mature. Juveniles are smaller than subadults and not sexually mature with grey and soft pelage (Hoffmann et al., 2010).

3.2.5.4 Sampling of Non-human primate

Non-human primates (NHP) were kept as pets hence trapping was not required. NHP were anaesthetized and sampled upon the agreement of its owner according to established protocols (Hoffmann et al., 2010; PREDICT One Health Consortium, 2016c). Further description on the sampling technique is in [Appendix X](#). Briefly, aesthesia drug used to sedate animals were the combination of: 1) 4mg/kg Ketamine and 0.15mg/kg Xylazine with Yohimbine 1:1 as reversal agent for Xylazine, or 2) Tiletamine-Zolazepam, Zoletil® 3-5mg/kg in more aggressive primates. A dart syringe and blowpipe were used to deliver anaesthetic drug intra-muscularly by an experienced and trained ranger. Anaesthetic monitoring was performed by a veterinarian. After immobilization, basic physical examination was performed. A sterile lubricant is placed into animal's eyes to prevent corneal drying or scratches during sedation.

NHP is placed in a supine position. Blood is withdrawn from femoral vein located in the inguinal region lateral and parallel to the femoral artery ([Figure 3.14](#)). Three to five ml

of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube. Processing of blood for serum extraction and storage are similar to previously mentioned in 3.2.4.

Figure 3. 14 Sampling of an anaesthetized pig-tailed macaque (*Macaca nemestrina*)

Photographs of the anterior and ventral view of the full body, anterior and lateral face, upper and lower dentition and genitalia were taken for future reference. Age was classified to 7 age class according to the PREDICT Operating Procedures for Non-Human Primates. Neonates are animals that show signs of being born within few days; infants are young that were still suckling and clinging on to mother; juveniles are mostly independent from mother, sexually immature and have not developed into adult size; immature primates are individual that have not sexually mature, subadults are fully independent, appears sexually mature but has not fully grown into adult size; adults are fully grown size with sexually mature sexual characteristics; old adults are adults with

signs of age degeneration. Monitoring is done from a safe distance until NHP is fully awake and ambulatory.

3.2.6 Sampling of Human

Human samples were collected from farmers in participating cattle farms. Sample size was limited to 10 farmers per farm due to logistical and budget constraints. Individuals were recruited based on their willingness to participate, were above 18 years old and have worked or assisted with handling of animals in participating farms. Individuals were recruited based on recommendations from the farm owner.

Human sampling was conducted by district health officers from Ministry of Health, Malaysia and staffs of EcoHealth Alliance in accordance to USAID Emerging Pandemic Threats PREDICT Operating Procedures (Huppenthal, 2009; C. K. Johnson & Saylor, 2016). A written informed consent from the participant was obtained for biological sampling collection and questionnaire. Participants were explained about the study objectives and that the biological testing is exploratory and not diagnostic for their health, the types of question asked, duration of questionnaire and potential risks of their participation. They were also informed that the study was voluntary and anonymous in nature.

Biological sampling and questionnaire were conducted in a convenient, comfortable and private environment. Further description on the sampling is in Appendix X. Briefly, blood was taken from the median cubital vein on the upper limb or metacarpal plexus or the dorsal venous arch on the dorsal surface of the hand. Three ml of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube. Processing of blood for serum extraction and storage are similar to previously mentioned in 3.2.4.

3.2.7 Data collection

Following biological sampling, interviews with farmers were conducted using questionnaire designed to gauge exposure or behavioural risks to zoonotic spillover events. The questionnaire has been approved for used by the Institutional Review Board for studies on human research subjects and has been verified in previous studies (Kamau et al., 2021; Li et al., 2019; The PREDICT Consortium, 2021). The questionnaire was designed into several parts to gather information on participants' demographics, exposure to different species of domestic animal and wildlife, forms of exposure to domestic animal and wildlife, reported unusual illnesses within the past year. The questionnaire took less than 30 minutes to be completed and were administered by trained EcoHealth Alliance staffs in Malay language.

Data for livestock, other domestic animals and wildlife were recorded accordingly during the sampling process as described above. Table below shows the data collected for each species (Table 3.2).

Table 3. 2 Types of data collected during sampling of animals and human from participating cattle farms located at the forest fringe in Perak and Kelantan, Malaysia

Species	Data collected
Livestock/Dogs	Date of sampling, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal classification (domestic, feral domestic, captive wild, wild), species scientific name, species' English name, breed, farm location GPS coordinates, husbandry, ecological setting, other animals at site, tag number, sex, pregnancy status, lactating status, descended testes, age class, age, age in captivity, health condition during sampling, presence of ectoparasite, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, GPS coordinates of sampling base
Rodent/Small mammal/Non-human primates/Wild boar	Date of capture, time of trap check, trap ID and type, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal taxa, species scientific name, species' English name, sex, pregnancy status, lactating status, descended testes, age class, health condition during sampling, presence of ectoparasite, morphometric measurements (body length, right ear height, right hind foot, tail length), recapture marking, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, GPS coordinates of traps, GPS coordinates of sampling base
Bats	Date of capture, time of capture, GPS coordinate of net, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal taxa, species scientific name, species' English name, sex, pregnancy status, lactating status, descended testes, age class, health condition during sampling, presence of ectoparasite, morphometric measurements (forearm or radius length, body length, ear length, hind foot length, tail length), recapture marking, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, volume of serum dilution, of traps, GPS coordinates of sampling base
Human	Participant ID, site location, GPS coordinates, date of sampling, body temperature, blood pressure, pulse, weight, height, obvious signs of illness, age, sex, ethnicity, education level, years of residence in village, frequency of entering forest, exposure to different species of domestic animal and wildlife (primate, bat, rodent, small mammal, wild boar, wild bird, swine, cattle, dog, cat, goat, chicken, others), forms of exposure to domestic animal and wildlife (1. General exposure: lived with pet, handled live animals, raised animals, share water source with animals, seen faeces in or near food, animal entered house, eaten food that were touched, disturbed or damaged by animal, scratched or bitten by animal; and 2. Exposure to wildlife: cook or handle recently slaughtered meat, offal or blood of wildlife, eaten raw or undercooked meat, offal or blood of wildlife, eaten wildlife of unknown health status, eaten or shared dead wildlife, collect and sell dead wildlife, slaughter or butcher wildlife), reported unusual illnesses within the past year (fever with headaches and lethargy @ encephalitis, haemorrhagic fever and rash, severe

3.2.8 Luminex Serology

Serum samples from all species of animals and from humans were analysed using a Luminex bead-based multiplex microsphere assay in a Bio-Rad Bio-Plex 200 (Bossart et al., 2007). This is an assay derived from the Luminex xMAP (xMAP = multianalyte profile) technology based on flow-cytometry principles which allows high-throughput, multiplex and simultaneous detection of up to 500 analytes in a 96-well plate. Since its invention in the late 1990s, this technology has been extensively used for detection of viral, bacterial, parasitical and fungal agents (Reslova et al., 2017). It has also been used increasingly for seroprevalence study of filoviruses and henipaviruses globally (Chowdhury et al., 2014; Dovih et al., 2019; Hayman et al., 2008; Laing et al., 2018; Peel et al., 2013b).

Filoviruses viral envelope glycoproteins (GPs) and henipaviruses receptor-binding proteins (G) were coupled to 5.6 µm diameter polystyrene magnetic beads for antigen-antibody binding. The list of filoviruses and henipaviruses tested are as shown in **Table**

3.3.

Table 3. 3 Filoviruses and Henipaviruses conjugated Bio-Plex beads used in multiplex assay for antibody detection.

Filoviruses (GPs)	Henipaviruses (Gs)
EBOV, Ebola virus	HeV, Hendra virus
BDBV, Bundibugyo virus	NiV, Nipah virus

BOMV, Bombali virus	CedV, Cedar virus
SUDV, Sudan virus	MojV, Mojiang virus
MLAV, Mengla virus	GhV, Ghana virus.
RESTVm, Reston virus monkey isolate	
RESTVp, Reston virus pig isolate	
LLOV, Lloviu virus	
MARV, Marburg virus	
RAVV, Ravn virus	

Prior to testing, individual samples were diluted 1:100 in phosphate-buffered saline (PBS) in 1.5ml Eppendorf tube and vortexed briefly to mix followed by heat inactivation at 56°C for 30 mins. A duplicate of a 100 µl diluted sera were added into 96-wells plate containing 100µl of bead master mix containing specific sGP- and sG-coated beads. Mixture is covered with plastic shield and aluminium foil and incubated on a shaker for 1200 r.p.m for 1 minute followed by 900 r.p.m for 45 minutes. Samples were washed to remove unbound antibodies three times and incubated on shaker with 100µl mastermix of 1:1000 biotinylated-Protein A and biotinylated Protein G (Thermo Fisher Scientific, Waltham, MA, USA) in PBS-Tween 20 (0.05%) (Bio-Rad). Mixture was washed three times and lastly incubated on a shaker with 100µl 1:1000 streptavidin-phycoerythrin (PE) in into each well and shook for 10 minutes. Results are read on Bio-Rad Bio-Plex 200 with at least 50 per spectral region and reported as Median fluorescence intensities (MFI). Cut-off values in the first round of testing at dilutions 1:100 were determined by 3*Sigma (3-fold change of the mean of adjusted MFI values or above the mean plus 3 standard deviations) (Dovih et al., 2019).

Positive samples in the first round were rerun at the optimum dilutions of 1:400 and 1:500 with added positive and negative controls. Sera from EBOV infected bats at dilutions of 1:6400 were used as positive controls for EBOV which resulted in an average MFI value of 20359. Negative rabbit polysera and PBS were used as negative controls with a maximum MFI value of 1629 and 1851 respectively. Naïve livestock sera (N=46) comprising of cattle, goat, sheep and pigs tested with filovirus and henipavirus antigens by collaborators in Uniformed Services University of the Health Sciences, USA yield a maximum MFI value of less than 900. Antigen-antibody binding were measured and read using a Bio-Plex 200 system. Data were transformed to adjusted MFI values by taking the mean MFI values duplicates of each sample and subtracting average PBS MFI per plate.

Cut-off were determined by using 3*Sigma and Latent cluster analysis (LCA). LCA was used in absence of gold standard assays and lack of positive and negative reference samples for the viral and animal species tested (Peel et al., 2013a). To improve cut-off determination, MFI values from local samples collected as part of the research programme were combined with this study dataset. Serum samples above the cut-off values were considered seropositive. The 3*Sigma cut-off values for filoviruses and henipaviruses were determined to be 4182 MFI and 4641 MFI respectively. LCA for filoviruses and henipaviruses were attempted but were not possible due to insufficient samples reactive samples.

3.2.9 Data Analysis

Serodetection of filoviruses and henipavirus for different species were calculated based on the number of seropositive animals over the total number of sample and reported as percentage (%). The association between the serological evidence and determinants from animals (such as, farm, sex, age, age class, species, reproductive status and health status) and humans (such as, farm, husbandry, sex, age range, ethnicity, education level, years of residence in village, frequency of entering forest, exposure to different species of domestic animal and wildlife, forms of exposure to domestic animal and wildlife, reported unusual illnesses within the past year) were analysed using Pearson Chi-Square test, X^2 or Fisher's exact test (two-tailed), when X^2 is not appropriate (one of expected cell value is less than 5) at significance level $\alpha = 0.05$. Post-hoc test Bonferroni corrections and Bonferroni adjusted p-value were used for multiple comparison. Odds ratio (OR) and OR 95% Confidence intervals (CI) with Haldane-Anscombe correction were applied when contingency table has values of 0. The difference between seropositivity and hypothesized risk factors were tested using Kruskal-Wallis, KW (more than two groups) test at $\alpha=0.05$ and post-hoc Dunn's test was applied if applicable. Variable was excluded from further analysis if data is insufficient or too small ($n<10$). All analysis were conducted using the Statistical Package for Social Sciences (SPSS 27) and Microsoft Excel.

3.3 Results

3.3.1 Population characteristics

3.3.1.1 Domestic animals

Six forest-fringed cattle farms were enrolled in the study in 2018 from Kuala Kangsar district, Perak and Gua Musang district, Kelantan. Serum samples were collected from farmers (n=55), cattle (n=156), goat (n=158), sheep (n=11), dogs (n=23), bats (n=265), rodents (n=36), civet (n=1), wild boar (n=1), rabbits (n=3) and non-human primates (n=2). In total, 709 serum samples were collected.

Cattle were mostly sampled from integrated cattle farms (Table 3.13). Other domestic animals such as goats and sheep were mainly sampled from semi-intensive goat and sheep farms (Table 3.14 and 3.15). Dogs sampled were either tethered or free-roaming in the village or plantation (Table 3.16). Besides these animals, a pet rabbit was also sampled. Majority of the farm animals sampled were adults.

3.3.1.2 Wildlife

A total of 265 bats that were sampled during the study with an average of 44 (25-56) bats sampled per farm. Out of 9 species captured, 6 species were frugivores or nectarivores and 3 species were insectivores. Species that were most sampled were mostly adult male *C. brachyotis* (n=108), *E. spelaea* (n=70) and *C. horsfieldii* (n=52) (Table 3.17).

<i>Rattus tiomanicus</i>	7
<i>Sundasciurus lowii</i>	1
<i>Tupaia glis</i>	1
	36

Other wildlife sampled were pet macaques (n=2), a wild boar (n=1) and a civet, *Viverricula indica* (n=1).

3.3.1.3 Human

A total of 56 farmers from participating cattle farms were enrolled but only 55 samples were obtained. An average of 9 farmers were sampled from each farm. Majority sampled were male, between 20-29 years old, with mean age of 42 (18-68) of the Malay race. Most have completed secondary school or above and have resided in the village for more than 10 years (51/55, 92.7%) (Table 3.19).

The most common domestic animals that farmers were exposed to within the past one year of sampling were cattle, cat and poultry. Whereas the most common wildlife exposed to were rodents and bats (Table 3.120). Farmers had general exposure to

domesticated animals and wildlife in the past one year primarily through handling of live animals, animal entering living quarters and living with pet. Farmers were exposed to wildlife primarily through slaughter, butchering, cooking and handling of recently slaughtered meat, offal or blood of wildlife (Table 3.21).

Out of the 55 farmers, many farmers reported Influenza-like illnesses (ILI), followed by fever with diarrhoea and vomiting, Severe acute respiratory infection (SARI), fever with headaches and lethargy (3/55, 5.5%), and fever with skin rash (1/55, 1.8%). No farmers reported haemorrhagic fever (Table 3.22).

3.3.2 Serological result

3.1.1.1 Filovirus

A total of 45 sera were reactive to filovirus (%??). The serological detection for filovirus among species in descending order were goat (15.2%, 95% CI 10-22), sheep (9.1%, 95% CI 0.2-41.3), human (9.1%, 95% CI 3-20), dog (8.7%, 95% CI 1.1-28), cattle (5.1%, 95% CI 2.2-9.9) and bat (1.9%, 95% CI 0.6-4.3) (Table 3.6, Figure 16-22). Bats species that were seropositive for filovirus were *C. brachyotis*, *E. spelaea* and *C. horsfieldii* (Table 3.7).

Most filovirus reactive samples were reactive to BDBV (29/45) followed by SUDV (16/45) and RESTV (16/45) (Table 3.8). Twenty-three (23/45, 51%) samples were reactive to only one antigen, with the most being BDBV (16/23), followed by EBOV (4/23), RESTVp (2/23) and SUDV (1/23). Whereas twenty-two (22/45, 48.9%) samples were reactive to two to five filovirus antigens which involved BDBV, SUDV, RESTVp the most. Cross-reactivity were observed between EBOV, BDBV, BOMV, SUDV, RESTVm, RESTVp, MARV, and RAVV (Appendix).

3.1.1.2 Henipavirus

A total of 36 sera were reactive to henipavirus. The reactive sera were in goat (13.9%, 95% CI 8.9-20.3), sheep (9.1%, 95% CI 0.2-41.3), human (7.3%, 95% CI 2-17.6), dog (4.3%, 95% CI 0.1-21.9), cattle (3.2%, 95% CI 1.0-7.3) and bat (1.1%, 95% CI 0.2-3.3) (Table 3.10 and Figure 3.23-29). Bats seropositive for henipavirus were *C. brachyotis* and *C. horsfieldii* (Table 3.11).

Most samples were reactive to GhV (32/36), HeV (22/36), NiV (19/36), CedV (9/36) and MojV (7/36) (Table 3.11). Eleven (11/36, 31%) samples were reactive to only one antigen, with the most being GhV (9/11), followed by MpjV (2/11). Twenty-two (25/36, 69.4%) samples were reactive to two to five henipavirus antigens which involved GhV,

HeV and NiV the most. Cross-reactivity were observed between all five antigens tested (Appendix).

HeV, Hendra virus; NiV, Nipah virus; CedV, Cedar virus; MojV, Mojiang virus; GhV, Ghana virus.

The range of MFI for henipavirus positive sera was between 4182 and 24689 with the highest being 24689 MFI against GhV in a farmer. There were 39 reactions with an MFI reading of 10000-19999 MFI (HeV, NiV, CedV, and GhV), and 5 reactions of >20000 MFI (HeV, CedV, MojV and GhV). Goat sera displayed many high MFI readings of >10000. In general, almost all henipavirus reactive sera had reactivity to GhV with many being >10000 MFI. (Table 3.13 and Appendix).

3.3.3 Serological evidence and demographic distribution

3.3.3.1 Cattle

The serological evidence of filovirus and henipavirus in cattle were 5.1%, 8/156 (95% CI 2.2-9.9) and 3.2%, 5/156 (95% CI 1.0-7.3) respectively. Among the filovirus positive (8/156) and henipavirus positive (5/156) cattle sera, most were female, adults and apparently healthy and had no observable ectoparasite at the time of sampling. No significant difference was observed between serological evidence of filovirus or henipavirus with husbandry, sex, age class and health status (Table 3.14).

Table 3. 14 Serological evidence of filovirus and henipavirus in cattle based on farm, sex, age class, reproduction status, health status and presence of ectoparasite

3.3.3.2 Goat

The serological evidence of filovirus and henipavirus in goat were 15.2%, 24/158 (95% CI 10-22) and 13.9%, 22/158 (95% CI 8.9-20.3) respectively. Among the filovirus positive (24/158) and henipavirus positive (22/158) goat sera, most were semi-intensively reared, female, adults and apparently healthy. Subadult goats were 6.3 times less likely to be seropositive for filoviruses as compared to adults (P= 0.028, OR=6.3, 95% CI=1.149, 34.383). No significant difference was observed between serological evidence of henipavirus and the various factors (Table 3.15).

Table 3. 15 Serological evidence of filovirus and henipavirus in goat based on farm, sex, age class, reproduction status, health status and presence of ectoparasite sampled from goat farms surrounding participating targeted cattle farms

3.3.4 Sheep

The serological evidence of filovirus and henipavirus in sheep were 9.1%, 1/11 (95% CI 0.2-41.3) for both. Out of 11 sheep sampled, only one sheep was seropositive for filoviruses and henipaviruses. The sheep was a female pregnant and lactating adult that was raised extensively, and apparently healthy (Table 3.16). Further analysis with the variables were not performed due to insufficient or too small data.

3.3.5 Dog

The serological evidence of filovirus and henipavirus in dog were 8.7%, 2/23 (95% CI 1.1-28) and 4.3%, 1/23 (95% CI 0.1-21.9) respectively. Filovirus positive dog (2/23) were adult and subadult tethered males. Whereas henipavirus positive dog was an adult male raised extensively. All filovirus and henipavirus positive dogs were apparently healthy with no observable ectoparasite at time of sampling. Further analysis with the variables were not performed due to insufficient or too small data (Table 3.17).

3.3.6 Bat

The serological evidence of filovirus and henipavirus in bat were 1.9%, 5/265 (95% CI 0.6-4.3) and 1.1%, 3/265 (95% CI 0.2-3.3) respectively. Majority of the filovirus positive (5/265) and henipavirus positive (3/265), bat sera were adult females that were apparently healthy (Table 3.18). Seropositivity was detected in 3 bat species (*C. brachyotis*, *E. spelaea* and *C. horsfieldii*). Further analysis with the variables were not performed due to insufficient or too small data.

3.1.1.1 Human

The serological evidence of filovirus and henipavirus in human were 9.1%, 5/55 (95% CI 3-20) and 7.3%, 4/55 (95% CI 2-17.6) respectively. Humans positive for filovirus (5/55) and henipavirus (4/55) were mostly males of Malay ethnicity, completed secondary level education and have resided in village for more than 10 years. No significant difference was observed between serological evidence of filovirus or henipavirus with the various factors (Table 3.19).

Filovirus and henipavirus serologically positive humans reported exposure to cat, cattle, poultry, goat, rabbit, rodent, wild bird, bat and deer. One henipavirus positive human had exposure to non-human primates. No significant findings were found between serological evidence of filovirus and henipavirus and exposure to different animal species (Table 3.20).

^aVariable is excluded from further analysis due to insufficient or too small data

A majority (26.7%, 4/15) filovirus seropositive humans have eaten food that were touched, disturbed or damaged by animals. These animals were 10 times more likely to be seropositive for filovirus compared to those who have not ($P=0.017$, $OR=10.3$, 95% $CI=1.45, 73.24$). For henipavirus, there was no significant association between seropositivity to the different forms of exposure to various animal species. However, there is a meaningful increase of risk for consuming food that were touched, disturbed or damaged by animal ($P=0.057$) and eating raw or undercooked meat, offal or blood of wildlife (0.097) (Table 3.21).

^aVariable is excluded from further analysis due to insufficient or too small data

*Humans that consumed food damaged by animal were more likely to be seropositive for filovirus (P=0.017, OR=10.3, 95% CI=1.45, 73.24).

Most farmers reported have had symptoms of Influenza-like illnesses (ILI) in the past one year. A few filoviruses and henipavirus seropositive farmers also reported other symptoms such as severe acute respiratory infection and fever with diarrhea and vomiting (Table 3.22). However, bivariate analysis between seropositivity and reported symptoms were not performed due to insufficient data for meaningful analysis.

*Only exposure to animal species with >2 reports were included in this comparison

ILI symptoms reported were also compared to forms of exposure to animals and wildlife within the past year of survey in farmers. All farmers that reported ILI symptoms have reported handling live animals and most of them lived with a pet animal. No significant findings were found between ILI and forms of exposure to animals and wildlife within the past year of survey (Table 3.24).

3.4 Discussion

In this study, domestic animals and wildlife in and around forest-fringe cattle farms were tested for exposure to the family filoviruses and the genus henipaviruses using Luminex bead-based multiplex microsphere assay. This technology has been developed and widely used for screening of viruses globally (Chowdhury et al., 2014; Dovih et al., 2019; Hayman et al., 2008, 2011; Laing et al., 2018; Peel et al., 2013b) but is not meant for diagnostic determinations. The findings can be used to target areas of surveillance for emerging pathogens but should not be used for policy decisions such as trade, quarantine or culling (MacNeil et al., 2011; Peel et al., 2013a). Serologically positive samples may indicate positivity to the tested virus or to antigenically related viruses. Antigenically related viruses share similar epitopes on its surface antigenic molecule that stimulates binding to antibodies or T cell receptor (Frank, 2020). Phylogenetically closely related viruses has higher epitope amino acid sequence similarity and binding to similar antibodies which result in cross-reactivity of antibodies (Brangel et al., 2018; Marsh et al., 2012; Schuh et al., 2019). Further testing and confirmation is necessary using virus neutralisation test (OIE, 2018).

Filovirus

Study found serological evidence for filoviruses is highest in goat (24/158, 15.2%), sheep (1/11, 9.1%), human (5/55, 9.1%), cattle (5/156, 5.1%) and lowest in bat (5/265, 1.9%). Seropositivity indicates evidence of past exposure to specific viruses

antigenically related to filoviruses. Studies on filoviruses in domestic animals has been scarce. Only dogs and pigs have been demonstrated to be infected with filoviruses (Allela et al., 2005; Chowdhury et al., 2014). In Gabon, 28% of dogs from Ebola epidemic areas were found to be IgG positive for Ebola virus (Allela et al., 2005). Meanwhile, Reston ebolavirus (RESTV) was identified in a spillover event between pigs and human in the Philippines and later in sick pigs in China (Barrette et al., 2009; Pan et al., 2014). To our knowledge, this study is the first to report evidence of exposure to filoviruses in cattle, goat and sheep. This is also the first evidence of exposure of filoviruses in human and dogs beyond Africa.

Highest seropositivity was reported among goats in this study particularly in semi-intensively reared goats which were 4 times more compared to cattle. The reasons for this may need further exploration however we suggest a few reasons for this findings: 1) Goat is known to browse extensively relative to other species (Hofmann, 1989; Rutagwenda et al., 1989) and have the habit of sampling wide ranges of items (edible and non-edible), therefore may increase their risk of exposure to multiple disease agents; 2) Many of the seropositive goats reported in this study were managed semi-intensively to browse freely around village and raised in close proximity where flowering and fruiting trees are abundant which attracts bats such as *C. brachyotis* (V. C. Lim et al., 2017; Tan et al., 1998). Goats are very likely to pick up partially eaten fruits consistent with their feeding behaviour therefore increases risk of contracting multiple disease agents.

Seropositivity of bats in this study is lower than previous reports of bats in this region. Local *P. hypomelanus* reported 10% and 5% reactivity to filoviruses closely related to EBOV and SUDV respectively (Laing et al., 2019). Study from neighbouring country, Singapore reported 9.1% (17/186) in *E. spelaea*, 8.5% (13/153) in *C. brachyotis* and 4.3% (3/70) in *P. lucasi*. Besides *E. spelaea* and *C. brachyotis*, *C. horsfieldii* was seropositive for filoviruses in our study. *Cynopterus sp.* and *E. spelaea* are adaptive species that occupy a range of habitats from orchards, plantations, primary and secondary forests and urban sites (Campbell et al., 2004; Fukuda et al., 2009; Heidenan & Heaney, 1989; Kitchener et al., 1990; V. Lim, 2018; Tan et al., 1998). Livestock farming in rural and sub-rural areas where fruit trees are plenty provides bat roosting and foraging areas (Fukuda et al., 2009). This overlapping spatial distribution of bats and livestock increase risk of viral spillover to livestock and agricultural workers (Mikhail et al., 2017). Longitudinal spatial-temporal distribution studies will ascertain the level of such risk (Zhao et al., 2022).

Antibody reactivity to specific filovirus antigen in our study suggests that circulating filovirus in this region is predominantly more closely related to BDBV, SUDV, EBOV, RESTV and less so with BOMV, MARV, and RAVV. Reactivity to filoviruses closely related to EBOV, BDBV and SUDV corresponds to a similar study in Singapore bats (Laing et al., 2018). However, in contrast to that study, we report a considerably high number of reactivity to antigenically related but not identical to RESTV-pig in a *C. brachyotis* and many goats. RESTV is a zoonotic Asiatic filovirus responsible for sporadic cases in non-

human primates, pigs and human (Barrette et al., 2009; CDC, 1993; Demetria et al., 2018; Miranda et al., 1999). Bats may be natural reservoirs for RESTV in the Philippines, Bangladesh and China (Jayme et al., 2015; Olival et al., 2013; Taniguchi et al., 2011; Yang et al., 2017). Finding of our study suggests direct transmission of RESTV-related viruses from bats to goat. Detection of RESTV genome is necessary to confirm spillover.

Henipavirus

Seropositivity to henipaviruses was highest in goats (13.9%), sheep (9.1%), human (7.3%), dog (4.3%), cattle (3.2%) and bat (1.1%). Seropositivity indicates evidence of past exposure to viruses antigenically related to henipaviruses. Our result is supported by several studies. Surveillance of NiV in human outbreak areas near Pteropus sp. bat roosts in Bangladesh using the Luminex platform found that 6.5% (26/400) of cattle and 4.3% (17/400) of goats were positive for henipavirus (Chowdhury et al., 2014). During the Nipah virus outbreak in Malaysia, dogs sampled near infected pig farms had detectable antibodies for Nipah virus (Mills et al., 2009; Yob, Field, et al., 2001). Since 2001, NiV have not been reported in domestic animals and wildlife locally using ELISA (Fikri et al., 2011; Naama et al., 2013). This study is the first report that uses Luminex technology of henipavirus infection in dogs since 1999 and in local cattle, goat and sheep. Reported seropositivity of henipaviruses in goats was high at 13.9% (22/158) particularly in semi-intensively reared goats and was 4 times more as compared to cattle 3.2% (5/156) for hypothetical reasons of risk of exposure to infectious materials as explained before.

Previous survey of bats in Malaysia were mostly focused in the *P. vampyrus* and *P. hypomelanus* species as reservoirs for Hendra virus and Nipah virus with a reported seroprevalence of 1-33% (Rahman et al., 2013; Yob, Jamaluddin, et al., 2001). Those studies used indirect ELISA and serum neutralization test to detect the antibodies against Nipah virus in samples. A recent survey using multiplex serological assay in the local *P. hypomelanus* bats samples found 25% reactivity to NiV (Laing et al., 2019). The reported seroprevalence in our study of 1% (2/108) in *C. brachyotis* and *C. horsfieldii* 2% (1/52) is much less than that of Laing et al. (2109) *Pteropus sp.* surveys and are comparable to the seroprevalence of 4% (2/56) in *C. brachyotis* and 5% (2/38) in *E. spelaea* in a separate study in 1999 (Yob, Field, et al., 2001).

Antibody reactivity to specific henipavirus antigen in our study suggests that circulating henipavirus in this region is predominantly more closely related to GhV, HeV, NiV and less so to CedV and MojV. The MFI values for GhV is high and many cross-reacted with other henipaviruses. Presently, little is known about GhV which was first detected in African bats and is the only African henipavirus (Drexler et al., 2009, 2012). GhV is also antigenically closer to ancestral henipaviruses (Pernet et al., 2014). Thus, reaction to GhV in our study indicates prevalence of henipavirus more antigenically related to the ancestral GhV than the other Asiatic viruses.

Interestingly, our study found two reactions only to MojV with no cross-reactivity in a cattle and dog from the same intensive cattle farm. MojV is a rodent henipavirus discovered in anal specimens of *Rattus flavipectus* in Southern China. This novel virus was identified in the same cave 6 months later where three patients died of respiratory illness of unidentified aetiology. MojV pathogenicity remains to be determined due to the absence of isolate (Wu et al., 2014). Cattle and dog may have acquired MojV closely related virus through contact with rodent excrement. Rodents are probable reservoir hosts or amplifying host for MojV (Cheliout et al., 2021). Increasing the sample size of rodents to detect antibodies and genome of MojV or MojV-like virus will improve chances of detection and determine its circulation locally.

Risk Factors

We detected exposure against viruses antigenically related to filoviruses, EBOV, BDVD and RAVV; and henipaviruses HeV, CedV, MojV in humans. Our study found those that consumed food that were touched, disturbed or damaged by animal were more 10 times more likely to be seropositive for filovirus. This is supported by the study by Adjemian et al., amongst febrile tribesmen presented to healthcare facilities in Uganda. Increased risk of filovirus infection was observed in activities such as hunting (37.5 times), touching (5.6 times) or eating wildlife (10.7 times) (Adjemian et al., 2011). Likewise, bushmeat slaughtering or working closely with infected pigs or horse enhanced risk of henipavirus infection (Chua, 2010; Pernet et al., 2014; Rogers et al., 1996). The finding is expected because the both viruses are transmitted via direct

contact with body fluids (Amal et al., 2000; Bausch et al., 2007; O'Sullivan et al., 1997; Saéz et al., 2015; Williamson et al., 1998). Therefore, poor hygiene practices or improper personal protective equipment may expose farmers to infectious materials, especially when handling sick or infected animals, animal waste or carcasses.

Approximately half of the humans sampled (21/55) reported Influenza-like illnesses (ILI), fever with diarrhoea and vomiting, fever with headaches and lethargy and severe acute respiratory infection (SARI) symptoms within the past year of survey. Half of the seropositive human for filovirus and/or henipavirus in our study had reported one of the symptoms in the past year, while the other half did not. The symptoms can be due to several multitude of reasons, unfortunately causal relationship between viral infection and symptoms in our study cannot be ascertain without clinical and longitudinal data. Syndromic surveillance incorporating important pathogens at the family or genus level will improve early detection and appropriate intervention.

The catastrophic Nipah outbreak in 1998 is a turning point for cross-sectoral ministerial integration in managing zoonotic disease and recognition that the country is susceptible to spillover of pathogenic viruses (Chua, 2003). Unfortunately, at present, novel or emerging viral surveillance in animal population is sporadic and scanty; usually linked to specific research endeavour. The ecological concerns and agricultural intensification in Malaysia strongly indicate the need for regular monitoring and

surveillance of livestock and humans working in close proximity to animals especially those that are located in geographic areas with high potential for wildlife viral spillover events. A better understanding on the interaction and viral transmission between human, livestock, other domestic animals and wildlife will inform disease surveillance and control policy to reduce the risk of transmission and prevent undesirable animal and public health consequences.

Limitations

This study was performed on highly targeted populations to increase the chance of viral detection in high-risk populations at the wildlife-livestock-human interface. Therefore, the findings should be interpreted in light of the sampling bias, limited sample size, non-random sampling, cross-reactions between antigenically related viruses and the diversity of uncharacterized filoviruses and henipaviruses that is missed from the test panel. Further characterization of filoviruses and henipaviruses in the region, larger data set, improved diagnostic assays and species-specific positive controls will influence cut-off values and reported sero-detection.

Additionally, infection status in bats fluctuates seasonally and are influenced by reproduction phases, nutritional stress, migrations or contacts with infected animals (Amman et al., 2012; Baker et al., 2014; Hayman, 2015; Plowright et al., 2008; Sohayati et al., 2011; Wang et al., 2013). This infection pattern in bats as a reservoir host would

subsequently impact degree of spillover to other potential hosts like cattle, goats or humans in our case (Amman et al., 2012; Plowright et al., 2017). Antibody post-infection also wax and wanes over time (Boardman et al., 2020; Diallo et al., 2021). Thus, the sero-detection reported in this cross-sectional study only provides information at the time of sampling which may be an underestimation or overestimation and will differ depending on time of sampling.

In addition, maternal antibodies to NiV can last up to 14 months, hence without longitudinal data, some reactivity in our study may be misrepresented (Sohayati et al., 2011). As a result of lack of longitudinal data, serological findings only demonstrate past exposure to filoviruses and henipaviruses. Despite these limitations, our study generated valuable information of filoviruses and henipaviruses in the multiple animal host species to inform future studies. Besides that, research on viral diversity characterization in this region will improve the depth of interpreting serological results.

3.5 Conclusion

This study provides the first evidence of exposure to viruses antigenically related to filoviruses and henipaviruses in domestic animals and humans in Malaysia, as well as viruses antigenically related to henipaviruses in previously unreported bat species. Results from our study supports more extensive and longitudinal viral surveillance in these populations to enhance disease preparedness and improve our understanding on

the viral distribution, diversity and potential spillover at the human-livestock-wildlife interface.

Chapter 3

FILOVIRUSES AND HENIPAVIRUSES AT THE HUMAN-LIVESTOCK-WILDLIFE INTERFACE IN FOREST FRINGE CATTLE FARMS IN SELECTED STATES OF PENINSULAR MALAYSIA

3.1 Introduction

Filoviruses and henipaviruses are high consequence emerging zoonotic pathogens that have caused severe outbreaks in many parts of the world leading to high mortality and morbidity and grave economic losses in both human and animal health sectors (Knust et al., 2017; Looi & Chua, 2007). The economic losses due to Ebola has been estimated to be USD2.8 billion in the 2014 Ebola outbreak and USD446 million in 1998 Nipah outbreak (FAO and APHCA, 2002; World Bank, 2016).

The viruses within the family Filoviridae; Ebola (EBOV) and Marburg virus (MARV) cause haemorrhagic fever outbreaks in Africa, Germany and isolated cases in other parts of the world like Spain, United States of America, United Kingdom, Philippines, Italy, and Russia (CDC, 2018; C. E. Smith et al., 1967; WHO, 2014). The mortality from Ebola disease in Africa was 50-90% in humans and almost 100% mortality in non-human primates (Bowen et al., 1978; Jaax et al., 1996; Jahrling et al., 1996; K. M. Johnson, 1978; Simpson, 1978). While *Henipavirus*); Hendra virus (HeV) and Nipah virus (NiV) have cause respiratory and neurological signs in humans, pigs and horses in

Malaysia, Australia, Bangladesh and India (Chadha et al., 2006; Chua et al., 1999; Hsu et al., 2004; Nor, Gan, Ong, et al., 2000; O'Sullivan et al., 1997). The mortality from Nipah virus infection was 40-70% in humans in Malaysia and Bangladesh; and of 1-5% in adult pigs and 40% in suckling pigs in Malaysia (Chua et al., 2000; Goh et al., 2000; Hsu et al., 2004; Luby et al., 2009; Nor, Gan, & Ong, 2000).

With an exception of Nipah virus which emerged in 1998 (Fikri et al., 2011; Laing et al., 2019; Rahman et al., 2013; Sohayati et al., 2011), limited information is available on both filoviruses and henipaviruses in Malaysia. The investigative work on Nipah has led to numerous works on bat ecology and bat-borne microbial agents. It is now understood that bats have co-evolved with multiple viruses that may be of public health significance such as Nipah (Hayman, 2016). Filoviruses have been detected in bats in Singapore, Bangladesh, China, and the Philippines (Laing et al., 2018; Olival et al., 2013; Taniguchi et al., 2011; Yuan et al., 2012). While henipaviruses widely circulate in bats in Malaysia, India, Vietnam, Cambodia, Indonesia and Australia (Breed et al., 2013; Epstein et al., 2008; Hasebe et al., 2012; Rahman et al., 2013; Reynes et al., 2005; Sendow et al., 2006). Besides bats, filoviruses' and henipaviruses can infect a broad range of mammals such as human primates, rodents, shrews, guinea pigs, bats, dogs, pigs, cattle, donkey, chicken; and rodents, horse, cats, pigs, dogs, goats respectively (Chua et al., 2000; Edson et al., 2015; Gonzalez et al., 2005; Leroy et al., 2004; Morvan et al., 1999; Wu et al., 2014).

Despite the apparently wide distribution and reported prevalence of these pathogens amongst the reservoir hosts in Southeast Asia, outbreak has been rare in both humans and domestic animals. Following the Nipah outbreak in 1998-1999 in Malaysia, no further cases have been reported in both humans and animals to date (Fikri et al., 2011; Muniandy et al., 2001; Naama et al., 2013; Sohayati et al., 2016). There has also been no human outbreaks in Cambodia despite serological and molecular evidence widely found in Cambodian bats (Olson et al., 2002; Reynes et al., 2005)s. However, the SEA region is considered a hotspot for emerging pathogens because several localized emerging zoonosis have occurred in the past two decades and because multiple factors that drives emerging infectious diseases are highly prevalent. For example, wide circulation and abundance of reservoir hosts, topographical or landscape changes and intensified systems of agriculture and animal production may increase contact opportunities for viral transmission at the wildlife-livestock-human interfaces (Breed et al., 2013; Horby et al., 2013; Jung & Threlfall, 2016; I. Smith & Wang, 2013). In additon,the global climatological changes may impact distribution and concentration of disease vectors which subsequently facilitates spatiotemporal changes of filovirus and henipavirus viral spillover events (Martin et al., 2018; McFarlane et al., 2011; Schmidt et al., 2017).

The one health approach of managing complex emerging diseases requires the understanding of all actors that take part at the environment-animal-human interface. For example, food animals may become infected with pathogens from wildlife that can

then be transmitted to human such as Nipah, Highly Pathogenic Avian Influenza H5N1, Pandemic Influenza H1N1 (2009) amongst others. Many livestock farms in this region are located in the rural or peri-urban areas bordering primary or secondary forests. In Malaysia, livestock especially cattle are commonly managed extensively or semi-intensively at forest fringes thus may have higher probability of contact with infectious materials from infected wildlife or domestic animals. Beef cattle are most commonly raised using the aforementioned systems where animals are let out to graze in a field, plantations or in a village located at forest fringes where wildlife and peri-domestic animals are plentiful. Such setting improves the chance and frequency for pathogen spillover events to livestock or humans (Hassell et al., 2017). The spillover occurrences varies given available drivers and rarely result in an epidemic, however frequent spillover events will increase the chance of an outbreak (Clayton et al., 2013; Hayman et al., 2011; Parrish et al., 2008; Plowright et al., 2017).

In this chapter, we targeted cattle farms located at forest fringe areas with high contact risk and probability of pathogen spillover events. We hypothesise that cattle, other domestic animals, wild animals and farmers are seropositive for filoviruses and henipaviruses. The objectives of this study are: 1) To determine the serological evidence of filoviruses and/or henipaviruses in cattle, farmers, and other domestic animals and wildlife in and at close proximity to the targeted cattle farm; 2) To determine risk factors of virus infection in those species.

3.2 Materials and Methods

3.2.1 Ethics statement

All human and animal samples from cattle farms were collected in accordance to an established USAID Emerging Pandemic Threats PREDICT Operating Procedures with permission from the local institutional and ministerial Institutional Animal Care and Use Committee from UPM (AUP-R064/2018), UC Davis (#19300) and Tufts (G2021-131) and the Institutional Review Board from the Medical Research and Ethics committee (MERC) from National Medical Research Register (NMRR), Malaysia (NMRR-17-3356-37135, IIR) and UC Davis (#804522) in collaboration with Ministry of Health (MOH), Malaysia, Department of Veterinary Services (DVS), Malaysia, and the Department of Wildlife and National Parks (PERHILITAN). The work performed for this project is part of a larger project in collaboration with the EcoHealth Alliance.

3.2.2 Study design and study sites

A cross-sectional survey was performed in 3 semi-intensive, 2 integrated and 1 intensive cattle farm. These farms were selected based on a defined selection criteria which include, 1) located in districts with existing NMRR and IRB approval for human study, 2) located 5km from periphery of forests as approved by the Department of Veterinary Services, Putrajaya, 3) a minimum of 30 cattle in farm, and 4) has other domestic animals and wildlife in or around farm. The approved districts were Kuala Kangsar in the state of Perak, Gua Musang in Kelantan and Kuala Lipis in Pahang. In

these districts, the district health officers had worked with EcoHealth Alliance on previous projects and have agreed to assist the human sampling aspects in this project.

The identification of the cattle farms consisted of several steps as in **Figure 3.1**. The details of the steps in identifying location and farms are further described in **Appendix**

X. All animals sampled in this study were within 5km radius of a primary forest.

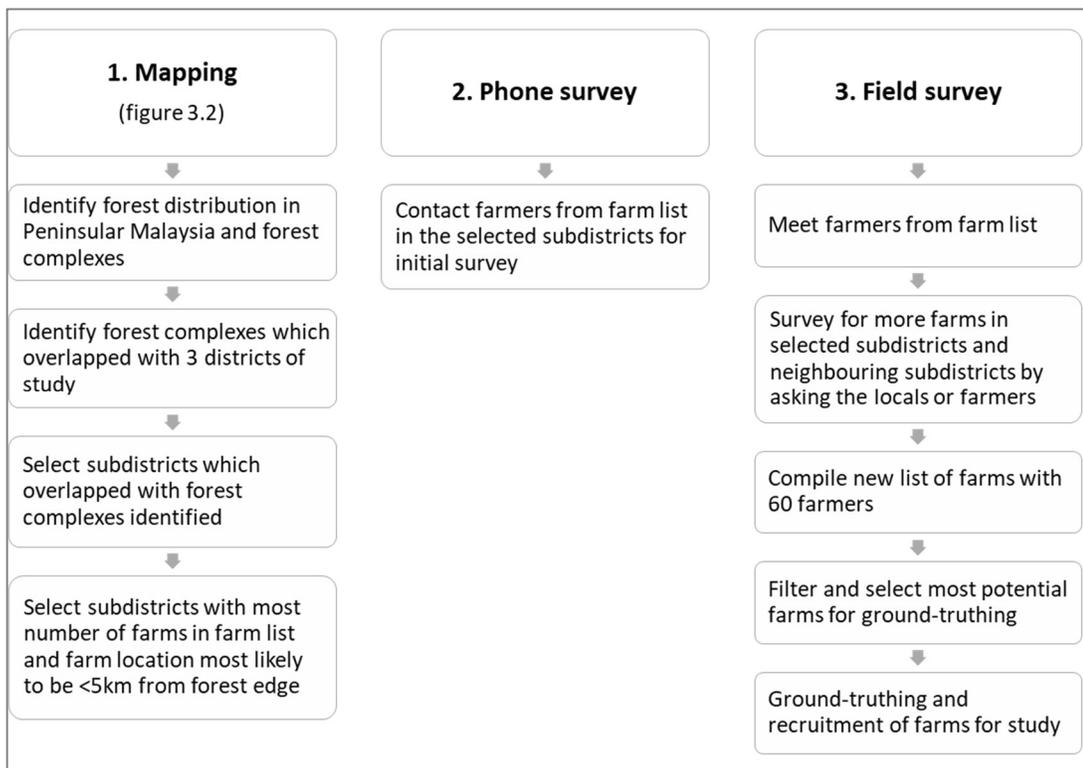

Figure 3. 1 Identification of forest-fringed cattle farm for the study on filovirus and henipavirus at the wildlife-livestock-human interface

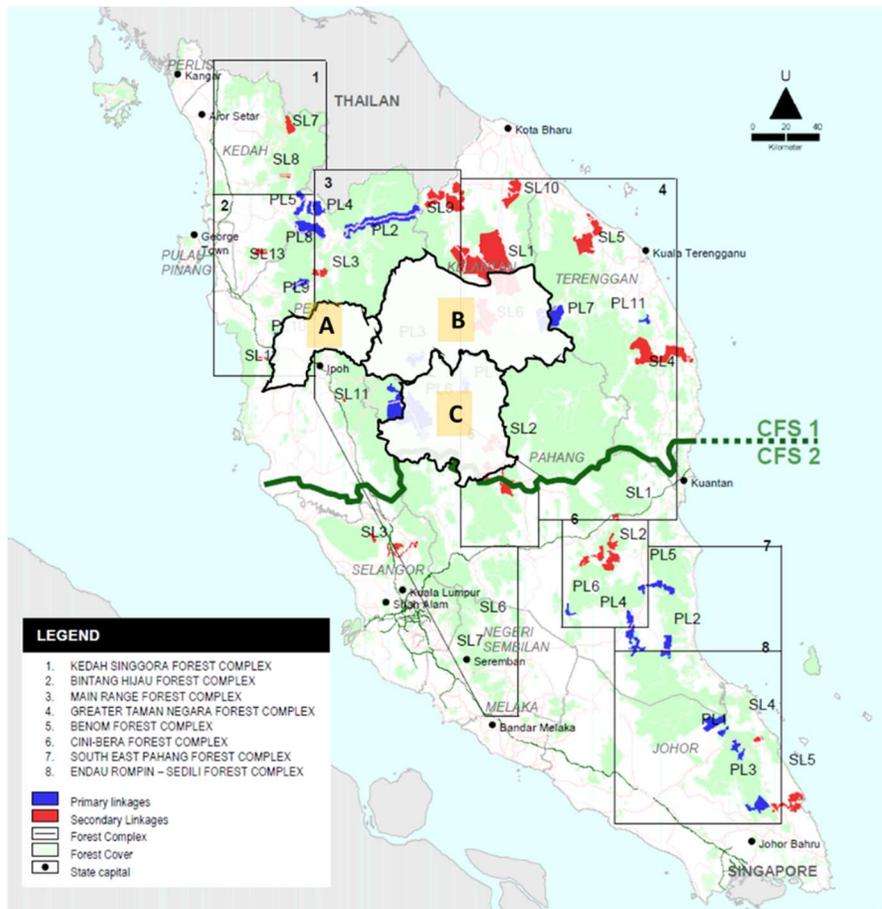

Figure 3. 2 Map of forest complexes in Peninsular Malaysia and the overlapping targeted districts in our study marked by A: Kuala Kangsar, B: Gua Musang, C: Lipis. (Source: Regional Planning Division, Department of Town and Country Planning, Peninsular Malaysia, 2009)

3.2.3 Sample size

Four cattle farms from Kuala Kangsar district, Perak and two cattle farms from Gua Musang district, Kelantan within 5km radius of forests were sampled beginning 2019.

Targeted sample size for each animal species per farm were 30 cattle from participating target farms, 30 other domestic animals (eg, goat, sheep, dog, etc) and 60 wildlife (eg, bats and rodents). The sample size (n) for this study (Table 3.1) was determined using

the Open-Epi Version 3 calculator. The software program applies the formula of $n = \frac{DEFF * N * p * (1-p)}{[(d/2Z_{1-\alpha/2} * (N-1) + p * (1-p))]}$, where N = population size, p = prevalence, d = confidence limits = 10%, and DEFF = design effect for cluster surveys = 1. The estimated prevalence used in the current study was 5% based on prevalence studies of filoviruses and henipaviruses in the region which reported seroprevalence of 0-6.5% in domestic animals and 1-20% in bats (Table). Other domestic animals and wildlife were opportunistically captured and sampled with priority given to animals in and closest to the participating target farms.

Table 3. 1 Sample size calculation for the sero-detection of filovirus and henipavirus in cattle, other domestic animals and wildlife in participating cattle farms located at the forest fringe in Perak and Kelantan, Malaysia

	Estimated Population Size, N per farm	Estimated Prevalence, p (% +/-5) ^a	Sample size, n per Farm	No. of farms	Total
Cattle : (Semi-intensive (n=3), Integrated oil palm (n=2), Intensive farm(n=1)	50	5	30	6	180
Other domestic animals : Goat, sheep, dog, etc.	50	5	30	6	180
Wildlife : Bat, rodent, other small mammal	1249 per roost for bats	5	70 (max of 60) ^c	6	360

^aPrevalence of 5% was decided based on prevalence studies of filoviruses and henipaviruses in the region (see Table ???).

^bEstimated population size for bats is based on the average roost size of bats. Total number of bats calculated is an overestimation as it will be highly dependent on the bats captured in nets and number of days the nets are placed in a location.

^cTotal number of wildlife are set to the maximum of 60 due to logistical and financial limitations.

3.2.4 Sampling of cattle and other domestic animals

Cattle and other domestic animals such as goat, sheep, dogs and rabbit were conducted with the team from the EcoHealth Alliance in accordance to USAID Emerging Pandemic Threats PREDICT Operating Procedures (PREDICT One Health Consortium, 2016b, 2016e).

All domestic animals were manually restraint for the sampling procedures (Appendix B). Blood samples were obtained from the appropriate venepuncture sites according to species. In cattle, goat, and sheep, the jugular vein or coccygeal vein was used (Figure 3.3). In dogs, blood was collected from the cephalic vein, jugular vein, femoral vein, lateral or medial saphenous vein. In rabbits, blood was collected from the lateral saphenous vein. Three to five ml of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube.

A basic physical examination was performed by veterinarian to assess the health status and identify the age and sex of the animal. Photographs of sampled animal was taken from the sides and front, including dentition, or presence of any lesions, abnormalities or identifying marks or characteristics for future reference.

All blood tubes were labelled appropriately and placed in cooler boxes and transported back to sampling processing base. Blood in BD Vacutainer® serum tubes were left to

clot for serum collection within 1 hour. After clot is form, serum tubes were centrifuged at 1300 r.p.m for 15 minutes and 1 ml of serum was transferred into 0.5ml cryovial tubes to produce at least two aliquots. Cryovial tubes were labelled appropriately. Samples were then placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to proper cold chain methods.

Figure 3. 3 Locating the jugular vein in the jugular groove for blood sampling

3.2.5 Sampling of wildlife

Permission was obtained from the local authorities or landowners before bat and rodent trapping and sampling begun. Selected sites were first surveyed with priorities given to potential trapping locations in the farm and nearest to farm within 5 km radius. All personnel handling trapping and sampling of wildlife had to be immunized

against rabies, Japanese Encephalitis, Hepatitis B, tetanus and negative sputum tests for Tuberculosis.

3.2.5.1 Sampling of bat

Bats were captured using mist nets suitable for capturing bats in open spaces as described by FAO Manual for Investigating the Role of Bats in Emerging Zoonoses (Food and Agriculture Organisation of the United Nations, 2011). Further description on the sampling procedure is in [Appendix X](#). Briefly, bats were captured using mist nets placed at anticipated bat flyways in the farm, village and in nearby plantations such as across streams or trails. The nets were also positioned near roosting or feeding sites such as near flowering banana trees and flowering durian trees ([Figure 3.4](#)).

Figure 3. 4 A bat trapping site with banana and durian plantation in a village near a participating cattle farm.

The mist nets were raised at 7.30pm at sunset and left opened until 12am for trapping to occur (Figure 3.5) and closed neatly after trapping period (Figure 3.6). Bat nets were repositioned to new locations when recapture rates were high, or captures were absent. The GPS coordinates for each mist nets were recorded.

Figure 3. 5 Extended mist nets for capture of bats at sunset.

Figure 3. 6 Retracted mist nets that is secured after trapping period

Mist nets were checked for bats every 30 mins to an hour. Captured bats were extracted from the nets carefully using at least one leather gloves on one hand and with the use of forceps or small stick to move the netting or bat mandibles then placed into a porous cotton bag with a draw-string mouth and taken to a sampling processing site where sampling was performed immediately (Figure 3.7). Approximately 20-30 bats were sampled in a night. No bats should be kept for more than 6 hours.

Figure 3. 7 Bags containing bats hung in draw-string cloth bags on a raffia string between two pillars

Bats were sampled and identified according to the USAID Emerging Pandemic Threats PREDICT Operating Procedures with some modifications (Hoffmann et al., 2010; PREDICT One Health Consortium, 2016a; C. Smith et al., 2010). Bat was removed from the cloth bag and manually restrained for sampling using leather gloves. In bats that were >100g, a non-heparinised syringe was used to collect blood from the cephalic vein, brachial vein or saphenous vein. Blood was then placed in a serum vacutainer tube containing serum-clotting factor and centrifuge. Extracted serum was placed into 2 cryovials of a minimum of 60 μ l if volume. If bats were <100g, the tip of a sterile 25G needle was used to puncture the brachial or propatagial vein (C. Smith et al., 2010).

A 1:10 serum dilution (10µl blood into 90µl PBS) was centrifuged, and the supernatant was transferred into a new cryovial tube. Cryovial tubes was labelled appropriately and placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to proper cold chain methods.

Figure 3. 8 Blood sampling from the cephalic vein of a bat by aspirating the drop of blood using a pipette.

Morphometric measurements and photographs of each bat were taken during the sampling procedure for the purpose of species identification. Identification of bat species was performed by an experienced rangers and field veterinarian based on the morphology and biometric measurements. Guide books were used for identification of bats on the field (Francis, 2008; Kingston et al., 2006; Payne et al., 1985; Phillipps & Phillipps, 2016).

Age of bats were classified according to adult, subadult and juvenile based on sexual characteristics and size. Males with descended testis and relative body size were considered adults while those with unfused epiphyses and undescended testis were considered subadults. Female bats with prominent nipples, were pregnant or lactating, relative body size and complete fusion of the phalangeal symphysis are classified as adult while those that were fully grown with unfused epiphyses were considered subadults. Pregnancy status was identified by gently palpating the abdomen and lactating status were identified by attempting to express milk from the teats. Bats that were small, clinging to dam and suckling were considered juveniles.

Typically, sampling per bat took less than 15 minutes with one person handling and performing the morphometric measurements, while the other person focused on the sampling. Bats nails were painted with a red nail polish as identification in case of recapture. Frugivorous or nectivorous bats were fed with approximately 1ml of 100% fruit juice or honey water prior to release. Bats were released after sampling.

3.2.5.2 Sampling of rodent and other small mammal

Rodents and other small mammals were trapped and sampled according to the USAID Emerging Pandemic Threats PREDICT Operating Procedures with some modifications (Aplin et al., 2003; Hoffmann et al., 2010; Mills et al., 1995; PREDICT One Health Consortium, 2016d, 2016e). Further description on the sampling technique is in

Appendix X. A total of 100 traps were used to trap rodents which encompasses 45 Sherman traps, 45 small Tomahawk for smaller mammals such as mice, rats, tree shrews and 10 large Tomahawk traps for larger mammals, such as civet (Figure 3.9).

Figure 3. 9 Sorting of 100 rodent traps according to transect lines before deployment

Sites for traps were first surveyed and divided between inside farm or nearby plantation or forest. Transect lines were used for placement of traps as opposed to grid to reduce overlapping and increase sampling area coverage and increase chance of capturing more species through coverage of small mammal home ranges and microhabitats (Pearson et al., 2003).

Traps containing appropriate baits were placed at strategic pathways for rodents (Figure 3.10). Oil palm fruit was the preferred option as it does not attract insects. Traps were placed at the same sites for a minimum of 3 consecutive nights from 6pm to 8am the next day. If adverse weather such as heavy rain is expected, traps will not be opened for that night.

Figure 3. 10 Placement of rodent trap by the fences in a farm

Figure 3. 11 Roasting of oil palm fruits that were used as baits for rodents

Trapped small mammal were gently transferred into a draw-string cloth bag by covering the bag over the opening of the trap and slightly tilting the trap downwards. Animals that were too stressed will be released, while animals found to be injured or weak will be brought back to sampling base for veterinary treatment.

Smaller rodents were removed from the bag gently and placed in a modified container for anaesthetic induction. Whereas, in small mammal species like civets, a gas mask was used for induction without completely removing animal out from the bag to reduce stress (Figure 3.12). Once animal is motionless and unresponsive, it is taken out and placed on the table with an appropriate fitting face mask for continue induction or

maintenance of anaesthesia. Monitoring of animal was performed by a veterinarian throughout during procedure along with a basic physical examination to assess health status.

Figure 3. 12 Induction of general anesthesia using isoflurane in a small Indian civet (*Viverricula indica*)

Blood samples were collected from the lateral tail vein, ventral tail artery or lateral saphenous vein or lateral saphenous vein in rodents and other small mammals (Hem et al., 1998; Lee & Goosens, 2015; Mills et al., 1995; Office of the University Veterinarian, 2017a; PREDICT One Health Consortium, 2016d). In smaller rodents, approximately 1ml of blood was collected, and in larger small mammals (~200g), 3-5ml of blood was collected. Blood collected was placed into 1:10 PBS and spin to collect serum. Subsequent steps in processing and storage are as mentioned in 3.2.5.1.

After blood collection, fluid volume replacement was given subcutaneously using Lactated Ringer's or 0.9% NaCL solution to avoid hypovolemic shock. Marking on sampled rodent or small mammal is done by clipping 3-5mm of hair at the right ventral thigh. Morphometric measurements and photographs of each animal were taken during the sampling procedure for the purpose of species identification.

Age was classified into adult, subadult and juvenile based on secondary sexual characteristics and size. Adults are fully grown with adult pelage and is sexually mature. Subadults are not fully grown with developing pelage and may or may not be sexually mature. Juveniles are smaller than subadults and not sexually mature with grey and soft pelage (Hoffmann et al., 2010). Animals were monitored in a small cage until fully recovered from anaesthesia before release at place of capture.

3.2.5.3 Sampling of Wild boar

Wild boar were sampled according to established protocols (Office of the University Veterinarian, 2017b, 2017c; PREDICT One Health Consortium, 2016b). Further description on the sampling technique is in **Appendix X**. Wild boar was trapped according to trapping protocol described for rodent and other small mammals. It is transported to sampling base in the cage for sampling (**Figure 3.13**).

Figure 3. 13 A subadult wild boar in a Tomahawk trap from an oil palm plantation

Wild boar is sedated with by creating an anaesthetic chamber for induction and maintained with a gas mask. Monitoring of anaesthesia was performed by a veterinarian throughout during procedure. Blood samples were collected from the anterior vena cava and is distributed equally in a BD Vacutainer® serum tube and an EDTA tube. Processing of blood for serum extraction and storage were similar to previously mentioned in 3.2.4. After blood collection, fluid volume replacement was given subcutaneously using Lactated Ringer's or 0.9% NaCL solution. A basic physical examination was performed by veterinarian to access health status. Morphometric measurements and photographs of each animal were taken during the sampling procedure for the purpose of species identification.

Wild boar was classified into adult, subadult and juvenile based on secondary sexual characteristics and size. Adults are fully grown with adult pelage and is sexually mature. Subadults are not fully grown with developing pelage and may or may not be sexually mature. Juveniles are smaller than subadults and not sexually mature with grey and soft pelage (Hoffmann et al., 2010).

3.2.5.4 Sampling of Non-human primate

Non-human primates (NHP) were kept as pets hence trapping was not required. NHP were anaesthetized and sampled upon the agreement of its owner according to established protocols (Hoffmann et al., 2010; PREDICT One Health Consortium, 2016c). Further description on the sampling technique is in [Appendix X](#). Briefly, aesthesia drug used to sedate animals were the combination of: 1) 4mg/kg Ketamine and 0.15mg/kg Xylazine with Yohimbine 1:1 as reversal agent for Xylazine, or 2) Tiletamine-Zolazepam, Zoletil® 3-5mg/kg in more aggressive primates. A dart syringe and blowpipe were used to deliver anaesthetic drug intra-muscularly by an experienced and trained ranger. Anaesthetic monitoring was performed by a veterinarian. After immobilization, basic physical examination was performed. A sterile lubricant is placed into animal's eyes to prevent corneal drying or scratches during sedation.

NHP is placed in a supine position. Blood is withdrawn from femoral vein located in the inguinal region lateral and parallel to the femoral artery ([Figure 3.14](#)). Three to five ml

of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube. Processing of blood for serum extraction and storage are similar to previously mentioned in 3.2.4.

Figure 3. 14 Sampling of an anaesthetized pig-tailed macaque (*Macaca nemestrina*)

Photographs of the anterior and ventral view of the full body, anterior and lateral face, upper and lower dentition and genitalia were taken for future reference. Age was classified to 7 age class according to the PREDICT Operating Procedures for Non-Human Primates. Neonates are animals that show signs of being born within few days; infants are young that were still suckling and clinging on to mother; juveniles are mostly independent from mother, sexually immature and have not developed into adult size; immature primates are individual that have not sexually mature, subadults are fully independent, appears sexually mature but has not fully grown into adult size; adults are fully grown size with sexually mature sexual characteristics; old adults are adults with

signs of age degeneration. Monitoring is done from a safe distance until NHP is fully awake and ambulatory.

3.2.6 Sampling of Human

Human samples were collected from farmers in participating cattle farms. Sample size was limited to 10 farmers per farm due to logistical and budget constraints. Individuals were recruited based on their willingness to participate, were above 18 years old and have worked or assisted with handling of animals in participating farms. Individuals were recruited based on recommendations from the farm owner.

Human sampling was conducted by district health officers from Ministry of Health, Malaysia and staffs of EcoHealth Alliance in accordance to USAID Emerging Pandemic Threats PREDICT Operating Procedures (Huppenthal, 2009; C. K. Johnson & Saylor, 2016). A written informed consent from the participant was obtained for biological sampling collection and questionnaire. Participants were explained about the study objectives and that the biological testing is exploratory and not diagnostic for their health, the types of question asked, duration of questionnaire and potential risks of their participation. They were also informed that the study was voluntary and anonymous in nature.

Biological sampling and questionnaire were conducted in a convenient, comfortable and private environment. Further description on the sampling is in Appendix X. Briefly, blood was taken from the median cubital vein on the upper limb or metacarpal plexus or the dorsal venous arch on the dorsal surface of the hand. Three ml of blood were taken from these animals and distributed equally in a BD Vacutainer® serum tube and EDTA tube. Processing of blood for serum extraction and storage are similar to previously mentioned in 3.2.4.

3.2.7 Data collection

Following biological sampling, interviews with farmers were conducted using questionnaire designed to gauge exposure or behavioural risks to zoonotic spillover events. The questionnaire has been approved for used by the Institutional Review Board for studies on human research subjects and has been verified in previous studies (Kamau et al., 2021; Li et al., 2019; The PREDICT Consortium, 2021). The questionnaire was designed into several parts to gather information on participants' demographics, exposure to different species of domestic animal and wildlife, forms of exposure to domestic animal and wildlife, reported unusual illnesses within the past year. The questionnaire took less than 30 minutes to be completed and were administered by trained EcoHealth Alliance staffs in Malay language.

Data for livestock, other domestic animals and wildlife were recorded accordingly during the sampling process as described above. Table below shows the data collected for each species (Table 3.2).

Table 3. 2 Types of data collected during sampling of animals and human from participating cattle farms located at the forest fringe in Perak and Kelantan, Malaysia

Species	Data collected
Livestock/Dogs	Date of sampling, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal classification (domestic, feral domestic, captive wild, wild), species scientific name, species' English name, breed, farm location GPS coordinates, husbandry, ecological setting, other animals at site, tag number, sex, pregnancy status, lactating status, descended testes, age class, age, age in captivity, health condition during sampling, presence of ectoparasite, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, GPS coordinates of sampling base
Rodent/Small mammal/Non-human primates/Wild boar	Date of capture, time of trap check, trap ID and type, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal taxa, species scientific name, species' English name, sex, pregnancy status, lactating status, descended testes, age class, health condition during sampling, presence of ectoparasite, morphometric measurements (body length, right ear height, right hind foot, tail length), recapture marking, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, GPS coordinates of traps, GPS coordinates of sampling base
Bats	Date of capture, time of capture, GPS coordinate of net, weather (clear, cloudy, rain), moon (full, half, new moon), weight, animal taxa, species scientific name, species' English name, sex, pregnancy status, lactating status, descended testes, age class, health condition during sampling, presence of ectoparasite, morphometric measurements (forearm or radius length, body length, ear length, hind foot length, tail length), recapture marking, notes (special characteristics/health status/injury/body condition), specimen type, specimen collected, volume of serum dilution, of traps, GPS coordinates of sampling base
Human	Participant ID, site location, GPS coordinates, date of sampling, body temperature, blood pressure, pulse, weight, height, obvious signs of illness, age, sex, ethnicity, education level, years of residence in village, frequency of entering forest, exposure to different species of domestic animal and wildlife (primate, bat, rodent, small mammal, wild boar, wild bird, swine, cattle, dog, cat, goat, chicken, others), forms of exposure to domestic animal and wildlife (1. General exposure: lived with pet, handled live animals, raised animals, share water source with animals, seen faeces in or near food, animal entered house, eaten food damaged by animal, scratched or bitten by animal; and 2. Exposure to wildlife: cook or handle recently slaughtered meat, offal or blood of wildlife, eaten raw or undercooked meat, offal or blood of wildlife, eaten wildlife of unknown health status, eaten or shared dead wildlife, collect and sell dead wildlife, slaughter or butcher wildlife), reported unusual illnesses within the past year (fever with headaches and lethargy @ encephalitis, haemorrhagic fever and rash, severe acute respiratory infection (SARI),

3.2.8 Luminex Serology

Serum samples from all species of animals and from humans were analysed using a Luminex bead-based multiplex microsphere assay in a Bio-Rad Bio-Plex 200 (Bossart et al., 2007). This is an assay derived from the Luminex xMAP (xMAP = multianalyte profile) technology based on flow-cytometry principles which allows high-throughput, multiplex and simultaneous detection of up to 500 analytes in a 96-well plate. Since its invention in the late 1990s, this technology has been extensively used for detection of viral, bacterial, parasitical and fungal agents (Reslova et al., 2017). It has also been used increasingly for seroprevalence study of filoviruses and henipaviruses globally (Chowdhury et al., 2014; Dovih et al., 2019; Hayman et al., 2008; Laing et al., 2018; Peel et al., 2013b).

Filoviruses viral envelope glycoproteins (GPs) and henipaviruses receptor-binding proteins (G) were coupled to 5.6 µm diameter polystyrene magnetic beads for antigen-antibody binding. The list of filoviruses and henipaviruses tested are as shown in **Table**

3.3.

Table 3. 3 Filoviruses and Henipaviruses conjugated Bio-Plex beads used in multiplex assay for antibody detection.

Filoviruses (GPs)	Henipaviruses (Gs)
EBOV, Ebola virus	HeV, Hendra virus
BDBV, Bundibugyo virus	NiV, Nipah virus

BOMV, Bombali virus	CedV, Cedar virus
SUDV, Sudan virus	MojV, Mojiang virus
MLAV, Mengla virus	GhV, Ghana virus.
RESTVm, Reston virus monkey isolate	
RESTVp, Reston virus pig isolate	
LLOV, Lloviu virus	
MARV, Marburg virus	
RAVV, Ravn virus	

Prior to testing, individual samples were diluted 1:100 in phosphate-buffered saline (PBS) in 1.5ml Eppendorf tube and vortexed briefly to mix followed by heat inactivation at 56°C for 30 mins. A duplicate of a 100 µl diluted sera were added into 96-wells plate containing 100µl of bead master mix containing specific sGP- and sG-coated beads. Mixture is covered with plastic shield and aluminium foil and incubated on a shaker for 1200 r.p.m for 1 minute followed by 900 r.p.m for 45 minutes. Samples were washed to remove unbound antibodies three times and incubated on shaker with 100µl mastermix of 1:1000 biotinylated-Protein A and biotinylated Protein G (Thermo Fisher Scientific, Waltham, MA, USA) in PBS-Tween 20 (0.05%) (Bio-Rad). Mixture was washed three times and lastly incubated on a shaker with 100µl 1:1000 streptavidin-phycoerythrin (PE) in into each well and shook for 10 minutes. Results are read on Bio-Rad Bio-Plex 200 with at least 50 per spectral region and reported as Median fluorescence intensities (MFI). Cut-off values in the first round of testing at dilutions 1:100 were determined by 3*Sigma (3-fold change of the mean of adjusted MFI values or above the mean plus 3 standard deviations) (Dovih et al., 2019).

Positive samples in the first round were rerun at the optimum dilutions of 1:400 and 1:500 with added positive and negative controls. Sera from EBOV infected bats were used as positive controls for EBOV. Negative rabbit polysera and PBS were used as negative controls. Antigen-antibody binding were measured and read using a Bio-Plex 200 system. Data were transformed to adjusted MFI values by taking the mean MFI values duplicates of each sample and subtracting average PBS MFI per plate.

Cut-off were determined by using 3*Sigma and Latent cluster analysis (LCA). LCA was used in absence of gold standard assays and lack of positive and negative reference samples for the viral and animal species tested (Peel et al., 2013a). To improve cut-off determination, MFI values from local samples collected as part of the research programme were combined with this study dataset. Serum samples above the cut-off values were considered seropositive. The 3*Sigma cut-off values for filoviruses and henipaviruses were determined to be 4182 MFI and 4641 MFI respectively. LCA for filoviruses and henipaviruses were attempted but were not possible due to insufficient samples reactive samples.

3.2.9 Data Analysis

Serodetection of filoviruses and henipavirus for different species were calculated based on the number of seropositive animals over the total number of sample and reported as percentage (%). The association between the serological evidence and determinants

from animals (such as, farm, sex, age, age class, species, reproductive status and health status) and humans (such as, farm, husbandry, sex, age range, ethnicity, education level, years of residence in village, frequency of entering forest, exposure to different species of domestic animal and wildlife, forms of exposure to domestic animal and wildlife, reported unusual illnesses within the past year) were analysed using Pearson Chi-Square test, X^2 or Fisher's exact test (two-tailed), when X^2 is not appropriate (one of expected cell value is less than 5) at significance level $\alpha = 0.05$. Post-hoc test Bonferroni corrections and Bonferroni adjusted p-value were used for multiple comparison. Odds ratio (OR) and OR 95% Confidence intervals (CI) with Haldane-Anscombe correction were applied when contingency table has values of 0. The difference between seropositivity and hypothesized risk factors were tested using Kruskal-Wallis, KW (more than two groups) test at $\alpha=0.05$ and post-hoc Dunn's test was applied if applicable. Variable was excluded from further analysis if data is insufficient or too small ($n<10$). All analysis were conducted using the Statistical Package for Social Sciences (SPSS 27) and Microsoft Excel.

3.3 Results

3.3.1 Population characteristics

3.3.1.1 Domestic animals

Six forest-fringed cattle farms were enrolled in the study in 2018 from Kuala Kangsar district, Perak and Gua Musang district, Kelantan. Serum samples were collected from farmers ($n=55$), cattle ($n=156$), goat ($n=158$), sheep ($n=11$), dogs ($n=23$), bats ($n=265$),

rodents (n=36), civet (n=1), wild boar (n=1), rabbits (n=3) and non-human primates (n=2). In total, 709 serum samples were collected.

Cattle were mostly sampled from integrated cattle farms (Table 3.13). Other domestic animals such as goats and sheep were mainly sampled from semi-intensive goat and sheep farms (Table 3.14 and 3.15). Dogs sampled were either tethered or free-roaming in the village or plantation (Table 3.16). Besides these animals, a pet rabbit was also sampled. Majority of the farm animals sampled were adults.

3.3.1.2 Wildlife

A total of 265 bats that were sampled during the study with an average of 44 (25-56) bats sampled per farm. Out of 9 species captured, 6 species were frugivores or nectarivores and 3 species were insectivores. Species that were most sampled were mostly adult male *C. brachyotis* (n=108), *E. spelaea* (n=70) and *C. horsfieldii* (n=52) (Table 3.17).

	<i>Rattus rattus</i>	1
	<i>Rattus tiomanicus</i>	7
	<i>Sundasciurus lowii</i>	1
	<i>Tupaia glis</i>	1

Other wildlife sampled were pet macaques (n=2), a wild boar (n=1) and a civet, *Viverricula indica* (n=1).

3.3.1.3 Human

A total of 56 farmers from participating cattle farms were enrolled but only 55 samples were obtained. An average of 9 farmers were sampled from each farm. Majority sampled were male, between 20-29 years old, with mean age of 42 (18-68) of the Malay race. Most have completed secondary school or above and have resided in the village for more than 10 years (51/55, 92.7%) (Table 3.19).

The most common domestic animals that farmers were exposed to within the past one year of sampling were cattle, cat and poultry. Whereas the most common wildlife exposed to were rodents and bats (Table 3.120). Farmers had general exposure to domesticated animals and wildlife in the past one year primarily through handling of live animals, animal entering living quarters and living with pet. Farmers were exposed to wildlife primarily through slaughter, butchering, cooking and handling of recently slaughtered meat, offal or blood of wildlife (Table 3.21).

Out of the 55 farmers, many farmers reported Influenza-like illnesses (ILI), followed by fever with diarrhoea and vomiting, Severe acute respiratory infection (SARI), fever with headaches and lethargy (3/55, 5.5%), and fever with skin rash (1/55, 1.8%). No farmers reported haemorrhagic fever (Table 3.22).

3.3.2 Serological result

3.1.1.1 Filovirus

A total of 45 sera were reactive to filovirus (%??). The serological detection for filovirus among species in descending order were goat (15.2%, 95% CI 10-22), sheep (9.1%, 95% CI 0.2-41.3), human (9.1%, 95% CI 3-20), dog (8.7%, 95% CI 1.1-28), cattle (5.1%, 95% CI 2.2-9.9) and bat (1.9%, 95% CI 0.6-4.3) (Table 3.6, Figure 16-22). Bats species that were seropositive for filovirus were *C. brachyotis*, *E. spelaea* and *C. horsfieldii* (Table 3.7).

Most filovirus reactive samples were reactive to BDBV (29/45) followed by SUDV (16/45) and RESTV (16/45) (Table 3.8). Twenty-three (23/45, 51%) samples were reactive to only one antigen, with the most being BDBV (16/23), followed by EBOV (4/23), RESTVp (2/23) and SUDV (1/23). Whereas twenty-two (22/45, 48.9%) samples were reactive to two to five filovirus antigens which involved BDBV, SUDV, RESTVp the most. Cross-reactivity were observed between EBOV, BDBV, BOMV, SUDV, RESTVm, RESTVp, MARV, and RAVV (Appendix).

3.1.1.2 Henipavirus

A total of 36 sera were reactive to henipavirus. The reactive sera were in goat (13.9%, 95% CI 8.9-20.3), sheep (9.1%, 95% CI 0.2-41.3), human (7.3%, 95% CI 2-17.6), dog (4.3%, 95% CI 0.1-21.9), cattle (3.2%, 95% CI 1.0-7.3) and bat (1.1%, 95% CI 0.2-3.3) (Table 3.10 and Figure 3.23-29). Bats seropositive for henipavirus were *C. brachyotis* and *C. horsfieldii* (Table 3.11).

Most samples were reactive to GhV (32/36), HeV (22/36), NiV (19/36), CedV (9/36) and MojV (7/36) (Table 3.11). Eleven (11/36, 31%) samples were reactive to only one antigen, with the most being GhV (9/11), followed by MpjV (2/11). Twenty-two (25/36, 69.4%) samples were reactive to two to five henipavirus antigens which involved GhV,

HeV and NiV the most. Cross-reactivity were observed between all five antigens tested (Appendix).

Table 3. 12 Reactivity with henipavirus across species using Luminex bead-based multiplex microsphere assay

	Total sampled	Total reactive	Reactivity with henipavirus, n (%)

HeV, Hendra virus; NiV, Nipah virus; CedV, Cedar virus; MojV, Mojiang virus; GhV, Ghana virus.

The range of MFI for henipavirus positive sera was between 4182 and 24689 with the highest being 24689 MFI against GhV in a farmer. There were 39 reactions with an MFI reading of 10000-19999 MFI (HeV, NiV, CedV, and GhV), and 5 reactions of >20000 MFI (HeV, CedV, MojV and GhV). Goat sera displayed many high MFI readings of >10000. In general, almost all henipavirus reactive sera had reactivity to GhV with many being >10000 MFI. (Table 3.13 and Appendix).

Table 3. 13 Henipavirus range of MFI of positive sera, number of high reactivity and its antigen among different species using Luminex bead-based multiplex microsphere assay

3.3.3 Serological evidence and demographic distribution

3.3.3.1 Cattle

The serological evidence of filovirus and henipavirus in cattle were 5.1%, 8/156 (95% CI 2.2-9.9) and 3.2%, 5/156 (95% CI 1.0-7.3) respectively. Among the filovirus positive (8/156) and henipavirus positive (5/156) cattle sera, most were female, adults and apparently healthy and had no observable ectoparasite at the time of sampling. No significant difference was observed between serological evidence of filovirus or henipavirus with husbandry, sex, age class and health status (Table 3.14).

Table 3. 14 Serological evidence of filovirus and henipavirus in cattle based on farm, sex, age class, reproduction status, health status and presence of ectoparasite

3.3.3.2 Goat

The serological evidence of filovirus and henipavirus in goat were 15.2%, 24/158 (95% CI 10-22) and 13.9%, 22/158 (95% CI 8.9-20.3) respectively. Among the filovirus positive (24/158) and henipavirus positive (22/158) goat sera, most were semi-intensively reared, female, adults and apparently healthy. Subadult goats were 6.3 times less likely to be seropositive for filoviruses as compared to adults (P= 0.028, OR=6.3, 95% CI=1.149, 34.383). No significant difference was observed between serological evidence of henipavirus and the various factors (Table 3.15).

3.3.4 Sheep

The serological evidence of filovirus and henipavirus in sheep were 9.1%, 1/11 (95% CI 0.2-41.3) for both. Out of 11 sheep sampled, only one sheep was seropositive for filoviruses and henipaviruses. The sheep was a female pregnant and lactating adult that was raised extensively, and apparently healthy (Table 3.16). Further analysis with the variables were not performed due to insufficient or too small data.

3.3.5 Dog

The serological evidence of filovirus and henipavirus in dog were 8.7%, 2/23 (95% CI 1.1-28) and 4.3%, 1/23 (95% CI 0.1-21.9) respectively. Filovirus positive dog (2/23) were adult and subadult tethered males. Whereas henipavirus positive dog was an adult male raised extensively. All filovirus and henipavirus positive dogs were apparently healthy with no observable ectoparasite at time of sampling. Further analysis with the variables were not performed due to insufficient or too small data (Table 3.17).

3.3.6 Bat

The serological evidence of filovirus and henipavirus in bat were 1.9%, 5/265 (95% CI 0.6-4.3) and 1.1%, 3/265 (95% CI 0.2-3.3) respectively. Majority of the filovirus positive (5/265) and henipavirus positive (3/265), bat sera were adult females that were apparently healthy (Table 3.18). Seropositivity was detected in 3 bat species (*C. brachyotis*, *E. spelaea* and *C. horsfieldii*). Further analysis with the variables were not performed due to insufficient or too small data.

3.1.1.1 Human

The serological evidence of filovirus and henipavirus in human were 9.1%, 5/55 (95% CI 3-20) and 7.3%, 4/55 (95% CI 2-17.6) respectively. Humans positive for filovirus (5/55) and henipavirus (4/55) were mostly males of Malay ethnicity, completed secondary level education and have resided in village for more than 10 years. No significant difference was observed between serological evidence of filovirus or henipavirus with the various factors (Table 3.19).

Filovirus and henipavirus serologically positive humans reported exposure to cat, cattle, poultry, goat, rabbit, rodent, wild bird, bat and deer. One henipavirus positive human had exposure to non-human primates. No significant findings were found between serological evidence of filovirus and henipavirus and exposure to different animal species (Table 3.20).

^aVariable is excluded from further analysis due to insufficient or too small data

A majority (26.7%, 4/15) filovirus seropositive humans have eaten food damaged by animals. Those that consumed food damaged by animal were 10 times more likely to be seropositive for filovirus compared to those who have not (P=0.017, OR=10.3, 95% CI=1.45, 73.24). For henipavirus, there was no significant association between seropositivity to the different forms of exposure to various animal species. However, there is a meaningful increase of risk for consuming food damaged by animal (P=0.057) and eating raw or undercooked meat, offal or blood of wildlife (0.097) (Table 3.21).

Table 3. 21 Serological evidence of filovirus and henipavirus in human based on different forms of exposures to animals and wildlife in the past year

^aVariable is excluded from further analysis due to insufficient or too small data

*Humans that consumed food damaged by animal were more likely to be seropositive for filovirus (P=0.017, OR=10.3, 95% CI=1.45, 73.24).

Most farmers reported have had symptoms of Influenza-like illnesses (ILI) in the past one year. A few filoviruses and henipavirus seropositive farmers also reported other symptoms such as severe acute respiratory infection and fever with diarrhea and vomiting (Table 3.22). However, bivariate analysis between seropositivity and reported symptoms were not performed due to insufficient data for meaningful analysis.

Table 3. 22 Seroprevalence of filovirus and henipavirus in human based on symptoms experienced by farmers in participating cattle farms within the past year

3.4 Discussion

In this study, domestic animals and wildlife in and around forest-fringe cattle farms were tested for exposure to the family filoviruses and the genus henipaviruses using Luminex bead-based multiplex microsphere assay. This technology has been developed and widely used for screening of viruses globally (Chowdhury et al., 2014; Dovih et al., 2019; Hayman et al., 2008, 2011; Laing et al., 2018; Peel et al., 2013b) but is not meant for diagnostic determinations. The findings can be used to target areas of surveillance for emerging pathogens but should not be used for policy decisions such as trade, quarantine or culling (MacNeil et al., 2011; Peel et al., 2013a). Serologically positive samples may indicate positivity to the tested virus or to antigenically related viruses. Antigenically related viruses share similar epitopes on its surface antigenic molecule that stimulates binding to antibodies or T cell receptor (Frank, 2020). Phylogenetically closely related viruses has higher epitope amino acid sequence similarity and binding to similar antibodies which result in cross-reactivity of antibodies (Brangel et al., 2018; Marsh et al., 2012; Schuh et al., 2019). Further testing and confirmation is necessary using virus neutralisation test (OIE, 2018).

Filovirus

Study found serological evidence for filoviruses is highest in goat (24/158, 15.2%), sheep (1/11, 9.1%), human (5/55, 9.1%), cattle (5/156, 5.1%) and lowest in bat (5/265, 1.9%). Seropositivity indicates evidence of past exposure to specific viruses

antigenically related to filoviruses. Studies on filoviruses in domestic animals has been scarce. Only dogs and pigs have been demonstrated to be infected with filoviruses (Allela et al., 2005; Chowdhury et al., 2014). In Gabon, 28% of dogs from Ebola epidemic areas were found to be IgG positive for Ebola virus (Allela et al., 2005). Meanwhile, Reston ebolavirus (RESTV) was identified in a spillover event between pigs and human in the Philippines and later in sick pigs in China (Barrette et al., 2009; Pan et al., 2014). To our knowledge, this study is the first to report evidence of exposure to filoviruses in cattle, goat and sheep. This is also the first evidence of exposure of filoviruses in human and dogs beyond Africa.

Highest seropositivity was reported among goats in this study particularly in semi-intensively reared goats which were 4 times more compared to cattle. The reasons for this may need further exploration however we suggest a few reasons for this findings: 1) Goat is known to browse extensively relative to other species (Hofmann, 1989; Rutagwenda et al., 1989) and have the habit of sampling wide ranges of items (edible and non-edible), therefore may increase their risk of exposure to multiple disease agents; 2) Many of the seropositive goats reported in this study were managed semi-intensively to browse freely around village and raised in close proximity where flowering and fruiting trees are abundant which attracts bats such as *C. brachyotis* (V. C. Lim et al., 2017; Tan et al., 1998). Goats are very likely to pick up partially eaten fruits consistent with their feeding behaviour therefore increases risk of contracting multiple disease agents.

Seropositivity of bats in this study is lower than previous reports of bats in this region. Local *P. hypomelanus* reported 10% and 5% reactivity to filoviruses closely related to EBOV and SUDV respectively (Laing et al., 2019). Study from neighbouring country, Singapore reported 9.1% (17/186) in *E. spelaea*, 8.5% (13/153) in *C. brachyotis* and 4.3% (3/70) in *P. lucasi*. Besides *E. spelaea* and *C. brachyotis*, *C. horsfieldii* was seropositive for filoviruses in our study. *Cynopterus sp.* and *E. spelaea* are adaptive species that occupy a range of habitats from orchards, plantations, primary and secondary forests and urban sites (Campbell et al., 2004; Fukuda et al., 2009; Heidenan & Heaney, 1989; Kitchener et al., 1990; V. Lim, 2018; Tan et al., 1998). Livestock farming in rural and sub-rural areas where fruit trees are plenty provides bat roosting and foraging areas (Fukuda et al., 2009). This overlapping spatial distribution of bats and livestock increase risk of viral spillover to livestock and agricultural workers (Mikail et al., 2017). Longitudinal spatial-temporal distribution studies will ascertain the level of such risk (Zhao et al., 2022).

Antibody reactivity to specific filovirus antigen in our study suggests that circulating filovirus in this region is predominantly more closely related to BDBV, SUDV, EBOV, RESTV and less so with BOMV, MARV, and RAVV. Reactivity to filoviruses closely related to EBOV, BDBV and SUDV corresponds to a similar study in Singapore bats (Laing et al., 2018). However, in contrast to that study, we report a considerably high number of reactivity to antigenically related but not identical to RESTV-pig in a *C. brachyotis* and many goats. RESTV is a zoonotic Asiatic filovirus responsible for sporadic cases in non-

human primates, pigs and human (Barrette et al., 2009; CDC, 1993; Demetria et al., 2018; Miranda et al., 1999). Bats may be natural reservoirs for RESTV in the Philippines, Bangladesh and China (Jayme et al., 2015; Olival et al., 2013; Taniguchi et al., 2011; Yang et al., 2017). Finding of our study suggests direct transmission of RESTV-related viruses from bats to goat. Detection of RESTV genome is necessary to confirm spillover.

Henipavirus

Seropositivity to henipaviruses was highest in goats (13.9%), sheep (9.1%), human (7.3%), dog (4.3%), cattle (3.2%) and bat (1.1%). Seropositivity indicates evidence of past exposure to viruses antigenically related to henipaviruses. Our result is supported by several studies. Surveillance of NiV in human outbreak areas near Pteropus sp. bat roosts in Bangladesh using the Luminex platform found that 6.5% (26/400) of cattle and 4.3% (17/400) of goats were positive for henipavirus (Chowdhury et al., 2014). During the Nipah virus outbreak in Malaysia, dogs sampled near infected pig farms had detectable antibodies for Nipah virus (Mills et al., 2009; Yob, Field, et al., 2001). Since 2001, NiV have not been reported in domestic animals and wildlife locally using ELISA (Fikri et al., 2011; Naama et al., 2013). This study is the first report that uses Luminex technology of henipavirus infection in dogs since 1999 and in local cattle, goat and sheep. Reported seropositivity of henipaviruses in goats was high at 13.9% (22/158) particularly in semi-intensively reared goats and was 4 times more as compared to cattle 3.2% (5/156) for hypothetical reasons of risk of exposure to infectious materials as explained before.

Previous survey of bats in Malaysia were mostly focused in the *P. vampyrus* and *P. hypomelanus* species as reservoirs for Hendra virus and Nipah virus with a reported seroprevalence of 1-33% (Rahman et al., 2013; Yob, Jamaluddin, et al., 2001). Those studies used indirect ELISA and serum neutralization test to detect the antibodies against Nipah virus in samples. A recent survey using multiplex serological assay in the local *P. hypomelanus* bats samples found 25% reactivity to NiV (Laing et al., 2019). The reported seroprevalence in our study of 1% (2/108) in *C. brachyotis* and *C. horsfieldii* 2% (1/52) is much less than that of Laing et al. (2109) *Pteropus sp.* surveys and are comparable to the seroprevalence of 4% (2/56) in *C. brachyotis* and 5% (2/38) in *E. spelaea* in a separate study in 1999 (Yob, Field, et al., 2001).

Antibody reactivity to specific henipavirus antigen in our study suggests that circulating henipavirus in this region is predominantly more closely related to GhV, HeV, NiV and less so to CedV and MojV. The MFI values for GhV is high and many cross-reacted with other henipaviruses. Presently, little is known about GhV which was first detected in African bats and is the only African henipavirus (Drexler et al., 2009, 2012). GhV is also antigenically closer to ancestral henipaviruses (Pernet et al., 2014). Thus, reaction to GhV in our study indicates prevalence of henipavirus more antigenically related to the ancestral GhV than the other Asiatic viruses.

Interestingly, our study found two reactions only to MojV with no cross-reactivity in a cattle and dog from the same intensive cattle farm. MojV is a rodent henipavirus discovered in anal specimens of *Rattus flavipectus* in Southern China. This novel virus was identified in the same cave 6 months later where three patients died of respiratory illness of unidentified aetiology. MojV pathogenicity remains to be determined due to the absence of isolate (Wu et al., 2014). Cattle and dog may have acquired MojV closely related virus through contact with rodent excrement. Rodents are probable reservoir hosts or amplifying host for MojV (Cheliout et al., 2021). Increasing the sample size of rodents to detect antibodies and genome of MojV or MojV-like virus will improve chances of detection and determine its circulation locally.

Risk Factors

We detected exposure against viruses antigenically related to filoviruses, EBOV, BDVD and RAVV; and henipaviruses HeV, CedV, MojV in humans. Our study found those that consumed food damaged by animal were more 10 times more likely to be seropositive for filovirus. This is supported by the study by Adjemian et al., amongst febrile tribesmen presented to healthcare facilities in Uganda. Increased risk of filovirus infection was observed in activities such as hunting (37.5 times), touching (5.6 times) or eating wildlife (10.7 times) (Adjemian et al., 2011). Likewise, bushmeat slaughtering or working closely with infected pigs or horse enhanced risk of henipavirus infection (Chua, 2010; Pernet et al., 2014; Rogers et al., 1996). The finding is expected because the both viruses are transmitted via direct contact with body fluids (Amal et al., 2000;

Bausch et al., 2007; O'Sullivan et al., 1997; Saéz et al., 2015; Williamson et al., 1998). Therefore, poor hygiene practices or improper personal protective equipment may expose farmers to infectious materials, especially when handling sick or infected animals, animal waste or carcasses.

Approximately half of the humans sampled (21/55) reported Influenza-like illnesses (ILI), fever with diarrhoea and vomiting, fever with headaches and lethargy and severe acute respiratory infection (SARI) symptoms within the past year of survey. Half of the seropositive human for filovirus and/or henipavirus in our study had reported one of the symptoms in the past year, while the other half did not. The symptoms can be due to several multitude of reasons, unfortunately causal relationship between viral infection and symptoms in our study cannot be ascertain without clinical and longitudinal data. Syndromic surveillance incorporating important pathogens at the family or genus level will improve early detection and appropriate intervention.

The catastrophic Nipah outbreak in 1998 is a turning point for cross-sectoral ministerial integration in managing zoonotic disease and recognition that the country is susceptible to spillover of pathogenic viruses (Chua, 2003). Unfortunately, at present, novel or emerging viral surveillance in animal population is sporadic and scanty; usually linked to specific research endeavour. The ecological concerns and agricultural intensification in Malaysia strongly indicate the need for regular monitoring and

surveillance of livestock and humans working in close proximity to animals especially those that are located in geographic areas with high potential for wildlife viral spillover events. A better understanding on the interaction and viral transmission between human, livestock, other domestic animals and wildlife will inform disease surveillance and control policy to reduce the risk of transmission and prevent undesirable animal and public health consequences.

Limitations

This study was performed on highly targeted populations to increase the chance of viral detection in high-risk populations at the wildlife-livestock-human interface. Therefore, the findings should be interpreted in light of the sampling bias, limited sample size, non-random sampling, cross-reactions between antigenically related viruses and the diversity of uncharacterized filoviruses and henipaviruses that is missed from the test panel. Further characterization of filoviruses and henipaviruses in the region, larger data set, improved diagnostic assays and species-specific positive controls will influence cut-off values and reported sero-detection.

Additionally, infection status in bats fluctuates seasonally and are influenced by reproduction phases, nutritional stress, migrations or contacts with infected animals (Amman et al., 2012; Baker et al., 2014; Hayman, 2015; Plowright et al., 2008; Sohayati et al., 2011; Wang et al., 2013). This infection pattern in bats as a reservoir host would

subsequently impact degree of spillover to other potential hosts like cattle, goats or humans in our case (Amman et al., 2012; Plowright et al., 2017). Antibody post-infection also wax and wanes over time (Boardman et al., 2020; Diallo et al., 2021). Thus, the sero-detection reported in this cross-sectional study only provides information at the time of sampling which may be an underestimation or overestimation and will differ depending on time of sampling.

In addition, maternal antibodies to NiV can last up to 14 months, hence without longitudinal data, some reactivity in our study may be misrepresented (Sohayati et al., 2011). As a result of lack of longitudinal data, serological findings only demonstrate past exposure to filoviruses and henipaviruses. Despite these limitations, our study generated valuable information of filoviruses and henipaviruses in the multiple animal host species to inform future studies. Besides that, research on viral diversity characterization in this region will improve the depth of interpreting serological results.

3.5 Conclusion

This study provides the first evidence of exposure to viruses antigenically related to filoviruses and henipaviruses in domestic animals and humans in Malaysia, as well as viruses antigenically related to henipaviruses in previously unreported bat species. Results from our study supports more extensive and longitudinal viral surveillance in these populations to enhance disease preparedness and improve our understanding on

the viral distribution, diversity and potential spillover at the human-livestock-wildlife interface.

Appendix A

Study design

First step involved mapping to identify the sub districts for phone and ground survey. In the mapping process, forest distribution in Peninsular Malaysia and forest complexes which overlapped the 3 targeted districts in our study were first identified using Google Earth (version 7.1.2.2600). Out of 8 forest complexes in Peninsular Malaysia, the forest complexes which overlapped with our targeted districts were the Bintang Hijau Forest Complex (FC2) which overlapped with Kuala Kangsar, the Main Range Forest Complex (FC3) which overlapped with Kuala Kangsar, Gua Musang and Lipis, and the Greater Taman Negara Forest Complex (FC4) which overlapped with Gua Musang and Lipis (Figure 3.2).

Secondly, the subdistricts which overlapped the 3 forest complexes were selected for the next step. Since FC2 overlaps with Kuala Kangsar, the subdistricts from this region of Kuala Kangsar was selected. They were Chegar Galah, Kampung Buaya, Kota Lama Kiri, Kota Lama Kanan, Lubuk Merbau, Senggang, Sungai Siput and Sayong. The east side of Gua Musang which overlapped with FC4 were selected because there were more subdistricts on the overlapping forest region. The subdistricts were Relai, Ketil, Limau Kasturi, Kuala Sungai and partial of Renok, Pulai and Bandar Gua Musang. While the west side of Lipis which overlapped FC3 were selected. The subdistricts were Ulu Jelai and partial of Batu Yon, Telang and Penjom.

Next, the list of sub-districts selected were compared to a list of cattle farm in Peninsular Malaysia. The farm list registered 339 farms from the three districts of interest. The subdistrict/s with the most number of farms and with farm location likely to be less than 5km from the fringe of forests were identified. This was done by using forest mapping data from state governments and marking positions of potential farms in Google Earth (version 7.1.2.2600) and measuring the farm distance to the nearest forest. The subdistrict/s identified were Chegar Galah in Kuala Kangsar, Relai and Renok in Gua Musang and Ulu Jelai in Lipis.

A phone survey was then conducted to contact the farmers in the selected sub-districts to obtain basic information about their production system, grazing practices, number of livestock and type of production. Only 50% of the farmers were contactable out of which only 19 farms had more than 30 cattle. Subsequently, a field survey was conducted to meet farmers in the selected sub districts from the three states. New farmers were enrolled using the snowball method where researchers were introduced to the new farmers by the locals or other interviewed farmers. At the initial discussion information of the farm such as production system, number of livestock, grazing and feeding practices, herd health, presence of wildlife in and around farm, estimated distance to nearest forest, and the willingness to participate in the research were noted. In cases where farmers were absent, information were obtained from their family members and consent was obtained to contact farmers through call at a later date. These conversations mainly occurred in their house, coffee shops or in the farm. Due to insufficient farms that meet the criteria of study in selected sub districts, other neighbouring sub districts in the same selected forest complex were also surveyed.

At the end of the field survey, a new list of farms was compiled with more than 60 potential farmers. A total of 11 farms were selected from the 60 as suitable for further ground-truthing. Ground-truthing and recruitment of farms were performed with a field manager and ranger from EcoHealth Alliance. Appointments with farmers were made in advance to meet and visit the farms. Ground-truthing is a process where ground information on the farm was obtained, formal farmers' participation was sought and sampling logistic requirements were noted. Information gathered comprised of: 1) the GPS location of farm and GPS location of the nearest forest to calculate the distance between farm and forest to confirm that farm is within 5km to forest, 2) observation of farm setting, size and periphery of farm and availability of facilities for handling and sampling of animals, processing of samples and storage space, 3) farm production system and type, number of animals, sex and age of animal, feeding and grazing schedule, 4) number of farm personnel, 5) presence of other domestic animals and wildlife, 6) pictures of farms, and 7) interest and willingness to participate in research.

At the end of these process, six farms were recruited from Kuala Kangsar, Perak and Gua Musang, Kelantan for the study. Only 2 districts were sampled due to the unavailability of collaborating district health officers from Lipis, Pahang. Sample size of farms is small and purposely selected to only include those with the set criteria listed for logistical ease and enhance viral detection probability. Due to the highly targeted nature of the design and sampling, the findings from this study may not be inferred to other farms, animals or humans in Malaysia.

Appendix B

Sampling of cattle and other domestic animals

Species	Restraining method	Blood collection
Cattle, goat, sheep	Cattle were first herded into an enclosure or chute system. For farms that did not have any chutes, chutes were built by field sampling team to ensure ease and safety of both animals and handlers during sampling. Fixing and modifying existing fences or chutes were also done to facilitate with herding and restraining of the cattle.	An 18G vacutainer needle attached to a vacutainer holder was used with needle inserted at a 45° angle for blood withdrawal from the jugular vein, whereas a needle was inserted perpendicularly to skin surface midway along the coccygeal vertebra. An approximate 3-5ml of blood was withdrawn and pressure was placed on venepuncture site until bleeding stops. Blood collected was distributed equally in a BD Vacutainer® serum tube (red top) and an EDTA tube (purple top).
Dog	Dogs were manually restrained with assistance from the owner. A gauze tie around the muzzle and a towel were used to cover eyes if necessary.	Blood collection was performed from the cephalic vein, jugular vein, femoral vein, lateral or medial saphenous vein using a 21G needle and 3ml syringe. BD Vacutainer® serum tubes (red top) and EDTA tube (purple top) were used to collect 3-5ml of blood. Blood volume is limited to a maximum of 1% body weight. Blood collected was distributed equally in a BD Vacutainer® serum tube (red top) and an EDTA tube (purple top).
Rabbit	Rabbit was manually restrained holding rabbit on its side. Towel was used to cover the eyes if necessary.	Rear leg was extended while putting pressure on the stifle area. Venepuncture site was disinfected with alcohol before withdrawal. Blood was taken withdrawal was performed from the lateral saphenous vein using a 23G needle and 3ml syringe to collect 3-5ml of blood. Blood volume is limited to a maximum of 1% body weight. Blood collected was distributed equally in a BD Vacutainer® serum tube (red top) and an EDTA tube (purple top).

Appendix C

Sampling of wildlife

Species	Trapping	Restraining method	Blood collection	Species identification
Bat	<p>Bats were trapped using mist nets. Mist nets used in our study were 6m x 3m in dimension, size no. 4, black, nylon material mist nets with 3-pouch construction. Mist nets were looped at the top end of an extendable aluminium pole which enables raising the net for capture and lowering the net for extraction of captured bats for sampling.</p> <p>Poles for the mist nets were typically secured by pressing it into the ground. The first pole was placed first followed by looping of mist net to the top of the pole and careful unravelling of the mist nets without touching the ground to prevent entangling of debris or leaves while walking to the other end where the second pole is located. Then, both poles were raised carefully by 2 persons on each pole by ensuring proper tension and pouches are formed for the bats to fall into.</p> <p>A total of 15 mist nets were employed to suitable sites with priority given to the participating cattle farm and its surrounding locations. The mist nets were raised at 7.30pm at sunset and left opened until 12am for trapping to occur (Figure 3.5). Bat nets were repositioned to new locations when recapture rates were high or captures were absent. The GPS coordinates for each mist nets were recorded.</p>	<p>Prior to taking bat out from the cloth bag, the bag is weighed with a Pesola digital hanging scale. After bat is taken out, the weight of the bag re-measured and subtracted from previous total to obtain the weight of the bat. The weight is important for calculating the maximum of blood (1% of bat body weight) that can be withdrawn. Bat is removed from the cloth bag and manually restrained for sampling using leather gloves. This was done while having a handler manually restraining a bat with one hand with the wing gently extended with another hand until a 90° angle.</p>	<p>Venipuncture site was swab with 70% alcohol swab prior to puncture. The droplet of blood to form on the surface of skin was then collected with a pipette tip and pipette (Figure 3.8). A cotton ball was used to apply pressure on venepuncture site until bleeding ceases (approximately 1 minute). The droplet of blood was expelled into a cryovial tube containing phosphate buffered saline (PBS).</p> <p>In bats that are >100g, a non-heparinized syringe was used to collect blood from the cephalic vein, brachial vein or saphenous vein. Blood is then placed in a serum vacutainer tube containing serum-clotting factor and centrifuge. A sterile pipette tip and pipette was used to extract serum and placed into 2 cryovials of a minimum of 60µl if volume.</p> <p>In bats that are <100g, the tip of a sterile 25G needle was used to puncture the brachial or propatagial vein (C. Smith et al., 2010).</p> <p>A dilution of 1:10 PBS is prepared by placing 10µl blood (1 drop) into 90µl PBS. The serum dilution is then centrifuged and the clear supernatant containing the serum dilution is transferred into a new cryovial tube.</p>	<p>Morphometric measurements such as, forearm or radius length (from elbow to wrist), ear length (from distal tip of ear to middle of base of ear), body length (from tip of nose to base of tail when bat is placed on a ventral recumbency), hind foot length (from ankle to toe) and tail length (from base of body to tip of tail) were measured in millimeters using a ruler or a caliper. Photographs of the full body, anterior face, lateral face and view of parted pelage on ventrum and dorsum were taken for the purpose of identification.</p>

	<p>Mist nets were checked for bats every 30 mins to an hour. Captured bats were extracted from the nets carefully using at least one leather gloves on one hand and with the use of forceps or small stick to move the netting or bat mandibles. In cases where bats were found badly entangled in the net, a small scissor was used to cut the net to release the bats. Bats were then placed into a porous cotton bag with a draw-string mouth and taken to a sampling processing site where sampling was performed immediately or hung on a rope until further handling. Net is erected after bats were released from the mist nets. Approximately 20-30 bats were sampled in a night. Sampling procedure starts from when the first bat is captured until sampling is done. No bats should be kept for more than 6 hours.</p>		<p>Cryovial tubes is labelled appropriately and placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to proper cold chain methods.</p>	
Rodent and other small mammal	<p>A total of 100 traps were used to trap rodents which encompasses 45 Sherman traps (12L x 3W x 3.75H), 45 small Tomahawk (19L x 6W x 6H) and 10 large Tomahawk traps (32L x 10W x 12H). Sherman trap is made of aluminum with a galvanized door and treadle for small mammals. The Tomahawk trap is a collapsible trap made from gauge galvanized wire mesh. Two sizes of Tomahawk trap were used to capture smaller mammals such as mice, rats, tree shrews and larger mammals, such as civet.</p> <p>A hundred traps were divided into 10 transect lines, each line consisted of 10 traps. Odd number transect lines had 1 big Tomahawk trap, 4 small Tomahawk traps</p>	<p>Prior to taking animal out from the cloth bag, the bag is weighed with a Pesola digital hanging scale. After animal is removed from the bag, the weight of the bag was re-measured and subtracted from previous total to obtain the weight of animal. The weight is used for calculating the maximum of blood (1% of bat body weight) that can be withdrawn.</p> <p>Gas anaesthesia was used for induction (5% isoflurane and 0.5% O₂) and maintained (2% isoflurane and 0.2% O₂) and adjusted according to depth of anaesthesia and vital signs. Small rodents like</p>	<p>Blood samples were collected from the lateral tail vein, ventral tail artery or lateral saphenous vein or lateral saphenous vein in rodents and other small mammals. Puncture site was swab with 70% alcohol swab prior to puncture. In the lateral tail venepuncture, animal is placed on ventral recumbency. The tail is immobilized with a non-dominant hand and rotated ¼ to access the lateral tail vein. Veins are located on either side of the tail which is quite superficial. Pressure is then placed proximal to the venepuncture site occlude the veins for venepuncture. Needle for blood collection is inserted</p>	<p>Morphometric measurements such as body length, length of ear and length of hind foot and tail length were taken for purpose of identification. Identification of animal species was performed by an experienced rangers and field veterinarian. Guide books were also used as reference for identification</p>

<p>and 5 Sherman traps, whereas even number transect lines had 1 big Tomahawk trap, 5 small Tomahawk traps and 5 Sherman traps. The Tomahawk and Sherman traps were placed alternately in each line.</p> <p>Traps in the farms were placed along fences for the paddocks or periphery near the forests in a transect line and/or in strategic positions in and around the farmhouse or store room. A red and white ribbon was used to mark the beginning of each trap or at every trap site in dense bushy areas. GPS coordinates for the front and ends of the first and last transect line were taken. Forest areas were selected based on its proximity to the participating cattle farm, topography and canopy cover. Site selected should have no flooding risk and have sufficient canopy to avoid direct sunshine and heat stress on the trapped animals. Materials such as leaves and branches are placed above and around the trap to provide shelter and camouflage. The traps may be placed on the ground, or secured on trees or fences with raffia string, away from human activity disturbance and livestock damage (Figure 3.10). Areas with stream or water source were also chosen to improve capture rate. Roasted oil palm fruits were used as baits and occasionally roasted coconuts, jackfruit, cempedak fruit (<i>Artocarpus integer</i>), bananas or grapes when capture rates were low (Figure 3.11). Oil palm fruit was the preferred option as it does not attract insects.</p> <p>Traps were placed at the same sites for a minimum of 3 consecutive nights to improve capture rates which may be influenced by</p>	<p>rats and tree shrews were secured by scuffing dorsal to neck region with thumb and forefinger carefully without restricting airway and cause cyanosis to be transferred into modified container with an inlet for anaesthetic gas for induction. Once animal is motionless and unresponsive, it is taken out and placed on the table. A modified tube for appropriate fitting of the face was used for maintenance of anaesthesia. In small mammal species like civets, a gas mask was used for induction without completely removing animal out from the bag to reduce stress. Upon successful induction, it is removed from bag and placed on table with the gas mask attached. Monitoring of animal was performed by a veterinarian throughout during handling to observe breathing rate, colour of ears, nose and oral cavity and withdrawal reflex. Isoflurane is turned off if an animal becomes cyanotic. A sterile lubricant is placed into animal's eyes to prevent corneal drying or scratches during sedation.</p>	<p>one third down the length of tail. In ventral tail artery blood collection, animal is placed on dorsal recumbency and vein is located on the centrally in the tail and pressure is place proximal to the venepuncture site occlude the artery for venepuncture. Needle for blood collection is inserted one third down the length of tail. In lateral saphenous venepuncture, animal is placed on lateral recumbency while an assistant stretch out the rear legs to its natural position and place pressure on the upper leg to occlude blood flow for visualization of vein and venepuncture site.</p> <p>A 25G or 27G needle and 1ml syringe is used to withdraw blood from lateral tail vein, ventral tail artery or lateral saphenous vein. Attempts to withdraw blood from animal is minimized to no more than three needle sticks. In cases where no blood is aspirated but a drop of blood is formed on the surface of the skin, a pipette tip and pipette is used to collect it. A cotton ball is used to apply pressure on venepuncture site until bleeding ceases. Blood collected is placed into 1:10 PBS and spin to collect serum. The serum dilution is then centrifuged and the clear supernatant containing the serum dilution is transferred into a new cryovial tube. Cryovial tubes is labelled appropriately and placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to proper cold chain</p>	<p>while in the field (Francis, 2008; Payne et al., 1985; Phillipps & Phillipps, 2016). Photographs of the full body dorsally and laterally, anterior face and lateral face or any special marking or characteristics were taken for future reference.</p>
-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

	<p>weather conditions and rodents' neophobic behaviour (Aplin et al., 2003). Rodent traps were set and opened at 6pm, left overnight and checked at 8am the next day. If adverse weather such as heavy rain is expected, traps will not be opened for that night. Trapped small mammal were gently transferred into a draw-string cloth bag by covering the bag over the opening of the trap and slightly tilting the trap downwards. Animals that were too stressed will be released, while animals found to be injured or weak will be brought back to sampling base for veterinary treatment.</p>		<p>methods. After blood collection, fluid volume replacement is given subcutaneously using Lactated Ringer's or 0.9% NaCL solution to avoid hypovolemic shock. A 25G or 27G needle is used to administer 1ml in small rodents (~25g) and 3-5ml in larger rodents (~200g) fluid replacement under the loose skin on the dorsal neck or flank. Gentle pressure is placed to ensure no leaking is seen from injection site. Marking on sampled rodent or small mammal is done by clipping 3-5mm of hair at the right ventral thigh.</p>	
Wild boar	<p>Wild boar was trapped according to trapping protocol described for rodent and other small mammals. It is transported to sampling base in the cage for sampling. *Wild boar trapping was incidental in our study.</p>	<p>Prior to taking animal out from the cage, the cage is weighed with a Pesola digital hanging scale. After animal is removed from the cage, the weight of the cage was re-measured and subtracted from previous total to obtain the weight of animal. A portable anaesthetic chamber was made for the induction procedure by placing a plastic large enough to cover entire cage with an anaesthetic gas tubing input to the opening of the plastic. Once animal is motionless and unresponsive, it is quickly taken out of the cage and placed on the table for sampling with gas mask fitted on the muzzle. Wild boar was induced with 5% isoflurane and 0.5% O2 and maintained with 2% isoflurane and 0.2% O2 and adjusted according to depth of anaesthesia and vital signs. A sterile</p>	<p>Blood sample is collected from the anterior vena cava using a 21G needle and 3ml syringe while animal is placed on dorsal recumbency. Venepuncture site was swab with 70% alcohol swab prior to puncture. Blood volume is limited to a maximum of 1% body weight. A cotton ball is used to apply pressure on venepuncture site until bleeding ceases. Blood collected is distributed equally in a BD Vacutainer® serum tube (red top) and an EDTA tube (purple top). Blood in BD Vacutainer® serum tubes were left to clot for serum collection within 1 hour. After clotting is form, serum tubes were centrifuged for 15 minutes and 1 ml of serum was transferred into 2 0.5ml cryovial tubes. Cryovial tubes were labelled appropriately. Samples were then placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to</p>	<p>Morphometric measurements such as body length, length of ear and length of hind foot and tail length were taken for purpose of identification. Identification of animal species was performed by an experienced rangers and field veterinarian. Guide books were also used as reference for identification while in the field (Francis, 2008; Payne et al., 1985; Phillipps & Phillipps, 2016). Photographs of the</p>

		<p>lubricant is placed into animal's eyes to prevent corneal drying or scratches during sedation. Monitoring of animal was performed by a veterinarian throughout during handling to observe heart rate, breathing rate, mucous membrane colour and withdrawal reflex. Isoflurane is turned off immediately if animal becomes cyanotic. A basic physical examination was performed by veterinarian to assess health status.</p>	<p>proper cold chain methods.</p> <p>After blood collection, fluid replacement was given subcutaneously using Lactated Ringer's or 0.9% NaCl solution. In young pigs, <2ml were given at the axillary area caudal to elbow or in the inguinal region and in adults, <3ml were given under the loose skin behind the ear (Office of the University Veterinarian, 2017c). Animal were monitored in a small cage until fully recovered from anaesthesia before release back at place of capture.</p>	<p>full body dorsally and laterally, anterior face and lateral face or any special marking or characteristics were taken for future reference.</p>
Non-human primate	<p>Non-human primates (NHP) were in our study were kept as pets hence trapping was not required.</p>	<p>NHP were anaesthetized and sampled upon the agreement of its owner according to established protocols (Hoffmann et al., 2010; PREDICT One Health Consortium, 2016c). Anaesthesia drug were the combination of: 1) 4mg/kg Ketamine and 0.15mg/kg Xylazine with Yohimbine 1:1 as reversal agent for Xylazine, or 2) Tiletamine-Zolazepam, Zoletil® 3-5mg/kg in more aggressive primates. A dart syringe and blowpipe was used to deliver anaesthetic drug intramuscularly by an experienced and trained ranger. The dart is targeted to muscles of the thigh, shoulder or upper arm. Immobilization is recognized by droopy eyelids, reduced movement, leaning against wall or lying on floor and unreactive to stimuli. Anaesthetic monitoring was performed by a veterinarian. Respiratory rate, heart rate, pulse</p>	<p>NHP is placed in a supine position. Blood is withdrawn from femoral vein located in the inguinal region lateral and parallel to the femoral artery. Venepuncture site is swabbed with 70% alcohol swab prior to puncture with a 21G needle and 3ml syringe. Blood volume is limited to a maximum of 1% estimated body weight. Firm pressure with a cotton ball is placed on venepuncture site for 1 minute to prevent hematoma formation. Blood collected was distributed equally in a BD Vacutainer® serum tube (red top) and an EDTA tube (purple top). All blood tubes were labelled appropriately and placed in cooler boxes and transported back to base station. Blood in BD Vacutainer® serum tubes were left to clot for serum collection within 1 hour. After clotting is form, serum tubes were centrifuged for 15 minutes and 1 ml of serum was transferred into 2 0.5ml cryovial tubes.</p>	<p>Photographs of the anterior and ventral view of the full body, anterior and lateral face, upper and lower dentition and genitalia were taken for future reference.</p>

		<p>quality, mucous membrane colour and muscle tone were taken and recorded.</p> <p>After immobilization, basic physical examination was performed. A sterile lubricant is placed into animal's eyes to prevent corneal drying or scratches during sedation.</p>	<p>Cryovial tubes were labelled appropriately. Samples were then placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to proper cold chain methods.</p>

Appendix D

Sampling of human

Species	Blood collection
Human	<p>Participants were asked to sit comfortably on a chair with their arm for venepuncture on the table. A quick release tourniquet is placed approximately 4 inches above intended venepuncture site. Blood is withdrawn from the median cubital vein on the upper limb or metacarpal plexus or the dorsal venous arch on the dorsal surface of the hand. Venepuncture site is swabbed with 70% alcohol swab prior to puncture with a 21G needle and 3ml syringe. Tourniquet is released upon filling of the syringe. A sterile gauze pad is placed over venepuncture site and needle is removed in a quick careful motion. Venepuncture site should be observed to ensure bleeding has stopped, followed by a bandage over site.</p> <p>Blood collected is transferred equally in a BD Vacutainer® serum tube (red top) and an EDTA tube (purple top). All blood tubes were labelled appropriately and placed in cooler boxes and transported back to base station. Blood in BD Vacutainer® serum tubes were left to clot for serum collection within 1 hour. After clot is form, serum tubes were centrifuged for 15 minutes at 1300 r.p.m and serum was transferred 0.5ml cryovial tubes to produce at least a minimum of two aliquots. Cryovial tubes were labelled appropriately. Samples were then placed in MVE Doble 34 liquid nitrogen tanks in the field and later stored at -80° freezer in the lab according to proper cold chain methods.</p>

Hi Eric,

Thank you for going through the chapter early. I appreciate the many great suggestions and helpful feedback.

Kindly see attached for the updated draft and attachment for the table of seroprevalence of filovirus and henipavirus in neighbouring countries mentioned in 3.2.3 Sample Size.

I'm also reattaching the breakdown of antigen reaction which I sent to you and Jon last time for Dr Broder. [@Christopher Broder](#), happy to hear from you.

Thank you for guiding me,
Chyna

Hi Eric,

The due date is 13 March. I think after 4th March is still doable. But if you have time to scheme through the results section and point out any problems before the 4th would be awesome too.

Safe travels!

Thanks,
Chyna

Hi Chyna,

Email received. Can I have a few days to review this, what's a due date? I'm traveling now and time is limited thru March 4. But if this is critical before then I can do my best.

Dear Jon and Eric,

This version is a newer version with more details on the positive & negative controls + results of USU's naive livestock sera.

If you have not reviewed the previous version, please review this one.

Looking forward to hearing from you.

Thanks!

Chyna

Subject: Thesis review - cattle farm chapter 3

Hi Jon and Eric,

Hope the both of you are well.

Attached is a chapter from my thesis that covers the cattle farm project + its Appendix for your review.

Please ignore the green highlights as those are for me to double-check when I compile the thesis.

@Eric, should I add the MFI baseline for the livestock samples that you've conducted in USU?

Appreciate if you could review it by end of this month if possible. Will send the archived pig chapter as soon as I finalize it with Prof Latiffah.

Thank you.

Kind regards,
Chyna

BUDGET JUSTIFICATION

The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (HJF) in partnership with the Uniformed Services University of the Health Sciences (USUHS) will manage this proposal, if awarded.

Personnel

Key Personnel:

Eric Laing, Ph.D., Co-Investigator (0.8 calendar month). Dr. Laing will be responsible for the coordination of the project activities with the principal investigator and other co-investigators. Dr. Laing will oversee the lab activities pertaining to the production of recombinant virus protein antigens and the establishment of the multiplex serology test. Dr. Laing will provide mentorship to the postdoctoral student and assist with data analysis. Dr. Laing will oversee serological training activities at the partner lab in Bong, Liberia and assist with in-country testing and data interpretation. He will provide the necessary concepts and practice of viral glycoprotein antigen preparation for serological application to co-investigators and collaborators. Dr. Laing will also provide the virological and immunological expertise necessary to understand the serological profiles of humans and wildlife antisera. Dr. Laing will be a government employee and no salary support is requested.

Other Personnel:

Dr. Si'Ana A. Coggins, PhD, Scientist I (3 calendar months, YR1; 2 calendar months, YR2-3). Dr. Coggins will assist with the supervision of all lab activities at USU and interface with the project management teams. As a trained biochemist Dr. Coggins will oversee all protein expression and maintain the quality and rigor of the research. Dr. Coggins will work closely with the research assistant, in year 1 to prepare protein antigens, verification of material quality, coordinate the transfer for materials to the partner institute in the regional partner labs and assist in the project activities. Dr. Coggins will participate in and provide serological assay training at the regional partner labs in years 2-3. Dr. Coggins is an employee of the Henry M. Jackson Foundation and salary support is requested for years 2-3.

TBD, Res Asst I (4 calendar months, YR1). A research assistant (RA) will assist Dr. Coggins in the production of soluble glycoproteins and be responsible for microsphere coupling in YR1. The RA will participate in serological testing and quality verification of the material, and will also prepare shipments of materials to the regional partner lab. The RA will be an employee of the Henry M. Jackson Foundation and salary support is requested for year 1.

Mr. Spencer L. Sterling, MPH, Research Project Coordinator (2 calendar month, YR2-3). Mr. Sterling will participate in the transfer of serology assay methods and data analysis. Mr. Sterling will work with the regional partner teams and EcoHealth Alliance scientists to assist in the analysis and development of serological results. Mr. Sterling will work closely with scientists at the prime institute to generate data for yearly reports. Mr. Sterling is an employee of the Henry M. Jackson Foundation and salary support is requested for year 2-3.

International Travel:

Based on FY23 Department of State per diem rates and historical travel to the Republic of Georgia, Oman, and Turkey, we estimate \$31,840 should cover the travel costs of two lab members to travel to initiate and maintain project activities in the partner labs. In year 3, only travel to the Republic of Georgia is required.

Supplies:

Based on current prices, the following equipment and supplies will be needed to support this project in year 1: Recombinant production of approximately 34 protein antigens, magnetic beads, plastic consumables, cell culture materials, affinity matrices and control antibody materials.

Year 1 - \$30,631

Recombinant protein production

Year 2 and 3 - \$5,000

Continuation of disposable and general lab supplies to support the research project.

Indirect Costs:

HJF indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The fringe rate used is 29.42 % for Tier 1 employees and 7.29% for Tier 2 employees (all employees in this proposal are Tier 1).

The HJF indirect cost is calculated based on the value-added cost base overhead rates. The IDC rate is 36.74% USU Onsite Overhead. Additionally, 16.70% Companywide G&A and applied on the total direct cost less subaward plus the USU Onsite Overhead. For proposals including subawards, an additional 1.93% is applied on total external subaward costs.

The above fringe benefits and indirect cost rates for FY2023 were approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

Fixed Fee:

HJF has proposed a Fixed Fee of 5% for all the cost items in this proposal. The proposed fixed fee is deemed reasonable for the contract type proposed and necessary to compensate HJF for contractual risks, to meet financial obligations not covered under the contract, to provide working operating capital and stability, and as a stimulant for efficient and effective contractor performance. This rate will only apply if awarded as a contract.

Current and Pending Support

Investigator: Eric D. Laing, PhD			
Support:	<input type="checkbox"/> Current	<input checked="" type="checkbox"/> Pending	<input type="checkbox"/> Submission Planned in Near Future
Project/Proposal Title:			
Strengthening capacity for bat-borne coronavirus, paramyxovirus, and filovirus threat reduction in Western Asia (current proposal)			
Objective: Detect and characterize known and novel CoVs, PMVs, and FVs at the human-wildlife interface in newly collected and archived bat samples using a combination of molecular screening, partial- and full-genome sequencing, and multiplex serological assays			
Source of Support: DTRA		Address: 8725 John J Kingman Rd #6201, Fort Belvoir, VA 22060	
Total Award Amount: \$301,988		Total Award Period Covered: 1 October 2023 – 30 September 2028	
Location of Project: US, Georgia, Jordan, Oman, Turkey			
Person-Months Per Year Committed to Project:		Cal: 0.8	Acad: Sumr:
Support:	<input checked="" type="checkbox"/> Current	<input type="checkbox"/> Pending	<input type="checkbox"/> Submission Planned in Near Future
Project/Proposal Title: Efficacy testing of a novel human monoclonal antibody therapy for late-stage rabies/lyssavirus			
Objective: The major goals of this project is to test the efficacy of mAb therapy at times beyond day seven post-infection, to more completely define the degree to which mAb therapy can confer protection from death post-onset of clinically evident severe neurological disease.			
Source of Support: USUHS/CGHE		Address: 4301 Jones Bridge Road, Bethesda, MD 20814	
Total Award Amount: \$518,000		Total Award Period Covered: 09/30/2019 – 09/29/2023	
Location of Project: US, Georgia, Kenya			
Person-Months Per Year Committed to Project:		Cal: 0.6	Acad: Sumr:
Support:	<input checked="" type="checkbox"/> Current	<input type="checkbox"/> Pending	<input type="checkbox"/> Submission Planned in Near Future
Project/Proposal Title: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EpiCC-EID)			
Objective: The major goals of this project are to utilize SARS-CoV-2 serology to explore hospital and community infection, correlates of COVID-19, and vaccinology.			
Source of Support: Defense Health Program		Address: 7700 Arlington Blvd. Suite 5101. Falls Church, VA 22042-5101	
Total Award Amount: \$1,178,876		Total Award Period Covered: 04/01/2020 – 09/30/2023	
Location of Project: US

Project/Proposal Title: Establishment of a Bat Resource for Infectious Disease Research

Objective: The major goals of this proposal is to contribute significant insight into the viral determinants that confer henipaviral pathogenesis. The construction and generation of recombinant henipavirus chimeric viruses will be the primary means for determining how virus receptor usage and the expression of virulence factors act individually or in conjunction to cause limited or severe disease. The recombinant constructs generated from the proposed studies will also be used to determine host determinants of immunity in Jamaican fruit bats and animal models.

Source of Support: NIH / NIAID | Address: 6701 Rockledge Drive, Room 1040 - MSC 7710 Bethesda, MD

BETHESDA, MARYLAND 20814-4799

www.usuhs.edu

February 15, 2023

To: DTRA C-WMD Thrust Area 6 Program

From: Eric D. Laing, PhD

I am writing to express my commitment to collaborate with EcoHealth Alliance on the project proposal, *Strengthening capacity for bat-borne coronavirus, paramyxovirus, and filovirus threat reduction in Western Asia*. I agree to undertake the tasks assigned to me as described in the project narrative of the proposal. I strongly support this project, which is designed to increase the capacity of Western Asian scientists to conduct and sustain bat-borne disease surveillance in the region. This will be accomplished through active surveillance of bat populations, improved capacity to conduct molecular and serological screening of viral families that pose a high risk to humans, and increased multi-sectoral engagement of governmental and non-governmental partners in the region to improve the timeliness of data sharing, zoonotic risk assessments, and mitigation of emerging diseases. This project is of mutual benefit in that it will enhance the existing capacity and build future sustainability for a proactive early warning system for bat-borne zoonoses throughout Western Asia. Moreover, this project will leverage the professional networks of the Western Asia Bat Research Network (WAB-Net), improve our scientific understanding of bat-borne viral diversity throughout Western Asia, and elucidate the risk factors associated with bat-borne virus shedding and spillover into human populations.

As you know one of my lab's focus is on the utility of serosurveillance to identify emergent zoonotic viruses such as coronaviruses, henipaviruses, and filoviruses. I have been developing tools for and analyzing serosurveillance data collected from wildlife (bats) and humans since 2015. I worked as a postdoctoral fellow with EcoHealth Alliance on BTRP funded project dating back to 2017, "Serological Biosurveillance for Spillover of Henipaviruses and Filoviruses at Agricultural and Hunting Human-Animal Interfaces in Peninsular Malaysia (HDTRA11710037)." In addition, my lab supported follow-up serological analysis of bat sera collected during the Ebola Host Project that was performed in collaboration with EcoHealth Alliance. Presently, I am a co-investigator within the EID-Southeast Asia Research Collaborative Hub (EID-SEARCH), one of the NIH Centers for Research in Emerging Infectious Diseases, of which you are a co-principal investigator. Within EID-SEARCH my lab develops, implements, and analyzes data generated from serological profiles of bats and human study participants. This proposed project will provide invaluable evidence to strengthen our understanding of and capacity to detect filovirus, coronaviruses, henipavirus (paramyxoviruses) circulation in bats in west Asia.

Sincerely,

(b) (6)

Eric D. Laing
Assistant Professor
Department of Microbiology and Immunology
Uniformed Services University

(b) (6)

Christopher Broder, Ph.D.
Chair and Professor
Department of Microbiology and Immunology - USU

Facilities and Other Resources

Uniformed Services University of the Health Sciences Dr. Eric Laing (Co-Investigator)

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Laing is an Assistant Professor in the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators. Dr. Laing is currently involved in active collaborations within the University, in areas of viral immunology and vaccine and antiviral therapeutics and animal model development. USU is also physically located directly across from the main NIH campus in Bethesda. The overall broad scientific environment at both USU and the NIH is highly conducive to productive collaborations. The PI often uses these resources to his advantage, both for his research objectives and interests and in assisting in adjunct faculty appointments within the Emerging Infectious Diseases graduate program for both on and off-campus scientists interested in participating in graduate education and graduate student training. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional. In addition, multi-lab Immunology journal club, Immunology data club, Virology journal club, and Virology data club exist. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club.

Dr. Laing has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., Bruker In Vivo Xtreme II; Siemens Inveon SPECT/PET/CT Scanner) are not overbooked and therefore readily available to the laboratory personnel. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase advanced and very expensive equipment, including the Zeiss 710NLO system and the FACSAria 15-parameter cell sorter. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by the most recent USU purchase of cutting-edge equipment: the Zeiss Elyra PS.1 super-resolution microscope.

Laboratory: Dr. Laing's laboratory is 453 sq. ft. and is currently supported by two graduate students, two research assistants, two research associates, and one scientist. Dr. Laing also has access to 3 rooms within the department totaling 1,440 sq. ft. where BSL-2 virus rescues are performed and blood specimen samples are handled. Dr. Laing has access to or possesses routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, waterbaths, free-standing biosafety cabinets, and CO₂-tissue culture incubators. Additionally, Dr. Laing has access to three BioPlex 200 HTF multiplexing systems, one MAGPIX multiplexing system, an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope, upgraded in 2015), and two complete GE-ATKA low pressure chromatography systems, with integrated UV detectors, fraction collectors, and pump systems, and gradient fractionator apparatus.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. The USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. It, and the University's animal care and use program, is managed by the Center for Laboratory Animal Medicine, which is directed by a veterinarian who is an ACLAM Diplomate and staffed with three other veterinarians, a graduate animal husbandryman, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates to lower vertebrates, to higher vertebrates including non-human primates and domestic livestock, as well as the more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers (Intel i5/i7 or similar processors and ≥ 2 GB of RAM) are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories of both investigators. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro.

Office: Dr. Laing has an office separate from but proximal to the laboratories. Trainees and technicians have desks in the laboratory or in a separate office area proximal to the laboratory. The department employees one senior program manager, administrative officer, administrative specialist and a microbiologist.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely consult with Cara Olsen, Research Assistant Professor (the full-time Biostatistics Consultant of the BCC), regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data. The USU Translational Imaging Facility (TIF) houses state-of-the art equipment for live animal imaging, including a Siemens Inveon SPECT/PET/CT Scanner, a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system, and a Bruker In-Vivo Xtreme II bioluminescence and X-ray imaging system.

The USU Biomedical Instrumentation Center (BIC) houses core equipment for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). The BIC Flow Cytometry Core includes two Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers, one 15-parameter FACSAria FACS sorter, and one Amnis Image Stream X Mark II imaging flow cytometer, as well as off-line analysis workstations.

The BIC Imaging Core houses three confocal microscopes, including a Zeiss 700 inverted system with 405/458/488/514/561/633 laser excitation; a Zeiss 710NLO inverted system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm; and a Zeiss AxioExaminer-Z1 upright microscope equipped with a direct-coupled Coherent Chameleon tunable infrared laser for ex vivo and in vivo multiphoton imaging projects. A Becker-Hickl two-detector FLIM system (for FRET analyses) is connected to the inverted Zeiss 710NLO system. Recently, the BIC has also acquired a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. The BIC also houses a Leica AF6000 system, consisting of an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control, allowing extended term (days) live cell analyses. Additionally, there is a stereology system consisting of a Zeiss AxioImager.M2 upright microscope connected to MicroBrightField's Stereo Investigator software package. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph Basic. The Imaging Core also includes a transmission electron microscope (Philips CM100 transmission EM) and an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment).

The BIC Genomics core includes an ABI 3900 DNA synthesizer, an ABI3500xl Genetic Analyzer (for sequencing), a RocheLightCycler 480 for real-time PCR, and Systec Mediaprep and Plate Pourer instrument. There is also an integrated Fuji FLA-5000/LAS-3000 imaging system for many applications that involve fluorescence and chemiluminescence imaging of gels and blots. The BIC Proteomics Core includes two Agilent 1100 HPLCs, an AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer, and an AB SCIEX Q-TOF tandem mass spectrometer.

The BIC Structural Biology Core includes a Rigaku HighFlux HomeLab X-ray diffraction system, with a MicroMax-007 HF microfocussing rotating anode generator, an R-Axis Imaging Plate detector, and an X-stream 2000 cryogenic system. Other available BIC instruments and services include histopathology and PET/CT instrumentation for small animal research.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available in print and via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology and is maintained through extramural grant support.

LETTER OF INTENT TO COLLABORATE

February 17, 2023

Luke Hamel
Program Coordinator
EcoHealth Alliance
520 8th Avenue
New York, New York 10018

Dear Mr. Hamel,

This letter confirms The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc.'s (HJF) intent to collaborate with EcoHealth Alliance in response to HDTRA1-14-24-FRCWMD-BAA and is offered on the condition that EcoHealth Alliance agrees that if it receives an award for the subject project, it will issue a subaward to HJF for the work hereby proposed.

Confidentiality Notice: *This letter of Intent, including all proposal documents attached hereto, contains HJF confidential and proprietary information and is provided for use solely in connection with HJF's and EcoHealth Alliance's joint pursuit of the project listed below. Any unauthorized use, disclosure or distribution is prohibited.*

Prime Institution:	EcoHealth Alliance	
Prime Principal Investigator:	Kevin Olival, MA, PhD	
Project Title:	Strengthening capacity for bat-borne coronavirus, paramyxovirus, and filovirus threat reduction in Western Asia	
Proposed Principal Investigator:	Eric Laing, PhD	
Proposed Project Period:	October 1, 2023 – September 30, 2026	
Proposed Budget Amount:	\$ 179,760	Direct Costs
	\$ 107,092	Indirect Costs
	\$ 14,341	Fee
	\$ 301,193	Total Cost

HJF confirms that it has in place a written and enforced financial conflict of interest policy that applies to all HJF investigators and any other HJF employees responsible for the design, conduct or reporting of the budgeted activities. U.S. Government Principal Investigator(s) (if any) are subject to federal regulations governing conflicts of interest.

Your submission of a prime proposal that includes the subaward activities hereby proposed by HJF will constitute your acknowledgment of, and agreement to, the terms set forth in this letter.

Sincerely 

Ms. Freda Denis-Cooper, CRA
Senior Proposal Manager-Team Lead
Investigator Initiatives-Business Development
Strategic Initiatives

Dear Mr. Hamel,

On behalf of Dr. Laing of USUHS, I attach the following documents for your review:

- Budget—RR and Excel,
- Budget Justification,
- Current and Pending Support-Dr. Laing,

- Biosketch-Dr. Laing,
- Letter of Support—Dr. Laing and Dr. Broder,
 - Facilities/Equipment,
 - Key Person/Performance site information,
 - Letter of Intent.

If you have any questions or concerns, please let me know. Thank you for this opportunity to collaborate with Dr. Olival and EcoHealth Alliance.

Best,

Peter Okagaki, MS, MBA

UNIFORMED SERVICES UNIVERSITY OF THE HEALTH SCIENCES

DEPARTMENT OF MICROBIOLOGY AND IMMUNOLOGY

4301 JONES BRIDGE ROAD

BETHESDA, MARYLAND 20814-4799

www.usuhs.edu

February 15, 2023

To: DTRA C-WMD Thrust Area 6 Program
From: Eric D. Laing, PhD

I am writing to express my commitment to collaborate with EcoHealth Alliance on the project proposal, *Strengthening capacity for bat-borne coronavirus, paramyxovirus, and filovirus threat reduction in Western Asia*. I agree to undertake the tasks assigned to me as described in the project narrative of the proposal. I strongly support this project, which is designed to increase the capacity of Western Asian scientists to conduct and sustain bat-borne disease surveillance in the region. This will be accomplished through active surveillance of bat populations, improved capacity to conduct molecular and serological screening of viral families that pose a high risk to humans, and increased multi-sectoral engagement of governmental and non-governmental partners in the region to improve the timeliness of data sharing, zoonotic risk assessments, and mitigation of emerging diseases. This project is of mutual benefit in that it will enhance the existing capacity and build future sustainability for a proactive early warning system for bat-borne zoonoses throughout Western Asia. Moreover, this project will leverage the professional networks of the Western Asia Bat Research Network (WAB-Net), improve our scientific understanding of bat-borne viral diversity throughout Western Asia, and elucidate the risk factors associated with bat-borne virus shedding and spillover into human populations.

As you know one of my lab's focus is on the utility of serosurveillance to identify emergent zoonotic viruses such as coronaviruses, henipaviruses, and filoviruses. I have been developing tools for and analyzing serosurveillance data collected from wildlife (bats) and humans since 2015. I worked as a postdoctoral fellow with EcoHealth Alliance on BTRP funded project dating back to 2017, "Serological Biosurveillance for Spillover of Henipaviruses and Filoviruses at Agricultural and Hunting Human-Animal Interfaces in Peninsular Malaysia (HDTRA11710037)." In addition, my lab supported follow-up serological analysis of bat sera collected during the Ebola Host Project that was performed in collaboration with EcoHealth Alliance. Presently, I am a co-investigator within the EID-Southeast Asia Research Collaborative Hub (EID-SEARCH), one of the NIH Centers for Research in Emerging Infectious Diseases, of which you are a co-principal investigator. Within EID-SEARCH my lab develops, implements, and analyzes data generated from serological profiles of bats and human study participants. This proposed project will provide invaluable evidence to strengthen our understanding of and capacity to detect filovirus, coronaviruses, henipavirus (paramyxoviruses) circulation in bats in west Asia.

Sincerely,

(b) (6)

Eric D. Laing
Assistant Professor
Department of Microbiology and Immunology
Uniformed Services University

Christopher Broder, Ph.D.
Chair and Professor
Department of Microbiology and Immunology - USU

Learning to Care for Those in Harm's Way

Facilities and Other Resources

Uniformed Services University of the Health Sciences Dr. Eric Laing (Co-Investigator)

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Laing is an Assistant Professor in the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators. Dr. Laing is currently involved in active collaborations within the University, in areas of viral immunology and vaccine and antiviral therapeutics and animal model development. USU is also physically located directly across from the main NIH campus in Bethesda. The overall broad scientific environment at both USU and the NIH is highly conducive to productive collaborations. The PI often uses these resources to his advantage, both for his research objectives and interests and in assisting in adjunct faculty appointments within the Emerging Infectious Diseases graduate program for both on and off-campus scientists interested in participating in graduate education and graduate student training. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional. In addition, multi-lab Immunology journal club, Immunology data club, Virology journal club, and Virology data club exist. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club.

Dr. Laing has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., Bruker In Vivo Xtreme II; Siemens Inveon SPECT/PET/CT Scanner) are not overbooked and therefore readily available to the laboratory personnel. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase advanced and very expensive equipment, including the Zeiss 710NLO system and the FACSAria 15-parameter cell sorter. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by the most recent USU purchase of cutting-edge equipment: the Zeiss Elyra PS.1 super-resolution microscope.

Laboratory: Dr. Laing's laboratory is 453 sq. ft. and is currently supported by two graduate students, two research assistants, two research associates, and one scientist. Dr. Laing also has access to 3 rooms within the department totaling 1,440 sq. ft. where BSL-2 virus rescues are performed and blood specimen samples are handled. Dr. Laing has access to or possesses routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, waterbaths, free-standing biosafety cabinets, and CO₂-tissue culture incubators. Additionally, Dr. Laing has access to three BioPlex 200 HTF multiplexing systems, one MAGPIX multiplexing system, an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope, upgraded in 2015), and two complete GE-ATKA low pressure chromatography systems, with integrated UV detectors, fraction collectors, and pump systems, and gradient fractionator apparatus.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. The USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. It, and the University's animal care and use program, is managed by the Center for Laboratory Animal Medicine, which is directed by a veterinarian who is an ACLAM Diplomate and staffed with three other veterinarians, a graduate animal husbandryman, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates to lower vertebrates, to higher vertebrates including non-human primates and domestic livestock, as well as the more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers (Intel i5/i7 or similar processors and ≥ 2 GB of RAM) are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories of both investigators. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro.

Office: Dr. Laing has an office separate from but proximal to the laboratories. Trainees and technicians have desks in the laboratory or in a separate office area proximal to the laboratory. The department employees one senior program manager, administrative officer, administrative specialist and a microbiologist.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely consult with Cara Olsen, Research Assistant Professor (the full-time Biostatistics Consultant of the BCC), regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data. The USU Translational Imaging Facility (TIF) houses state-of-the art equipment for live animal imaging, including a Siemens Inveon SPECT/PET/CT Scanner, a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system, and a Bruker In-Vivo Xtreme II bioluminescence and X-ray imaging system.

The USU Biomedical Instrumentation Center (BIC) houses core equipment for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). The BIC Flow Cytometry Core includes two Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers, one 15-parameter FACSAria FACS sorter, and one Amnis Image Stream X Mark II imaging flow cytometer, as well as off-line analysis workstations.

The BIC Imaging Core houses three confocal microscopes, including a Zeiss 700 inverted system with 405/458/488/514/561/633 laser excitation; a Zeiss 710NLO inverted system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm; and a Zeiss AxioExaminer-Z1 upright microscope equipped with a direct-coupled Coherent Chameleon tunable infrared laser for ex vivo and in vivo multiphoton imaging projects. A Becker-Hickl two-detector FLIM system (for FRET analyses) is connected to the inverted Zeiss 710NLO system. Recently, the BIC has also acquired a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. The BIC also houses a Leica AF6000 system, consisting of an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control, allowing extended term (days) live cell analyses. Additionally, there is a stereology system consisting of a Zeiss AxioImager.M2 upright microscope connected to MicroBrightField's Stereo Investigator software package. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph Basic. The Imaging Core also includes a transmission electron microscope (Philips CM100 transmission EM) and an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment).

The BIC Genomics core includes an ABI 3900 DNA synthesizer, an ABI3500xl Genetic Analyzer (for sequencing), a RocheLightCycler 480 for real-time PCR, and Systec Mediaprep and Plate Pourer instrument. There is also an integrated Fuji FLA-5000/LAS-3000 imaging system for many applications that involve fluorescence and chemiluminescence imaging of gels and blots. The BIC Proteomics Core includes two Agilent 1100 HPLCs, an AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer, and an AB SCIEX Q-TOF tandem mass spectrometer.

The BIC Structural Biology Core includes a Rigaku HighFlux HomeLab X-ray diffraction system, with a MicroMax-007 HF microfocussing rotating anode generator, an R-Axis Imaging Plate detector, and an X-stream 2000 cryogenic system. Other available BIC instruments and services include histopathology and PET/CT instrumentation for small animal research.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available in print and via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology and is maintained through extramural grant support.

BUDGET JUSTIFICATION

The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (HJF) in partnership with the Uniformed Services University of the Health Sciences (USUHS) will manage this proposal, if awarded.

Personnel

Key Personnel:

Eric Laing, Ph.D., Co-Investigator (0.8 calendar month). Dr. Laing will be responsible for the coordination of the project activities with the principal investigator and other co-investigators. Dr. Laing will oversee the lab activities pertaining to the production of recombinant virus protein antigens and the establishment of the multiplex serology test. Dr. Laing will provide mentorship to the postdoctoral student and assist with data analysis. Dr. Laing will oversee serological training activities at the partner lab in Bong, Liberia and assist with in-country testing and data interpretation. He will provide the necessary concepts and practice of viral glycoprotein antigen preparation for serological application to co-investigators and collaborators. Dr. Laing will also provide the virological and immunological expertise necessary to understand the serological profiles of humans and wildlife antisera. Dr. Laing will be a government employee and no salary support is requested.

Other Personnel:

Dr. Si'Ana A. Coggins, PhD, Associate Scientist (3 calendar months, YR1; 2 calendar months, YR2-3). Dr. Coggins will assist with the supervision of all lab activities at USU and interface with the project management teams. As a trained biochemist Dr. Coggins will oversee all protein expression and maintain the quality and rigor of the research. Dr. Coggins will work closely with the research assistant, in year 1 to prepare protein antigens, verification of material quality, coordinate the transfer for materials to the partner institute in the regional partner labs and assist in the project activities. Dr. Coggins will participate in and provide serological assay training at the regional partner labs in years 2-3. Dr. Coggins is an employee of the Henry M. Jackson Foundation and salary support is requested for years 2-3.

TBD, Res Asst I (4 calendar months, YR1). A research assistant (RA) will assist Dr. Coggins in the production of soluble glycoproteins and be responsible for microsphere coupling in YR1. The RA will participate in serological testing and quality verification of the material, and will also prepare shipments of materials to the regional partner lab. The RA will be an employee of the Henry M. Jackson Foundation and salary support is requested for year 1.

Mr. Spencer L. Sterling, Mph, Research Project Coordinator (2 calendar month, YR2-3). Mr. Sterling will participate in the transfer of serology assay methods and data analysis. Mr. Sterling will work with the regional partner teams and EcoHealth Alliance scientists to assist in the analysis and development of serological results. Mr. Sterling will work closely with scientists at the prime institute to generate data for yearly reports. Mr. Sterling is an employee of the Henry M. Jackson Foundation and salary support is requested for year 2-3.

International Travel:

Based on FY23 Department of State per diem rates and historical travel to the Republic of Georgia, Oman, and Turkey, we estimate \$32,300 should cover the travel costs of two lab members to travel to initiate and maintain project activities in the partner labs. In year 3, only travel to the Republic of Georgia is required.

Supplies:

Based on current prices, the following equipment and supplies will be needed to support this project in year 1: Recombinant production of approximately 34 protein antigens, magnetic beads, plastic consumables, cell culture materials, affinity matrices and control antibody materials.

Year 1 - \$30,630.60

Recombinant protein production

Indirect Costs:

HJF indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The fringe rate used is 29.42 % for Tier 1 employees and 7.29% for Tier 2 employees (all employees in this proposal are Tier 1).

The HJF indirect cost is calculated based on the value-added cost base overhead rates. The IDC rate is 36.74% USU Onsite Overhead. Additionally, 16.70% Companywide G&A and applied on the total direct cost less subaward plus the USU Onsite Overhead. For proposals including subawards, an additional 1.93% is applied on total external subaward costs.

The above fringe benefits and indirect cost rates for FY2023 were approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

FEE LANGUAGE HERE.

Hello Luke,

I don't anticipate any major changes But here is what we have. Note - there is a fee added to the project total costs. It is very minimal and we will include the language in the justification. Also, getting a countersignature from the chair, we should have that this morning also.

Thanks much Kim

Title: Strengthening capacity for bat-borne coronavirus, paramyxovirus, and filovirus threat reduction in Western Asia

Abstract: Bats are reservoir hosts for several viral families that pose significant threats to human and livestock health. The diversity of bat viruses and their potential for emergence remain largely unknown across Western Asia – a region with a mixture of bat species from northern Africa, Europe, and Asia, which may facilitate viral sharing and diversification. Over the last five years, our team established a field-to-laboratory biosurveillance network including wildlife biologists, virologists, and public health experts from seven Western Asian countries. Here we propose to build on that regional network with an in-depth zoonotic disease surveillance project targeting bats and multiple pathogens. Specifically, we will: 1) detect and characterize known and novel viral threats (coronaviruses, paramyxoviruses, and filoviruses) from newly collected and archived bat samples from Western Asian countries using virus-family specific and next-generation sequencing approaches and multiplex serological assays; 2) identify risk factors for virus shedding and transmission at the individual-, population-, and metapopulation-levels using repeated, longitudinal sampling of key bat species that are known reservoirs for zoonotic viruses (i.e. *Rousettus aegyptiacus*, *Rhinolophus ferrumequinum*); 3) strengthen the professional capacity of regional partners and local students to conduct and sustain One Health disease surveillance; and 4) expand multi-sectoral engagement of governmental and non-governmental partners in the Western Asia Bat Research Network to improve the timeliness of data sharing, zoonotic risk assessments, and mitigation. Our project will leverage prior DTRA investments to further enhance the capacity of regional stakeholders to rapidly detect, diagnose, report, and develop policies to mitigate zoonotic disease threats.

Background and Justification: Bats are important reservoirs for zoonotic viruses, including coronaviruses (CoVs, e.g. SARS, MERS), paramyxoviruses (PMVs, e.g. Hendra and Nipah), and filoviruses (FVs, e.g. Ebola and Marburg) that cause fatal diseases in human populations, livestock, and other wildlife species [1]. Yet there remains a lack of knowledge about bat-borne viral threats in Western Asia that may lead to a heightened risk of destabilizing zoonotic disease outbreaks [2]. Under the BTRP-funded project ‘Understanding the Risk of Bat-Borne Zoonotic Disease Emergence in Western Asia’ (HDTRA1170064) from 2017-22, we conducted a robust, regional surveillance effort to characterize CoV prevalence and diversity in 37 bat species distributed in 7 countries and established the Western Asia Bat Research Network (WAB-Net) [2]. Overall CoV prevalence across all species in Western Asia was relatively high (15%) as compared to previous surveillance findings from other regions, e.g. SE Asia (1.7 - 8.6%) [3].

Our previous BTRP project led to several key discoveries warranting further investigation. Using partial-gene sequencing, we characterized a wide diversity of newly-discovered CoVs circulating in the region, including a large cluster of alpha- and beta-CoVs with potential to cause human and/or livestock disease outbreaks. While our cross-sectional surveillance across many bat species and sites led to critical insights into the vast diversity of bat CoVs, there remains a critical need for *longitudinal studies* of bat species with high potential for transmitting these viruses across broad geographic distributions. Two bat species distributed in Western Asia are ideal candidates for such studies: *Rhinolophus ferrumequinum* and *Rousettus aegyptiacus*. Specifically, *R. ferrumequinum*, a species with the largest distribution of any bat species in Western Asia, had the highest CoV prevalence (33%) of all 37 species we tested, and is a known host for other CoVs and PMVs [4]. Whereas *R. aegyptiacus* has a patchy distribution across Western Asia and Africa, and is host to FVs with high mortality rates (i.e. Marburg virus

[5]), CoVs, and PMVs [4]. Longitudinal studies of these target bat species would allow for a more complete understanding of viral emergence risk, including what factors promote viral shedding and when (seasonally) spillover is most likely. Conducting in-depth longitudinal studies from sites across a wide geographic area will inform bat-borne viral dynamics at multiple levels, from individual to population and metapopulation, and across spatio-temporal scales [6].

Scientific & Threat Reduction Impact: Our project will fill in critical knowledge gaps related to the diversity of viruses in high consequence pathogen groups circulating in Western Asia, and identify drivers of viral dynamics and transmission risk at the individual-, population-, and metapopulation-levels in target bat reservoir species. **Our project will additionally serve multiple objectives of the Cooperative Biological Engagement Program (Thrust Area 6)** by 1) engaging country partners in hypothesis-driven, One Health research; 2) advancing our scientific knowledge of how, when, and why bats shed viruses that can lead to outbreaks; 3) supporting enhanced biosurveillance capacity of five partner laboratories to rapidly detect, diagnose, and report diverse zoonotic viruses using molecular and serological approaches; 4) employing best practices for biosafety management during hands-on field and lab trainings; 5) promoting sustainability via multidisciplinary, cross-border student training initiatives from field-to-lab-to-analysis; and 6) promoting multi-sectoral government engagement in regional disease surveillance and monitoring to improve data sharing and reporting.

Objectives:

- 1) Detect and characterize known and novel CoVs, PMVs, and FVs at the human-wildlife interface in newly collected and archived bat samples using a combination of molecular screening, partial- and full-genome sequencing, and multiplex serological assays;
- 2) Identify factors that influence virus shedding and transmission at the individual, population, and metapopulation-level via targeted, longitudinal sampling of key bat species in order to better forecast disease spillover risk;
- 3) Strengthen field and laboratory capacity of in-country partners, including the next-generation of One Health students, to conduct zoonotic disease surveillance and research;
- 4) Increase engagement of community and multisectoral government stakeholders to improve data sharing, zoonotic risk assessment and mitigation activities.

Our proposed project will test the following initial hypotheses to understand the risk of bat-borne viral emergence, to be refined during the project in collaboration with in-country partners: **H1)** Molecular and serological screening of diagnostic samples will lead to the detection of currently unrecognized virus threats circulating in bat populations of Western Asia (e.g. known or novel FVs); **H2)** Individual-level host traits (i.e. demographic and physiological) influence infection dynamics and transmission (e.g. transmission may increase during the reproductive period when immune suppression is greatest); **H3)** Population-level interactions (i.e. bat density, species diversity) play a role in infection dynamics within a site (e.g. greater species diversity leads to increased opportunities for transmission within and among species); **H4)** Viral diversity and infection dynamics will vary across spatiotemporal scales at the metapopulation-level, such that spillover risk will not be uniform across the geographic distribution in the region; and **H5)** Sites with increased bat-human interactions (e.g. cave tourism, rapid habitat modification) will be at greatest risk for a spillover event.

Methodology: *Site selection* (Y1): We will identify 6 sites that serve as roosts for our target bat species: *Rousettus aegyptiacus* (3) and *Rhinolophus ferrumequinum* (3) for prospective,

longitudinal sampling. Sites will be located in 3 countries: Turkey, Georgia, and Oman (*see map*).

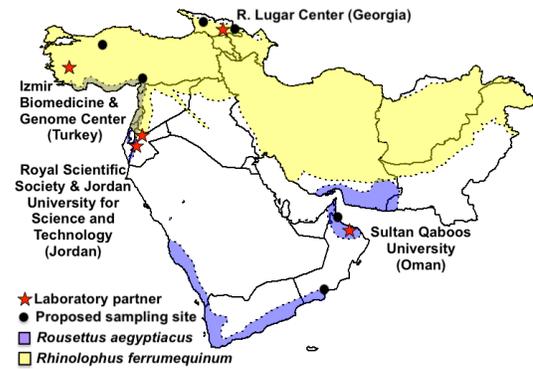

Site characterization (Y1-OY1): Using a multiscale approach, we will characterize environmental context at sampling sites for potential bat-human interfaces that may promote transmission risk. We will assess ecological and human disturbance factors during each sampling visit to monitor changes in bat-human interactions and spillover risk factors over time at each site, and assess broader land-cover and habitat changes using satellite images.

Bat sampling (Y1-OY1): We will conduct quarterly sampling (4 events/year) for 3 years at sites identified as roosts of target bat species. Specifically, we will collect non-lethal and field-inactivated (DNA/RNA Shield) diagnostic samples to screen for CoVs, PMVs, and FVs by: 1) capturing individual bats to safely collect non-lethal samples, specifically oral swabs, feces/rectal swabs, and blood samples, to assess the role of individual traits (e.g. sex, age, reproductive status) on infection dynamics; and 2) placing sterile plastic sheeting under aggregations of roosting individuals to collect pooled fecal and urine samples to further capture population-level viral dynamics and diversity. During each sampling event, we will sample at least 50 individual bats and collect additional pooled samples.

Virus screening of newly collected and archived samples (Y1-OY2): We will use family-specific consensus PCRs and subsequent partial- and full-genome sequencing to detect and characterize pathogen diversity in viral groups known to include select agents and important zoonoses: CoVs, PMVs, and FVs. We will begin with screening archived samples (i.e. oral swabs, feces/rectal swabs) previously collected from 4,275 individual bats from 50 sites in seven Western Asian countries under our previous BTRP-funded project (2017-22). Archived samples have been tested for CoVs, thus we will begin screening archived samples in Y1 for PMVs using PCR (FVs will be screened using serology given low molecular detection rates). In Y1, we will also begin further molecular characterization (Spike gene or full-genome) of selected, previously-identified CoVs to better understand phylogenetic relationships and infection risk. In addition, we will establish and use Luminex-based *multiplex* serological assays (validated via other DTRA-funded projects) to screen for antibodies (IgG) against viruses in target viral families (e.g. all FVs, select PMVs (henipaviruses), and diverse CoVs). Serological data will allow us to model infection dynamics in the population and among subpopulations.

Data management & analysis (Y1-OY2): We will establish a secure data management system to integrate field and laboratory data, and train country partners on best practices in data management and quality control. We will use multivariate and spatio-temporal modeling approaches to test hypotheses of individual-, population-, and metapopulation-level factors on infection dynamics, and conduct training with country partners on using these analyses. EHA will develop data analysis pipelines and ‘dashboards’ that integrate directly with our data management system, which will allow for ‘real-time’ generation of reports and outputs for communicating project findings with in-country stakeholder, including local communities.

Capacity Building: We will: **a)** Provide hands-on field trainings for relevant government staff, university faculty, and students to expand capacity to implement a longitudinal surveillance program while following strict biosafety and biosecurity standards; **b)** Develop and share

laboratory protocols for partial- and full-genome sequencing and multiplex serological assays and coordinate a regional training workshop (Y1) for country partners to implement protocols; **c)** Host 2x/year virtual “hot topic” biosurveillance workshops to strengthen research skills of country partners and encourage regional sharing of best practices and lessons learned. **d)** Host annual WAB-Net meetings (hybrid, in-person/virtual) with project partners, multisectoral government and non-government stakeholders to discuss project results and facilitate cross-sectoral data sharing. Y1-2 focus will be on integrating project data with existing national surveillance platforms to enhance biological threat reduction strategies in the region. **e)** Modify, translate, and use EHA’s “Living Safely with Bats” tool for community engagement at each site.

Tasks	Y1	Y2	Y3	OY1	OY2
Site selection for longitudinal sampling of target species	■	■			
Collect diagnostic samples from target species	■	■	■	■	■
Screen newly collected samples for corona-, paramyxo- & filoviruses		■	■	■	■
Screen archive samples for paramyxo- & filoviruses		■	■	■	■
Partial- and full-genome sequencing of prioritized samples		■	■	■	■
Data management, analysis, and hypothesis testing		■	■	■	■
Field & lab training for bat-borne disease surveillance	■	■	■	■	■
Facilitate topic-focused training workshops	■	■	■	■	■
Host annual meeting with stakeholders, including community engagement	■	■	■	■	■

Partner Institutions and Roles: **1) EcoHealth Alliance (EHA, PI Olival and co-PI Phelps)** will oversee all aspects of project implementation – study design, permissions, coordinate field and laboratory activities, and analyze and publish project findings with collaborators. EHA will be responsible for all contractual obligations, including tax liabilities, and maintaining regular communication with DTRA and project sub-awardees. EHA has worked with each partner institution for 5+ years. **2) R. Lugar Center, Georgia** will conduct longitudinal sampling at 2 roost sites for *R. ferrumequinum*; screen and conduct partial- and full-genome sequencing of viruses from 2,564 archived samples and newly collected samples. **3) Royal Scientific Society, Jordan** will screen and sequence viruses from 1,711 archived samples. **4) Jordan University for Science and Technology** will conduct full-genome sequencing on a subset of archived samples. **5) Boğaziçi University, Turkey** will conduct longitudinal sampling at 2 roost sites, 1 per species. **6) Izmir Biomedicine and Genome Center, Turkey** will screen newly collected samples using viral family-specific PCRs and partial- and full-genome sequencing. **7) Environment Authority, Oman** will conduct longitudinal sampling at 2 roost sites for *R. aegyptiacus*. **8) Sultan Qaboos University, Oman** will screen newly collected samples using viral family-specific PCRs and partial- and full-genome sequencing. **9) Uniformed Services University, USA** will lead in-country training, reagent development, and analysis for multiplex serological assays. Partner institutions will support cross-institution trainings for students and professionals. A **Scientific Advisory Board** with Western Asia representation will be established for overall project and scientific oversight.

Cost Estimates: Y1 (\$950,000) + Y2 (\$985,000) + Y3 (\$985,000) = \$2,920,000
 OY1 (\$980,000) + OY2 (\$950,000) = \$1,930,000

We will allocate > 50% of funds to in-country partners via subawards and direct benefits.

Funding Opportunity Title: Fundamental Research to Counter Weapons of Mass Destruction (FRCWMD) Broad Agency Announcement (BAA)

Announcement Type: This is an amended announcement of this funding opportunity. This BAA is in effect from March 2015 through September 2024. It is anticipated that a majority of the actions funded from this announcement will be in the form of grants; however, other instruments such as contracts, cooperative agreements (CAs) or other transactions agreements (OTAs) may also be awarded from this announcement. Submissions for this BAA may occur in two ways: 1) in response to the published topics detailed in [Attachment 1](#) or 2) to a general thrust area as described in [Section 1.5](#).

In general, all topic-specific and general thrust area submissions require pre-coordination in accordance with the guidelines in [Section 1.5](#) and [Section 4.2.1](#). DTRA reserves the right to waive the pre-coordination requirement for topics on a case-by-case basis; and will state the waiver applies within the individual topic description. If a pre-application white paper is received without prior coordination, DTRA may not review it. From the date of the disposition email the applicant has 63 days to submit the pre-application white paper. If the submission is not feasible within this 63-day window, the abstract must be coordinated again to ensure the interest in the white paper remains.

The evaluation of all submissions will be conducted in two phases. Phase I is for receipt and evaluation of pre-application white papers in direct response to a published topic or by invitation based on the assessment of the idea by the Technical POC. Phase II is for receipt and evaluation of invited proposal applications. Invitation to the Phase II, invited proposal submission, will be based on the evaluation results of the Phase I pre-application white paper.

Funding Opportunity Number: HDTRA1-14-24-FRCWMD-BAA

Catalog of Federal Domestic Assistance (CFDA) Number: 12.351

Dates: This BAA is open continuously from March 2015 through September 2024. Published topics will include instructions on any topic-specific opening and closing dates as well as any topic-specific limitations on award types, dollar values, and eligibility. Submissions to a general thrust area may occur at any time this BAA is in effect. Applicants should take care to note requirements for pre-coordination of an abstract.

ADDITIONAL OVERVIEW CONTENT

Research, educational program, or other effort proposals are sought from accredited degree-granting colleges and universities. Research, educational program, or other effort proposals are also sought from industrial, commercial (including small businesses), and not-for-profit research entities. DTRA strongly encourages and may give preference to pre-application white papers and proposals that demonstrate a significant contribution (significant is defined as a minimum of

30% of total value) by one (1) or more universities.

All submissions (pre-application white papers and invited proposals) must be made in accordance with the submission instructions in this BAA through www.grants.gov using the application packages linked with this BAA (under the "Package" tab) on www.grants.gov. Applicants are responsible for ensuring compliant and final submission of their pre-application white papers and proposal applications. Any submission that does not conform to the requirements outlined in the BAA and in the invitation for proposal may not be reviewed or considered further at the discretion of DTRA.

Pre-application white papers may be evaluated any time after receipt. Invitations for full proposal submission may occur any time after the pre-application white paper evaluation and will be limited to available program funds.

Efforts may be proposed for up to five (5) years. Awards may be for a base period of one (1) year with four (4) additional years as possible options, a base period of two (2) years with three (3) additional years as possible options, or a base period of three (3) years with two (2) additional years as possible options. Applicants should take care to propose the most logical mix of base and option years for the scope of work. Further, the base period should yield a logical completion point for the work. In cases where option years are proposed, decisions regarding exercising those options will be based on the evaluation of the work accomplished in the base period. Pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable; however, the Government reserves the right to invite option years for awards that originally only included a base period.

Grants may range from small dollar value (e.g., \$25K) up to \$1M annually (total, including both direct and indirect costs) depending on the nature and the scope of work. Payments on grants will be made in advance, subject to the conditions described in 2 CFR 200.305. Funding amounts for contracts, CAs, and other procurement instruments will be considered on a case-by-case basis. Thirty (30)-60 individual awards are anticipated each year.

Any assistance instrument awarded under this announcement will be governed by the award terms and conditions, which conform to DoD's implementation of OMB circulars applicable to financial assistance. This includes DoD implementation of OMB guidance in 2 CFR part 200, "Uniform Administrative Requirements, Cost Principles, and Audit Requirements for Federal Awards."

1. FUNDING OPPORTUNITY DESCRIPTION

1.1. DTRA safeguards America and its allies from weapons of mass destruction (WMD) and provides capabilities to reduce, eliminate, and counter the threat and effects from chemical, biological, radiological, nuclear, and high yield explosives. DTRA seeks to identify, adopt, and adapt emerging, existing and revolutionary sciences that may demonstrate high payoff potential to Counter-WMD (C-WMD) threats. This BAA is an extramural endeavor that combines the fundamental research, educational program, or other effort needs appropriate for basic or applied research funding of DTRA and other DoD interests.

This announcement solicits ideas and topic-based pre-application white papers for long-term challenges that offer a significant contribution: to the current body of knowledge, to the understanding of phenomena and observable facts, to significantly advance revolutionary technology, to new concepts for technology application, or that may have impact on future C-WMD threat reduction, expertise, or capabilities.

A portion of this effort is expected to be devoted to awards for science, technology, engineering and mathematics education programs with a C-WMD focus; such as, but not limited to postdoctoral fellowships, stipends, degrees, visiting scientist programs, student exchange programs, and development of accredited C-WMD curricula.

1.2. Fundamental research means basic and applied research in science and engineering, the results of which ordinarily are published and shared broadly within the scientific community, as distinguished from proprietary research and from industrial development, design, production, and product utilization, the results of which ordinarily are restricted for proprietary or national security reasons.

Contracted Fundamental Research includes research performed under grants, contracts (awards), or OTAs that are (a) funded by budget Category 6.1 (Basic Research), whether performed by universities or industry or (b) funded by budget Category 6.2 (Applied Research) performed on-campus at a university. Fundamental research provides for science and technology (S&T) research and early applied development. It seeks to lower performance risk to a manageable level and facilitate transition and funding to capability end-state programs.

1.3. Technology Readiness Levels (TRLs) provide a systematic metric/measurement system that supports assessments of the maturity of a particular technology and the consistent comparison of maturity between different types of technology. Fundamental research may be defined within the first four (4) TRLs.

1.4. This BAA seeks optimum approaches to meet DTRA fundamental research objectives. The Government encourages pre-application white papers and proposals that span a wide spectrum of research to expand fundamental scientific knowledge in response to specific topics and to the more general thrust areas. The Government reserves the right to award any combination of approaches which offer the best overall value to the Government and to oversee any and all processes and approaches once ongoing.

1.5. Thrust Areas 1-7 are described below. When a specific set of topics has been identified, these detailed needs will be described in [Attachment 1](#) along with any topic-specific submission instructions, deadlines, anticipated award structure, and funding requirements. Otherwise, pre-application white papers and proposals may be written against one of the general thrust area descriptions.

DTRA may not review any pre-application white papers without prior coordination of the idea with the appropriate thrust area- e-mail address ([Section 7](#)). Applicants should note that there is extremely limited funding available for many of the thrust areas; Thrust Areas 1-5 are not currently accepting abstracts for pre-coordination. Pre-application white papers will only be accepted from the coordinated abstracts under limited circumstances.

1.5.1. Thrust Area 1—*Science of WMD Sensing and Recognition*: The science of WMD sensing and recognition investigates the fundamental understanding of materials that demonstrate measurable changes when stimulated by radiation or particles from WMD in the environment. This involves the exploration and exploitation of interactions between materials and various electromagnetic phenomena, molecules, nuclear radiation, and particles. Furthermore, these interactions and the specific form of recognition they offer are used for the subsequent generation of information, providing knowledge of the presence, identity, and quantity of material or energy in the environment that may be significant. The goal of this thrust area's portfolio is to advance the following capabilities: location, identification and characterization of radiological-nuclear (RN) materials; detection of RN materials at significant stand-off distances; and the reduction of the technical nuclear forensics timeline. Thrust Area 1 is currently not interested in research focusing on the sensing of explosives or the detection of Improvised Explosive Devices (IEDs). **Thrust Area 1 is NOT currently accepting abstracts for pre-coordination.**

1.5.2. Thrust Area 2—*Network Sciences*: The fundamental science of network sciences includes advancing knowledge of complex disparate but interdependent networks critical to military operations where WMD-related robustness, resiliency, recovery of, and informational and operational utility is required. It includes response, resilience, and recovery of interdependent, multi-layered physical networks after exposure from electromagnetic pulse and other nuclear weapons effects, rapid discovery and analyzing low-observable WMD-related information from large, disparate WMD-related data sets from multiple types of networks, and to develop theories and representations for low observable WMD-related radical ideation from social networks. **Thrust Area 2 is NOT currently accepting abstracts for pre-coordination.**

1.5.3. Thrust Area 3—*Science for Protection*: Fundamental science for protection involves advancing knowledge in physical, biological, and engineering sciences to protect personnel, sensitive electronic systems, and structural infrastructure from the effects of weapons of mass destruction. Protection includes both passive and active defense against threats. Approaches include advanced highly-ordered materials and nanomaterials to hardening infrastructure and facilities against blast, nuclear events, or other CBRNE effects; exploring new methods to experimentally and computationally simulate the effects of a nuclear event; investigations of the interaction of radiation with sensitive electronics and systems as well as development of novel materials and methods that are robust against radiation effects; novel methods to protect personnel from the physical, radiological, and nuclear effects of WMDs; and the study of biological systems, including intact structures, metabolic products, or discrete components and pathways, as applied to protection of U.S. Forces during operations in areas actually or potentially contaminated by radiation. For protection of personnel the areas of interest include development of radiation countermeasures to prevent biological damage associated with exposure to ionizing radiation and development of novel biologically-based or -produced detection systems for wide area surveillance to determine the nature, extent, and distribution of contamination. **Thrust Area 3 is NOT currently accepting abstracts for pre-coordination.**

1.5.4. **Thrust Area 4—*Science to Defeat WMD***: Fundamental science for significantly improving energetic materials for use against WMD facilities and systems with minimal collateral effects from post-blast WMD release, for deeper penetration to deny the adversary sanctuary of WMD, and for predictable modeling of counter-WMD munitions and simulation of in-theater scenarios with accurate lethality calculations. ****Thrust Area 4 is NOT currently accepting abstracts for pre-coordination.****

1.5.5. **Thrust Area 5—*Science to Secure WMDs***: Fundamental science to support securing WMD includes: revolutionary means to safely handle, transport, control access, or eliminate WMD components and weapons; new physical or other methods to monitor compliance to support future agreements or treaties; and, exploring phenomena and means that facilitate reduction of nuclear or non-nuclear WMD proliferation pathways. This includes focus on: science principles to assist tagging, tracking, location to secure WMD; novel means to mark and read objects in order to secure inventories; remote or unattended monitoring to understand the nature of objects (e.g., is it nuclear, biological, chemical or conventional?); monitoring to detect intrusion, diversion or substitution, tampering, and other adverse activity; and, understanding of both physical and life science environmental signatures as witnesses of WMD-related activity. The ability to secure WMD may impact either verification of treaties, or control of WMD outside treaty regimes. ****Thrust Area 5 is NOT currently accepting abstracts for pre-coordination.****

1.5.6. **Thrust Area 6—*Cooperative Counter WMD Research with Global Partners***: Cooperative fundamental research to reduce the global threat of WMD in collaboration with a broad range of global research partners. This thrust area involves exploratory basic and applied research that will address opportunities to reduce, eliminate, and counter WMD across the Chemical, Biological, Radiological, Nuclear, and High Explosive (CBRNE) spectrum. Efforts in this area will develop strong international relationships which will foster a smooth transition of program ownership to the partnering country. The goal is to improve international collaboration to detect, characterize, and report WMD, and to advance partner nation sustainment through a culture of long-term cooperation and scientific responsibility for such programs. Multi-disciplinary, multinational research in science, technology, engineering, and mathematics development will be conducted to promote transparency through quality research publications and continual dialogue between scientists/engineers and young researchers.

The Cooperative Biological Engagement Program (CBEP), a component of the DoD Cooperative Threat Reduction (CTR) Program, recognizes the danger to U.S. and global health security posed by the risk of outbreaks of dangerous infectious diseases, whether natural or manmade. Consistent with the national and departmental strategies, CBEP strives to address this risk by promoting best practices in biological safety and security, improving partner country capability to safely and rapidly detect and report dangerous diseases, and establish and enhance international research partnerships that focus on informing the disease surveillance network. The desired end state for CBEP engagements is the development of sustainable partner country capabilities to:

- Employ responsible bio-risk management best practices and principles,
- Conduct a modern and effective disease surveillance mission,
- Independently sustain engagement with, and effectively compete for funding within, the international scientific community,

- Comply with World Health Organization (WHO) International Health Regulations (IHR) and World Organization for Animal Health (OIE)/U.N. Food and Agriculture Organization (FAO) reporting guidelines, and
- Promote the One Health Concept.

The goals and objectives of CBEP international research partnerships are to:

- Goal 1: Support Biosurveillance, Biosafety and Biosecurity (BS&S) Capability Building Efforts
 - Objective 1: Inform and enhance operational biosurveillance strategies and implementation through improved understanding of endemic disease burden and pathogen biology.
 - Objective 2: Institutionalize responsible biorisk management best practices with partner country scientists.
- Goal 2: Engage Partner Country Scientists in Hypothesis-Driven Research
 - Objective 1: Support local, national, and regional priorities for understanding and mitigating human and animal disease risk (e.g., small, focused projects within individual countries linked by broad, integrating projects that include regional partners).
 - Objective 2: Improve international collaborations to survey, detect, characterize, and report disease.
- Goal 3: Promote One Health Initiative
 - Objective 1: Emphasize the nexus of human health, animal health, and the environment, and seek to further understand the mechanisms and factors involved in disease transmission.
 - Objective 2: Advance partner country sustainment of global health security initiatives.
- Goal 4: Foster an International Culture of Responsible and Ethical Conduct in Biological Research
 - Objective 1: Transition to a culture of responsibility and ethical conduct in biological research through thoughtful experimental design and good laboratory practices that result in high-quality data, and active participation in professional societies and the peer-review process.
 - Objective 2: Train partner country researchers to think critically in the pursuit of ethical research and to be competitive in soliciting funding from the international scientific community.

Ultimately, the techniques, procedures, and approaches must be sustainable for the partner country and linked with appropriate training in order to promote global health security, reinforce norms of safe and responsible conduct, obtain timely and accurate insight on current and emerging infectious disease risks, and transform the international dialogue on biological threats.

CBEP research projects are not determined by or limited to specific biological agents, but must be plausibly linked to pathogens of security concern and aimed at measurably supporting threat reduction objectives that:

- Enhance partner country's/region's capability to identify, consolidate, and secure collections of pathogens and diseases of security concern in order to prevent the sale, theft, diversion, or accidental release of such pathogens and diseases.
- Enhance partner country's/region's capability to rapidly and accurately survey, detect, diagnose, and report biological terrorism and outbreaks of pathogens and diseases of security concern in accordance with international reporting requirements.

Region-specific areas of interest are described in CBEP Regional Science Plans. Examples of general CBEP research areas of interest include: Epidemiology (e.g. studies measuring disease prevalence and incidence), Pathogen Biology, Pathogen Characterization, Assay Adaptation and Optimization, Microbial Ecology within a Public Health Context, and Preventative Strategies and Countermeasures. For clarification, medical countermeasure development (i.e., development of diagnostic tools, vaccines, therapeutics) is supported by many other U.S. Government or international agencies and is generally not supported by CBEP; however, research projects may inform medical countermeasure development and support validation and verification testing (e.g., as part of proficiency testing, pilot studies/testing, or exercises, etc.). Additionally, CBEP does *not* generally support research with common disease agents such as HIV/AIDS, malaria, and tuberculosis where other U.S. agencies have dedicated missions to do so; however, the program may choose to capitalize on opportunities to leverage research on these diseases to further CBEP goals, for example by testing samples collected under the auspices of other programs. CBEP also *will not* support research which poses risks to the overall threat reduction mission of CBEP, Dual-Use Research of Concern, or related activities (i.e., *in vivo* pathogenicity studies, virulence studies, animal passaging, etc.).

CBEP is interested in collaborative research engagements with foreign partners in any one of the following regions: Countries of the Former Soviet Union (FSU) (specifically, Armenia, Azerbaijan, Georgia, Kazakhstan, and Ukraine), Africa (including, but not limited to, Kenya, Tanzania Uganda, South Africa), Southeast Asia (including, but not limited to, Cambodia, Indonesia, Laos, Malaysia, Philippines, Thailand), and Middle Eastern /South Asian countries (including, but not limited to, Afghanistan, Iraq, India and Pakistan). CBEP encourages proposers to develop projects in conjunction with foreign institutions in CBEP-engaged countries.

1.5.7. Thrust Area 7—*Fundamental Science for Chemical and Biological Defense:*

Fundamental science for chemical and biological (CB) defense includes science and technology research that advances knowledge in physical and life sciences to defend and counter chemical and biological WMD that could be used against our Nation's warfighters. Fundamental research efforts enable capabilities such as development of improved detection devices for traditional and nontraditional chemical agents; development of diagnostics for existing and emerging infectious disease threats; increasing knowledge and improved capabilities for development of new or improved medical and material countermeasures to CB threats for both pre- and post-exposure scenarios; enhanced personal protection against, modeling of, prevention of, or decontamination of CB threats; and providing effective elimination strategies via non-kinetic approaches for threat agent destruction, neutralization and/or sequestration.

1.6. This BAA, in addition to any amendments issued in conjunction with this BAA, will be posted to the Grant Opportunities Website (<https://www.grants.gov>), the System for Award Management website (<https://sam.gov/>), and the DTRA website (<https://www.dtra.mil>). The

DTRA website is not the official sites; applicants are responsible for monitoring both sam.gov and www.grants.gov. Posted amendments supersede all previous versions of the BAA. Note that topics will be listed in [Attachment 1](#) and will be added/closed with Amendments to this BAA.

1.7. All coordination and communication between applicants and the Government will be conducted using the e-mail address associated with this BAA, specified in [Section 7](#). Applicants should include both the administrative email and the relevant thrust area email address. DTRA will not release employee personal contact information.

2. AWARD INFORMATION

2.1. Award Types. The full range of flexible procurement instruments available to DTRA are possible results from this announcement, including but not limited to contracts, grants, CAs, and OTAs; however, grants will likely be the predominant procurement instrument. Each of the applicable procurement instruments offer different advantages, liabilities and responsibilities for applicants and the Government.

Applicants must specify in their submittal their recommended approach (e.g. contract, grant, CA, or OTA); however, the Government reserves the right to negotiate and award the types of procurement instruments determined most appropriate under the circumstances. If warranted, portions of resulting awards may be segregated into pre-priced options.

Except for OTAs, the Government actions under this BAA shall adhere to the requirements of the Federal Acquisition Regulation (FAR), Defense Federal Acquisition Regulation Supplement (DFARS) and/or DoD Grant and Agreement Regulations (DoDGARS), as appropriate for the type of instrument. DoDGARS can be accessed online at <http://www.ecfr.gov/cgi-bin/text-idx?SID=e5d686f6760f3274b3368f36723fbb7e&mc=true&tpl=/ecfrbrowse/Title32/32CISubchapC.tpl>. See also 32 Code of Federal Regulations (CFR) 22, which can be accessed online at <http://www.ecfr.gov/cgi-bin/text-idx?rgn=div5;node=32%3A1.1.1.3.16>. Any assistance instrument awarded under this announcement will be governed by the award terms and conditions, which conform to DoD's implementation of OMB circulars applicable to financial assistance.

On average, DTRA expects to award 30-60 individual awards each year. The predominance of awards will be grants. Payments on grants will be made in advance, subject to the conditions described in 2 CFR 200.305.

2.2. Scope of Awards. Awards may range from focused, exploratory projects with a high risk approach in innovative research in subjects with potential for high impact to C-WMD science to comprehensive programs of innovative research in an interdisciplinary area with potential for high impact.

Awards may have multiple Co-Principal Investigators (Co-PIs) and subawards. Authors of pre-application white papers and proposals should detail the contribution of all Co-PIs and any subawards to the C-WMD scientific impact.

Preference will be given to projects where undergraduate and/or graduate students, and/or postgraduate students are supported by the awards. Details regarding the participation of the students and the value of the research to the students as part of the pre-application white paper

and full proposal are expected. Additional guidance regarding student and/or postgraduate student participation may be provided in the published topics or in communications with the applicant to include the coordination of the abstract or in the debrief summary of the pre-application white paper. Any specific guidance provided in a topic or to an applicant supersedes the information provided herein.

2.3. Subawards. Subawards (subgrants and/or subcontracts) are permitted. Subawards may be used to carry out a portion of the research or efforts. Awards may have multiple subawards. Awards will be made by a single award, e.g., grant or contract, to the lead organization. All subawards are the responsibility of the award recipient; exceptions will not be made.

For submissions made to Thrust Area 6 and associated topics, there is no limitation on subawards. DTRA will review and consider the proposed subawards for all pre-application white papers and proposals on a case-by-case basis. The prime awardee will be responsible for transferring funds to the subawardee. Applicants are reminded that priority is given to projects with the main locus of activity in the region-of-interest, so budgets should be allocated accordingly. Preference will be given to proposals where the subaward component to the region-of-interest partner(s) represents more than half of the award value (as measured in U.S. dollars).

2.4. Award Values. Grants resulting from submissions to Thrust Areas 1-7, including topics associated with these thrust areas, may range from small dollar value (e.g., \$25K) up to \$1M annually (total, including both direct and indirect costs) depending on the nature and the scope of work. Contracts, CAs, and OTAs will be considered on a case-by-case basis. All awards are subject to the availability of funds. Additional guidance regarding award values may be provided in the published topics or in communications with the applicant to include the coordination of the abstract or in the debrief summary of the pre-application white paper. Any specific guidance provided in a topic or to an applicant supersedes the information provided herein. Funding for participation in this program is highly competitive and the cost of proposed research should strictly be maintained as detailed herein or as indicated in the invitation instructions.

2.5. Period of Performance and Award Structure. Efforts for Thrust Areas 1-7, including topics associated with these thrust areas, may be proposed for up to five (5) years. Awards may be for a base period of one (1) year with four (4) additional years as possible options, a base period of two (2) years with three (3) additional years as possible options, or a base period of three (3) years with two (2) additional years as possible options. Additional guidance regarding award structure may be provided in the published topics or in communications with the applicant to include the coordination of the abstract or in the debrief summary of the pre-application white paper. Any specific guidance provided in a topic or to an applicant supersedes the information provided herein.

Applicants should take care to propose the most logical mix of base and option years for the scope of work. Further, the base period should yield a logical completion point for the work. In cases where option years are proposed, decisions regarding exercising those options will be based on the evaluation of the work accomplished in the base period.

DTRA is flexible on the award structure unless otherwise specified in the published topics or in communications with the applicant to include the coordination of the abstract or in the debrief summary of the pre-application white paper. Applicants should take care to clearly label the tasks and anticipated outcomes for the base and option years in the pre-application white papers

and the proposals. Pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable; however, the Government reserves the right to invite option years for awards that were originally awarded with only a base period.

2.6. The Government Accountability Office, in its report GAO-16-14, WOMEN IN STEM RESEARCH: Better Data and Information Sharing Could Improve Oversight of Federal Grant-making and Title IX Compliance, December 3, 2015, recommended that the DoD collect certain demographic and career information to be able to assess the success rates of women who are proposed for key roles in applications in science, technology, engineering, or mathematics disciplines. To enable this assessment, DTRA will include with each Phase II application package the Research and Related Senior/Key Person Profile (Expanded) form and the Research and Related Personal Data form.

2.7. The Government does not anticipate the need to provide any hardware or software to execute the proposed research. However, DTRA will review and consider any hardware/software requests for all pre-application white papers and proposals on a case-by-case basis.

2.8. The Government reserves the right to fund all, some, or none of the proposals submitted; may elect to fund only part of any or all proposals; and may incrementally fund any or all awards under this BAA. The Government also reserves the right to request applicants make any changes necessary to submitted full proposals to increase the feasibility of making the proposal fundable. Applicants may decline to participate in any revisions to application packages requested by DTRA.

2.9. The Government may offer funding for any full proposals or portions of proposals at any time during the lifetime of this BAA.

3. ELIGIBILITY INFORMATION

3.1. Pre-application white papers and proposals submitted for this BAA will be considered from the following U.S. and Foreign Institutions as follows:

- Accredited degree-granting colleges, universities, and academic institutions.
- Industrial and commercial entities, including small businesses.
- Not-for-profit entities with a portfolio predominantly in research and foreign government laboratories. Proof of 501(c)(3) status from the Internal Revenue Service may be required. For foreign-based establishments entirely based outside the U.S. and/or its territories, proof of not-for-profit status may be required. Foreign based government laboratory equivalents include those residing in the Ministry of Defense, Ministry of Health, Ministry of Agriculture, Ministry of Education and Science and Food Safety Agencies.

DTRA strongly encourages and may give preference to pre-application white papers and proposals that demonstrate a significant contribution (significant is defined as a minimum of 30% of total value) by one (1) or more universities. Applicants should note that university participation may be mandatory for some published topics. Additional guidance regarding university participation may be provided in the published topics or in communications with the

applicant to include the coordination of the abstract or in the debrief summary of the pre-application white paper. Any specific guidance provided in a topic or to an applicant supersedes the information provided herein.

The following entities may not participate as prime awardees nor furnish Principal Investigators (PIs) in awards made under this BAA but may act as collaborators, including as Co-PIs, and/or subawardees:

- Federal Academic organizations (e.g., Naval Postgraduate School).
- Federal laboratories (including DoD and Department of Energy (DOE)).
- U.S. Government agencies.
- DoD-sponsored Federally Funded Research and Development Centers (FFRDCs) specified in the Defense Federal Acquisition Regulation Supplement (DFARS) 235.017-1 (<http://farsite.hill.af.mil/VFDFARA.HTM>) and click on 'DFARS Part 35'.
- DOE-sponsored FFRDCs.

Note: Federal laboratories (including DoD and DOE) and FFRDCs are eligible to submit abstracts (when required), pre-application white papers, and proposals in response to the Government Call (HDTRA1-16-24-FRCWMD-Call). However, a FFRDC (other than the DoD FFRDCs specified in DFARS 235.017-1) must have authorization from its sponsoring agency in accordance with FAR 35.017-1. Eligibility requirements under the Call are subject to change. See <http://www.dtrasubmission.net> and after logging in, follow the link to the 'FY16-24 Fundamental Research to Counter Weapons of Mass Destruction (C-WMD) Government Call'.

3.2. Cost Sharing or Matching. In general, cost sharing or matching is not required for applications to this announcement. However, DTRA reserves the right to require cost sharing or matching on a case-by-case basis. Such instances will be specifically detailed in the published topics or in communications with the applicant to include the coordination of the abstract or in the debrief summary of the pre-application white paper.

3.3. Other. DTRA uses the System for Award Management (SAM) to exclude recipients ineligible to receive Federal awards. SAM can be accessed online at <http://sam.gov> (Reference 2 CFR 1125).

4. APPLICATION AND SUBMISSION INFORMATION

4.1. Address to Request Application Package. This announcement contains all information required to submit a pre-application white paper and invited proposal.

4.1.1. The required application packages for the pre-application white papers and for the invited proposals are posted with this announcement. Note that each thrust area (as outlined in [Section 1.6](#)) and each topic (as outlined in [Attachment 1](#)) has a unique application package posted with this BAA. The application package corresponding to both: a.) the thrust area or topic of interest and b.) the phase, should be used for submission of pre-application white papers and invited full proposals.

4.1.2. The application packages posted to www.grants.gov consist of the forms as detailed in

Table 2.

Form Name	Phase I Pre-Application White Paper	Phase II Invited Proposal
SF-424 (R&R) Application for Federal Assistance Form	Required	Required
RR Budget Form	N/A	Required
R&R Subaward Budget Attachment(s) Form(s)	N/A	If Applicable
Research & Related Senior/Key Person Profile Form (Expanded)	N/A	Required
RR Personal Data	N/A	Required
Research & Related Other Project Information	N/A	Required
Disclosure of Lobbying Activities (SF-LLL)	N/A	If Applicable
Attachments Form	N/A	Required

Table 2: Forms. The instructions for completing each of these forms may be found online at the following web link: <http://www.grants.gov/web/grants/form-instructions.html>.

4.2. Content and Form of Application Submission. Submissions for this BAA will be conducted in two phases. Phase I is for receipt of pre-application white papers. Phase II is for receipt of invited proposal applications. Invitation to the Phase II proposal submission will be based on the evaluation results of the Phase I pre-application white paper.

4.2.1. The predominance of efforts, including all submissions to the thrust areas and some submissions to topics posted in [Attachment 1](#), as noted within the topic, **must be** coordinated with the relevant technical point of contact (POC) for the appropriate thrust area prior to submission of a pre-application white paper; an e-mail for the DTRA technical POCs for Thrust Areas 1-7 are provided in [Section 7](#). Applicants should note that Thrust Areas 1-5 are not currently accepting abstracts for pre-coordination. Coordination of research ideas and efforts must be accomplished via these email addresses, except in cases where a topic specifically states that pre-coordination is not required, and includes submission of an abstract (recommend less than 250 words) of the proposed project/effort or a paragraph description of the proposed project/effort to the email address in [Section 7](#) and a reply email from the relevant email address in [Section 7](#) with the disposition to the applicant. Pre-coordination may not be accomplished with email addresses other than those listed in [Section 7](#). DTRA will not review white papers without prior coordination. Please note that attachments to e-mails may not be reviewed.

Applicants should note that there is extremely limited funding available for the general thrust areas. Pre-application white papers will only be accepted from the coordinated abstracts under very limited circumstances.

Topics may be posted in [Attachment 1](#) of this announcement that may not require pre-coordination of an abstract. Please review the topics carefully.

4.2.2. Pre-application white papers and invited proposals **must be** submitted electronically

using www.grants.gov and the corresponding application packages linked with this BAA on www.grants.gov (under the “Packages” tab). All applications, including all supporting documents, must be submitted in the English language.

Applicants are responsible for ensuring compliant and final submission of their Phase I pre-application white paper and Phase II invited proposal application. Note that this also applies to applicants using third party systems to submit application packages and attachments. Any submission that does not conform to the requirements outlined in the BAA and in the invitation for proposal may not be reviewed or considered further at the discretion of DTRA.

4.2.3. DTRA will not review any of the following:

- Pre-application white papers that are not pre-coordinated as required
- Pre-application white papers and proposals that are not submitted in the English language.
- Pre-application white papers that are submitted to topics that have been previously closed via an amendment to the BAA.
- Application packages and proposals for Phase II submissions that were not invited.

Exceptions WILL NOT be made under any circumstances.

4.2.4. Phase I Pre-Application White Paper Submission and Content. Each pre-application white paper must address only one thrust area or topic. Each pre-application white paper must use the corresponding thrust area or topic application package.

Each Phase I application package contains the following forms:

Form	Attachment	Action
SF-424 (R&R) Application for Federal Assistance Form	Up to four (4) page white paper	Enter the appropriate information in data fields

Table 3: Phase I Pre-Application White Paper Package Chart.

Each Phase I application package contains the SF 424 (R&R) Application for Federal Assistance. To be considered a complete package, an up to four (4) page white paper is required to be uploaded as an attachment to the SF 424 (R&R).

DTRA-specific instructions for completing the SF 424 (R&R) Application for Federal Assistance are below, general application instructions can be found on www.grants.gov:

- Block 1 – Type of Submission. Applicants should indicate the Phase I submission is a “Pre-Application.”
- Block 2.1 – Applicant Identifier. Not applicable.
- Block 3 – Date Received by State. Not applicable.
- Block 3.1 – State Application Identifier. Not applicable.
- Block 5 – Applicant Information. You must provide a Business Office Point of Contact (BPOC) with an e-mail address.
- Block 19 – Authorized Representative. The “signature of AOR” is not an actual signature and is automatically completed upon submission of the electronic application package. Hard copies or email attachments of applications will not be accepted.

- Block 20 – Pre-application. Must be used to attach an up to four (4) page white paper. The white paper itself should provide sufficient information on the research being proposed (e.g., the hypothesis, theories, concepts, approaches, data measurements and analysis, etc.) to allow for an assessment by a technical expert.

Any pages submitted for the white paper that exceed the limit of four pages will not be read or evaluated. A page is defined as 8 ½ x 11 inches, single-spaced, with one-inch margins in type not smaller than 12 point Times New Roman font. The white paper must be provided in portrait layout.

At minimum, the white paper should address the following:

- A project abstract, which should be concise (less than 250 words), provide a summary of the proposed work, and demonstrate relevance to the topic being addressed. The abstract should not contain any proprietary data or markings.
- Potential scientific impact to provide greater knowledge or understanding of the fundamental aspects of phenomena and of observable facts, including how the research contributes to the C-WMD science needs outlined in the thrust area or topic.
- The impact of the research on C-WMD science must be clearly delineated.
- Cost estimate by year and total dollars required to accomplish the research as presented in the white paper (no details or breakout of costs is required).
- Potential team and management plan, including details on student involvement.
- Multidisciplinary white papers should carefully detail each of the institutions/departments involved and the contribution that will be made by each of the investigators.
- Do NOT include corporate or personnel qualifications, past experience, or any supplemental information with the white paper. References may be included within the 4-page limit at the discretion of the applicant; however, extensive references are not required.
- Thrust Area 6 pre-application white papers must also include a description of the extent and duration of the relationship/collaboration between the universities/institutes/entities and/or scientists.
- The thrust area or the topic should be included as a header on the white paper attachment and referenced in the text of the white paper.

4.2.5. Phase I Pre-Application White Paper Re-Submission and Content. On a limited basis a second pre-application white paper may be submitted without pre-coordination of an abstract. These re-submissions will be based on the review of the original pre-application white paper and will be allowed when changes to the project scope, technical approach, and/or cost are envisioned for any potential full proposals. Revised pre-application white papers must conform to the standards for the pre-application white papers detailed in [Section 4.2.4](#).

All submissions should be made with the appropriate Phase I application package which contains the following form:

Form	Attachment	Action
SF-424 (R&R) Application for Federal Assistance Form	Up to four (4) page white paper	Enter the appropriate information in data fields

Table 4: Phase I Pre-Application White Paper Package Chart.

Each Phase I application package contains the SF 424 (R&R) Application for Federal Assistance. To be considered a complete package, an up to four (4) page white paper is required to be uploaded as an attachment to the SF 424 (R&R).

The DTRA-specific instructions for completing the SF 424 (R&R) Application for Federal Assistance are the same as for the original pre-application white paper submission except for the following:

- Block 1 – Type of Submission. Applicants should indicate the Phase I re-submission is a “Changed/Corrected Application.”
- Block 4c – Previous Grants.gov Tracking ID. Enter the Phase I Grant ID for the original submission.

At minimum, the revised white paper should address the issues and questions detailed in the debrief summary.

4.2.6. Phase II - Invited Proposal Submission and Content. Each proposal must address only the thrust area or topic for which it was invited. The application package corresponding to the thrust area or topic of interest should be used for submission of invited full proposals.

Each Phase II application package contains the following forms and attachments:

Form	Attachment	Action
SF-424 (R&R) Application for Federal Assistance Form	<i>N/A</i>	Enter the appropriate information in data fields
RR Budget Form	Budget Justification for entire performance period	Attach to Section K in budget period one
RR Sub-award Budget Attachment(s) Form (<i>if applicable</i>)	Individual sub-award budgets	Attach a separate budget with justification for each sub-award
Research & Related Senior/Key Person Profile Form	PI Biographical Sketch	Attach to Biographical Sketch field
	PI Current/Pending Support	Attach to Current & Pending Support field
	Key Personnel Biographical Sketches	Attach to Biographical Sketch field for each senior/key person
	Key Personnel Current/Pending Support	Attach to Current & Pending Support field for each senior/key person
RR Personal Data Form	<i>N/A</i>	Enter the appropriate information in data fields
Research & Related Other Project Information Form	Publicly Releasable Proposal Summary/ Abstract	Attach to Block 7 Project Summary/ Abstract

	Project Narrative/Technical Proposal	Attach to Block 8 Project Narrative
Disclosure of Lobbying Activities (SF-LLL) (if applicable)	N/A	Enter the appropriate information
Attachments Form	Attachment 1 – SOW	Upload as Attachment 1
	Attachment 2 – Quad Chart	Upload as Attachment 2
	Attachment 3 – Supporting Documentation (Thrust Area 6 submissions only)	Upload as Attachment 3

Table 5: Phase II Proposal Package Forms and Attachments.

DTRA reserves the right to consider incomplete application packages and required attachments and to request any missing information via email. Should the applicant fail to provide all the requested information either as part of the www.grants.gov submission or in response to email requests from DTRA, at their discretion, DTRA may not consider the proposal further.

SF 424 (R&R) Application for Federal Assistance: DTRA-specific instructions for completing the SF 424 (R&R) are below. General application instructions can be found on www.grants.gov:

Block 1 – Type of Submission. Applicants should indicate the Phase II submission is an “Application.”

Block 2.1 – Applicant Identifier. Not applicable.

Block 3 – Date Received by State. Not applicable.

Block 3.1 – State Application Identifier. Not applicable.

Block 4b – Agency Routing Identifier. Enter the corresponding Phase I Grant ID. If resubmissions were involved, enter the Grant ID for the last submission.

Block 5 – Applicant Information. You must provide a Business Office Point of Contact (BPOC) with an e-mail address.

Block 17 – Regarding Disclosure of Funding Sources. By checking "I Agree" you agree to abide by the following statement: "By signing this application, I certify the proposing entity is in compliance with Section 223(a) of the William M. (Mac) Thornberry National Defense Authorization Act for Fiscal Year 2021 which requires that: (a) the PI and other key personnel certify that the current and pending support provided on the proposal is current, accurate and complete; (B) agree to update such disclosure at the request of the agency prior to the award of support and at any subsequent time the agency determines appropriate during the term of the award; and (c) the PI and other key personnel have been made aware of the requirements under Section 223(a)(1) of this Act. I am aware that any false, fictitious, or fraudulent statements or claims may subject me to criminal, civil, or administrative penalties. (U.S. code, Title 18, Section 1001)."

Block 19 – Authorized Representative. The “signature of AOR” is not an actual signature and is automatically completed upon submission of the electronic application package.

RR Budget Form: The Research and Related Budget Form provided as part of the application package for the Phase II submission should be filled out in its entirety for each project year proposed. Applicants are responsible for ensuring appropriate, approved rates are used in their budget forms. When notified of selection applicants will be requested to provide their current

rate agreement and the rate agreement of their subcontractor(s), if applicable. Applicants should note that in accordance with 32 CFR 22.205(b), grants shall not provide for the payment of fee or profit to the recipient. Applicants should also carefully review [Section 4.5.4](#) to appropriately evaluate inclusion of Value Added Tax (VAT) or other taxes for assistance awards.

Applicants should plan and budget for travel to accommodate the two meetings outlined below:

- National Conferences/Workshops/Symposia: Applicants are strongly encouraged to attend a nationally recognized conference, workshop, or symposium in the field of research each calendar year (1 at minimum). Research should be presented as soon as adequate data are available to support posters and presentations. Conferences/workshops/symposia should be attended by the PI and students supporting the research, as appropriate.
- Annual Technical Review: Applicants should plan to attend an annual technical program review meeting. For planning purposes the review will be for five days and will be held in Northern Virginia.

Budget Justification: Applicants are required to submit a budget justification. The budget justification should be prepared as outlined in the instructions for the Research and Related Budget and uploaded as an attachment to Section K “Budget Justification” of the Research and Related Budget Form. The budget justification does not have a page limit, but should include sufficiently detailed information for meaningful evaluation. In addition, the budget justification must specifically address subaward costs and type to include the portion of work to be subawarded with a supporting rationale. The budget justification should include a discussion of how the subawardee(s) cost was determined to be fair and reasonable. The budget justification must specifically address VAT and other taxes in accordance with [Section 4.5.4](#).

RR Subaward Budget Attachment(s) Form (if applicable): Detailed cost estimates are required for each proposed subaward. The cost estimate for the subawards should include sufficiently detailed information for meaningful evaluation, including labor rates and indirect cost rates.

Research and Related Senior/Key Person Profile Form (Expanded): The Research and Related Senior/Key Person Profile Form (Expanded) should be completed in its entirety for each of the PIs and Co-PIs on the project. The inclusion of additional personnel is at the discretion of the PI. The Degree Type and Degree Year fields will be used by DoD as the source for career information to assess the success rates of women. In addition to the required fields on the form, applicants should complete these two fields for all individuals that are identified as senior or key persons. For Thrust Area 6 submissions, the PI (and Co-PIs) in the region-of-interest should be included as key personnel.

A biographical sketch is required for each PI and Co-PI on the project. DTRA does not have a preference for the format of the biographical sketch; however, it should be limited to 1 page per person. The biographical sketch should be uploaded as an attachment to the corresponding field on the Research and Related Senior/Key Person Profile Form.

Additionally, a statement of current and pending support must be provided for each of the key personnel (e.g., PI and Co-PI) on the project. This statement must include the following items and requires disclosure of all grants and contracts through which each of the key personnel is currently receiving or may potentially receive financial support:

- A list of all current projects the individual is working on, in addition to any future support the

individual has applied to receive, regardless of the source.

- Title and objectives of the other research projects.
- The percentage per year to be devoted to the other projects.
- The total amount of support the individual is receiving in connection to each of the other research projects or will receive if other proposals are awarded.
- Name and address of the agencies and/or other parties supporting the other research projects.
- Period of performance for the other research projects.

Applicants should note that in accordance with the instructions for completion of the SF 424, checking of Block 17 is required. Further, applicants should note that by checking block 17 and submitting an application package, you agree to abide by the following statement: "By signing this application, I certify the proposing entity is in compliance with Section 223(a) of the William M. (Mac) Thornberry National Defense Authorization Act for Fiscal Year 2021 which requires that: (a) the PI and other key personnel certify that the current and pending support provided on the proposal is current, accurate and complete; (B) agree to update such disclosure at the request of the agency prior to the award of support and at any subsequent time the agency determines appropriate during the term of the award; and (c) the PI and other key personnel have been made aware of the requirements under Section 223(a)(1) of this Act. I am aware that any false, fictitious, or fraudulent statements or claims may subject me to criminal, civil, or administrative penalties. (U.S. code, Title 18, Section 1001)."

RR Personal Data Form: This form will be used by DoD as the source of demographic information, such as gender, race, ethnicity, and disability information for the PI and Co-PI(s). Each application must include this form with the name fields of the PI and any Co-PI(s) completed; however, provision of the demographic information in the form is voluntary. The demographic information, if provided, will be used for statistical purposes only and will not be made available to merit reviewers. Applicants who do not wish to provide some or all of the information should check or select the "Do not wish to provide" option.

Research and Related Other Project Information Form:

Block 7 – Project Summary/Abstract. To fulfill the requirements of Section 8123 of the Defense Appropriations Act, which states: "The Secretary of Defense shall post grant awards on a public Web site in a searchable format," DTRA will collect and post via the Defense Technical Information Center (DTIC) basic information about all awards made under this BAA. The information posted will include the abstract submitted to Block 7 of this form.

The uploaded project abstract should be less than one page and provide a summary of the proposed work and demonstrate relevance to the topic being addressed. Most importantly, the abstract **must be** written such that the general public may easily understand the potential scientific contribution and the impact of the research. The header of this uploaded document must contain the following statement:

"This publically releasable abstract is provided to DTRA for use in fulfillment of Section 8123 of the Defense Appropriations Act and future versions of the same."

The abstract absolutely must not contain any proprietary data or markings.

Block 8 – Project Narrative (Technical Proposal). The uploaded technical proposal must not exceed 20 pages (including references). If the proposal exceeds 20 pages, only the first 20 pages will be reviewed. A page is defined as 8 ½ x 11 inches, single-spaced, with one-inch margins in type not smaller than 12 point Times New Roman font. The technical proposal must be provided in portrait layout.

The project narrative (technical proposal) must include the following components:

- **Abstract.** Should be a technical project abstract that is distinct from the Project Summary/Abstract that is attached to Block 7.
- **Scope.**
- **Objective.** A clear and concise objective of the proposed project.
- **Background.** Provide the necessary technical and scientific background to support the scientific and/or technical merit of the proposed project.
- **Programmatic.** Describe your organization’s management plan for the proposed project; list supporting and collaborating centers, and the roles/responsibilities of each identified academic and/or industrial subcontractor supporting the project. Authors of multidisciplinary proposals must take great care to clearly outline the impact to C-WMD science that is to be gained from the investment and justify the scientific contribution from each investigator.

Thrust Area 6 narratives must also describe of the extent and duration of the relationship/collaboration between the universities/institutes/entities and/or scientists. Teams with pre-existing collaborative research relationships and those which propose to establish new collaborations will be considered, provided teams can supply documentation to demonstrate that an operational framework exists to support the proposed work. Please see Attachment 3 below for information on the submission of this documentation.

- **Relevance.** Describe the relevance of the proposed project in terms of advancing the state of the science and the anticipated scientific impact on capabilities to potentially reduce, eliminate, counter, provide greater knowledge or understanding of the threat, and mitigate the effects of WMD fundamental aspects of phenomena and of observable facts.
- **Credentials.** Describe the PI’s qualifications and the organization’s qualifications to perform the proposed work. Summarize the credentials of the primary performing center, and supporting academic and industrial partners to perform the work. Describe specific examples of equipment and/or facilities available to perform the proposed work. Focus on information directly relevant to the proposed work.
- **Work to be Performed.** Provide details of the work to be performed by task and subtask. Tasks must be grouped by project year; base and option years should be clearly labeled. Additional details that are required include the following:
 - **Sample Repository.** Thrust Area 6 narratives must also clearly identify how the applicant plans to maintain samples collected during the proposed research effort, along with relevant metadata, for at least 12 months after the project end date. Note that annual sample repository information must be submitted using a DTRA-specified format that will be made available to awardees.
 - **Protection of Human Subjects.** For full discussion, see [Section 6.2.2](#). If the proposed

work involves human subjects or the use of human anatomical substances (e.g., biospecimens, blood, tissue, cell lines), either living or post-mortem, applicants are required to: a) justify and b) outline the use, and c) include the source of the human subjects, human biospecimens and/or human data involved in the research. The DTRA Research Oversight Board (ROB) will provide ongoing oversight throughout the duration of the effort to ensure proper approvals are in place. Further information will be required if the proposal is selected for award.

- **Animal Use.** For full discussion, see [Section 6.2.3](#). If the proposed work involves the use of animals, applicants are required to: a) justify and b) include detailed information on the use of animals, and c) include the location(s) of where the animal work is to be performed. The DTRA Research Oversight Board (ROB) will provide ongoing oversight throughout the duration of the effort to ensure proper approvals are in place. Further information will be required if the proposal is selected for award.
- **Performance Schedule.** Provide a table of tasks and sub-tasks and the duration of performance of each in a Gantt or other suitably formatted chart.
- **References.** List any relevant documents referenced.

Disclosure of Lobbying Activities (SF-LLL) Form: The Disclosure of Lobbying Activities Standard Form-LLL, if applicable, should be completed.

Attachments Form: The attachments form should be used to include the following three items with the application:

Attachment 1 – SOW. The SOW does not have a page limit, but should be approximately 3-5 pages in length for incorporation into an award document. The SOW should not contain any proprietary data or markings. Pages should be numbered and the initial page should have a date (document date) shown under the title (the title of the SOW should match that of the proposal).

The proposed SOW must accurately describe the research to be performed. The proposed SOW must also contain a summary description of the technical methodology as well as the task description, but not in so much detail as to make the SOW inflexible. The SOW format/guidance is as follows:

- **Objective:** Brief overview of the specialty area. Describe why the research is being pursued and what knowledge is being sought.
- **Scope:** Include a statement of what the SOW covers including the research area to be investigated, objectives/goals, and major milestones and schedule for the effort.
- **Background:** The applicant must identify appropriate documents, including publications that are applicable to the research to be performed. This section includes any information, explanations, or constraints that are necessary in order to understand the hypothesis and scientific impact on capabilities needed to reduce, eliminate, and counter the threat, and also mitigate the effects of WMD. It may also include previously performed relevant research and preliminary data.
- **Tasks/Scientific Goals:** This section contains the detailed description of tasks which represent the research to be performed that are contractually binding. Thus, this portion of the SOW should be developed in an orderly progression and presented in sufficient detail to

establish the methodology and feasibility of accomplishing the overall program goals. The work effort should be segregated by performance period for all tasks to be performed and anticipated milestones realized in that year (e.g., Year 1, Year 2, etc., should be detailed separately). Identify the major tasks in separately numbered sub-paragraphs. Each major task should delineate, by subtask, the research to be performed by year and number each task using the decimal system (e.g., 4.1, 4.1.1, 4.1.1.1, 4.2, etc.). The sequence of performance of tasks and achievement of milestones must be presented by project year and task in the same sequence as in the Project Narrative/Technical Proposal. The SOW must contain every task to be accomplished to include a detailed schedule.

- The tasks must be definite, realistic, and clearly stated. Use “the awardee shall” whenever the work statement expresses a provision that is binding. Use “should” or “may” whenever it is necessary to express a declaration of purpose. Use active voice in describing work to be performed. Do not use acronyms or abbreviations without spelling out acronyms and abbreviations at the first use; place the abbreviation in parenthesis immediately following a spelled-out phrase. If presentations/meetings are identified in your schedule, include the following statement in your SOW: “Conduct presentations/meetings at times and places specified in the grant schedule.”
- ***Deliverables:*** Thrust Area 6 **requires** several additional items be included in the SOW. These items are as follows:
 - Submission of annual sample repository information using a DTRA-specified format.
 - Access to all samples collected and data generated during the course of the project, up to and including at least 12 months after the project end date.

Attachment 2 – Quad Chart. The quad chart must be presented on one (1) page. The quad chart must not contain any proprietary data or markings. The quad chart must be provided in landscape layout. The quad chart should be uploaded as “Attachment 2” of the Attachments Form.

Attachment 3 – Supporting Documentation. For Thrust Area 6 proposals ONLY. Thrust Area 6 narratives must also describe an operational framework to support the proposed work. This includes, but is not limited to the following: the extent and duration of the relationship/collaboration between the universities/institutes/entities and/or scientists. Teams with pre-existing collaborative research relationships and those which propose to establish new collaborations will be considered, provided teams can supply documentation to demonstrate that an operational framework exists to support the proposed work. Each of the following should be concatenated into a single document, in the order specified:

- Specific identification of foreign Principal Investigators (PIs) and number of/job title for other members of the foreign research team.
- Detailed description of the relationship between the proposed research project and current research efforts at the foreign institution.
- Description of facilities and any other evidence of suitability of foreign collaborators and sites. In the event that the foreign research component will involve human or other vertebrate animal use, appropriate facilities compliance and certifications documents must be provided. Refer to [Section 6.2.2](#) and [Section 6.2.3](#) for specific information on required

approvals and documentation.

- Foreign PI letter of collaboration describing, at minimum, the suitability of the proposed work with respect to ongoing research efforts at the foreign institution, merit of the proposed collaboration, and the expected mutual benefits.

Protocol Risk Assessment Tool (PRAT). For Thrust Area 6 proposals ONLY. Applicants will be provided a copy of the PRAT file following their invitation to submit a Phase II full proposal and complete it in its entirety for **each** foreign institution participating in the project. Additional instructions for completing the PRAT may be found within the file. The completed PRAT file(s) should be emailed as a Portable Document File (PDF) format to HDTRA1-FRCWMD-A@mail.mil within two (2) weeks of the full proposal submission. **DO NOT** attempt to attach the PRAT(s) to the www.grants.gov submission.

4.2.7. Phase II - Additional Information Requests by DTRA. A revised proposal may be requested based on the review of the original proposal. Revised proposals will be requested when changes to the project scope, technical approach, and/or cost are required before the proposal could be further considered for an award. Applicants whose proposals are of interest to DTRA may be contacted to provide additional information or to make requested revisions prior to the final decision on funding. This request for further information may include revised budgets or budget explanations, revised SOWs, and other information, as applicable, to the proposed award. Additional instructions may be provided in the request for a revised proposal. Applicants who are not responsive to Government requests for information in a timely manner, defined as meeting Government deadlines established and communicated with the request and not making satisfactory updates as requested, may be removed from award consideration. Applicants may also be removed from award consideration if the applicant and the Government fail to negotiate mutually agreeable terms within a reasonable period of time.

Re-submissions should be made with the appropriate Phase II application package for the thrust area or topic of interest and should be completed in accordance with the instructions provided in the notification email.

The DTRA-specific instructions for completing a proposal re-submission are the same as for the original submission, except the SF 424 (R&R) Application for Federal Assistance should be marked as follows:

- Block 1 – Type of Submission. Applicants should indicate the Phase II submission is a “Changed/Corrected Application.”
- Block 4b – Agency Routing Identifier. Enter the corresponding Phase I Grant ID.
- Block 4c – Previous Grants.gov Tracking ID. Enter the Phase II Grant ID for the original Phase II submission.

4.2.8. File Format. Documents should be uploaded as a Portable Document File (PDF) format. Perform a virus check before uploading any files to www.grants.gov as part of your application package. If a virus is detected, it may cause rejection of the file.

Do not lock or encrypt any files you upload to www.grants.gov as part of your application package. Movie and sound file attachments will not be accepted.

4.2.9. All submissions must be completely UNRESTRICTED and UNCLASSIFIED;

submissions must not contain Controlled Unclassified Information (CUI), other Proprietary information or export controlled information or be marked as such.

4.2.10. Confirmed Proposal Expiration Date. Applicants requesting contracts must provide written confirmation that holds the proposal, to include proposed costs, firm for 180 days after the submission due date, as included in the invitation to submit a full proposal. This information must be included in the text of the technical proposal.

4.2.11. Withdrawal of Proposals. Proposals may be withdrawn by written notice received at any time before award. Withdrawals are effective upon receipt of notice by the Grants/Contracting Officer via the administrative e-mail address listed in [Section 7](#).

4.3. Submission Dates and Times.

Coordination of abstracts may be accomplished at any time that this BAA is in effect, unless otherwise stated as part of a specific topic. Once an applicant has been notified that a pre-application white paper is welcomed, the white paper should be submitted within 60 days. If the white paper is not submitted within 60 days, DTRA reserves the right to require the applicant to re-initiate the process with another abstract coordination.

Pre-application white papers may be submitted anytime that this BAA is in effect (as long as it occurs within the 60 day window following pre-coordination of the abstract), unless otherwise stated as part of a specific topic. Pre-application white papers may be evaluated at any time after submission and invitations for full proposal submission may occur any time after pre-application white paper evaluation. Note that proposal invitations may be limited to available program funds.

The due date for the Phase II invited proposal submissions will be provided in the letter of invitation. The applicant will not be allowed less than 45 days to prepare a full proposal submission; there is no penalty for early submissions. An extension for submission of the Phase II proposal submission may be requested by emailing the administrative email address in [Section 7](#) prior to the deadline for the proposal submission. Full proposals may be evaluated at any time after submission.

Applicants are responsible for submitting all materials to www.grants.gov. When sending electronic files, the applicant should allow for potential delays in file transfer from the originator's computer server to the www.grants.gov website/computer server, as well as the delay associated with the www.grants.gov validation of applications, which may be up to 48 hours. Applicants are encouraged to submit their proposals early to avoid issues with file transfers, rejection of applications by www.grants.gov, and delays due to high website demand.

Acceptable evidence to establish the time of receipt at the Government office includes documentary and electronic evidence of receipt maintained by DTRA. Applicants should also print, and maintain for their records, the electronic receipt following submission of a proposal to www.grants.gov.

Applicants should note that DTRA uses a system that pulls applications from www.grants.gov en masse, but this system does not mark applications as "retrieved" on www.grants.gov. As a result, when applicants check the status on www.grants.gov the applications will always look like they have not been retrieved by DTRA. Should you require confirmation of receipt by the Agency, you may request such via the administrative email address provided in [Section 7](#). Note that such requests will generally be treated with low priority by the Agency.

Please note 15 U.S.C. 260a establishes daylight saving time as the standard time during the daylight saving period.

If the application package and required attachments are submitted to www.grants.gov after the exact time and date specified in this announcement or in any written communications provided by DTRA, the application may be considered "late" and may not be reviewed.

If an emergency or unanticipated event interrupts normal Government processes so that proposals cannot be submitted to www.grants.gov by the exact time specified by DTRA correspondence, the time specified for receipt of applications will be deemed to be extended to the same time of day specified in the BAA or in the letter of invitation on the first work day on which normal Government processes resume.

4.4. Intergovernmental Review. Not Applicable.

4.5. Other Submission Requirements.

4.5.1. Organizations must have an active System for Award Management (SAM) registration, and Grants.gov account to apply for grants. Creating a Grants.gov account can be completed online in minutes, but SAM registrations may take additional time. Therefore, an organization's registration should be done in sufficient time to ensure it does not impact the entity's ability to meet required application submission deadlines.

All organizations applying online through Grants.gov must register with the SAM and will receive a unique entity identifier (UEI) number. Failure to register with SAM will prevent your organization from applying through Grants.gov. SAM registration must be renewed annually. For more detailed instructions for registering with SAM, refer to: <https://www.grants.gov/web/grants/applicants/organization-registration/step-2-register-with-sam.html>. Additional information may be found on Grants.gov here: <https://www.grants.gov/web/grants/applicants/organization-registration.html>

4.5.2. Compliance with Appendix A to 32 CFR 28. All awards require certifications of compliance with Appendix A to 32 CFR 28 regarding lobbying. Proposers are certifying compliance with this regulation by submitting the invited proposal. It is not necessary to include the certification text with your invited proposal. If applicable, proposers should submit the Disclosure of Lobbying Activities (SF-LLL) Form in accordance with [Section 4.2.6](#).

4.5.3. Marking Guidance for Pre-Application White Paper and Invited Proposal and Disclosure of Proprietary Information other than to the Government. The pre-application white papers and invited proposals submitted in response to this BAA may contain technical and other data that the applicant does not want disclosed to the public or used by the Government for any purpose other than application evaluation. Public release of information in any pre-application white paper and invited proposal submitted will be subject to existing statutory and regulatory requirements.

If proprietary information which constitutes a trade secret, proprietary commercial or financial information, confidential personal information, or data affecting national security, is provided by an applicant in a pre-application white paper and/or invited proposal, it will be treated in confidence, to the extent permitted by law, provided that the following legend is included on the front page of the pre-application white paper and/or invited proposal:

“For any purpose other than to evaluate the pre-application white paper and/or proposal, this data

shall not be disclosed outside the Government and shall not be duplicated, used, or disclosed in whole or in part, provided that if an award is made to the applicant as a result of or in connection with the submission of this data, the Government shall have the right to duplicate, use or disclose the data to the extent provided in the agreement. This restriction does not limit the right of the Government to use information contained in the data if it is obtained from another source without restriction. The data subject to this restriction is contained in page(s) _____ of this pre-application white paper and/or proposal.”

Any other legend may be unacceptable to the Government and may constitute grounds for removing the pre-application white paper and/or invited proposal from further consideration without assuming any liability for inadvertent disclosure.

The Government will limit dissemination of properly marked information to within official channels. In addition, the pages indicated as restricted must be marked with the following legend:

“Use or disclosure of the pre-application white paper and/or proposal data on lines specifically identified by asterisk () are subject to the restriction on the front page of this pre-application white paper and/or proposal.”*

The Government assumes no liability for disclosure or use of unmarked data and may use or disclose such data for any purpose.

In the event that properly marked data contained in a pre-application white paper and/or invited proposal submitted in response to this BAA is requested pursuant to the Freedom of Information Act (FOIA), 5 U.S.C. § 552, the applicant will be advised of such request and prior to such release of information, will be requested to expeditiously submit to DTRA a detailed listing of all information in the pre-application white paper and/or invited proposal which the applicant believes to be exempt from disclosure under the Act. Such action and cooperation on the part of the applicant will ensure that any information released by DTRA pursuant to the Act is properly identified.

By submission of a pre-application white paper and/or invited proposal, the applicant understands that proprietary information may be disclosed outside the Government for the sole purpose of technical evaluation. DTRA will obtain a non-disclosure agreement from the evaluator that proprietary information in the pre-application white paper and/or invited proposal will only be used for evaluation purposes and will not be further disclosed or utilized.

4.5.4. VAT and Other Taxes in Assistance Awards. Prior to proposal submission, the applicant will require any supplier of goods or services to assess and verify potential VAT, excise duties, and other tax implications to avoid the imposition of such charges with respect to the goods and/or services in question to the maximum extent possible.

In instances where the supplier of goods or services is exempt from the VAT, excise duties, or other taxes or is entitled to claim reimbursement thereof, the taxes must not be included in the proposed cost of the award.

In instances where the supplier of goods or services is not exempt from the VAT, excise duties, or other taxes or is not entitled to claim reimbursement thereof, the applicant must itemize the VAT and/or other taxes in the proposal. Further, applicants are advised that prior to the award of any grant or cooperative agreement, DTRA and the recipient will mutually agree upon the use of DTRA funds for the VAT, excise duties, or other taxes, and project activities may be revised

accordingly. All applicants may include costs in their proposal to pay for VAT costs associated with lodging, meals, and transportation for travel.

4.6. Applicants that Propose Use of Contracts or OTAs.

4.6.1. Recommended Procurement Instrument and Pricing Arrangement. Applicants that propose use of contracts or OTAs must provide a summary of their recommended procurement instrument and pricing arrangement as part of the Phase II proposal. However, the Government reserves the right to negotiate and award the types of instruments determined most appropriate under the circumstances. It is anticipated that most instruments will be grants.

4.6.2. Representations and Certifications. Representations and Certifications must be completed at the time of Phase II submission. The applicant must complete the annual representations and certifications electronically via the System for Award Management (SAM) website at <https://www.sam.gov/portal/SAM/#1#1>. After reviewing their information, the applicant verifies by submission of the application that the representations and certifications currently posted electronically have been entered or updated within the last 12 months.

4.6.3. Organization Conflict of Interest Advisory. Certain post-employment restrictions on former federal officers and employees may exist, including special Government employees (including but not limited to 18 U.S.C § 207, the Procurement Integrity Act, 41 U.S.C. § 2101 *et.seq*). If a prospective applicant believes that a conflict of interest exists, the situation should be raised to the DTRA Contract/Grant Officer before time and effort are expended in preparing a proposal. All applicants and proposed sub-contractors must therefore affirmatively state whether they are providing scientific, engineering and technical assistance (SETA), advisory and assistance services (A&AS) or similar support, through an active contract or subcontract, to any DoD technical office to include, but not limited to, the Joint Program Executive Office (JPEO), the Office of the Assistant Secretary of Defense for Nuclear, Chemical, and Biological Defense Programs (ASD-NCB), or the Office of the Special Assistant for Chemical and Biological Defense and Chemical Demilitarization Programs (OSA (CBD&CDP)). This information must be included in Technical Proposal of the Phase II full submission. All affirmations must state which office(s) the applicant(s) supports, and identify the prime contract number. Affirmations must be furnished at the time of Phase II full proposal submission. All facts relevant to the existence or potential existence of organizational conflicts of interest, including but not limited to those arising out of activities with the above-referenced organizations, must be disclosed. The disclosure must include a description of the action the applicant has taken or proposes to take to avoid, neutralize, or mitigate such conflict.

4.6.4. Contracts with Subcontracts. Any applicant, other than small businesses, submitting a proposal that exceeds \$750,000.00 must submit a subcontracting plan in accordance with FAR 19.704(a) (1) and (2). This information must be included in Technical Proposal of the Phase II full submission. The plan format is outlined in FAR 19.704. Pursuant to Section 8(d) of the Small Business Act (15 U.S.C. § 637(d)), it is the policy of the Government to enable small business and small disadvantaged business concerns to be considered fairly as subcontractors to contractors performing work or rendering services as prime contractors or subcontractors under Government contracts, and to assure that prime contractors and subcontractors carry out this policy.

4.6.5. Limitations on OTAs. Applicants are advised that an Other Transaction for Research Agreement (10 U.S. Code § 2371) or an Other Transaction for Prototype Agreement (10 U.S.

Code § 2371b) will only be awarded if the use of a standard contract or CA is not feasible or appropriate. Applicants are advised that an OTA may only be awarded if there is:

- a. At least one nontraditional defense contractor participating to a significant extent in the prototype project, or
- b. All significant participants in the transaction other than the Federal Government are small businesses or nontraditional defense contractors; or
- c. At least one-third of the total cost of the prototype project is to be paid out of funds provided by the parties to the transaction other than the Federal Government. The cost share should generally consist of labor, materials, equipment, and facilities costs (including allocable indirect costs).
- d. Exceptional circumstances justify the use of a transaction that provides for innovative business arrangements or structures that would not be feasible or appropriate under a procurement contract.
- e. Although use of one of these options is required to use an Other Transaction for Prototype agreement as the procurement vehicle, no single option is encouraged or desired over the others.

NOTE: For purposes of determining whether or not a participant may be classified as a nontraditional defense contractor or a small business and whether or not such participation is determined to be participating to a significant extent in the prototype project, the following definitions are applicable:

- a. "Nontraditional defense contractor" means an entity that is not currently performing or has not performed, for at least the one-year period preceding this solicitation, any of the following for the Department of Defense: any contract or subcontract that is subject to full coverage under the cost accounting standards prescribed pursuant to section 26 of the Office of Federal Procurement Policy Act (41 USCS §§ 1501 et seq.) and the regulations implementing such section; or any other contract in excess of \$500,000 under which the contractor is required to submit certified cost or pricing data under section 2306a of this title (10 USCS § 2306a).
- b. "Small business" means a small business concern as defined under Section 3 of the Small Business Act (15 U.S.C. § 632).

"Participating to a significant extent in the prototype project" means that the nontraditional defense contractor or small business is supplying a new key technology or product, is accomplishing a significant amount of the effort wherein the role played is more than a nominal or token role in the research effort, or in some other way plays a significant part in causing a material reduction in the cost or schedule of the effort or an increase in performance of the prototype in question.

NOTE: Applicants are cautioned that if they are classified as a traditional defense contractor, and propose the use of an Other Transaction for Prototype Agreement, the Government will require submittal of both a cost proposal under the guidelines of the FAR/DFARS, and a cost proposal under the proposed Other Transaction for Prototype Agreement, so that an evaluation may be made with respect to the cost tradeoffs applicable under both situations. The Government reserves the right to negotiate either a FAR based procurement contract, or Other Transaction for

Prototype Agreement as it deems is warranted under the circumstances.

5. APPLICATION REVIEW INFORMATION

5.1. Evaluation Criteria. The four evaluation criteria to be used for responses received to this BAA are as follows:

1. Scientific and Technical Merit. The objective of this criterion is to assess the extent to which the applicant presents ideas that are innovative and/or unique with the potential for high payoff in the science area and details a comprehensive technical approach based on sound scientific principles. Innovation will be judged contextually against the white paper's/proposal's scope, goals, and setting. To the extent possible, the technical risks, including those of biosafety and security, to accomplish the research or project should be identified with appropriate mitigation/management details.

For Thrust Area 6 white papers/proposals, innovation will also be considered with respect to partner country capabilities.

2. Value to Mission Goals. The objective of this criterion is to assess the extent to which the applicant demonstrates an understanding of the C-WMD research or mission challenges and the contribution to the C-WMD research or mission needs of that thrust area/topic. White papers/proposals must detail research or a project that is responsive to the thrust area/topic as presented in this solicitation. This criterion also addresses the benefit of the proposed effort on enabling knowledge, technology, or capabilities over current methods and/or practices and on the transition potential that is appropriate to the proposed effort. Applicants must also demonstrate an impact of the proposed effort on the institution's ability to perform research relevant to reducing the global WMD threat; and/or to train, through the proposed effort, students and/or partner scientists in science, technology, engineering and/or mathematics.

Thrust Area 6 white papers/proposals must demonstrate an understanding of the CBEP priorities and mission. As such, the degree to which the proposed collaborations may lead to long-term partner country self-sufficiency and sustainment of the jointly developed capabilities will be considered.

3. Capability of the Personnel and Facilities to Perform the Proposed Effort. The objective of this criterion is to assess the extent to which the applicant's team has the requisite expertise, skills and resources necessary to perform the proposed program. This includes an assessment of the team's management construct, key personnel, facilities and past technical experience in conducting similar efforts of the proposed scope. Applicants must demonstrate that their team has the necessary background and experience to perform this project. Facilities should be detailed with discussion of any unique capabilities pertinent to the research. Subcontractors may include Government facilities or Agencies; however the unique expertise or specialized facilities provided through their inclusion must be clearly presented and the validity of the proposer-Governmental relationship must be clearly documented.
4. Cost Realism Evaluation. The objective of this criterion is to establish that the proposed costs are reasonable, realistic, and justified for the technical approach offered and to assess the applicant's practical understanding of the scope of the proposed effort.

5.2. Review and Selection Process. The pre-application white paper and proposal selection

process will be conducted based upon a technical review as described in the DoDGARs (32 CFR 22.315(c)) and includes the use of non-Government peer-reviewers.

Each pre-application white paper and invited proposal submitted to a general TA will be reviewed on a rolling basis; topic-based submissions will be reviewed as a batch following receipt deadlines. All applications will be reviewed based on the merit and relevance of the specific pre-application white paper/proposal as it relates to the DTRA program, rather than against other pre-application white papers/proposals for research in the same general area.

Pre-application white paper (Phase I) evaluation will be based on the two (2) equally weighted criteria of (1) Technical/Scientific Merit and (2) Value to Mission Goals. The criteria will be scored as Outstanding (O), Good (G), Acceptable (A), Marginal (M) or Unacceptable (U). Any criterion scored as “Unacceptable (U)” will render the pre-application white paper “Not Selectable,” and the pre-application white paper will not be considered further.

The full proposal evaluation will be based on the four criteria listed above. Of these, the first two (2) criteria of (1) Technical/Scientific Merit and (2) Value to Mission Goals are equally weighted and more important than the third criterion of (3) Capability of the Personnel and Facilities to Perform the Proposed Effort. These first three criteria will be scored Outstanding (O), Good (G), Acceptable (A), Marginal (M) or Unacceptable (U). The fourth criterion of Cost Realism will be scored as either Acceptable (A) or Unacceptable (U). Any criterion scored as “Unacceptable (U)” will render the proposal “Not Selectable,” and the proposal will not be considered further.

Other factors that may be considered are duplication with other research, program balance, past performance and budget limitations. Prior to award, the Government reserves the right to perform a review of past performance. Sources that may be used for past performance review may include the Past Performance Information Retrieval System (PPIRS) and the Federal Awardee Performance and Integrity Information System (FAPIIS). The Government will also evaluate the impact of any proposed limitations to the use of intellectual property (e.g. asserted technical data/computer software restrictions or patents) during the selection and/or negotiation process, and may request additional information from the applicant, as may be necessary, to evaluate the applicant’s assertions. Accordingly, proposals may be selected for funding which are not reviewed as highly as others, which are of higher risk and/or which may be of a higher cost.

The Government reserves the right to select all, some, or none of the proposals, or any part of any proposal received in response to this BAA and to make awards without discussions with applicants; however, the Government reserves the right to conduct discussions if determined necessary.

5.3. DTRA anticipates that the total Federal share of awards made under this announcement will be greater than the simplified acquisition threshold over the period of performance (see §200.88 Simplified Acquisition Threshold). Therefore, in accordance with Appendix I to 2 CFR Part 200, Section E.3, this section serves to inform applicant:

- i. That DTRA, prior to making a Federal award with a total amount of Federal share greater than the simplified acquisition threshold, is required to review and consider any information about the applicant that is in the designated integrity and performance system accessible through SAM (currently Federal Awardee Performance and Integrity

Information System (FAPIS)) (see 41 U.S.C. 2313);

- ii. That an applicant, at its option, may review information in the designated integrity and performance systems accessible through SAM and comment on any information about itself that a Federal awarding agency previously entered and is currently in the designated integrity and performance system accessible through SAM;
- iii. That DTRA will consider any comments by the applicant, in addition to the other information in the designated integrity and performance system, in making a judgment about the applicant's integrity, business ethics, and record of performance under Federal awards when completing the review of risk posed by applicants as described in §200.205 Federal awarding agency review of risk posed by applicants.
- iv. For awards that exceed \$500,000 over the period of performance, DTRA will employ the additional post-award reporting requirements reflected in Appendix XII—Award Term and Condition for Recipient Integrity and Performance Matters of 2 CFR 200.

5.4. Technical and Administrative Support by Non-Government Personnel. It is the intent of DTRA to use both Government and non-Government personnel to assist with the review and administration of submittals for this BAA. All pre-application white papers and invited proposals may be reviewed by subject matter experts, including, but not limited to, peer reviewers from across the academic and industrial community, as applicable to the research proposed.

Further, participation in this BAA requires DTRA support contractors to have access to pre-application white paper and invited proposal information including information that may be considered proprietary or otherwise marked with restrictive legends Each contract contains organizational conflict of interest provisions and/or includes contractual requirements for non-disclosure of proprietary contractor information or data/software marked with restrictive legends. The applicant, by submitting a white paper or proposal, is deemed to have consented to the disclosure of its information to the aforementioned contractors under the conditions and limitations described herein.

All individuals—including subject matter experts and support contractors—having access to any proprietary data must certify that they will not disclose any information pertaining to this BAA including any submittal, the identity of any submitters, or any other information relevant to this BAA. All applicants to this BAA consent to the disclosure of their information under these conditions.

6. AWARD ADMINISTRATION INFORMATION

6.1. Award Notices. Applicants will be notified regarding the status of their applications (invitation/non-invitation for full proposals, re-submission of white papers, selection/non-selection for award, etc.) via e-mail to the BPOC listed in Block 5 of the SF-424 and the PI listed in Block 14 of the SF-424 provided at the time of submission. A debrief summary will be provided as part of all notification e-mails.

A notice of selection should not be construed as an obligation on the part of the Government; only duly authorized procurement personnel may commit resources, this will be done by issuing a grant or contract document to the selected applicant. Also, this notification must not be used as

a basis for accruing costs to the Government prior to award. Selected applicants are not authorized to begin work, as any award is subject to successful negotiations (if determined necessary by DTRA) between the DTRA contracting division and the selected organization, and to the availability of funds.

All notifications will be made from notification@dtrasubmission.net. **E-mails to this e-mail address will not be answered or forwarded.**

Applicants must be aware that it is their responsibility to ensure: (1) correct e-mail addresses are provided at the time of submission, (2) this e-mail notification reaches the intended recipient(s), and (3) the e-mail is not blocked by the use of ‘spam blocker’ software or other means that the recipient’s Internet Service Provider may have implemented as a means to block the receipt of certain e-mail messages.

If for any reason there is a delivery failure of these e-mail notices, DTRA will not further attempt to contact the applicants.

6.2. Administrative and National Policy Requirements. All awards require certifications of compliance with national policy requirements. Statutes and Government-wide regulations require some certifications to be submitted at the time of proposal submission. See [Section 4.5.2](#) and [Section 4.6.2](#) for the certification(s) required at the time of submission.

This BAA focuses on fundamental research in a DoD contractual context, which was defined in [Section 1.2](#) of this BAA. Per DoD policy¹, “...products of fundamental research are to remain unrestricted to the maximum extent possible.” Furthermore, “The DoD will place no other restrictions on the conduct or reporting of unclassified fundamental research, except as otherwise required by statute [sic], regulation, or Executive Order.” As such, fundamental research is normally exempt from controls under the International Traffic in Arms Regulation (ITAR) (22 CFR Parts 120-130) and/or the Department of Commerce regarding the Export Administration Regulations (15 CFR Parts 730-774), but the DoD rule recognizes that there are “rare” situations where export-controlled information or technology may be used in fundamental research that may require a license(s) or restrictions on products.

6.2.1. Export Control Notification. Applicants are responsible for ensuring compliance with any export control laws and regulations that may be applicable to the export of and foreign access to their proposed research. Applicants may consult with the Department of State with any questions regarding the International Traffic in Arms Regulation (ITAR) (22 CFR Parts 120-130) and/or the Department of Commerce regarding the Export Administration Regulations (15 CFR Parts 730-774). Please note that the prime awardee is responsible for monitoring ITAR compliance of all subawardees.

6.2.2. Protection of Human Subjects. If the proposed work involves human subjects or the use of human anatomical substances (e.g., biospecimens, blood, tissue, cell lines), either living or post-mortem, applicants are required to: a) justify and b) outline the use, and c) include the source of the human subjects, human biospecimens and/or human data involved in the research,

¹ Under Secretary of Defense for Acquisition, Technology and Logistics Memorandum, SUBJECT: Contracted Fundamental Research, dated 26 Jun 2008

hereafter referred to as “research.”

The DTRA Research Oversight Board (ROB) will provide ongoing oversight throughout the duration of the effort to ensure proper approvals are in place. Further information will be required if the proposal is selected for award. Further information will be required if the proposal is selected for award.

DTRA PMs responsible for the research are required to complete and submit Section A of the DTRA Form 156, available through the DTRA1 Forms Library, to the DTRA Research Oversight Board (ROB) through the ROB Central Mailbox, dtra.belvoir.rd.mbx.research-oversight-board@mail.mil.

Through an Agreement with DTRA and the U.S. Army Medical Research Development Command, Office of Human and Animal Research Oversight(MRDC OHARO), OHARO must review and approve all DTRA funded or supported research prior to the start of the proposed work. This review requirement is in addition to the DTRA ROB review. Therefore, along with the DTRA Form 156, the DTRA PM/STM must complete and submit the MRDC OHARO form titled “USAMRDC_ORP_Proposal Submission_Form” to the DTRA ROB for review of the proposed work. These forms are available through the ROB DTRA1 Sharepoint site, <https://dtra1portal.unet.dtra.mil/RD/ROB/default.aspx>. Allow up to four months, from date award is submitted to the DTRA ROB, for regulatory review and approval processes. Applicants are to build the review time into their project schedules.

All work under any award made under this BAA involving research must be conducted in accordance with 32 CFR 219, 10 U.S.C. § 980, and DoD Instruction (DoDI) 3216.02, DTRA Instruction (DTRAI) 3216.01, and, as applicable, 21 CFR parts 11, 50, 56, GCP, the International Council for Harmonization (ICH) as well as other applicable federal and state regulations. Contracts must include DFARS clause 252.235-7004 and DTRA Clause 252.223-9002. Other funding vehicles (e.g., grant, OTA) must include similar language. Non-compliance with any provision of this clause may result in withholding of payments under the contract pursuant to the terms and conditions. The Government shall not be responsible for any costs incurred for research involving human subjects prior to protocol approval by the MRDC OHRO and ROB.

It is the responsibility of the PM to ensure performers are cognizant of and abide by the additional restrictions and limitations imposed by the DoD regarding research involving human subjects and human anatomical substances, specifically in regards to vulnerable populations (32 CFR 219 modifications to subparts B-D of 45 CFR 46), recruitment of military research subjects (32 CFR 219), and surrogate consent (10 U.S.C. § 980).

Through the Component Management Plan (CMP), reviewed and approved by USD(R&E), the DTRAI 3216.01 establishes the DTRA Human Research Protection Program (HRPP), and sets forth the policies, defines the applicable terms, and delineates the procedures necessary to ensure DTRA compliance with federal and DoD regulations and legislation governing human subject research, and is managed by the DTRA ROB. The regulations mandate that all DoD activities, components, and agencies protect the rights and welfare of human subjects in DoD funded or supported research, development, test and evaluation, and related activities.

The DTRAI 3216.01 requires that research involving human subjects or human anatomical substances may not begin or continue until the DTRA ROB and MRDC OHRO have reviewed

and approved the proposed work. The requirement to comply with the regulations applies to new starts and continuing research for the life of the project, until closure. The completion of a research project requires closure document (e.g., IRB Final Review submission) submitted to the DTRA ROB and/or the MRDC OHRO.

A study is considered to involve human research subjects if: 1) there is interaction with the subject (even simply talking to the subject qualifies; no needles are required); and 2) if the study involves collection and/or analysis of personal/private information about an individual, or if material used in the study contains links to such information.

A study is considered to use human anatomical substances if it involves human biospecimens such as peripheral blood mononuclear cells, primary cells, blood, saliva, tissue, etc. Commercially available sources (e.g., a vendor, medical facility's discarded materials, research collaborators, biobanks, repositories) of human anatomical substances require review. This includes cadaveric specimens and substances.

Commercially available cell lines are exempt from this definition and do not require review (note: commercially available embryonic cell lines are not exempt, and must be reviewed).

Approval to begin research or to subcontract under the proposed protocol will be provided in writing from the MRDC OHRO and the DTRA ROB Executive Secretary (ES) or Program Manager, in absence of the ROB ES. Both the contractor and the Government must maintain a copy of this approval. Any proposed modifications or amendments to the approved research must be submitted to the DTRA ROB and/or the MRDC OHRO for review and approval. Examples of modifications or amendments to the approved work that would require a new review of the project include, but are not limited to:

- a change of the Principal Investigator (PI);
- a change or addition of an institution (note: review and approval of institution is required),
- elimination or alteration of the informed consent process,
- a change in the human subjects study population (e.g., adding children, active duty, etc.) has regulatory implications
- changes in duration or intensity of exposure to some stimulus or agent;
- changes in the information requested of volunteers, or changes to the use of specimens or data collected;
- changes in perceived or measured risks or benefits to volunteers that require changes to the study,
- a change in the IRB of record;
- a change that could potentially increase risk to human subjects
- significant change in study design (i.e., would prompt significant additional scientific review).

Research pursuant to such modifications or amendments must not be initiated without IRB and OHRO approval except when necessary to eliminate apparent and immediate hazards to the subject(s). All unanticipated problems involving risk to subjects or others (UPIRTSOs),

suspensions, clinical holds (voluntary or involuntary), or terminations of the research by the IRB or regulatory agencies, the institution, the sponsor, or any instances of serious or continuing noncompliance with the federal regulation or IRB requirements, must be promptly reported to the DTRA ROB and/or MRDC OHRO.

Greater than minimal risk research projects lasting more than one year require IRB and OHRO review at least every 365 days, or more frequently as required by the responsible IRB. ROB review and approval is required annually from the date of Section A of the DTRA Form 156, through recertification of the DTRA Form 156. The awardee must provide documentation of continued IRB review of protocols for MRDC OHRO review and approval. Research must not continue without renewed OHRO and ROB approval unless necessary to eliminate apparent and immediate hazards to the subject(s).

6.2.3. Animal Use. If the proposed work involves the use of animals, applicants are required to: a) justify and b) include detailed information on the use of animals, and c) include the location(s) of where the animal work is to be performed. The DTRA Research Oversight Board (ROB) will provide ongoing oversight throughout the duration of the effort to ensure proper approvals are in place. . Further information will be required if the proposal is selected for award.

DTRA PMs responsible for the research are required to complete and submit Section A of the DTRA Form 156, available through the DTRA1 Forms Library, to the DTRA Research Oversight Board (ROB) through the ROB Central Mailbox, dtra.belvoir.rd.mbx.research-oversight-board@mail.mil.

Through an Agreement with DTRA, the Animal Care and Use Review Office (ACURO), a component of the USAMRDC Office of Human and Animal Research Oversight (MRDC OHARO) must review and approve all DTRA funded or supported research involving animal use prior to the start of the proposed work. This review requirement is in addition to the DTRA ROB review. Therefore, along with the DTRA Form 156, the DTRA PM must complete and submit the MRDC OHARO form titled “USAMRDC_ORP_Proposal Submission_Form” to the DTRA ROB for review of the proposed work. This form is available through the ROB DTRA1 Sharepoint site, <https://dtra1portal.unet.dtra.mil/RD/ROB/default.aspx>. Allow up to four months, from date award is submitted to the DTRA ROB, for regulatory review and approval processes. Applicants are to build the review time into their project schedules.

All work under any award made under this BAA involving the use of animals must be conducted in accordance with DoD Instruction (DoDI) 3216.01, DTRA Instruction (DTRAI) 3216.01, and Army Regulation (AR) 40-33. Provisions include rules on animal acquisition, transport, care, handling, and use in: (i) 9 CFR parts 1-4, Department of Agriculture rules that implement the Laboratory Animal Welfare Action of 1966 (U.S.C. 2131-2156); and (ii) the “Guide for the Care and Use of Laboratory Animals,” National Institutes of Health Publication No. 86-23. Contracts must include DFARS Clause 252.235-7002 and DTRA Clause 252.235-9001. Other funding vehicles (e.g., grant, OTA) must include similar language. Non-compliance with any provision of this clause may result in withholding of payments under the contract pursuant to the terms and conditions. The Government shall not be responsible for any costs incurred for research involving animal use prior to protocol approval by the MRDC ACURO and ROB. It is the responsibility of the PM to ensure performers are cognizant of and abide by the additional restrictions and limitations imposed by the DoD regarding animal-use research.

The DTRAI 3216.01 requires that research using animals not begin or continue until the DTRA

ROB and MRDC ACURO have reviewed and approved the proposed work.

Through the DTRA Component Animal Use Management Plan (CAUMP), reviewed and approved by the USD(R&E), the DTRAI 3216.01 establishes the DTRA Animal Use Oversight Program (AUOP), and sets forth the policies, defines the applicable terms, and delineates the procedures necessary to ensure DTRA compliance with federal and DoD regulations and legislation governing research involving animal use, and is managed by the DTRA ROB. The regulations mandate that all DoD activities, components, and agencies protect the care and welfare of animals in DoD funded or supported research, development, test and evaluation and training, and related activities. The requirement to comply with the regulations applies to new starts and continuing research for the life of the project, until closure. The completion of a research project requires closure document (e.g., IACUC Final Review submission) submitted to the DTRA ROB and/or the MRDC ACURO.

The DoD definition of animal is “any living or dead vertebrate animal, including birds, cold blooded animals, rats of the genus *rattus* and mice of the genus *mus*.” “Dead” is defined as animals killed for the direct purpose of conducting RDT&E or training.

Approval to begin research or to subcontract under the proposed protocol will be provided in writing from the MRDC ACURO and the DTRA ROB Executive (ES) Secretary or the ROB PM, in the absence of the ROB ES. Both the awardee and the Government must maintain a copy of this approval. Any proposed modifications or amendments to the approved research must be submitted to the DTRA ROB and/or the MRDC ACURO for review and approval. Examples of modifications or amendments to the approved protocol that would require a new review of the project include, but are not limited to:

- a change of the Principal Investigator (PI),
- a change or addition of an institution (note: review and approval of institutions is required),
- a change in the duration or intensity of exposure to a stimulus or agent,
- a change in the animal model and/or numbers of animals used,
- a change in the IACUC of record, or
- a significant change to in study design (i.e., would prompt significant additional scientific review).

Research pursuant to such modifications or amendments must not be initiated without IACUC and ACURO approvals.

6.2.4. Biological Defense Research Program (BDRP) Requirements: BioSurety and Select Agent Use.

Proposals must specify what Select Agent work will be conducted at the applicant’s facility and what Select Agent work will be performed in other facilities. Proposals also must provide the source of the Select Agent(s), any appropriate registration information for the facilities, and specify the Laboratory Bio-safety Level. All Select Agent work is subject to verification of information and certifications. Further information may be required if the proposal is successful.

For those institutions in which PI’s are conducting research with Bio-safety Levels 3 and 4 material, a Facility Safety Plan must be prepared and made available during the project award

phase in accordance with 32 CFR 626.18. For grants awarded to foreign institutions, you must follow either local or U.S. laws (as stated above) depending on which laws provide stronger protection. (DTRA requires that research using Select Agents not begin or continue until DTRA has reviewed and approved the proposed agent use. See URL:

<https://www.gpo.gov/fdsys/pkg/CFR-2002-title32-vol3/pdf/CFR-2002-title32-vol3-sec626-18.pdf> for a copy of 32 CFR 626.18, Biological Defense Safety Program.)

For projects that will employ the use of chemical agents, either neat agent or dilute agent, the offeror must provide approved Facility Standard Operating Procedures that conform to Federal, State and local regulations and address the storage, use and disposition of these chemical materials.

6.2.5. Dual-Use Potential. In accordance with National Science Advisory Board for Biosecurity (NSABB) recommendations, DTRA will not support research that, based on current understanding, can reasonably be anticipated to provide knowledge, information, products, or technologies that could be directly misapplied to pose a significant threat with broad potential consequences to public health and safety, agricultural crops and other plants, animals, the environment, materiel, or national security. Research involving select agents and toxins is within scope of the DTRA mission; however, the use of select agents and toxins in certain experimental categories is considered “dual-use research of concern” (DURC) according to U.S. policy. (<http://www.phe.gov/s3/dualuse/Documents/us-policy-durc-032812.pdf>) Proposals that contain DURC will not be funded. Dual-use potential will be assessed based on application of the following criteria:

- Use of select agents or toxins. This factor evaluates whether the proposed research involves use of one or more select agents or toxins [as identified by the Select Agent Program under Federal Law (7 C.F.R. part 331, 9 C.F.R. part 121, and 42 C.F.R. part 73)] which pose significant risk of deliberate misuse with potential for mass casualties or devastating effects to the economy, critical infrastructure, or public confidence.
- Scope of proposed experiments. This factor evaluates whether the proposed research involves experiments that will produce, aim to produce, or is reasonably anticipated to produce: (a) Enhanced harmful consequences of the agent or toxin; (b) Disruption of immunity or effectiveness of an immunization against the agent or toxin without clinical or agricultural justification; (c) Conferred resistance by the agent or toxin to clinically or agriculturally useful prophylactic or therapeutic interventions against the agent or toxin, or facilitated ability to evade detection methodologies; (d) Increased stability, transmissibility, or dissemination ability of the agent or toxin; (e) Altered host range or tropism of the agent or toxin; (f) Enhanced susceptibility of a host population to the agent or toxin; or (g) Eradicated or extinct select agents or toxins.

6.2.6. Military Recruiting. This is to notify potential applicants that each award under this announcement to an institution of higher education, with exception of any grants awarded to institutions of higher education entirely located outside the United States and/or its territories, must include the following term and condition: “As a condition for receipt of funds available to DoD under this award, the recipient agrees that it is not an institution of higher education (as defined in 32 CFR 216) that has a policy of denying, and that it is not an institution of higher education that effectively prevents, the Secretary of Defense from obtaining the following for military recruiting purposes: (A) entry to campuses or access to students on campuses; or (B)

access to directory information pertaining to students. If the recipient is determined, using procedures in 32 CFR 216 to be such an institution of higher education during the period of performance of this agreement, and therefore to be in breach of this clause, the Government will cease all payments of DoD funds under this agreement and all other DoD grants and CAs, and it may suspend or terminate such grants and agreements unilaterally for material failure to comply with the terms and conditions of award.” 32 CFR 216 may be accessed electronically at http://www.ecfr.gov/cgi-bin/text-idx?SID=ee45add5e352854b7089ce420c7fd0a6&mc=true&tpl=/ecfrbrowse/Title32/32cfr216_main_02.tpl. If your institution has been identified under the procedures established by the Secretary of Defense to implement Section 558 of Public Law 103-337, then: (1) no funds available to DoD may be provided to your institution through any grant, including any existing grant; and (2) your institution is not eligible to receive a grant in response to this BAA. This is to notify potential applicants that each award under this announcement to an institution of higher education, with exception of any grants awarded to institutions of higher education entirely located outside the United States and/or its territories, must include the following clause: 32 CFR 22.520 (DoDGARS 22.520), Military Recruiting and Reserve Officer Training Corps Program Access to Institutions of Higher Education.

6.2.7. Combating Trafficking in Persons. The recipient agrees to comply with the trafficking in persons requirement in Section 106(g) of the Trafficking Victims Protection Act of 2000 (TVPA), as amended (22 U.S.C. 7104(g)).

6.2.8. Reporting Subawards and Executive Compensation. The recipient agrees to ensure they have the necessary processes and systems in place to comply with the reporting requirements of the Transparency Act, as defined at 2 CFR 170.320, unless they meet the exception under 2 CFR 170.110(b).

6.2.9. Representation Regarding the Prohibition on Using Funds under Grants and Cooperative Agreements with Entities that Require Certain Internal Confidentiality Agreements. By submission of its proposal or application, the applicant represents that it does not require any of its employees, contractors, or subrecipients seeking to report fraud, waste, or abuse to sign or comply with internal confidentiality agreements or statements prohibiting or otherwise restricting those employees, contractors, or subrecipients from lawfully reporting that waste, fraud, or abuse to a designated investigative or law enforcement representative of a Federal department or agency authorized to receive such information. Note that: (1) the basis for this representation is a prohibition in section 743 of the Financial Services and General Government Appropriations Act, 2015 (Division E of the Consolidated and Further Continuing Appropriations Act, 2015, Pub. L. 113-235) and any successor provision of law on making funds available through grants and cooperative agreements to entities with certain internal confidentiality agreements or statements; and (2) section 743 states that it does not contravene requirements applicable to Standard Form 312, Form 4414, or any other form issued by a Federal department or agency governing the nondisclosure of classified information.

6.2.10. Prohibition on Covered Telecommunications Equipment or Services. Section 889 of the National Defense Authorization Act (NDAA) for Fiscal Year (FY) 2019 (Public Law 115-232) prohibits the head of an executive agency from obligating or expending loan or grant funds to procure or obtain, extend, or renew a contract to procure or obtain, or enter into a contract (or extend or renew a contract) to procure or obtain the equipment, services, or systems prohibited systems as identified in section 889 of the NDAA for FY 2019.

(a) In accordance with 2 CFR 200.216 and 200.471, a recipient and subrecipient are prohibited from obligating or expending grant funds to:

1. Procure or obtain;
2. Extend or renew a contract to procure or obtain; or
3. Enter into a contract (or extend or renew a contract) to procure or obtain equipment, services, or systems that use covered telecommunications equipment or services as a substantial or essential component of any system, or as critical technology as part of any system. Covered telecommunications equipment is telecommunications equipment produced by Huawei Technologies Company or ZTE Corporation (or any subsidiary or affiliate of such entities).
 - For the purpose of public safety, security of government facilities, physical security surveillance of critical infrastructure, and other national security purposes, video surveillance and telecommunications equipment produced by Hytera Communications Corporation, Hangzhou Hikvision Digital Technology Company, or Dahua Technology Company (or any subsidiary or affiliate of such entities);
 - Telecommunications or video surveillance services provided by such entities or using such equipment; or
 - Telecommunications or video surveillance equipment or services produced or provided by an entity that the Secretary of Defense, in consultation with the Director of the National Intelligence or the Director of the Federal Bureau of Investigation, reasonably believes to be an entity owned or controlled by, or otherwise connected to, the government of a covered foreign country.

(b) In implementing the prohibition under Public Law 115-232, section 889, subsection (f), paragraph (1), heads of executive agencies administering loan, grant, or subsidy programs shall prioritize available funding and technical support to assist affected businesses, institutions and organizations as is reasonably necessary for those affected entities to transition from covered communications equipment and services, to procure replacement equipment and services, and to ensure that communications service to users and customers is sustained.

(c) See Public Law 115-232, section 889 for additional information.

COVERED FOREIGN COUNTRY means the People's Republic of China.

6.3. Reporting. General requirements are provided below; however, each awardee should check the award agreement and its contract data requirements list (CDRLs) and/or terms and conditions to determine the requirements for that specific award.

6.3.1. Annual Reports. Annual Reports will be due no later than 1 July of each year. Awards effective after 31 January will not require an Annual Report until 1 July of the following year. The Annual Report is *not* a cumulative report.

6.3.2. Final Technical Reports. A comprehensive final technical report is required prior to the end of an effort, due on the date specified in CDRLs and/or the terms and conditions of the award document. The purpose of the Final Report is to document the results of the effort. The Final Report *is* a cumulative report.

The final report will always be sent to the Defense Technical Information Center (DTIC) and reports may be available to the public through the National Technical Information Service (NTIS).

6.3.3. Financial Reports. Federal Financial Reports (SF-425) are due no later than 1 July of each year. Grants effective after 31 January will not require a Federal Financial Report until 1 July of the following year.

6.3.4. Foreign Travel Reports. Within thirty (30) days after returning to the United States from foreign travel, the PI may be required to submit an acceptable trip report summarizing the highlights of the trip. For grants, contracts, or OTAs awarded to institutions entirely located outside the United States and/or its territories, this is not required.

6.4. After-the-Award Requirements for *Grants*. Closeout, subsequent adjustments, continuing responsibilities, and collection of amounts due are subject to requirements found in 32 CFR 32.71 – 73 (Institutions of Higher Education, Hospitals, and Other Non-Profit Organizations) and 32 CFR 34.61 – 63 (For-Profit Organizations).

7. AGENCY CONTACTS

Administrative Correspondence and Questions	HDTRA1-FRCWMD-A@mail.mil
<u>Thrust Area 1</u> : <i>Science of WMD Sensing and Recognition</i>	HDTRA1-FRCWMD-TA1@mail.mil
<u>Thrust Area 2</u> : <i>Network Sciences</i>	HDTRA1-FRCWMD-TA2@mail.mil
<u>Thrust Area 3</u> : <i>Science for Protection</i>	HDTRA1-FRCWMD-TA3@mail.mil
<u>Thrust Area 4</u> : <i>Science to Defeat WMD</i>	HDTRA1-FRCWMD-TA4@mail.mil
<u>Thrust Area 5</u> : <i>Science to Secure WMD</i>	HDTRA1-FRCWMD-TA5@mail.mil
<u>Thrust Area 6</u> : <i>Cooperative Counter WMD Research with Global Partners</i>	HDTRA1-FRCWMD-TA6@mail.mil
<u>Thrust Area 7</u> : <i>Fundamental Science for Chemical and Biological Defense</i>	HDTRA1-FRCWMD-TA7@mail.mil

Table 6: Agency Contacts.

7.1. Questions regarding administrative content of this BAA must be addressed to the administrative e-mail address listed above. Applicants should include the relevant thrust area email address.

7.2. Questions regarding technical content of this BAA must be referred to the thrust area email listed above.

DTRA will not release employee personal contact information.

8. OTHER INFORMATION

Topics from previous periods may or may not be repeated. DTRA will not provide additional information regarding the posting of future topics, including dates for posting, the potential for a topic to be repeated in out years, the potential for similar topics to be posted, and/or topic details in advance of issuance of an amended BAA.

ATTACHMENT 1: SPECIFIC TOPICS

The Post Doc-Topic B spans the technical areas covered by Thrust Areas 1-7 and is ***NO longer accepting pre-application white paper submission. Submissions to the general thrust area descriptions for Thrust Areas 1-7 are closed; abstracts and pre-application white papers submitted to the general descriptions for Thrust Areas 1-7 will NOT be reviewed.

DTRA anticipates that the award(s) made under Post Doc-Topic B will be contracts. Pre-application white papers and proposals submitted to Post Doc-Topic B must have a single lead organization and single submission for the pre-application white paper and the invited proposal. Awards will be made by a single award to the lead institution. Subawards, including all grants and/or contracts, are the responsibility of the award recipient; exceptions will not be made.

Post Doc-Topic B: Postdoctoral Scholars Program (Thrusts 1-7)

*****PRE-APPLICATION WHITE PAPERS FOR THIS TOPIC ARE NO LONGER BEING ACCEPTED.**

Background: The Defense Threat Reduction Agency (DTRA) Postdoctoral Scholars Program started more than 20 years ago and has a proven track-record of success—measured by program participation by excellent professionals and follow-on career decisions. The future of the Postdoctoral Scholars Program remains consistent with the initial program goals of fostering and strengthening long-term strategic partnerships with the scientific community while leveraging the best and the brightest professionals to address critical science and technology challenges of interest to DTRA. This topic seeks a contracted partner(s) to continue the Postdoctoral Program at DTRA.

The benefits to the contracted partner(s) are that of enhanced institutional ability to effectively combat the threat posed by WMD through strengthened relationships with DTRA as well as workforce development. The benefit for the individual program participants is also tremendous. Each Postdoctoral Scholar is exposed to a breadth of information and gains knowledge of current capabilities, critical national security challenges, and the business of government—areas of skill development that are not readily available through many other early career opportunities.

Impact: The overall purpose of this programmatic initiative is to provide advanced research support, technical expertise, and execution capabilities in scientific, technical, and engineering disciplines relevant to the DTRA mission, specifically those that directly enhance the institutional ability to effectively combat the threat posed by WMD.

Objective: To find a contracted partner(s) organization that is capable of providing up to eight Postdoctoral Scholars (as an initial estimate of the program). The overall program contract period of performance will be 60 months (5 years).

Postdoctoral Scholars will possess doctoral degree credentials. They will be American citizens, capable of obtaining security clearances at the Secret level; clearances at higher levels will be considered on a case-by-case basis. They will exhibit such academic, research, and/or professional credentials as to demonstrate a disciplinary “state of the art” focus, flexibility, and innovation in methodology and approach, which will ultimately enhance the mission capabilities of DTRA.

Requirements and needs for the provision and assignment of such Postdoctoral Scholars, as may be selected to participate under this program, will be defined and prioritized by Agency

leadership, as deemed appropriate. The successful applicant(s) to this topic will provide an appropriate process for the provision of suitable candidates with advanced educational credentials and capabilities responsive to the stated requirements and needs.

Science, technology, engineering, and mathematical skills particularly critical and highly desirable to the enhancement of the Agency mission include: nuclear and radiation physics; weapons engineering; structural, electrical, and mechanical engineering; broad-based nano-technological engineering and applications; weapons effects and system response technologies; physics, chemistry, and biological sciences related to detection, characterization, and destruction of WMD materials; medical and pharmaceutical sciences; information technology, modeling, technical editing and publication, data visualization, data science, and advanced computational sciences; social, adversarial, and behavioral modeling, science, and analysis. This is not an exclusive listing, and DTRA reserves the right to amend this skill list as mission requirements warrant.

Postdoctoral Scholars will be assigned to DTRA functions, missions, and projects according to their respective specialties and at such places and locations determined to be in the best interests of the Agency (taking into practicable account individual career and professional needs). These locations may include DTRA facilities, national and/or DoD laboratories, other government facilities, military facilities, and contractor sites. They will serve as independent technical advisors and professional subject matter experts (SME) on scientific, technical, and engineering issues related to the execution of the DTRA mission.

Each Postdoctoral Scholar will be assigned a DTRA Mentor to guide, lead, and ensure the optimal utilization of each participant, ensuring that all assigned Postdoctoral Scholars' duties maximize individual intellectual contributions to the overall enhancement of the Agency's capabilities. The Postdoctoral Scholars will report to these individuals on a regular basis to provide informal status reports, to present feedback, and to obtain guidance on current and future activities. Institutionally provided online library services is an important aspect to the success of the Postdoctoral Scholar.

To ensure the goals of the program are met to the maximum extent possible, as well as minimize disruption on academic and professional careers, a minimum commitment of one calendar year of effort per Scholar appointment is required. Two additional one calendar year extensions may be made available as determined by the DTRA manager and on the desire of the Postdoctoral Scholar to extend.

Postdoctoral Scholars will be expected to perform some travel (both local and non-local) approximately once a month during their assignment to DTRA to maintain their technical proficiency. This travel will include, but is not limited to, national conferences, symposia, workshops, interfacing with their home organizations, and site visits for outreach. Travel may also include, but is not required, one or more international conferences.

Thrust Area 7 has ten (10) topics —Topics M1-M10 —detailed below. Submissions to the general thrust area descriptions for this thrust area in accordance with the requirements detailed in this BAA are also welcome.

- If NOT submitting to one of the specific topic numbers detailed below, use one of the **Thrust Area NO TOPIC** application packages
- If you ARE submitting to one of the specific topic numbers detailed below, use the applicable **Basic Research-Thrust Area 7-Topic M1 to M10** application package

Great care must be taken to use the appropriate application package on www.grants.gov, as the package selection dictates how each submission will be reviewed:

*****BASIC RESEARCH TOPICS M1-M10*****

In accordance with Section 4.2.1, the requirement for abstract pre-coordination is waived for Topics M1-M10; these topics do NOT require pre-coordination of an abstract prior to the submission of pre-application white papers. All other pre-coordination requirements remain in effect.

The pre-application white paper deadline for Topics M1-M10 is 3 February 2023. **PRE-APPLICATION WHITE PAPERS FOR THESE TOPICS MUST BE SUBMITTED BY 11:59 PM (MIDNIGHT) EST ON 3 February 2023.** White papers submitted to Topics M1-M10 may not be considered if they are received after this deadline.

Topics M1-M10 are interested in research projects that span from those that focus on exploratory aspects of a unique problem or approaches to those that involve a comprehensive program with interdisciplinary areas. Consistent across all proposals should be the focus on innovative research with the potential for high impact to C-WMD science.

The following topics are Basic Research topics, and proposals should not be solely written with or marketed to a DoD centric application; the offerer should also present a description of the broader implications of their work to our Nation and the whole of society.

DTRA anticipates that the predominance of awards made under Topics M1-M10 will be grants. Pre-application white papers and proposals submitted to Topics M1-M10 must have a single lead organization and single submission for the pre-application white paper and the invited proposal. Awards will be made by a single award to the lead institution. Sub-awards, including all grants and/or contracts, are the responsibility of the award recipient; exceptions will not be made.

Thrust Area 7, Topic M1: Host Response to Emerging Viral Threats: Discovery of Common Mechanisms for Therapeutic Intervention

Award Amounts for this topic are anticipated to be up to \$500,000 per year (total dollar value = direct and indirect costs). In all cases, the proposed award value should be clearly substantiated by the scope of the effort. Further guidance on scope and cost may be provided in each full proposal invitation.

The preferred award structure for this topic is a base period of two (2) years with up to three (3) additional years as possible options. However, pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable. Pre-application white papers and proposals that outline scope and effort for different base period and option combinations may also be considered; however, note that pre-application white

papers and proposals that outline scope and effort that exceed a total of five (5) years will not be considered.

Background: Direct acting antivirals deployed during the COVID-19 pandemic have helped mitigate the effects of the viral infection when administered early in the course of disease; however, the disease processes targeted and induced by SARS-COV2 have been persistent and have contributed to long periods of morbidity in several subsets of the population. The COVID-19 pandemic highlights the need for additional therapeutic strategies, such as host-targeted therapeutics, that are effective in mitigating or reversing symptoms caused by viral infection.

This solicitation seeks research to understand host processes and mechanisms involved in viral infection, replication and disease progression for members of viral families Filoviridae (e.g. Sudan, Marburg, Ebola), Hantaviridae (e.g. Hantaan), Arenaviridae (e.g. Lassa, Machupo), and/or Togaviridae (e.g. VEEV, EEV), which can be leveraged to identify common host targets for broad-spectrum (i.e., multi-pathogen) therapeutic intervention.

Impact: If successful, this effort will result in the discovery and validation of host processes and mechanisms common among/within viral families that can be targeted to develop broad-spectrum, host-directed therapeutic medical countermeasures for emerging threats.

Objective: Pre-application white papers and proposals will describe technical approaches to characterize and identify host processes and mechanisms common among/within viral families of interest to the ChemBio Defense Program that are involved in the propagation of viral pathogens and/or are linked to the progression of disease in an infected patient. The approach proposed must include methods for confirming the role of identified targets in viral infection or pathogenesis in more than one orthogonal assay. Experimental methods may include cell cultures, micro-physiological systems, *ex-vivo* systems, and small animal models of disease. The data collected must be documented and formatted such that it can be used by potential collaborators for future development of therapeutic medical countermeasures.

Thrust Area 7, Topic M2: Exploration of Consumer Non-invasive Brain-Computer Interface (BCI) Technologies for Chemical and Biological Defense (CBD) Applications

Award Amounts for this topic are anticipated to be up to \$500,000 per year (total dollar value = direct and indirect costs). In all cases, the proposed award value should be clearly substantiated by the scope of the effort. Further guidance on scope and cost may be provided in each full proposal invitation. Award amounts for this topic are anticipated to be commensurate with the

proposed work involved in exploring consumer non-invasive brain-computer interface for CBD applications, evaluating materials, and other aspects of this program outlined in the metrics below. It is anticipated that teams with varying expertise are required to meet the metrics outlined below.

The preferred award structure for this topic is a base period of one (1) years with up to four (4) additional years as possible options. However, pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable. Pre-application white papers and proposals that outline scope and effort for different base period and option combinations may also be considered; however, note that pre-application white papers and proposals that outline scope and effort that exceed a total of five (5) years will not be considered.

Note: For this topic, awardees will be required to grant the US Government a licensing agreement to all software and or hardware in perpetuity for all Chemical and Biological Defense Program (CBDP) uses.

Background: The battlespace is a complex environment with the six fundamental variables of combat represented by the military acronym METT-TC (Mission, Enemy, Troops, Terrain and weather, Time available, and Civilian considerations). For CBRN operators, the operation variables are further complicated by the threat of operating in contaminated environments. To protect our Warfighters, Mission Oriented Protective Posture (MOPP) is the standard protective gear used when operating in contaminated environments. However, it is known that wearing MOPP gear can cause physical and mental stress as well as reduction in mobility, sensory awareness, attention, alertness, and both gross and fine dexterity [1-3]. The situational uncertainties, physical limitations, and the associated risks can impact awareness of the situation while operating in such a complex and dynamic environment. Yet, effective decision making is built off of situational awareness and the ability to recognize the essence of a given problem and the creative ability to devise a practical solution. These abilities are the products of experience, education, and intelligence [4]. Therefore, the Joint Science and Technology Office Digital Battlespace Management Division (JSTO CBI) is seeking methods that can allow easier access to information while operating to enable comprehensive decision making, and promote the inheritance of knowledge and experience.

JSTO CBI has identified brain-computer interface and the related neurotechnologies as the potential solution. The human brain, formed by nearly 100 billion neurons and 100 trillion connections, is one of the greatest mysteries in science. With the dedication of neuroscientists, it is now common knowledge that these neurons and connections work to process and transmit electrophysiological signals. Jacques Vidal asked in his publication *Toward Direct Brain-computer Communication* nearly half a century ago [5], “Can these observable electrical brain signals be put to work as carriers of information in man-computer communication or for the purpose of controlling such external apparatus as prosthetic devices or spaceships?”. In this topic, JSTO CBI would like to ask a similar question—can these observable electrical brain

signals be put to use in order to serve our Warfighters in Chem/Bio defense missions and tasks.

A brain-computer interface (BCI) is a communication system that allows human interactions with surroundings without the involvement of peripheral nerves and muscles. Such interaction is achieved by leveraging control signals generated from electroencephalographic activity [6]. BCI can serve to record data from the brain for further decoding to transform the data into meaningful outputs for purposes such as control of external devices (e.g., robotic limb) [7]. Because of the possible external device control, BCI applications in medical fields for restoration purposes are often seen. However, the advancements in neuroscience and BCI is shining light on other applications. This expansion toward other applications is evident with an unprecedented amount of corporate investments in neurotechnologies, such as Nissan's brain-to-vehicle [8], Valve Software's focus on BCI for virtual reality (VR) interaction [9], Facebook's optical BCI investment [10], and Neuralink's focus of bringing neurotechnology to the mass market. Although nascent, this trend is expanding toward applications other than restoration of physical functions.

The combination of BCI, Team Awareness Kit (TAK), and heads-up display technologies are potential tools that can provide enhanced situational awareness to the Warfighters while operating in highly dynamic and hazardous environment as an alternative to commonly seen hand gesture, eye-tracking, or voice controls, allowing Warfighters to have hands on tasks, eyes on target, and minimal risk of exposing their locations. It is desired to explore whether consumer non-invasive BCI can be exploited for human interest detection (HID) [11] and decision making [12, 13] to support CBD situational awareness and mission readiness. JSTO CBI is seeking to investigate the possibility of leveraging consumer non-invasive BCI for human interest detection (HID) in combination with artificial intelligence (AI) or machine learning (ML) models to help reduce cognitive load by reducing amount of information to be projected on head-up displays (HUD). It is also of interest to explore if and how the detected interest can be leveraged to enhance or facilitate decision making. Additionally, we seek to answer the question whether consumer non-invasive BCI can assist understanding the key responses that lead to successful completion of tasks in hazardous and dynamic environments.

Impact: The research in this topic seeks to explore the potential and possibilities of leveraging signals from consumer non-invasive BCI for detecting human interest toward the applications of HUD content control, CBD knowledge inheritance, and decision making. The results of the studies are envisioned to reduce cognitive load and enhance decision making when operating in high-stress, dynamic, and hazardous environments as well as to promote the preservation of critical CBD operational knowledge.

Objective: Pre-application white papers and proposals should describe the development and demonstration of the potential to leverage signals from consumer non-invasive BCI to detect human interest for the purposes of HUD content control to reduce cognitive load, enhance decision making, and preserve and extract critical knowledge or responses from experienced

CBD operators.

Applicants should consider methods that leverage consumer non-invasive BCI and related neurotechnologies for the above mentioned 3 areas. Proposed work focusing on selecting any number of the above listed areas will be considered. Proposed work should employ a phased approach with the following recommended stages of applications:

- Demonstrate capabilities in controlled indoor settings to allow explorations and baselining
- Demonstrate capabilities in controlled outdoor settings to explore influences from outdoor environment
- Demonstrate capabilities in a stressed outdoor environment that simulates a dynamically changing battlefield
- Demonstrate capabilities in a stressed outdoor environment with tasks to simulate the level of complexity to carry out a mission in dynamically changing battlefield

The order and stages of milestones are open to modifications that best support the proposed studies. The number of subjects to be involved in phases should be considered. Applicant should consider IRB and HRPO processes when proposing the research schedule.

Research areas may include, but are not limited to:

- Exploration of applicability of one or multiple consumer non-invasive BCIs for signal extraction
- Exploration of different modalities of consumer non-invasive BCI (e.g. EEG-based, in-ear BCI)
- Development of necessary AI/ML algorithms or models to achieve the goals of HID for HUD content control, achieve enhanced decision making, or preserve critical CDB knowledge

Proposed work may leverage a combination of multiple consumer non-invasive BCI devices. It should be noted that minimum modifications to consumer non-invasive BCI devices are acceptable. However, this topic is not aimed at hardware development and should focus on making use of signals available from consumer non-invasive BCI devices. Applicants are encouraged to consider leveraging TAK variants when reasonable.

It is anticipated that this topic will require teams of researchers with different expertise in brain-computer interface, neurotechnologies, AI/ML, computer science modeling, and extended reality. A justification of the budget will need to be provided to supplement the costs proposed for this effort.

Thrust Area 7, Topic M3: Leveraging quantum effects to improve diagnostic and detection capabilities for threat agents

Award Amounts for this topic are anticipated to be up to \$500,000 per year (total dollar value = direct and indirect costs). In all cases, the proposed award value should be clearly substantiated by the scope of the effort. Further guidance on scope and cost may be provided in each full proposal invitation. Award amounts for this topic are anticipated to be commensurate with proposed research seeking to characterize, control, or exploit quantum mechanical effects and properties involved in biological interactions for the purpose of improving detection and diagnostic tools. It is anticipated that teams with varying expertise are required to meet the metrics outlined below.

The preferred award structure for this topic is a base period of two (2) years with up to three (3) additional years as possible options. However, pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable.

Pre-application white papers and proposals that outline scope and effort for different base period and option combinations may also be considered; however, note that pre-application white papers and proposals that outline scope and effort that exceed a total of five (5) years will not be considered.

Background: Current diagnostic and detection technologies are largely based on our understanding of biological processes at the macromolecular scale. In order to develop transformative solutions that improve our ability to identify threats and approach the ultimate limit of single cell and single molecule detection in handheld assays, we must seek to understand and leverage knowledge of the processes that occur in the quantum realm. There are numerous ways quantum mechanics can be exploited to improve portable, handheld diagnostic and detection assays including leveraging knowledge gained through quantum biological processes, exploitation of quantum light properties, and the use of quantum materials that interact with biological molecules.

The burgeoning field of Quantum biology seeks to achieve a better understanding of quantum mechanics in biological processes. It involves the study of the influence of non-trivial quantum phenomena which can be explained by reducing the biological process to fundamental physics. Quantum measurements in noisy biological environments pose a formidable challenge, but work in this field has already begun leveraging higher resolution tools and even synthetic biology methodologies to elucidate biological activities that involve quantum effects such as tunneling, coherence, and entanglement. Is it possible that knowledge gained from this work could be leveraged to increased signal amplification or reaction speeds for biological assays?

Diagnostic and detection technologies could also be improved by exploiting the quantum properties of light. Many biological assays, such as optical microscopy, cellular histology, and fluorescence immunoassays use classical light for detection/readout. In contrast to classical light, quantum light can have unique properties, such as temporal/spatial coherence or entanglement that can provide unique advantages, including increased sensitivity, lower light dose, superior spatial resolution, or wider and novel spectral windows of observation. Recent work has brought together quantum physics and biology to show that quantum light can be used to track enzyme reactions in real time. This made it possible to use low illumination without disrupting the enzymes, with the potential to achieve a better sensitivity. This type of work is an important step toward development of quantum sensors for biomedical applications.

Another potential area of exploration is the use of quantum materials to improve sensitivity of assay read out. Here, we define quantum materials as systems where key material properties (such as discrete and quantized fluorescence emission or altered/enhanced electrical conductivity properties) stem from quantum effects such as quantum confinement. This confinement may come in zero dimensional materials (e.g. quantum dots or vacancy centers), 1D materials (such as carbon nanotubes or nanowires) or 2D quantum materials such as graphene. The small and reduced dimension of these materials generally makes them sensitive to their local nano-environments, which have the potential to be used as ultra-sensitive reporters of chem/bio agents and their effects on cellular and human health.

This topic seeks to leverage quantum mechanics to gain better understanding of biological processes and to exploit quantum mechanical effects or properties to develop transformative

solutions for the diagnosis of disease and detection of threat agents.

Impact: This topic encompasses broad topics related to applying quantum mechanics and quantum tools and materials, as well as exploitation of quantum effects to improve diagnostic and detection capabilities for chemical/biological threats. Successful efforts from this topic will provide novel solutions for improving the sensitivity or specificity of diagnostic and detection capabilities.

Objective: Proposals for this topic should address the broad objective of using quantum mechanics to improve diagnostic and detection capabilities. Quantum material proposals for this call should focus on novel materials and synthesis methods, therefore, proposals including established commercial off-the-shelf (COTS) materials will not be considered. Examples of specific research questions that may be addressed include but are not limited to the following:

- What quantum effects play a non-trivial role in biological processes and how can these effects be exploited to improve point of care diagnostic and detection capabilities?
- Can quantum mechanical effects or properties be used to enhance the sensitivity, resolution, or specificity of biological assays in areas important to biological health or chemical/biological agent detection?
- Can quantum mechanical effects or properties be used to extend bio-imaging and sensing to important novel spectral windows difficult to obtain via classical methods?
- Can quantum mechanical effects or properties be used to extend the observation period or increase the spatial resolution of visualizing host-pathogen or host-agent interactions and interventions?
- Can quantum mechanical effects or properties be used to reduce the cost or SWAP (Size, Weight, and Power) requirements for standard biological assays, chemical/biological agent detection, or imaging methods?
- Are there key biological molecule and quantum materials interactions of relevance to chemical and biological agent interactions that could be shaped/manipulated/detected because of quantum interactions?
- Can new quantum materials be developed and exploited to measure parameters of interest to biological health in response to chemical/biological agents?
- Can new quantum materials be developed for chem/bio detection and sensing, measuring key biomolecular properties on spatial or temporal scales un-obtainable via classical methods?

Thrust Area 7, Topic M4: Let's Get Moving: Surface Agitation and Self-propellant Materials in Liquid Films for Decontamination

Award Amounts for this topic are anticipated to be up to \$500,000 per year (total dollar value = direct and indirect costs). Award Amounts for this topic are anticipated to be indicative of the amount of work involved to comprehensively address the objectives of this program outlined below. It is anticipated based on this topic that there will be teams with varying expertise that is required. In all cases, the proposed award value should be clearly substantiated by the scope of the effort. Further guidance on scope and cost may be provided in each full proposal invitation.

The preferred award structure for this topic is a base period of two (2) years with up to three (3) additional years as possible options. However, pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable. Pre-application white papers and proposals that outline scope and effort for different base period and option combinations may also be considered; however, note that pre-application white papers and proposals that outline scope and effort that exceed a total of five (5) years will not be considered.

Background: Decontamination and protection rely on diffusion of toxic chemicals (for example GD, HD, and VX) to active/catalytic sites that will then detoxify those materials. Although highly efficient towards toxic chemical decomposition these active/catalytic materials have the rate limiting step of being controlled by diffusion of the toxic chemical to active sites. Having a reactive or catalytic decontamination technology with the capacity to be “mobile” could impact the ability for the decontaminant to improve efficacy with respect to time (increasing the amount of analyte decontaminated in a specific time) and/or allow for migration of the decontaminant into small spaces where the current dominant mechanism is reliant on chemical diffusion out of these small spaces such as rivets or metal joints on vehicles.

Current research in micromotors, active droplets, small scale/micro-swimmers, and propelled metal organic frameworks (as examples) have explored these “mobile” materials for toxic chemical remediation, detection and neutralization, improved mixing to reduce increase reaction efficiency and also including wastewater remediation of various chemical and biological contaminants. Researchers have also studied mechanisms of particulate self-propellancy and interactions with other particles (e.g. swarm behaviors) and different geometries and chemistries to introduce additional functionalities for detection, monitoring, and decontamination. These technologies have the potential to allow for self-propellancy of the decontamination technology such that the decontaminant could maneuver across surfaces and/or into complex features to allow for self-propellant behavior to/from contaminated areas or surfaces increasing rates of decontamination and getting into complex features where current diffusion based mechanisms

are dominant.

This topic seeks to develop a fundamental understanding of how to develop and integrate components for both self-propellant and decomposition of toxic chemicals (surrogates, simulants or model systems) into one material. Initial studies can be initially demonstrated in solution, with the ultimate goal to minimize the solvent to a liquid film on a surface. This topic also seeks self-propellant behavior through utilizing internal or external stimuli (chemical reactions, attraction/repellency, enzymatic, biologically inspired, light, pH, magnetism, electrostatic, ultrasound, predator/prey relationships or other mechanism) without requiring mechanical stirring or other direct intervention.

Impact: If successful the methods and materials developed during this effort could be developed into a new decontamination technology or integrated with existing platforms to increase rates of surface decontamination and increased diffusion/decontamination rates in areas that are difficult to decontaminate.

Objective: This topic seeks to develop a fundamental understanding of how to develop and integrate components for both self-propellant and decomposition of toxic chemicals (surrogates, simulants or model systems) into one material capable of neutralizing toxic chemicals. Proposals should describe the approach for investigation of the components and integration of these materials for eventual use in or on surfaces or in complex features that will be self-propellant with internal or external additives or other triggers (e.g. chemicals, catalytically propelled, light, pH, magnetic particles, Marangoni effect, thermal, concentration gradients, other particle attraction/repulsion interactions) and reactive or catalytic towards toxic chemicals decomposition/destruction. Proposal designs should include the following:

- Base Period Goals:
 - Proof-of-concept (iterative design, development, fabrication, and characterization) of an active/self-propellant material or self-propellant phase (micromotor, active droplet, etc.) and a catalytic or reactive component for decomposition of surrogates/simulants or a model system for one or more toxic chemicals.
 - Initial studies of mechanisms and kinetics of decomposition with these materials in the model system or for simulants/surrogates including determination of efficacy of static versus self-propellant version of the material in liquid films
 - Initial studies of multiple materials in close proximity (e.g. aggregation potential)
 - Preliminary fundamental studies of self-propellancy and development/use of methods to measure self-propellancy of these materials in liquid films
 - Demonstration of relative efficacy for simulants of static and self-propellant version of the offerors concept and demonstration of self-propellancy of the initial designs in liquid films to adjudicate potential for future work
- Option Period(s) Goals
 - Year 3: Refined studies of mechanisms and kinetics of decomposition with these materials in the model system or for simulants/surrogates ; continued advancement of decontamination rates and improved kinetics of diffusion to/from

these integrated materials on surfaces; continued study of efficacy rates relative to static materials

- Year 4: Determine stability (mechanical, chemical); formal study of behavior of multiple self-propellant materials in close proximity; determination of initial ability for use on actual surface materials or in complex features
- Year 5: Determination of ability to maneuver, traverse longer distances and encounter other materials; determination of efficacy of reaction of simulant/surrogates and efficacy relative to time, determination of chemical decomposition rates relative to static material using DMMP, DIMP, CEES or other simulants.

The selected providers must provide appropriate model systems/reactions for CB defense applications showing promise for compatibility with potential protection and hazard mitigation technologies.

Proposals should focus on one or more toxic chemicals and associated model compounds. It is expected that the awardees will work only with simulant/surrogates and/or model compounds as part of this research. Actual chemical agents should be considered but not proposed as part of this work.

Thrust Area 7, Topic M5: Medical Countermeasures Against the Aging of Acetylcholinesterase Complexed with Organophosphate Agents

Award Amounts for this topic are anticipated to be up to \$500,000 per year (total dollar value = direct and indirect costs). In all cases, the proposed award value should be clearly substantiated by the scope of the effort. Further guidance on scope and cost may be provided in each full proposal invitation. Award amounts for this topic are anticipated to be commensurate with the proposed work involved in developing novel in vitro models. It is anticipated that teams of collaborating organizations with varying expertise maybe required to meet the metrics outlined below.

The preferred award structure for this topic is a base period of three (3) years with up to two (2) additional years as possible options. However, pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable. Pre-application white papers and proposals that outline scope and effort for different base period and option combinations may also be considered; however, note that pre-application white papers and proposals that outline scope and effort that exceed a total of five (5) years will not be considered.

Background: Organophosphate agents (OP) continue to be a threat to the Armed Forces and

agricultural workers, and there are no broad spectrum medical countermeasures for treatment of OP intoxication. The management of OP exposure is further compounded by the phenomenon of “aging,” during which the OP-ChE conjugate is dealkylated, and the enzyme inhibition becomes irreversible. Once aging has occurred, existing medical countermeasures become ineffective. The rate of onset of aging is variable **across** OP agents, but can occur fast enough to severely limit treatment options post-exposure.

The structural basis of the aging process for OP-ChE conjugate has been investigated, and protein structural effects seem to be critical to the irreversibility of aging. As early as 2008, X ray diffraction and other analysis have shown that the aging process involves agent O-dealkylation resulting in a negatively charged oxygen “salt bridge” to a proximal histidine in AChE, as well as conformational changes. These insights have not, however led, to progress against the problem of aging.

Since then, there are multiple lines of evidence that the aging phenomenon both is dependent on particular enzyme structural features in order to occur, and imposes structural effects on the enzyme that prevent reactivation. Specifically, aging can be inhibited by both mutations to the AChE and interactions with other molecules that affect protein structural dynamics. On the other hand it is shown that aged OP-AChE conjugate has increased rigidity compared to the native enzyme, which is thought to prevent countermeasure access to the active site and interaction to restore function.

Separately the science of structural biology has advanced significantly since the time of these findings. There are now theoretical and analytical tools for structural analysis that have not yet been fully investigated for their relevance to this problem. Therefore, the intent of this topic is to support novel approaches using emerging structural tools and insights to defeat the problem of OP-AChE aging and to expand the utility of existing OP countermeasures.

Impact: Successful execution of this effort will establish the foundation for novel therapeutic approaches using the prevention of OP-AChE aging as an adjunct or alternative to the standard of care, reactivation of AChE from OP inhibition. As a result, the utility of existing countermeasures will be expanded to a larger therapeutic window after exposure, and exposures to fast-aging OPs that were previously not treatable in practical terms will become more available to medical intervention.

Objective: This program seeks to leverage the known structural aspects of the OP-AChE aging process and the emerging technologies in the prediction, study, and control of protein structure to establish a basis for preventing OP-AChE aging.

Pre-application white papers and proposals should describe the development and demonstration of novel insight into the role of protein structure changes in the OP-AChE aging process as well as approaches to modulating structural effects to prevent or reverse OP-AChE aging.

- Considerations for a responsive proposal can include the following:
- The investigation of a structural basis for restoring catalytic function to aged OP-AChE conjugate.
- The investigation of a structural basis for preventing formation of aged OP-AChE conjugate.
- The targeting of OPs, e.g. with small molecules, to prevent them from being able to age with AChE.

- Mechanistic understanding of any of the above processes.
- Ensuring the mechanisms developed are broadly applicable to a spectrum of OP agents.
- Use of AI/ML and/or microphysiological systems (MPS) (e.g. organ-on-a-chip or human-on-a-chip) to establish and characterize rational approaches to these solutions.
- Integrating the issue of physiological relevance early in the development of these medical solutions, to support their ability to eventually transition to human use.

Thrust Area 7, Topic M6: In Vitro Model Development of Alphavirus Infection

Award Amounts for this topic are anticipated to be up to \$500,000 per year (total dollar value = direct and indirect costs). In all cases, the proposed award value should be clearly substantiated by the scope of the effort. Further guidance on scope and cost may be provided in each full proposal invitation. Award amounts for this topic are anticipated to be commensurate with the proposed work involved in developing novel in vitro models. It is anticipated that teams of collaborating organizations with varying expertise maybe required to meet the metrics outlined below.

The preferred award structure for this topic is a base period of three (3) years with up to two (2) additional years as possible options. However, pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable. Pre-application white papers and proposals that outline scope and effort for different base period and option combinations may also be considered; however, note that pre-application white papers and proposals that outline scope and effort that exceed a total of five (5) years will not be considered.

Background: Neuroinflammation is present in nearly all pathological conditions in the central nervous system (CNS) by either being the primary cause of the condition or as a response to the disruption of homeostasis following disease progression. Microglia and astrocytes become

activated following insult or injury to the CNS. The resulting crosstalk between neurons, astrocytes, and microglia has been shown to play a significant role in the observed neuroinflammatory response including dysregulation of endothelial signaling pathways.

For alphaviruses the pathology surrounding brain inflammation is a significant factor of the disease and is therefore a target for medical countermeasure development. For example, Severe Combined Immunodeficient (SCID) mice survive longer than immune-competent mice suggesting that it is the inflammation that is the major contributor to morbidity, rather than any immune deficiency.

Alphaviruses poorly elicit an innate immune response in cell culture which leads to mischaracterization of in vivo tropisms. In addition, current cell culture models are limited in their ability to observe the effects of membrane-bound or cell proximity-dependent mechanisms and such innate responses. Recent advances in the manipulation of individual cell types and culture systems offers new possibilities to develop cell, tissue, and 3-D models to better represent animal model systems.

Impact: The research explored in this topic seeks to develop new neurotropic cell and tissue based models that better mimic the natural response to infection. Few current neuroinflammatory models are able to capture the important interplay between neurons, astrocytes, and microglia. Thus, there is a need for new, multicellular culture systems that are capable of modeling the impact of crosstalk between different cells in the CNS. This could result in an enhanced understanding of the fundamental regulators of the CNS, increase target identification, better prediction and screening for promising medical countermeasures.

Objective: Pre-application white papers and proposals should describe how their proposal would be used in drug discovery.

Research areas may include, but are not limited to:

- Neurovascular tissues and alphaviruses (VEEV/EEEV/WEEV)
- Characterization of molecular pathways and/or mechanisms of action for alphavirus-induced inflammation.
- Identify common molecular pathways and/or mechanisms of action for alphavirus-induced host response that may be suggestive of novel targets for therapeutic intervention.
- Scaffold based techniques such as hydrogel-based support, polymeric hard material-based support, hydrophilic glass fiber, and organoids
- Scaffold free hanging drop microplates, magnetic levitation, and spheroid microplates with ultra-low attachment coating
- The development of CNS organoids, spheroids, 3D printed microfluidics, methods of improving imaging, automation of liquid handling, and other innovative technologies.

It is anticipated that this topic will require teams of researchers with different expertise in modeling, synthesis and characterization of these materials. A justification of the budget will

need to be provided to supplement the costs proposed for this effort.

Pre-application white papers and proposals may focus on incremental and high risk attempts to develop realistic in vitro models.

Thrust Area 7, Topic M7: Correlating Multi-omics Changes with Measurable Physiological Responses

Award amounts for this topic are anticipated to be commensurate with the proposed work involved in elucidating the underlying principles for multi-omics and other biomarkers in response to chemical and biological (CB) agent exposure and the ability to use them to quantify human physiological responses. It is anticipated that a multi-disciplinary team is required to meet the metrics outlined below.

The preferred award structure for this topic is a base period of one (1) year with up to two (2) additional years as possible options. However, pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable. Pre-application white papers and proposals that outline scope and effort for different base period and option combinations may also be considered; however, note that pre-application white papers and proposals that outline scope and effort that exceed a total of three (3) years will not be considered.

Background: Infectious disease pathogenesis is often first recognized at the onset of symptoms in an infected individual. A cascade of chemical mediators and cellular pathways trigger the inflammatory response to infection and cause measureable physiological symptoms, such as increased temperature and a change in cardiac rhythms, which are felt by the individual as having a fever and feeling generally unwell.¹ Throughout this response to infection, changes in specific biomarkers have been characterized, to include total white blood cell count (WBC), C-reactive protein (CRP), and procalcitonin (PCT).

Beyond vital signs and biomarkers, multi-omics (transcriptomic, proteomic, and metabolomics) have been increasingly studied to advance the molecular understanding of host-pathogen interactions during viral and bacterial infections. Specifically, multi-omic approaches have been

used to characterize virulence, pathogenicity, and metabolic pathway regulation after infection.ⁱⁱ

Similarly, exposure to chemical agents has been shown to cause substantial omics changes, notably significant downregulation of multiple proteins. A proteomic-based study examined the impact of the nerve agent soman on brain tissue in small animals. The soman-induced proteomic changes impacted key pathways for cell inflammation, metabolism, neurodegeneration, and cell death, among others, and demonstrated that persistent proteomic changes in the brain can cause multiple neurological effects.ⁱⁱⁱ

While research on both physiological effects and multi-omics data related to CB agent exposure continue to advance alongside one another, there is limited evidence correlating the two research areas. This topic seeks to determine the feasibility of correlating multi-omics from the course of infection or chemical exposure with specific physiological responses such as *changes* in heart rate, temperature, respiratory rate, and blood pressure.

Impact: DTRA continues to invest in leveraging data collected from wearable devices to provide early warning of CB threat agent exposure^{iv}, as well as in advancing research on understanding multi-omics effects of CB exposure to aid in improved diagnostics, therapeutics, and medical intervention to minimize warfighter casualties. However, physiological data collected from wearable devices is limited to more common infections, such as influenza and COVID, and does not cover the full breadth of CB threats. By answering fundamental questions on the feasibility of correlating multi-omics data with the physiological response to infection/exposure, it may be possible to extend the current state-of-the-art for wearables-based early warning to encompass additional threat agents. Organ-on-a-chip (OOC) technology provides an opportunity to explore multi-omics changes across a wide array of tissue types in response to different CB threats, which may allow for data collected from multi-omics OOC studies to be leveraged to improve predictive wearable based algorithms specific to CB agents.

Objective: Pre-application white papers and proposals should describe an approach for inferring changes in, and quantifying, if possible, specific physiological responses (e.g., vital signs) as they relate to biomarkers and multi-omics data collected during biological pathogenesis or chemical agent exposure. Applicants should propose access to datasets that include **both** physiological and multi-omics data for the same patient during course of infection or chemical exposure, and may consider leveraging additional Sponsor-provided datasets.

Applicants should demonstrate expertise in the areas below and propose methodology to assess the following:

- Commercial-off-the-shelf (COTS) wearable-based data analysis
 - Understand changes in the physiological response after exposure to CB agents.
 - Propose methodology to compare COTS wearable data with varying temporal resolutions, varying devices, and varying features.
 - Hypothesize key feature importance and probability for correlation to host response to infection.
- Multi-omics data analysis
 - Demonstrate experience with analyzing multi-omics data (e.g., proteomics,

- metabonomics, transcriptomics, epigenomics) from blood, serum, interstitial fluid, saliva, or breath for biomarkers in response to disease/infection or exposure to chemical agents
 - Propose methodology for identifying key markers and/or specific cellular pathways following infection or chemical exposures and the intended approach for analyzing the impact of multi-omics changes on physiological response.
- Machine Learning (ML) approaches for analyzing disparate datasets
 - Propose intended ML approaches and demonstrate experience in selecting ideal approaches depending on dataset parameters and intended algorithm development.
- Hypothesis on correlating multi-omics and other biomarkers to vital sign data
 - Propose methodology and anticipated capability to leverage multi-omics data to qualitatively correlate it with changes in physiological responses (e.g., temperature, heart rate).
 - If feasible, expand the qualitative correlation between multi-omics data and the physiological responses to explore if changes in vital signs can be quantified (e.g., actual temperature or heart rate) based on multi-omics data alone.
 - Hypothesize the granularity of any correlation and methodology to assess this.

Final output of this topic should be a report on the feasibility of correlating multi-omics data with the physiological response (e.g., changes in vital signs) to a CB threat exposure. If a qualitative or quantitative correlation can be demonstrated, the methodology and underlying data analysis to support the correlation is an expected deliverable.

Data collections are not a part of this topic, and data proposed must already exist. Responses should discuss availability of or access to in-vivo datasets of omics and vital sign data, and/or expect to be able to Sponsor-provided datasets which include in-vivo omics data and vital sign data for all individuals.

It is anticipated that this topic will require teams of researchers with expertise spanning data analytics, ML and algorithm development, physiology, CB threat agents, and immunology / molecular cell biology. A justification of the budget will need to be provided to supplement the costs proposed for this effort.

Thrust Area 7, Topic M8: Project MAGNETO, lowering SWaP for Microsensors

Award Amounts for this topic are anticipated to be up to \$500,000 per year (total dollar value = direct and indirect costs). In all cases, the proposed award value should be clearly substantiated by the scope of the effort. Further guidance on scope and cost may be provided in each full proposal invitation. Award amounts for this topic are anticipated to be commensurate with the proposed work involved in elucidating the underlying principles for multiferroic materials, evaluating materials, integrating materials into a sensor prototype, computational models to understand the properties of proposed materials, and other aspects of this program outlined in the metrics below. It is anticipated that teams with varying expertise are required to meet the metrics outlined below.

The preferred award structure for this topic is a base period of three (3) years with up to two (2) additional years as possible options. However, pre-application white papers and proposals that outline scope and effort for only the base period and do not propose options are also acceptable. Pre-application white papers and proposals that outline scope and effort for different base period and option combinations may also be considered; however, note that pre-application white papers and proposals that outline scope and effort that exceed a total of five (5) years will not be considered.

Background: A variety of sensors are being researched and developed to detect chemical and biological (CB) threats in ambient conditions. Recently, there has been a paradigm shift in the field towards developing lower size, weight, and power (SWaP) microsensors to detect CB threats. As sensors are being studied to possibly use for detection applications of CB threats, there is a need to address how to smartly store the data gathered from the sensor. Employing a data storage capability that enables magnetoelectrically-coupled multiferroic materials to write electrically (faster, low power) and read magnetically (nondestructive), this integration into a sensor could provide a means to advance innovation into this area, resulting in a smaller bit size and reducing the applied external fields required within the circuitry of the sensor. By having a lower demand on power, this will also help reduce the battery power needed to operate the sensor. Collectively, this could lower SWaP to advance microsensor development, enabling technologies that can operate longer in the battlefield due to lower power consumption and smarter data storage. This would equip the Warfighter with state-of-the-art innovative microsensors to support their mission and increase their situational awareness.

However, the challenge is to find single-phase materials exhibiting multiferroic properties, i.e. more than one type of ferroic property, at room temperature or composites merging ferroelectric and ferromagnetic materials. A major step toward making viable magnetoelectric technology would be the ability to alternate ferroelectric states with relatively minor voltages. The discovery of more magnetoelectrically-coupled materials or composites would help in the potential development of such sensors and modernizing technology.

This topic seeks to develop a fundamental understanding of multiferroic materials or composites (characterizing bulk materials and thin films), computational models to investigate the structural, magnetic, and electrical properties of materials and to compare to experimental studies, and

integration of the magnetoelectrically-coupled materials or composites into a sensor prototype. This topic also seeks to evaluate these materials integrated into a sensor prototype during year 5, and if milestones are achieved, this technology will be transitioned into a 6.2 program, supporting the Unconventional Detection Modalities Thrust Area listed in Division CBA's portfolio. This project also seeks to potentially develop a microsensor prototype to detect CWAs, emerging threats, and/or simulants of CWAs, and utilize data storage capacity to collect measurements. Measurements collected by the sensor can be AC impedance, infrared, Raman, photovoltaics, but not limited to.

While the ultimate intention is to integrate these materials into suit-based technologies that detect CB threats when exposed to low levels of emerging threats, CWAs, and/or simulants, the basic research should be focused solely on the magnetoelectrically-coupled multiferroic materials or composites to use as data storage for potential optimization and development of the next generation of microsensors.

Impact: The research explored in this topic seeks to develop a fundamental understanding of multiferroic materials (characterizing bulk materials and thin films), computational models to investigate the structural, magnetic, and electrical properties of materials and to compare to experimental studies, and integration of the magnetoelectrically-coupled materials or composites into a sensor prototype. This could be integrated into suit technology for microsensors that could be used to detect agents and other toxic emerging threats, mitigating risk for operational deployment and increasing the Warfighter's situational awareness. Thus, this technology can help unburden the Warfighter and promote integrated layer defense to support the mission.

Objective: Pre-application white papers and proposals should describe the research, development, and demonstration of the technology. Applicants should keep in mind the technology must be operationally relevant to support the Warfighter's mission and ability to tolerate varying environmental conditions in the battlefield.

Applicants should propose magnetoelectrically-coupled multiferroic materials or composites merging ferroelectric and ferromagnetic materials that will be able to have adequate activity to meet metrics including:

- Multiferroic properties –
 - More than one ferroic property: ferromagnetism, ferroelectricity, ferroelasticity, ferrotoroidicity
 - Antiferromagnetism and weak ferroelectricity will also be considered
 - Minimally magnetoelectric materials
- Characterization profile of the structural, magnetic, and electrical properties –
 - X-ray diffraction for crystal structure identification, phase verification, and Rietveld structure refinement
 - Neutron diffraction for crystal structure and magnetic structure identification as well as determining the atomic positions and bond lengths in the unit cell
 - Zero-field and field cooled susceptibility curves and hysteresis loops to provide information about the magnetism
 - Electrical polarization hysteresis loop to monitor the current density and

- ferroelectricity
 - Dielectric constant as a function of temperature to provide insights toward the ferroelectric behavior and magnetoelectric coupling
- Fabrication of thin films –
 - Characterization profile of the structural, magnetic, and electrical properties
 - Investigation of films for data storage capability
- Computational models to help understand properties of materials
- Integration of materials into a sensor prototype as an optional year –
 - Demonstration that sensor can operate for at least an hour (threshold) and up to 12 hours (objective) after powered on.
 - Maintain ability to detect emerging threats, CWAs, and/or simulants for 1 to 12 hours but not necessarily continuously monitoring of agents or simulants
 - Ability to operate in varying environmental conditions, such as low and high relative humidity conditions, low and room temperature conditions, and salty, sandy, and smoky conditions
 - Demonstration of threshold metrics (above) within base period (3 years from award) or prove significant progress towards those goals
 - Require little or no external resources required to operate
- Live warfare agent testing should be strongly considered but not limited to as part of this effort or proposed work.

Ultimately, these materials should be cost-realistic and deployment in varying environmental conditions should be strongly considered.

Research areas may include, but are not limited to:

- Determination (theoretical and experimental) of magnetoelectrically-coupled materials or composites that work in ambient conditions, using external fields, that are capable of storing the data over time to allow for measurements to continue for 1 to 12 hrs.
 - Experimental synthesis and characterization of the materials (bulk materials and thin films) and measurements at the laboratory scale
 - Applicants are encouraged to submit magnetoelectrically-coupled materials or composites for data storage capability and will function at ambient conditions.
 - Applicants are encouraged to evaluate technologies including the potential for detection capability of emerging threats, CWAs, and/or simulants (as vapors or aerosols).
 - Applicants should propose determination of environmental conditions (e.g., light, temperature, relative humidity, salty, sandy, smoky), preferably ambient conditions, for operational relevance of technology.
 - Applicants should propose evaluation of emerging threats, CWAs, and/or simulants (as vapors or aerosols) with these magnetoelectrically-coupled materials or composites.

It is anticipated that this topic will require teams of researchers with different expertise in modeling, synthesis, and characterization of these materials (bulk materials and thin films). A justification of the budget will need to be provided to supplement the costs proposed for this

effort.

Pre-application white papers and proposals should focus on a fundamental understanding of research, development, integration, and demonstration of magnetoelectrically-coupled multiferroic materials or composites to use as data storage and integrate these materials into a sensor prototype aimed to detect emerging threats, chemical warfare agent, and/or simulants for potential use with Warfighter suit of technologies.

Thrust Area 7, Topic M9: “Next” Next-Generation Material(s) for Chemical and Biological (CB) Protection and Decontamination

Award Amounts for this topic are anticipated to be up to \$200,000 (total dollar value = direct and indirect costs) for a maximum of one (1) year effort.

The preferred award structure for this topic is a base period of a maximum of one (1) year with no option years. Phase I white papers and proposals that outline scope and effort for periods beyond the base period will not be considered.

Award Amounts for this topic are anticipated to be indicative of the amount of work involved in demonstrating feasibility of highly innovative basic research areas that may serve as the basis for advancement of new concepts for chemical and biological protection and decontamination, and other aspects of this program outlined below.

Background: DTRA/JSTO’s recent basic research investments relevant to chemical and biological (CB) protection and decontamination have identified materials that demonstrate adsorption, reactivity, selective permeability or a combination thereof. Examples include metal-organic frameworks, metal oxide nanoparticles, reactive polymers, and biomimetic and bioengineered systems. While studies with these material classes continue to evolve, new foundational materials research and discoveries are essential to shape future technological capabilities for the Warfighter.

In order to realize new materials with extraordinary function, the exploration of novel scientific opportunities is desired. These studies should seek to identify scientific breakthroughs that may begin to address technical or logistical challenges associated with materials utilized in current

protection and hazard mitigation technologies. For example, conventional adsorbent materials function by means of both physical adsorption and chemisorption; however the lack of selectivity and reactivity limits the chemical protection that can be attained. Elastomers provide excellent barrier properties but at the trade-off of reduced tactility and moisture vapor transport. Polyfluoroalkyl (PFAS)-based coatings provide a high level of surface repellency, but due to environmental and health impacts, efforts are shifting towards non-PFAS material alternatives. Decontaminants have proven to reduce hazard levels, but materials that can turnover agent efficiently and are compatible with complex surfaces are needed.

Impact: This topic will foster innovative ideas to advance the scientific state-of-the-art, with potential of identifying creative material solutions to modernize CB filtration, decontamination, and protective suit technologies.

Objective: This topic seeks short-term, fundamental research investigations focused on proof-of-concept studies and collection of preliminary data of highly innovative research initiatives in support of the “*next*” next-generation material(s) and concepts for CB protection and decontamination. Example research areas *include but are not limited to:*

- Catalysis and reaction engineering to generate concepts that demonstrate rapid, efficient turnover
- Polymer and soft materials to generate concepts that demonstrate stretchable, repellent barriers
- Hybrid or multifunctional materials to generate concepts that demonstrate a combination of adsorptive, catalytic, and/or repellent properties
- Interface and colloid science to generate concepts that demonstrate the ability to enhance reaction rates, diffusion, transport, and/or mechanical properties
- Computational approaches that provide a new means of screening novel materials, developing quantitative structure-activity relationships and other models, predicting the properties of materials, and performing other materials-related studies

Additional considerations:

- Research must be completed within 12 months of award of the agreement.
- No capital equipment may be purchased under this award.
- Due to the relatively small dollar amount and short-term nature of this award, applicants are encouraged to maximize the benefit derived from this funding by prioritizing labor and employing other cost-saving measures in support of the effort. In particular, applicants are strongly encouraged to contribute as a cost-share or significantly reduce the indirect costs associated with the proposed effort.
- The Phase II project narrative (technical proposal) should reflect the level of work to be performed within 12 months, and emphasize the key tasks leading to proof of idea. Due to the short-term nature of this award, the Phase II project narrative (technical proposal) should not exceed 10 pages (including references), and does NOT require the following components/attachments: programmatics, performance schedule, and quad chart. For budgeting purposes, there is no travel requirement for an annual technical review.
- Under this reward, reporting requirements are reduced to a final technical report only.

Thrust Area 7, Topic M10: Leveraging Protein Structure Insights and Allosteric Effectors of MCM Targets

Award Amounts for this topic are anticipated to be up to \$500,000 per year (total dollar value = direct and indirect costs). Award amounts for this topic are anticipated to be indicative of the amount of work involved to comprehensively address the objectives of this program outlined below. It is anticipated based on this topic that there will be teams with varying expertise that is required.

The preferred award structure for this topic is a base period of three (3) years with up to two (2) additional years as possible options with options being dependent on meeting benchmarks established in the proposal and statement of work. Phase I white papers and proposals that outline scope and effort for only the base period and do not propose options are acceptable, but note if

option(s) are not proposed they will not be granted at a later date. Note that efforts that propose exceeding a total of five (5) years will not be considered.

Background: Development of safe and effective pre-exposure prophylactic or post-exposure therapeutic medical countermeasures (MCMs) to counter the adverse effects of CWAs (including blister agents, nerve agents, pharmaceutical based agents and other emerging chemical threats) is necessary to protect the warfighter and maintain Force Lethality in CWA-contested environments.

The full complement of protein receptors, metabolic pathways, and tissue distribution of receptor targets of chemicals of concern are not well understood. The improved understanding of the identity, abundance, and tissue-specific distribution of receptors in humans and animal models affected by various chemicals of concern will provide a significantly improved profile to facilitate enhanced medical countermeasure development and identify receptors that are impacted by more than one class of existing and emerging chemical threats.

In order to develop more effective and broadly acting medical countermeasures there is a need to identify host-related biomarkers and biochemical pathways that overlap amongst various threat exposures.

There is also a need to implement a state-of-the-art computational approach, including artificial-intelligence (AI) and machine-learning (ML) based predictive methods that will prioritize specific protein targets for further experimental validation. Use of experimental and/or predicted protein structures to discover novel receptors for CWAs (including blister agents, nerve agents, pharmaceutical based agents and other emerging chemical threats) will help to determine the basis for potential new CWA -protein interactions that can include active sites, ligand binding sites and/or allosteric sites.

Impact: This approach can leverage protein structure prediction capabilities to identify novel protein targets that are most likely to be functionally impacted by CWA interactions. There are breakthroughs happening in the understanding of protein structure, through both analytical methods and AI- and ML-based predictive methods.

An in-depth understanding of the nature of the molecular recognition/interaction is also of great importance in facilitating the discovery, design, and development of new MCMs.

This approach also enables prioritization of the most biologically meaningful proteins for further study and development of MCMs.

Objective: CWAs continue to be a threat to the warfighter, against which there are no broad spectrum medical countermeasures.

Identification of overlapping biomarkers and biochemical pathways that are affected by exposure to various types of chemical agent threats can help with development of broad-spectrum, potentially cross-toxidromic, medical countermeasures.

The proposal should include one or several of the following approaches, as applicable:

- Enable discovery and quantification of both known and novel (e.g., off-target) receptors of CWAs to allow for development of novel MCMs for broad-spectrum prophylactic and/or therapeutic interventions.

- Use of multi-omic approaches and other pathway analysis to identify nodes of convergence for identifying targets for cross-toxidromic MCM development.
- Use of AI/ML and/or microphysiological systems (MPS) (e.g. organ-on-a-chip or human-on-a-chip) to identify MCMs that can be used to treat multiple chemical toxidromes, allowing for broad-spectrum chemical agent MCMs to enable a suite of MCMs that addresses CWAs (including blister agents, nerve agents, pharmaceutical based agents and other emerging chemical threats).
- Leverage novel protein structure prediction capabilities to identify novel protein targets that are likely to be impacted by CWA interactions to help prioritize specific protein targets for further experimental validation.
- Identify common molecular pathways and/or mechanisms of action for adverse effects resulting from exposure to a broad range of chemicals (e.g., blister agents, organophosphorus compounds, opioids, non-opioid sedatives and other emerging chemical threats) in order to identify new areas for broad-spectrum, cross-toxidromic pre-exposure prophylactic and/or post-exposure therapeutic interventions.
- Include mapping of receptors and enzymes across various CWA-relevant laboratory animal models to allow for more relevant animal model selection in medical countermeasure development.

The CWAs (including blister agents, nerve agents, pharmaceutical based agents and other emerging chemical threats) of interest may include, but are not limited to, organophosphorus compounds, opioids and non-opioid sedatives.

ATTACHMENT 2: INTELLECTUAL PROPERTY

(Applies to FAR Contracts & OTAs)

Applicants must describe any limitations on the use of any intellectual property (patents, inventions, trade secrets, copyrights, trademarks, technical data or computer software) that will impact the offeror's performance of the contract or impact the Government's subsequent use of any deliverable under the contract. In particular, the applicant must describe the intellectual property in sufficient detail and describe the limitations on its use (potential patent licenses required by the Government, data assertions of the offeror or any subcontractor, etc.) and describe how the Government can accomplish the stated objectives of this BAA with the limitations described or proposed by the offeror.

Patents. Applicants must list any known patents, patent applications, or inventions which the offeror may be required to license in order to perform the work described in the Applicant's proposal, or which the Government may be required to license to make or use the deliverables of

the contract should the Applicant’s proposal be selected for award. For any patent, patent application or invention listed, the Offeror must provide the invention title, a summary of the invention, patent number, patent application publication number, or provisional patent application number, and indicate whether the offeror is the patent or invention owner. If a patent or invention is in-licensed by the offeror, identify the licensor.

If any listed patent, patent application or invention is owned or licensed by the applicant, the applicant must provide a statement, in writing, confirming that it either owns or possesses the appropriate licensing rights to patent, patent application or invention to perform the work described in the proposal and/or to grant the Government a license to make or use the deliverables for this program. If any listed patent, patent application or invention is not owned or licensed by the applicant, then the applicant must explain how it will obtain a license, how the Government may obtain a license and/or whether the offeror plans to obtain these rights on behalf of the Government.

Be advised that no patent, patent application, or invention disclosure will be accepted if identified in the Data Rights Assertion list. **The list of patents, patent applications, and inventions of this section must be a separate list from the Data Rights Assertion list.**

Government rights in any technology that might be invented or reduced to practice under the contract are addressed in the patent rights clause to be included in the contract.

Data Rights. Applications submitted in response to this BAA shall identify, to the extent known at the time an offer is submitted to the Government, the technical , the technical data, or computer software that the Offeror, its subcontractors or suppliers, or potential subcontractors or suppliers assert should be furnished to the Government with restrictions on use, release, or disclosure, in accordance with DFARS 252.227-7017, Identification and Assertion of Use, Release or Disclosure Restrictions, and DFARS 252.227-7028, Technical Data or Computer Software Previously Delivered to the Government. The applicant’s assertions, including the assertions of its subcontractors or suppliers, or potential subcontractors or suppliers, shall be submitted in the following format, dated and signed by an official authorized to contractually obligate the applicant. If the applicant will deliver all technical data and computer software to the Government without restrictions, enter “NONE” in this table under the heading “Technical Data or Computer Software to be Furnished with Restrictions.”

Identification and Assertion of Restrictions on the Government's Use, Release, or Disclosure of Technical Data or Computer Software.

The applicant asserts for itself, or the persons identified below, that the Government's rights to use, release, or disclose the following technical data or computer software should be restricted:

Technical Data or Computer Software to be Furnished with Restrictions*	Basis for Assertion**	Asserted Rights Category***	Name of Person Asserting Restrictions****
(LIST)*****	(LIST)	(LIST)	(LIST)

*For technical data (other than computer software documentation) pertaining to items,

components, or processes developed at private expense, identify both the deliverable technical data and each such item, component, or process. For computer software or computer software documentation identify the software or documentation.

**Generally, development at private expense, either exclusively or partially, is the only basis for asserting restrictions. For technical data, other than computer software documentation, development refers to development of the item, component, or process to which the data pertain. The Government's rights in computer software documentation generally may not be restricted. For computer software, development refers to the software. Indicate whether development was accomplished exclusively or partially at private expense. If development was not accomplished at private expense, or for computer software documentation, enter the specific basis for asserting restrictions.

***Enter asserted rights category (e.g., government purpose license rights from a prior contract, rights in SBIR data generated under another contract, limited, restricted, or government purpose rights under this or a prior contract, or specially negotiated licenses).

****Corporation, individual, or other person, as appropriate.

*****Enter "none" when all data or software will be submitted without restrictions.

Date _____
Printed Name _____
Printed Title _____
Signature _____

Applicants responding to this BAA requesting an Other Transaction or Other Transaction for Prototype shall specifically identify any asserted restrictions on the Government's use of intellectual property contemplated under those award instruments. For this purpose, applicants must propose specific Intellectual Property terms and conditions and a data deliverable list. Further, the applicants must explain why an Other Transaction is necessary and, in particular, how the intellectual property terms and conditions proposed will meet the objectives of this BAA.

Hello Luke and Dr Laing,

Attached is the budget. If it is OK - we will proceed with the rest of the documentation.

Can you also send me a copy of the proposal/guidelines? It is needed for the review process.

Thanks much Kim

Vertebrate Animals (Laing, Uniformed Services University)

1. Description of Procedures

New Zealand whites are used for polyclonal antibody development, aged 4 to 6 months, and housed and supplied by Noble Life Sciences (formerly Spring Valley Laboratories, Inc.). We use only three rabbits per any one immunogen. Rabbits will be immunized with purified recombinant glycoproteins. The adjuvant used will be the Ribi-Adjuvant-System (RAS). Animals will be monitored for an immune response to recombinant protein by an immunoblot procedure. We will provide the necessary protein antigen (400 ug per rabbit) for the immunizations. Whole blood will be collected and sera processed from immunized rabbits at four time points, a pre-bleed, and then after the first, second, and third immunizations spaced 21 days apart. Following the third immunization, a terminal bleed will be performed. We anticipate making protein-specific polyclonal antiserum to 28 glycoproteins. For henipaviruses, the F and RBP glycoproteins will be immunized in combination, thereby limiting the requirement to have two distinct sets of rabbits receiving either F or G proteins, which decreases the number of animals required.

2. Justifications

The goals of this project are to characterize the magnitude and breadth of the polyclonal antibody response to filovirus and henipavirus envelope glycoprotein, in order to establish the expected antigenic distances and space of each virus species, and examine glycoprotein-based serogroups. For this work, we must use an experimental animal model to allow the course of virus protein antigen-specific polyclonal antibodies development to be studied. Rabbits are a standard choice for the production of polyclonal antibodies. We intend on using only three rabbits per any one purified recombinant protein immunogen (e.g., EBOV GP, NiV RBP+F). We aim to examine how multiple immunizations with the same virus antigen shapes the magnitude and breadth of the antibody response to the immunizing antigen and those derived from closely-related viruses. We have chosen to utilize rabbits due to their ease of care, the prior use of rabbits as models for polyclonal antibody studies, and our preliminary data henipavirus RBP immunizations of these rabbit models performed in by my former lab. Rabbits are required because larger volumes of specific antisera are required to evaluate the antigenic relationships detailed in the grant application. The total number of required rabbits is 75, split over years 1 and 2 of the proposal study.

3. Minimization of Pain and Distress

Noble Life Sciences is fully certified and licensed by the US Department of Agriculture as a research facility; accredited by AAALAC (Association for Assessment and Accreditation of Laboratory Animal Care International); Their Assurance of Compliance with Public Health Service Policy on Human Care and Use of Laboratory Animals is filed with the OPRR, National Institutes of Health, #A3731-01; registered for the veterinary and research use of schedules 2 through 4 controlled substances by the Drug Enforcement Agency; and their IACUC approval #SVL 002 is for antibody production in rabbits. Attending veterinary care will be provided by SVL. Animals are routinely observed at least twice daily and additional observations are made following procedures.

Bleeding will be performed with hypodermic needle (19 ga.) from auricular artery. One or two prebleed blood draws will be performed prior to immunizations. Blood samples will be drawn no more than once every three weeks. The maximum volume of blood obtained will be 30 ml. Rabbits will be placed in restraining cages. However, rabbits are given Ketaset, 10.0mg/lb. body weight and Rompun, 2.0mg/lb body weight (intramuscularly; hind leg/ thigh; with 25 ga. needle) prior to exsanguination by cardiac puncture

4. Method of Euthanasia

Rabbits will be euthanized by intravenous barbiturate overdose, i.e. approx. 40 mg/kg body weight according to label instructions. Both of these methods are consistent with the recommendations of the Panel on Euthanasia of the American Veterinary Medical Association (AVMA).

SPECIFIC AIMS

Serosurveillance provides powerful measures of the infectome of wildlife and humans that can shed light on the disease ecology of zoonotic viruses. Yet **serological data is plagued with ambiguities that limit our ability to use it to identify zoonotic reservoirs or identify populations at risk from exposure to emerging viruses.** For example, the wildlife source of Ebola virus (EBOV), a continued ~~source~~ cause of deadly outbreaks, has eluded researchers since the 1970s. Molecular surveillance has yielded extremely few detections, but serology paints a muddled picture as EBOV antisera are extensively cross-reactive with antigens from other filoviruses. Human seroprevalence estimates vary widely and positive EBOV detections in wildlife hosts are not distinguishable signals of other known or uncharacterized related filoviruses. Similarly, Nipah virus (NiV) a zoonotic henipavirus that has caused repeated outbreaks in Malaysia, Bangladesh and India with fatality rates greater than 70%, has a known host in flying foxes. Yet many other reservoir species test positive for NiV ~~path~~ antibodies without neutralization or molecular confirmation. ~~Further, rRecent expansion description of of known henipaviruses diversity, such as Langya virus in acutely ill patients and shrews, suggests these serologic signals are footprints of other, the serologic footprints of potentially zoonotic henipaviruses have gone unnoticed by current serological testing strategies.~~

Our previous work has developed native-like antigens of filoviruses and henipaviruses for multiplex microsphere-based immunoassays, detected those viruses in humans and wildlife hosts, and used these data to model the circulation of zoonotic disease in wildlife and humans. **We propose to extend our methods into new laboratory and statistical techniques that can definitively identify the species of viruses from through serology, antibodies** and characterize the properties and epidemiology of novel viruses only detectable by their antigenic ~~signals~~ — shadow viruses shadows.

Our specific aims are to:

- 1. Create multiplex serological panels optimized for discovery and characterization of novel viruses.** We will generate serological discovery panels of native-like filovirus and henipavirus proteins with mixtures of sensitive and specific antibody binding properties that collectively can distinguish between the signatures of targeted known viruses and unknown shadow virus shadows in antisera. We will measure their cross-reactive properties via experimental immunizations, including the effects of repeat exposure and multiple-virus interactions. We will test consistency of results in model organisms against reference sera for humans (NiV, EBOV, Marburg virus) and sera collected from bat species with serological profiles consistent with exposure to wild-type samples with known specific serologic exposure to select viruses (NiV, Bundibugyo virus), yet the authenticity of this specificity being unclear, and that are reactive despite highly unlikely exposure.
- 2. Develop novel statistical methods to extract viral signatures from discovery panel data and integrate rich multidimensional serology into epidemiology.** Will extend *spectral mixture* methods from image analysis to develop statistical models that use discovery panel data to disentangle the signals of multiple viruses and extract the antigenic signature of shadow viruses as well as quantify immune response. We will measure the discriminatory power of our models via simulation and validate them via a leave-one-out strategy, testing if we can identify viruses omitted from our panels. We will integrate these methods with cross-scale immuno-epidemiological models, improving the accuracy and precision of both individual- and population-level serology measures.
- 3. Apply these methods to characterize novel and emerging viruses and their epidemiology in wildlife and humans.** We have identified wildlife and human populations demonstrating exposure to potentially novel but indeterminate filoviruses and henipaviruses. **This work will leverage investment from active NIH and DTRA-BTRP surveillance projects** in South Africa, Thailand, and Bangladesh by further testing and analyzing samples from these projects under our new protocols to antigenically characterize sera and distinguish known viruses from shadow viruses. We will use our cross-scale epidemiological models to determine the risk factors and spatiotemporal patterns of exposure and host-level immunological response to identify reservoirs and likely exposure interfaces.

This work has broad significance, addressing NIAID's Pandemic Preparedness Plan priorities of immunology and assay development, reagents and resources, and epidemiology and pathogen discovery. **It will produce biological resources, published protocols, and reusable statistical software to enable the rapid dissemination and adoption of these methods.**

RESEARCH STRATEGY

I. SIGNIFICANCE

Estimates of the cost of global virus discovery range in the billions of dollars [1]. One driving factor is the exceedingly low detection rate of viruses of concern, especially those in the *Ebolavirus*, *Marburgvirus*, and *Henipavirus* genera. The wildlife hosts of Ebola virus (EBOV), a continued source of deadly outbreaks in West and Central Africa, have eluded researchers since the 1970s despite considerable effort. In 2005, EBOV RNA was detected in three bat species [2]. Then in 2019 the USAID-funded Ebola Host Project sampled over 45,000 specimens from 10,000 bats discovering the complete genome of one novel ebolavirus (Bombali virus, *BOMV*), and a one-fifth genome of EBOV [3]. Wildlife reservoirs for related ebolaviruses, Sudan virus (SUDV), Bundibugyo (BDBV) virus, and Tai Forest virus (TAFV), have not been identified. Nipah virus (NiV), a zoonotic henipavirus that has caused repeated outbreaks in Malaysia, Bangladesh and India with fatality rates greater than 70% responsible for annual outbreak of fatal encephalitis in Bangladesh and southern India with some outbreak fatalities exceeding 90% [4-7], is known to circulate in flying foxes (*Pteropus* spp.). Even in a flying fox colony with known circulation, estimates of viremia are <2%, and a study of 3,600 bats over five years, including a period where an outbreak occurred, yielded only eight molecular detections [8]. The recent discovery of Langya virus (LayV) in patients with acute febrile illness and shrews in eastern China [9], indicates that unknown and undetected henipaviruses are also a global health concern [10].

In contrast to molecular surveillance, targeted and broad serology can provide a more cost-effective approach to detecting emerging viruses in wildlife hosts and humans, and to measuring exposure rates to identify at-risk populations [11-13]. Viral shedding occurs over a short window, with most shedding often occurring over a period of only days, while viral antibodies can last the lifetime of an organism. In the study of NiV circulation above, 3029% of individuals had NiV antibodies, and NiV seropositivity ranges from 11-40% across populations and species of flying foxes in South and Southeast Asia [PMID: 33139552, PMID: 31855143, PMID: 34218820, ERIC-cite]. Using the adaptive humoral memory to indirectly measure prior infection and identifying the serologic footprints left behind after virus infections has the potential to vastly improve our understanding of zoonotic virus diversity, distributions, and dynamics.

Since serology is an indirect measurement of virus infection, wildlife and human zoonotic virus serosurveillance faces limitations in the interpretation of data, especially when attempting to identify natural hosts of viruses [14]. Expected and unexpected antibody cross reactions frequently confound conclusions from single-antigen assays. EBOV-positive antisera is extensively cross-reactive with protein antigens from heterotypic ebolaviruses [15]. Antisera from survivors infected with EBOV, BDBV, and RESTV is highly cross-reactive with heterotypic virus antigens; furthermore, RESTV antisera preferentially interacted with EBOV antigens [16]. This is likely the reason for many bewildering serologic observations: seroprevalence for EBOV was found in humans without a history of Ebola Virus Disease (EVD). This likely contributes to the challenges of estimating EBOV spillover [PMID: 31194734] and bewildering serologic observations: EBOV seroprevalence in humans without a history of Ebola Virus Disease (EVD) [17]. In non-outbreak settings people who had contact with wildlife were found seropositive or indeterminate against EBOV, SUDV, BDBV [18, 19]. Community health volunteers with indirect contact of EVD patients were also ebolavirus seropositive [20]. Bush meat hunters sampled in Guinea had serologic evidence of infection by ebolaviruses, but seropositivity was detected by measuring immunoreactivity against several antigens and neutralization tests [21]. It is unclear whether assay performance are sensitive or specific enough to draw meaningful conclusions on the role of wildlife contact on human EBOV seropositivity. Antigen-based serosurveillance studies of fruit bats have also yielded ambiguous conclusions about wildlife reservoir statuses [22-24]. With >1200 species of bats and an unknown diversity of uncharacterized filoviruses the challenges of distinguishing EBOV-positive antisera from other ebolaviruses is daunting.

Similar challenges impede serosurveillance of henipaviruses. Since 1999, NiV surveillance has remained a top priority in south and southeast Asia. After the first documented cases of NiV emergence in Peninsular Malaysia, and an understanding of the factors that lead to transmission to humans [25, 26], government regulations on agricultural practices have limited further spillovers in Malaysia. The current epicenter of NiV disease is a region in western Bangladesh termed the *Nipah Belt*, where annual outbreaks are linked to the consumption of NiV contaminated unpasteurized date palm sap [27]. Flying foxes (*Pteropus* spp.) are considered the wildlife reservoirs of NiV, and in south and southeast Asia, NiV has been detected and

Formatted: Not Highlight

Formatted: Highlight

isolated from many species of pteropodid bats sampled in India, Bangladesh, Malaysia, Cambodia, and Thailand [28-33]. Despite isolation of NiV from flying foxes, detection of neutralizing NiV neutralizing antibodies, and experimental challenge models of NiV in flying foxes to confirm reservoir status, other bats across Asia test seropositive for NiV and their role in inter-species transmission remains unclear [34-36]. Rousettes and mouse-eared bats collected in China, Vietnam, and Kerala, India tested seropositive for NiV via a combination of [nucleocapsid protein \(NP\)](#), [envelope receptor-binding glycoprotein \(RBP\)](#) and cell lysate ELISA, but tested negative via neutralization tests. [37-39]. It is unclear whether seropositivity in [these rousette bats](#) is a factor of sensitivity and specificity issues with the immunoassay or the presence of another similar henipavirus. In sub-Saharan Africa, NiV-like neutralizing antibodies were detected in pigs in Ghana and Uganda, [40, 41] and humans sampled in Cameroon [42]. Genomic assemblages of two henipaviruses, Ghana virus and Angavokeely virus, were detected in closely related fruit bat species (genus *Eidolon*) [43, 44]. Recently ~~found~~ ~~we found~~ ~~we~~ genetic evidence of novel henipaviruses detected in Egyptian rousette bats [45], which adds to conclusions that rousette bats may be in fact harboring henipaviruses that cross-react with single antigen NiV ELISA.

Serology is also dependent on the quality and qualification of protein antigen. The EBOV envelope attachment glycoprotein (GP), [nucleocapsid protein \(NP\)](#), and matrix protein (VP40) have been utilized by several groups in antigen-based serology [PMID: 2948188](#), [PMID: 34748613](#), [PMID: 33827978](#) [\[ERIC cite\]](#). In one longitudinal study of Ebola virus disease survivors, [seroconversion-against anti-GP and VP40 IgG occurred at XXXXX% respectively, increased with days post-infection](#) along with affinity maturation of GP-positive B cells [\[PMID: 32053790ERIC-cite\]](#). However, studies that detail the frequency of seroconversion against ~~the the~~ [nucleocapsid protein \(NP\)](#) after EBOV infection, or the frequency of seroconversion against GP, VP40, and NP with non-EBOV ebolaviruses have not been verified.

Most statistical approaches to interpreting serosurveillance data are limited to single antigen analysis and unrealistically simple models of host immunology and epidemiology. The state of the art approach to dealing with serological assay data in wildlife or with viruses without standardized controls has been clustering approaches [46] that assume seropositive and seronegative individuals separate into two distinct groups by a threshold antibody titer. Yet most real data is far less distinct, due a mix of processes including cross reactions, host heterogeneity, and antibody waning and nonlinearities in the physio-chemical processes of antibody assays [47] [\(Figure HOTEL\)](#). More sophisticated multi-antigen, [multiplex](#), analyses [48] can account for cross reactions to distinguish amongst known viruses, but **fundamentally current serological laboratory and statistical approaches are not designed to deal with the challenges of detecting and characterizing novel viruses.**

The major goal of this proposal is to dramatically improve the utility of antigen-based serosurveillance for new viral discovery and epidemiology of emerging zoonotic diseases by addressing the challenges of cross-reaction and statistical rigor. We will create *discovery panels* - qualified and optimized panels of multiplexed immunoassays designed to detect [and](#) characterize shadow viruses, and distinguish known from novel viruses through mixtures of sensitive and specific binding properties. (Aim 1). We will develop new statistical approaches to extract the signals of novel viruses from those of known viruses or mixtures of multiple previous viral exposures, as well as integrating quantitative measures of immune response into epidemiological models (Aim 2). Finally, we will apply these techniques to identifying and characterizing filoviruses and henipaviruses in bat populations in South Africa and at-risk human populations in Thailand, and capturing immune-epidemiological dynamics of [Nipah virus V](#) circulation in Bangladesh (Aim 3).

This work has broad significance, addressing NIAID's Pandemic Preparedness Plan priorities of immunology and assay development, reagents and resources, and epidemiology and pathogen discovery. It will produce biological resources, published protocols, and reusable statistical software to enable the rapid dissemination and adoption of these methods.

Commented [EL2]: Usage?

Commented [EL3]: This is repeated from the Specific Aims.

Commented [NR4R3]: I think that is OK. They are separate documents and sometimes specific aims, but will reward to avoid too much repetition.

II. INNOVATION

We propose a unique and innovative approach to characterizing antibodies induced by prior infections to discover the signals of novel viruses – *shadow viruses* – in wildlife and human hosts through antigen-based multiplex serology. While serology is an increasingly common technique in viral surveillance, multiplex panels have hitherto been composed of several proteins each designed specifically to bind antibodies of individual antigens, optimizing for specificity to individual viruses. We will instead design and test *discovery panels* composed of proteins with a mixture of sensitivities and specificities to a range of viral antigens within a family. This will simultaneously cover *antigenic space*, enabling detection of previously unknown viruses, and enable definitively ruling out or confirming the signal of known pathogens via their unique *antigenic signatures*. We will build these panels on a multiplex microsphere-based immunoassays (MMIA) platform [ERIC cite]. This enables cost-effective testing of dozens of antigens simultaneously and is easily updated with new reagents. We have successfully deployed this assay in laboratories for surveillance projects in low-resource environments [PMID: 32034942, PMID: 31671094, PMID: 29260678] [ERIC cite]. Through the multiplex discovery approach, we can achieve accuracy far more readily adoptable than low-throughput panels such as indirect ELISA [48], or neutralization tests requiring containment and virus isolates or verified pseudovirus systems.

We further innovate by adapting statistical methods from image-processing – nonlinear spectral unmixing models, implemented in a Bayesian framework [49-51] – to analyze multiplex serological data as joint rather than individual response signals. This flexible approach allows us to incorporate nonlinearities in the interaction of viruses and antigens, as well as those introduced in the physiochemical processes of the assay. It will enable us to disambiguate data that could represent a variety of exposure histories, including exposure to multiple viruses, known viruses with cross-reactions to multiple antigens, or novel viruses with an intermediate antigenic profile between known viruses, assigning probabilities to each hypothesis. This framework is applicable to serological methods beyond MMIA such quantitative LFIA and ELISA, as well as large-scale peptide multiplexing via PhIP-seq [52], which currently lacks unifying computational or analytical frameworks [53].

We will integrate our statistical framework with population-level epidemiological models to capture cross-scale immunological patterns and dynamics. The dominant threshold-based approach to seroepidemiology determines serostatus at the individual level from antibody titer or assay response, then describes population-level patterns as frequencies of seronegative/positive states. This discards the rich quantitative information on antibody levels and the role of processes such as individual immune variation, antibody waning, and inheritance that can be informative of population processes. By linking the estimation of individual- and population-level quantities, we increase the accuracy and precision of both. We will develop cross-scale statistical models that model individuals' complex binary and continuous immune state, and jointly model the variation of this complex serostatus across time, space, and groupings (species, populations, and demographic groups).

Finally, this proposal leverages active federal investments in global viral surveillance programs by partnering with them to rapidly validate these techniques. We will partner with an NIH Centers for Research in Emerging Infectious Disease (CREID) study of high wildlife-contact individuals in Thailand, a DTRA Biological Threat Reduction Program survey of bat virus diversity in Southern Africa, and an NIH NIAID research program on Nipah virus circulation and spillover in Bangladesh. In each, serosurveillance has generated preliminary but ambiguous evidence of novel virus circulation. We will test archived samples to corroborate these data and characterize the suspected shadow viruses and their epidemiology.

Terms

shadow virus: a novel or unidentified virus only detected in a population via serology of infected individuals

discovery panel: a multiplexed immunoassay designed to detect shadow viruses and distinguish them from known viruses

antigenic space: the phenotypic range of antigens of known and unknown viruses in a family

antigenic signature: a combination of responses of an antiserum against a panel of antigens that identifies a virus

reaction/cross reaction matrix: the full combination of response curves of all antisera to all antigens in a multiplexed immunoassay

cross-binding interaction: the change in response of antisera to an antigen in the presence of another antigen due to preferential binding

III. APPROACH

RESEARCH TEAM AND MANAGEMENT

We have assembled a team with a unique combination of laboratory, analytic, and field expertise and a history of successful collaboration in zoonotic disease surveillance. Project PIs Laing and Ross are early-stage investigators with methodological expertise on laboratory and statistical methods for serological analysis, respectively. Other Co-Investigators lead viral discovery surveillance projects across Bangladesh (Epstein), Southern Africa (Markotter, Epstein), and Southeast Asia (Wacharapluesadee). [PI Laing and other significant contributor \(OSC\), Brook, are collaborators on other surveillance projects; and OSC Munster is an established lab chief with a history of collaboration and whose research interests in virus ecology align with project PIs Laing and Ross.](#)

Formatted: English (United States)

The PIs began working together in 2017 on a project titled, Serological Biosurveillance for Spillover of Henipaviruses and Filoviruses at Agricultural and Hunting Human-Animal Interfaces in Peninsular Malaysia (HDTRA11710037). Both PIs remain respective methodological experts for active surveillance projects, Biosurveillance for Viral Zoonoses around Bat-Livestock-Human interfaces in Southern Africa (HDTRA12010025), and CREID EID-SEARCH.

We have designed our program so that laboratory and mathematical methods development are complementary but can proceed independently. Each benefit from data and innovations of the other. Statistical innovations enhance interpretation of discovery panel data and the data in turn can be used to parameterize and increase power of statistical techniques. However, we will be able to make progress on both in parallel, test their success on their own terms and apply outputs to the surveillance studies even if their success and completion time differ.

See the **MULTIPLE PD/PI LEADERSHIP PLAN** for additional team and project management detail.

AIM 1: OPTIMIZATION OF ANTIGEN-BASED MULTIPLEX SEROLOGY FOR DISCOVERY AND DETECTION

We have developed, [expressed, and purified envelope attachment glycoprotein \(GP\) of filoviruses GP and envelope receptor binding glycoprotein \(RBP\) of henipaviruses RBP antigens inexpressed in](#) mammalian cell culture systems as native-like ectodomain trimers and tetramers, respectively, retaining conformation-dependent epitopes [54-58]. We have used these antigens to create MMIAAs focused on the detection of presently described ebolaviruses, marburgviruses, and henipaviruses. These have been successfully transferred to laboratories globally and used in completed and ongoing biosurveillance projects including DARPA PREEMPT, our CREID center EID-SEARCH (Co-I Wacharapluesadee), our DTRA BTRP-funded project in southern Africa at the University of Pretoria (Co-I Markotter), and for collaborative projects with OSCs Munster and Brook. Through these projects, these panels have been used to identify wildlife hosts of filoviruses and henipaviruses, and detect evidence of prior infection of high-risk human populations [59, 60]. The panels are continually expanding with each novel virus discovery, e.g., [Bombali-virusBOMV](#) and [Langya-virusLYV](#). However, without standardized protein antigens for antigen-based serosurveillance and sera standards for each virus, demonstrating specificity in wildlife reservoirs and human populations without outbreak histories remains a challenge. When screening samples collected from wildlife, it remains unclear if we are capturing antibodies induced by known virus infections or by antigenically related uncharacterized viruses. Here, we propose a strategy to overcome this fundamental limitation.

Commented [EL6]: Do we need a 3 panel figure to show the varying processes occurring, I don't know if there's space but I'll work on it more tomorrow.

Designing the discovery panel with a two-protein approach

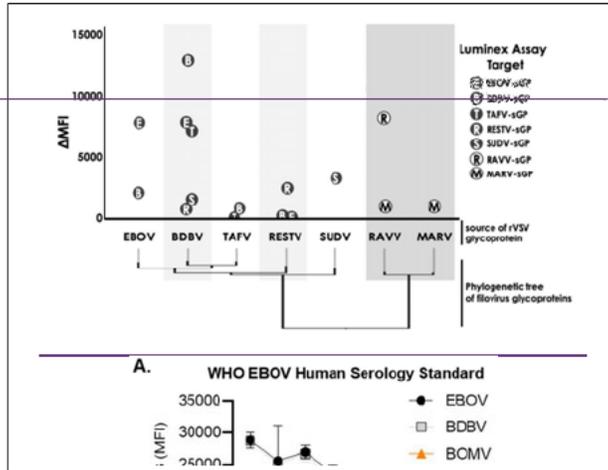

Preliminary Data: Cross reaction among filoviruses and henipaviruses. Antibodies induced by ebolavirus infections are cross-reactive with GP antigens, likely the [resultresult](#) of several contributing factors such as amino acid sequence similarity, conserved [epitopesepitopes](#), and [glycoepitopesepitopes](#) or glycosylations in the glycan gap and mucin-like domain [61, 62]. Previous groups have attempted to distinguish homotypic and heterotypic known ebolavirus IgG binding to GP antigens by performing multiple ELISAs for each known ebolavirus [48]. This technique conferred specificity but at a great cost to throughput, and has unclear applications for the detection of unknown ebolaviruses.

In our GP₁-based MMIA, the WHO EBOV antibody standard reacted equally against both EBOV and BDBV GP₁ antigens (Figure FOXTROT A). Although ebolavirus antisera are cross-reactive with heterotypic ebolaviruses, through a GP-based multiplex approach we have been able to specifically identify the homotypic infecting ebolavirus after a single infection by a VSV-filoGP in a bat infection model despite observable cross reactions (preliminary data, not shown Figure 1). This indicated that pooled polyclonal antisera from human EVD survivors may include more cross-reactive antibodies than those generated after single infections in a putative wildlife host. Further, preliminary data from polyclonal antisera from rabbits hyperimmunized with EBOV GP corroborated data with the WHO EBOV serology standard that EBOV and BDBV specific antibodies are cross-reactive with GP trimers, though preferential binding to the homotypic EBOV antigen was noted. However, the GP1 subunit protein improved specificity (Figure FOXTROT B Figure 2B).

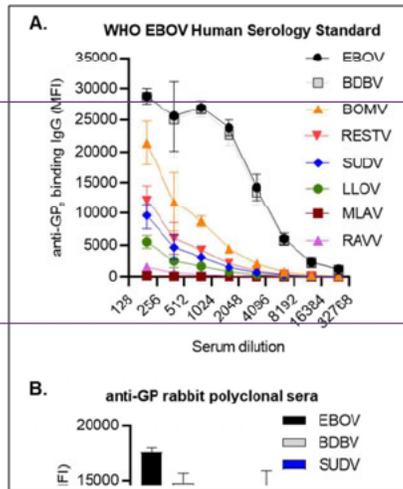

Cross-reaction among the other henipaviruses is less described. HeV antisera is known to display a fair degree of cross-reaction with NiV, however the inverse does not hold true [PMID: 18556094, PMID: 22875827 GTE]. We have examined henipavirus cross-reactivity with polyclonal antisera from rabbits immunized with recombinant RBP antigens and observed little cross-reactivity outside of HeV-positive antisera with NiV G (Figure CHARLIE Figure 3).

Approach: Protein development. Here, we propose to design antigen-based discovery panels that can distinguish between targeted and cross-reactive signals using a two-protein approach, selecting a highly specific (GP1) and a broadly sensitive (GP trimer) antigen for each filovirus in the panel. This approach draws from our successful approach to large-scale COVID-19 serosurveillance, which used SARS-CoV S glycoprotein expressed as a trimeric prefusion stabilized spike ectodomain and a monomeric receptor-binding domain antigens, providing an optimal balance of assay sensitivity and specificity. We note this indicates that a similar strategy to succeed for surveillance and discovery of novel and zoonotic coronaviruses in the future.

Thus, our two-protein panel approach requires a sensitive protein antigen that could be the cross-reactive target for antibodies induced by shadow henipaviruses. Since the henipavirus RBP provides the specific antigen, we plan to develop the soluble native-like trimeric fusion (F) glycoproteins into the sensitive antigen. HeV and CedV RBP share ~2330% sequence identity while the F proteins share ~44% amino acid expressed, and purified and has been extensively studied as a target for monoclonal antibodies [57, 63-65]. In its role to mediate virus-cellular fusion, these F proteins share higher sequence identity and similarity across henipaviruses than the RBP sequence identity. The F protein has been similarly

Formatted: Font: Not Bold

Field Code Changed

designed, sequence identity. The F protein has been similarly designed, expressed, and purified and has been extensively studied as a target for monoclonal antibodies [57, 63-65]. In its role to mediate virus-cellular fusion, these proteins share higher sequence identity and similarity across henipaviruses than the RBP. Thus, we plan to explore the ability of the henipavirus F protein as to function as a sensitive antigen for antigenic discovery of novel henipaviruses. We will develop GP/GP1 antigen pairs for each of the filoviruses and RBP/F antigens comprising the range of currently known mammalian filoviruses and henipaviruses (Table ALPHA).

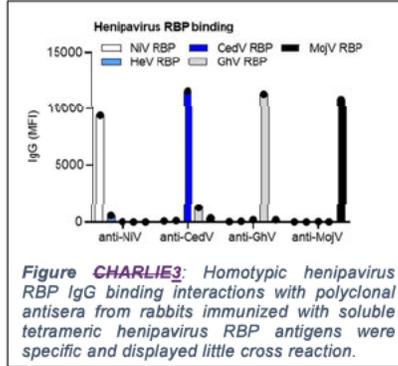

Figure CHARLIE3: Homotypic henipavirus RBP IgG binding interactions with polyclonal antisera from rabbits immunized with soluble tetrameric henipavirus RBP antigens were specific and displayed little cross reaction.

...Filoviruses	Sensitive antigen	Specific antigen
Ebola-virus (EBOV)	GPe (trimer)	GP1-subunit
Bundibugyo-virus (BDBV)	GPe (trimer)	GP1-subunit

Commented [GU7]: I think this is too big of table and eats up space, maybe I can summarize this as a sentence or have I covered the 2 antigen approach enough?

Commented [NR8R7]: We are one page over right now so that's probably the way to go. It would be good to do this in maybe a four line table? One listing files, one listing henipas, One line for each of the two multiple interaction groups? Each saying 3 rabbits, 3 bleeds.... If you think it's all clear in the text that's fine, but this might be just as compact.

Formatted: Space Before: 6 pt

Formatted: Space Before: 6 pt

Approach: Quantifying cross-reactions: To optimize a discovery panel for discovery and detection, we first need to fully qualify the pairwise cross-reactions amongst proteins, generating a comprehensive reaction/cross reaction matrix via protein immunization experiments in rabbits. This will establish and qualify (a) the homotypic virus reactivity, (b) heterotypic cross-reactivity across other viruses in the family, and (c) how multiple immunogen exposures shape homotypic antigen binding and the cross-reactive breadth against heterotypic viruses. Since wildlife reservoirs are naturally exposed to these viruses throughout their lives, repeated exposures shape the magnitude, durability, and breadth of humoral responses. Data from (c) will support use be used to estimate time-from-infection and antigenic-relatedness. Using our filovirus GP antigens and henipavirus RBP & F antigens, we will sequentially immunize rabbits (n = 3 rabbits per virus antigen) with up to two immunogen boosts (100 µg of protein antigen per injection), and whole blood will be collected three times, 21 days

after each immunization; ~~experimentation will end after the final bleed of day 72 (Figure 4, Scenario 1) followed by a terminal bleed after 84 days.~~

Sera will be tested against all antigens within the panel at a range of dilutions to find the optimal dilution factors within the range of the linear slope of the MMIA median fluorescence intensity (MFI) output signal. For the prototypical viruses, EBOV, NiV, and MARV, we will include WHO human serology standards developed by the National Institute for Standards and Control for interpolations of MFI into IgG concentrations. For each pair in the matrix, we will quantify cross-reaction by fitting logistic functions to the reactivity vs (log) dilution and estimating the slope parameter as the measure of reaction. Utilizing MFI values from optimal dilution factors, we will apply antigenic mapping [66], projecting the heterotypic cross-reactivity matrix into *antigenic space* for both filoviruses and henipaviruses, separately for the *specific* (GP1/RBP) and *sensitive* (GP/F) antigen of each virus. We expect the mappings of sensitive antigens, e.g., filo GP and henipa F, to cluster closely together and for some closely related viruses to broadly overlap as serogroups in antigenic space, while specific antigens, e.g., filo GP1 and henipa G will not. Gaps in antigenic space will indicate areas unlikely to be detected by the panel, while overlaps from specific antigens will indicate likely ambiguities. The *antigenic signature* data of viruses will serve as priors for our statistical models (Aim 2).

Determining how virus interactions shape antigenic signatures

The wildlife reservoirs of EBOV, BDBV, TAFV, and SUDV remain unknown. Outbreaks of Ebola virus disease EVD caused by EBOV, SUDV, and BDBV have all occurred either in the Democratic Republic of Congo or nearby in Sudan and Uganda. The close spatial relationships of these outbreaks suggest the possibility that these viruses may co-circulate in certain bat species, populations, or multi-host communities. Furthermore, the degree of antigen-specific cross reactions between EBOV, BDBV, SUDV, TAFV may confound current serologic testing studies that rely on a single antigen or only investigate EBOV immunoreactivity. Thus, antibodies induced by BDBV or SUDV infections may seemingly be interpreted as evidence of prior EBOV infections. We aim to determine separate three distinct scenarios that may shape serological profiles, (a) **exposure to one virus and cross-reaction with the second**, (b) **independent exposures to both viruses**, or (c) **exposure to a third, uncharacterized virus with cross-reaction to both viruses**.

Approach: Multiple Immunization: As described in Figure 4, we will sequentially immunize a sets of rabbits with a GP against antigens from EBOV, BDBV, and SUDV two viruses from the same family to simulate multiple exposures to different ebolaviruses, determine the additivity of spectral signatures, and test our ability to extract the signature of each via our statistical models (Aim 2). For example, rabbits will be first immunized with BDBV GP (100 µg) then EBOV GP (100 µg), EBOV then BDBV, or SUDV then BDBV. The immunization pairings simulate hypotheses of common circulation in wildlife such as ambiguous EBOV and BDBV serologies, and overlapping EVD outbreak regions where BDBV and SUDV are known to circulate. fe...

We will apply a similar approach to address these three scenarios for henipaviruses, focusing on the more recently described rodent-associated henipaviruses. Mojjiang virus (MojV) was detected in the southern province of Yunnan, China, whereas LayV has been detected in eastern Shangdong and Henan provinces. Reports of shrew-associated henipaviruses in South Korea, Gamak virus and Daeryong virus, have contributed to an expansion of rodent-associated henipaviruses discovered since 2020. In Thailand we have detected serologic evidence infection by a MojV-like henipavirus (see Aim 3). As the field does not yet understand the antigenic-relationships among these rodent-associated henipaviruses we cannot confidently interpret serologic evidence of MojV-like in Southeast Asia. Thus, similar to the experiments described for the ebolaviruses, we will sequentially immunize rabbits with multiple Asiatic rodent-henipaviruses to examine how imprinted antibody memory and heterologous boosting shapes reaction and cross reactions to homotypic and heterotypic ebolavirus GP and GP1, and henipavirus RBP and F antigens. The effects of heterologous boosts will be utilized to refine antigenic shape modeling in Aim 2;

A
Approach: Measuring Cross-Binding Interactions: Antigen-antibody binding is context-dependent; the degree of binding may vary due to the presence of other antigens to which antibodies exhibit preferential binding. We will measure the extent of this *cross-binding interaction* by conducting *in vitro* "leave-one-out"

Formatted: Space Before: 6 pt

Formatted: Space Before: 6 pt

Commented [EL9]: Noam – read over this.

Formatted: Not Highlight

Formatted: Not Highlight

Commented [EL10]: Noam....

assays, where the virus-specific antigens matching each antiserum (both specific and sensitive), are removed from the panel and only forcing only cross-reactions can-to occur. This simulates the detection conditions of antibodies to-induced previously by uncharacterized viruses – shadow viruses – in the antisera. We will measure the difference in cross-reaction strength in the presence and absence of the with and without the target antigen, and determine the dilution levels that minimize this effect.

Approach: Testing consistency in non-model organisms: To further test the consistency of cross-binding interactions beyond our rabbit animal models-organisms, we will also conduct leave-one-out experiments within wild-type sera collected from bats and WHO polyclonal reference sera for EBOV, MARV, and NiV. Through a collaboration with Dr. Vincent Munster (other significant contributor, OSC; see Letter of Support), we identified BDBV-like ebolavirus immunoreactivity in populations of hammer-headed fruit bats (unpublished data). Hammer-headed fruit bats have been cited as putative EBOV reservoirs [PMID: 17848072, PMID: 31574111 site], yet in our GP-based MMIA we detected greater immunoreactivity to BDBV. The distribution of these bats in southern Uganda is consistent with BDBV-driven EVD outbreaks. In addition, through ongoing research with Dr. Cara Brook (OSC; see Letter of Support), we identified 16% seroprevalence for a BDBV-like ebolavirus in populations of Madagascar roussette bats (Figure 5 ECHO). The result was surprising for two reasons, a) roussette bats are a reservoir of marburgviruses, not ebolaviruses [PMID: 19649327, PMID: 33219802 cite] and b) Madagascar is >2500 km from Uganda where all confirmed BDBV outbreaks have been reported [PMID: 34467242, PMID: 21122234, PMID: 25910637 cite]. These two bat species do not share overlapping geographic distribution, so how do we interpret seemingly similar serological profiles suggesting BDBV circulation? We propose to test the hammer-headed fruit bat and Madagascar roussette bat sera in multiplexes that leave-out the BDBV GP antigens, and to examine how the polyclonal antibodies shift binding patterns to other ebolavirus GP antigens. These shifts in serological profiles in the absence of BDBV GP antigens will be compared to the cross-reaction data established by the protein immunized rabbit antisera standards. We expect that the hammer-headed fruit bat sera would increase preferential binding to EBOV GP in the absence of BDBV GP, consistent with phylogenetic data, providing compelling data that these bats have a high probability of hosting BDBV. Whereas we may expect the Madagascar roussette bat sera to bind to ebolavirus GP in serologic pattern that was not predicted in polyclonal rabbit antisera standards. We anticipate that unexpected serological profiles, which break the serological-serological standards, will help us to identify unique clusters of serogroups that would indicate unknown ebolaviruses.

Risks, limitations, and mitigating factors

We have proposed to establish antibody responses and antisera cross reactions via protein immunization and rabbits as our animal model. In the absence of WHO serology standard for all ebola-, marburg-, and henipaviruses, the development of antigen immunized rabbit polyclonal standards is a feasible goal. The uniqueness of the bat immune response among mammals has been an area of research interest for over a decade. The growing body of literature suggests that bats as an Order may have a uniquely adapted immune response including dampened inflammatory responses, and heavily favored innate immunity [67-70]. Thus, there may be distinctions unique to the bat humoral response to viral infections that we will not be reflected by protein immunizations in a rabbit model. However, outside of immunoglobulin (Ig) repertoire sequencing [PMID: 20816694, PMID: 20162414 eric cite], the adaptive response has been less readily investigated, and questions about the functional role of cellular and humoral immunity for viral infection control remains. From field-collected bat sera, we observe robust virus-specific IgG responses, and do anticipate that conservation of humoral responses between rabbits and bats will reflect our ability to accurately determine serogroups through antigenic cartography. Further, we can verify selected rabbit-protein immunization results in a nascent bat infectious disease model being developed by application OSC, Dr. Vincent Munster, r (see Letter of Support), W e We have previously collaborated with Dr. Munster to investigate whether we can differentiate homotypic and heterotypic ebolavirus antibodies collected from captive Egyptian fruit bats experimentally infected with replication-competent vesicular stomatitis viruses expressing transmembrane bound ebola- and marburgvirus GP (Figure MIKE1). Additionally, it is possible that immunological imprints after the first immunization may be recalled following heterologous henipavirus G+F/ebolavirus GP booster immunization, and affect the development of *de novo* antibodies against the booster immunizing antigen. In this case, the order of protein antigens used for multiple exposures is important and we will increase the redesign the sequential strategy of immunizations if additional experiments are necessary.

AIM 2: NOVEL STATISTICAL MODELS FOR MULTIPLEX SEROLOGICAL ASSAYS

Preliminary data: We and others have used clustering approaches [46] to establish virus-specific seropositivity thresholds relying on our knowledge of confirmed virus-host interactions [8, 60, 71, 72]. However, we find that in many cases the required assumptions of this approach – that individuals separate out into distinct positive and negative groups, and that clusters conform to expected, usually symmetric distributions – break down.

Rather, large numbers of antibody responses fall into an indeterminate range without distinct breaks, and nonlinear assay response breaks down expectations at the high and low end of the response range (Fig-Figure 56HOTEL). As a result, many results, are classified as indeterminate or assigned a serostatus with high uncertainty. On the other hand, we have extended these cluster methods to multidimensional panel data and found that they are more successful at disentangling groups of sera by their ratio of response to different antigens, indicating the *kind* of antigenic response had distinct differences, while magnitude of response was a more continuous measure (Fig-BOByre 67). This initial work indicates that clustering can detect distinct signals of samples that react to viral antigens in different ratios, indicating exposure to different viruses in intermediate antigenic space between known filoviruses. However, these multidimensional models conflate two components of these data – distinct reaction ratios as signals of exposure to different viruses, and clustering of the strength of serological response between seropositive and seronegative individuals. We propose a new class of multidimensional models for serology panel data that take a mechanistic approach to representing these two processes, disentangling the different types of clustering and deal with their separate complexities

Detecting shadow viruses in panel data via antigenic signatures

Model structure: Our minimal model of serological mixing is

$$R_i = \sum_{j=1}^M f_{ij}(t_j) + \varepsilon_{ij}$$

Here R_i , the *response* (measured in as the \log_{10} mean fluorescent intensity), is the sum of the responses f_{ij} of assay i against each antibody titer t_j that binds to the antigens presented on that assay, plus measurement error ε_{ij} , for all M antigens present in the sample. If the response curve f_{ij} is linear this model resembles that of Schuh [48], as well as the structure of approaches to signal extraction from remote sensing imagery [49], but due to saturation of the biochemical or instrument response, it is typically sigmoidal.

Cross-binding interactions in the multiplex assay, where antigens in the same solution attract the same antibodies, modify the additive framework of the spectral mixing model. In the absence of these interactions, we could fully test the ability of the multiplex panel to identify the signal of a novel "shadow virus" *in silico* simply by removing the response data from one target antigen and determining if it could be identified via cross-reactions of antibodies against closely related viruses. However, with these

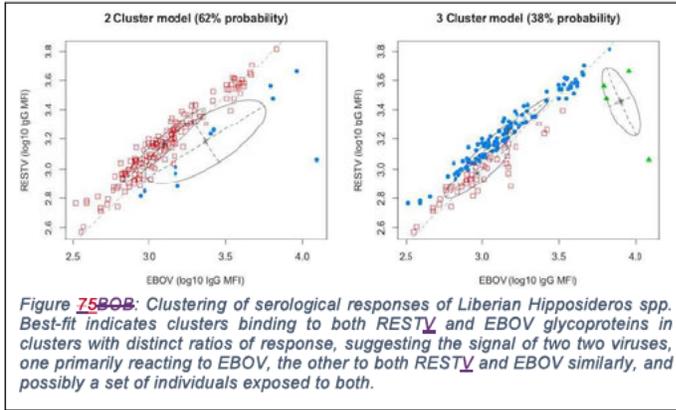

Figure 75BOB: Clustering of serological responses of Liberian Hipposideros spp. Best-fit indicates clusters binding to both RESTV and EBOV glycoproteins in clusters with distinct ratios of response, suggesting the signal of two viruses, one primarily reacting to EBOV, the other to both RESTV and EBOV similarly, and possibly a set of individuals exposed to both.

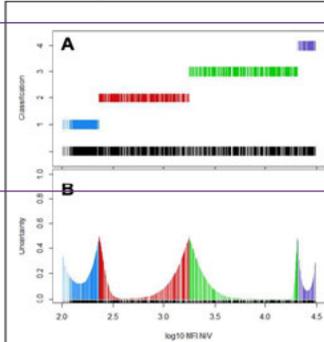

Figure 6HOTEL: Degenerate clustering in real antigen data. (A) Latent cluster models divide data into four rather than two clusters due to lack of distinct breaks, with central clusters interpretation ambiguous. (B) Measure of cluster uncertainty shows that distinction between clusters is weak over a wide range.

Commented [NR12]: Distinguish from landscape, e.g. <https://pubmed.ncbi.nlm.nih.gov/36356586/>

interactions, the response of antigen j against antibody i depends on the presence of the other antigens present. We can decompose this effect in our model into the core titer-antibody-response function $f_{ij}(t_j)$ and an additional interaction term

$$R_i = \sum_{j=1}^J f_{ij}(t_j) + \sum_{j=1}^J \sum_{l=1}^L g_{ij}(t_i, t_j) + \varepsilon_{ij}$$

Fully estimating $g_{ij}(t_i, t_j)$, especially with nonlinearities in the response, would not be realistic. But nonlinear models from image processing provide reasonable approximations where these interactions take a set of reduced forms [50, 51]. Moreover, we can constrain the model with priors based on our experimental data. Our leave-one out experiments will estimate the size, consistency and linearity of the cross-binding interaction effects in both model and wild organisms and optimize our procedures to minimize it.

Experimental Approach: We will develop a Bayesian representation of this model and conduct simulation-based experiments to determine the conditions under which it can distinguish between different immunological conditions. We will test the ability to distinguish between a target virus and related shadow virus response as a function of antigenic distance, breadth of cross-reaction of both the target and shadow virus, sample and individual level variation, and sample size. We will use data from our challenge experiments to parameterize the models, initially using preliminary data so that we can conduct these aims in parallel. We will use the data from our experimental replicates to simulate sample-level variation and data from previous surveillance work (see Aim 3) to simulate individual variation in response within seropositive and seronegative groups. We will also simulate a range of scenarios for cross-reactive binding interactions, ranging from small, consistent effects to highly variable interactions amongst different viral pairings. We will conduct both *in silico* and *in vitro* validation tests to determine if the method can extract the antigenic signal of a shadow virus. We will create simulated leave-one-out tests by using data from our rabbit immunization experiments, with data from each virus in the panel removed in turn, and determine if the model identifies the signal of a non-target virus from cross-reactions alone. We will repeat this with the data from our *in vitro* leave-one-out experiments.

Cross-scale immuno-epidemiological modeling

Zoonotic serosurveillance, in wildlife and human populations, faces the challenge of a lack of controls. Surveillance requires testing many understudied host species, and by definition no standard controls can be created for novel viruses. Thus, standard cut-offs cannot be pre-determined and inference of individual immune states and population seroprevalence and risk factors is best conducted jointly, modeling individual serostatuses as continuous or probabilistic states informed by population measures.

Model structure: To build this cross-scale framework, we extend our mixing model above to the population scale. Titer t_j becomes t_{jk} , a sample k drawn from a population of individuals x . In this population with a seroprevalence $E(\omega_j)$, the distribution t_{jk} is a mixture of titer values $(F(\mu, \sigma))$ in both seronegative and seropositive individuals.

$$E(t_{jk}) \sim (1 - E(\omega_j))F(\mu_{j-}, \sigma_{j-}) + E(\omega_j)F(\mu_{j+}, \sigma_{j+})$$

Both the individual probability of seropositivity ω_{jk} and the distributions $F()$ of seronegative and seropositive distributions are affected by host traits, infectious dosage, and environmental factors. Immunological state has both binary (serostatus) and continuous (antigen-reactive IgG levels, concentrationstiter) components that are intertwined. In the simple case assuming $F()$ are normal distributions and those traits and risk factors have linear effects, these can be represented as the relationships

$$\rho \sim \text{Probit}(\beta_{\rho 0j} + \beta_{\rho j} x_k); \mu_{j-} \sim \text{Normal}(\beta_{\mu 0j-} + \beta_{\mu j-} x_k); \mu_{j+} \sim \text{Normal}(\beta_{\mu 0j+} + \beta_{\mu j+} x_k);$$

with seroprevalence ρ , seronegative titer-concentration μ_{j-} , and seropositive titer-concentration μ_{j+} modeled as a joint distribution, and the β values the marginal effect of risk factor on both seropositivity and antibody titer-concentration.

This allows us to integrate estimation of the factors affecting the probability of individual seropositivity (demographics, geography, host species), along with how those factors modify the titer-antibody concentration or response within seropositive or seronegative groups. For instance, if juvenile hosts have stronger responses than adults, but also are less likely to be exposed to the virus of interest, these will

Formatted: Underline

Formatted: Underline

Formatted: Font: Italic

separate out under this approach. Under a traditional threshold-based approach these effects would mask each other.

One application of this joint modeling of the continuous and binary components is robust cross-species seroprevalence comparisons through combining mixed-effect structures [73] with this model framework. In many serosurveillance studies, large numbers of species are screened for evidence of antigen response to determine likely viral reservoirs, but species sample sizes vary due the difficulty of capture. This poses a challenge in comparing seroprevalence among species. Also, baseline or seropositive response binding levels may vary along with seroprevalence, and for some species sample numbers are not sufficient to establish species-level baselines. The joint approach will enable partial-pooling of species-level effects on both seroprevalence and titer/antibody concentration, reducing noise from small size groups while capturing important differences.

Commented [EL13]: Virus or host?

Experimental Approach: We will simulate application of this model for two common surveillance inference problems. In each, we will compare this joint estimation approach to two-step threshold-based approaches based on outlier detection or simple clustering.

Formatted: Underline

First, we simulate determining seroprevalence in a single group (species) of hosts, the probability of seropositivity and the strength of seropositive response are correlated. We will determine how seroprevalence, degree of correlation, sample size affect the accuracy of each method.

Second, we will perform studies of the case of sampling many species with mixed baseline and seropositive response rates to compare seroprevalence rates. Will simulate and fit from a mixed-effect model of the form

$$\begin{bmatrix} \mu_- \\ \mu_+ \\ \text{Probit}(\rho) \end{bmatrix} \sim MVN(\beta_0 + \beta_s \text{species}) + \epsilon; \beta_s \sim MVN(\mu_s, \sigma_s)$$

where the response distributions and seroprevalence vary as joint random effects by species. We will compare the mixed-model structure to a form where each species is evaluated independently and models where all species are pooled. In both cases we also compare two-step threshold-based approaches to the joint approach. We will use realistic sample and group sizes based on previous multispecies serosurveys [74], varying the size of interspecies differences and the evenness of sampling across groups to determine where the mixed-effect joint approach has the greatest differences from the alternatives.

Statistical approach and implementation:

All our simulation experiments will use a principled Bayesian framework [75] of simulating data from a structured model and testing the ability of the model as well as alternatives to retrieve the original parameters. We will implement models in the Stan probabilistic programming language [76], using Hamiltonian Markov Chain Monte Carlo to estimate model parameters. The R language [77] and will be used for data and model manipulation, workflows, and visualization.

Creating reusable software tools

We will develop an open-source software package for fitting, visualizing, and interpreting these models, written in the R computer language [77]. To maximize usability, we will test reduced-forms of all models, as well as multiple model-fitting algorithms including HMCMC, variational inference or maximum-likelihood optimization. For each we will measure model performance differences and model runtimes on both standard laptop on high-performance environments. The software package will include the ability to select amongst these options and include sensible defaults and guidance on trade-offs so that users can run tests in their compute environment. Reaction-cross reaction curve data and interaction will be packaged together with the software for users to use in their own model calibration.

Software will follow community best practices for software usability, maintenance and algorithmic testing and correctness as developed under the rOpenSci Project [78, 79]. We expect to conduct training on software use for staff across all the cooperating surveillance projects as well as teach at least one workshop at an applicable conference in Year 4 or 5 of the projects. See RESOURCE SHARING PLAN and DATA MANAGEMENT AND SHARING PLAN for additional detail on software standards and dissemination.

Risks, limitations, and mitigating factors

Several factors may limit the scope of applicability of these approaches. First, the high dimensionality and thus parameter size of these models may limit their use to large sample-size studies with moderate to high

seroprevalence levels. Our pilot studies (Aim 3), have sample sizes of hundreds to thousands, with initial estimates of seroprevalence in the range of 15-20%. Second, if cross-binding interactions are strong between antigens in our panels as well as [validation-verification](#) tests in wild-type [bat serum](#), it will make it difficult to distinguish cross-binding from a shadow virus signal within close antigenic distance. This will effectively increase the minimum antigenic distance needed to separate. However, even if strong, cross-binding is expected to predictably reduce with antigenic distance. That can be exploited to incorporate into explicit structures that predict associated uncertainty in the model structure or in model diagnostics.

AIM 3: APPLYING NOVEL METHODS TO OPEN QUESTIONS IN SPILLOVER IMMUNOLOGY

Our discovery panels and statistical models have direct applications to current open questions in serological surveillance. We will apply Aims 1 and 2 and leverage active serosurveillance projects where the identities of known or shadow viruses in sera from wildlife and humans could not be determined with current multiplex assays and statistical analyses. As testing will be conducted by and with local project teams, these projects will also serve as mechanisms for transfer and training and to refine protocols for publishing.

Henipaviruses in human community surveillance in Thailand

Preliminary Data: As part of the NIH CREID EID-SEARCH in Thailand, team members have been conducting clinical and community surveillance of humans in contact with wild bats cave guano mining. We implemented our standard (non-discovery) filovirus and henipavirus glycoprotein antigen-based panels for MMIA testing. During these research activities, we identified that 19% (54/284) of study participants sampled near the Khao Chong Phran Non-hunting Area in Ratchaburi Province, were specifically immunoreactive with the MojV G (Figure ~~78~~~~XXX~~). We also identified one participant with a distinct serological pattern that was had cross reactive and preferential binding to GhV, HeV, and CedV antigens. These data provide preliminary evidence that study participants may have been infected with two serologically distinct henipaviruses, one that is MojV-like and one that is ancestral to HeV/CedV and GhV-like. However, their identities indeterminate, and other hypotheses such as exposure to multiple viruses are plausible.

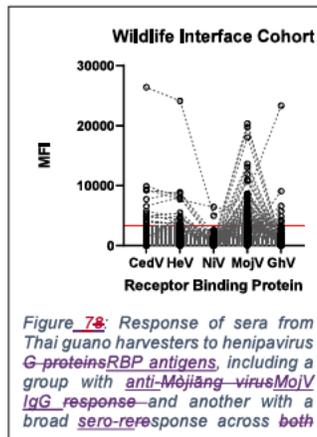

Figure 78: Response of sera from Thai guano harvesters to henipavirus G-proteins RBP antigens, including a group with anti-Mojiang-virus MojV IgG response and another with a broad sero-response across both

Formatted: Normal

Formatted: Normal

Approach: In Year 3 of this project, we will re-test sera from individuals with high wildlife contact currently being collected under the EID-SEARCH project using our full discovery 38plex antigen panels developed in Aim 1. With current archival sera and planned collection in the next two years, we estimate we will test 550 samples. Using the spectral mixture approach developed in Aim 2, we will fit models to determine (a) whether individuals with response to MojV were exposed to MojV or a closely henipavirus, and (b) whether individuals with response to GhV, CedV, and HeV were exposed one of these with cross-reaction to the other, multiple henipavirus with cross reaction to both or a new shadow virus. Using the antigenic mapping approaches, we will determine the relatedness of any shadow viruses to known henipaviruses. We will use our multi-scale models to determine how the presence and strength of response to each of these known or shadow viruses varies with sex, age, and occupational exposures.

Expected results and limitations:

Filoviruses in Egyptian fruit bats in South Africa

Preliminary Data: Through ongoing research activities with co-investigator Dr. Wanda Markotter (University of Pretoria), our team has detected seroprevalances of 17.5% (77/440) for an unknown ebolavirus that is most antigenically-like EBOV/BOMV, as well as 4.5% (20/440) for RAVV marburgvirus (Figure K1LO A) in *R. aegyptiacus* (Figure 89A-B). This degree of co-positivity is unexpected based on the WHO EBOV antisera, which favored preferential cross-reaction between EBOV and BDBV (Figure 2AFOXTRA A). This data is highly suggestive of the existence of a novel intermediate ebolavirus that is antigenically equidistant from both EBOV and BOMV.

Approach: Years 3 and 4 of this project we propose to test *R. aegyptiacus* and other bat sera collected from across Southern Africa using our panel and methods. Under the SABRENET project, over 15,000 samples are expected to be collected via longitudinal and cross-sectional sampling across Southern Africa. Based on current seropositive rates and planned sampling, we estimate 3,000 samples will have nonzero signals of a filovirus. Using a case-control approach we will select matching seronegative samples from collections for a total of approximately 6,000 samples. We will adapt our multi-scale models to a spatiotemporal framework to model the dynamics of these shadow viruses across different bat colonies.

Expected results and limitations: We expect that the sera IgG from Egyptian rousette bats reactive with BOMV and EBOV GP would be minimally reactive with the GP1 antigen from both viruses. This expectation would fit our reasoning that GP1 subunit antigen provide specificity to for the homotypic infecting virus and minimize cross reaction potentials.

We expect that sera IgG collected from humans who participate in guano mining and have evidence of cross reaction with a MojV-like henipavirus would be reactive with the F protein of MojV as well as the F proteins of LayV, which is closely related to MojV. We expect that this anti-MojV-like virus IgG response will form a unique serogroup based on both RBP and F proteins and would provide strong evidence that a novel henipavirus that is antigenically-distinct from those detected in southern and eastern China, and South Korea is present in Thailand and is able to cross the species barrier.

Formatted: Font: *Italic, Underline*
Formatted: Normal, Space Before: 0 pt

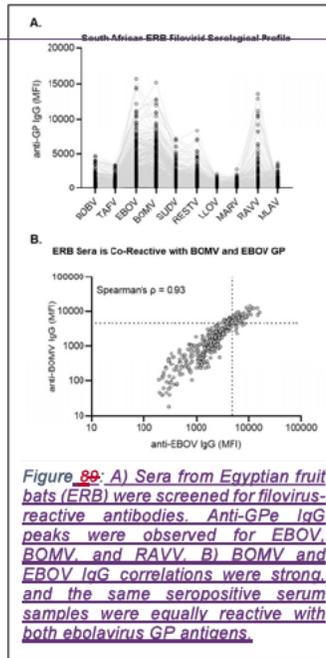

Figure 89: A) Sera from Egyptian fruit bats (ERB) were screened for filovirus-reactive antibodies. Anti-GP1 IgG peaks were observed for EBOV, BOMV, and RAVV. B) BOMV and EBOV IgG correlations were strong, and the same seropositive serum samples were equally reactive with both ebolavirus GP antigens.

Commented [MOU14]: Just one of these subheadings for both Thailand and RSA.

Commented [MOU15]: Noam what can you add from an expected modeling standpoint.

Formatted: Normal, Space Before: 0 pt

Commented [MOU16]: Noam – expectation from a model standpoint and overall limitation for SABRENET/SEARCH?

Linked serological-epidemiological models: Viral circulation in NiV reservoir Pteropus colonies

Preliminary data: In our previous and ongoing work studying NiV in Indian flying fox (*Pteropus medius*) colonies in Bangladesh, we found cyclical but non-seasonal patterns in seropositivity and viral shedding in a colony complex, a study we are now repeating across several colonies to understand geographic variation in seasonal shedding. We also found evidence of annual circulation of other filoviruses, based on antibodies binding to EBOV and Menangle virus (genus *Rubulavirus*) envelope protein antigens. Data collected in these serological studies was analyzed using a Bayesian cluster modeling to determine a threshold IgG level for serostatus, and threshold-based serostatus used as a binary variable in subsequent epidemiological analyses. However, this approach masks considerable complexity and uncertainty in the relationship between the individual binding levels in actual serostatus. For instance, for filovirus responses, the cluster of “baseline” responses of presumed seronegative bats increases with age, while in pre-weaned bats, an upper cluster of “seropositive” individuals has considerably weaker responses (Figure 949, publication in prep). Binding response also appears to change both seasonally and interannually.

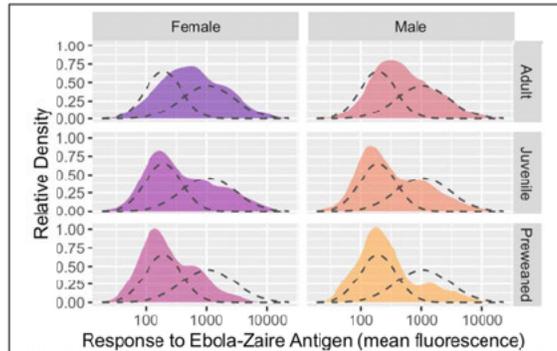

Figure 109: Clustering of binding response of Bangladeshi *Pteropus* sera to Ebola-Zaire antigen (filled densities), with clusters distributions from a Bayesian mixture model (dotted lines). Model thresholds do not capture within-cluster changes across demographic groups, which confound measures of seroprevalence.

Approach: We will use the antigenic relationships developed in Aim 1, and the cross-scale modeling approach developed in Aim 2, to re-analyze longitudinal and spatial extensive data on NiV, filo-, and rubulavirus binding response in *Pteropus* colonies. We will model the changes in baseline response binding (μ_-), seropositive response binding (μ_+), and seropositive binding probability (ρ , i.e. seroprevalence) as joint responses of a spatio-temporal model

$$\begin{bmatrix} \mu_- \\ \mu_+ \\ \rho \end{bmatrix} \sim \text{Multivariate}(f(\beta_0 + \beta_1 \text{sex} + \beta_2 \text{age} + s(\text{time}[\text{annual}, \text{seasonal}], \text{location}))) + \epsilon$$

Where $\text{Multivariate}(\dots)$ is a joint multivariate normal-probit distribution representing the correlated response of all three outcomes, $f(\dots)$ is the pseudotiter-response relationship, and $s(\dots)$ is a term with a spatio-temporal correlation structure. We will test several joint hypotheses by determining the consistency of posterior model results: Does baseline serological response increase with age, and how much does this vary across viral types? Does average seropositive response (as well as seroprevalence) decline following peaks of seroprevalence, consistent with antibody decline following an outbreak? Do maternal traits determine the strength of vertical transmission of antibody titer?

Expected results and limitations:

RESOURCE SHARING PLAN

I. REAGENTS

In-house expressed and purified ...pProtein antigens and commercially sourced polyclonal rabbit antisera will be made available upon reasonable request.

II. PROTOCOLS

Protocols for generating reagents, performing assays, etc....will be published on <https://www.protocols.io/>

III. SOFTWARE

As part of activities in statistical model development we will create a software package to enable researchers to implement their methods. The program will be implemented in the R language (with Stan and C++ components as needed). It will be written to be compatible with Windows, macOS, and Linux platforms and tested on each. Algorithm implementation, code style, user and documentation will all follow rOpenSci standards for statistical software implementations (<https://stats-devguide.roppensci.org/>). It will be released under an Open Source Initiative-compatible license.

The software will include both reference documentation and tutorials on implementing the software on example data. We will test both software usability and documentation quality by distributing alpha versions to researcher, students, and postdoctoral scholars at PI and co-I institutions and collecting feedback. Beginning with alpha versions, the software will be publicly released on a platform inviting user reports.

The software will be published on several platforms allowing easy retrieval and installation (CRAN, R-Universe, GitHub, Zenodo). A project website will be created for documentation. We will maintain the software, including bug fixes, and updates to maintain compatibility with changing dependencies and platforms, for 5 years after the end of the funding period. Containerized versions of the software at any major release, packaged together with all dependencies and compute environment, will also be archived so that archival analyses using the software may be run even after the end of maintenance.

See DATA MANAGEMENT AND SHARING PLAN for further details on publication, archiving and standards.

Commented [NR17]: Eric. Expand/remove as appropriate.

VERTEBRATE ANIMALS (LAING, USUHS)

1. Description of Procedures

New Zealand whites are used for polyclonal antibody development, aged 4 to 6 months, and housed and supplied by Noble Life Sciences (formerly Spring Valley Laboratories, Inc.). We use only three rabbits per any one immunogen. Rabbits will be immunized with purified recombinant glycoproteins. The adjuvant used will be the Ribi-Adjuvant-System (RAS). Animals will be monitored for an immune response to recombinant protein by an immunoblot procedure. We will provide the necessary protein antigen (400 ug per rabbit) for the immunizations. Whole blood will be collected and sera processed from immunized rabbits at four time points, a pre-bleed, and then after the first, second, and third immunizations spaced 21 days apart. Following the third immunization, a terminal bleed will be performed. We anticipate making protein-specific polyclonal antiserum to 28 glycoproteins. For henipaviruses, the F and RBP glycoproteins will be immunized in combination, thereby limiting the requirement to have two distinct sets of rabbits receiving either F or G proteins, which decreases the number of animals required.

2. Justifications

The goals of this project are to characterize the magnitude and breadth of the polyclonal antibody response to filovirus and henipavirus envelope glycoprotein, in order to establish the expected antigenic distances and space of each virus species, and examine glycoprotein-based serogroups. For this work, we must use an experimental animal model to allow the course of virus protein antigen-specific polyclonal antibodies development to be studied. Rabbits are a standard choice for the production of polyclonal antibodies. We intend on using only three rabbits per any one purified recombinant protein immunogen (e.g., EBOV GP, NiV RBP+F). We aim to examine how multiple immunizations with the same virus antigen shapes the magnitude and breadth of the antibody response to the immunizing antigen and those derived from closely-related viruses. We have chosen to utilize rabbits due to their ease of care, the prior use of rabbits as models for polyclonal antibody studies, and our preliminary data henipavirus RBP immunizations of these rabbit models performed in by my former lab. Rabbits are required because larger volumes of specific antisera are required to evaluate the antigenic relationships detailed in the grant application. The total number of required rabbits is 75, split over years 1 and 2 of the proposal study.

3. Minimization of Pain and Distress

Noble Life Sciences is fully certified and licensed by the US Department of Agriculture as a research facility; accredited by AAALAC (Association for Assessment and Accreditation of Laboratory Animal Care International); Their Assurance of Compliance with Public Health Service Policy on Human Care and Use of Laboratory Animals is filed with the OPRR, National Institutes of Health, #A3731-01; registered for the veterinary and research use of schedules 2 through 4 controlled substances by the Drug Enforcement Agency; and their IACUC approval #SVL 002 is for antibody production in rabbits. Attending veterinary care will be provided by SVL. Animals are routinely observed at least twice daily and additional observations are made following procedures.

Bleeding will be performed with hypodermic needle (19 ga.) from auricular artery. One or two prebleed blood draws will be performed prior to immunizations. Blood samples will be drawn no more than once every three weeks. The maximum volume of blood obtained will be 30 ml. Rabbits will be placed in restraining cages. However, rabbits are given Ketaset, 10.0mg/lb. body weight and Rompun, 2.0mg/lb body weight (intramuscularly; hind leg/ thigh; with 25 ga. needle) prior to exsanguination by cardiac puncture.

4. Method of Euthanasia

Rabbits will be euthanized by intravenous barbiturate overdose, i.e. approx. 40 mg/kg body weight according to label instructions. Both of these methods are consistent with the recommendations of the Panel on Euthanasia of the American Veterinary Medical Association (AVMA).

DATA MANAGEMENT AND SHARING PLAN

I. DATA TYPES

Types and amount of scientific data expected to be generated in the project

This project will produce data on antigen binding responses via multiplex bead array assays, as generated from Bio-Rad Bio-Plex and Luminex MAGPIX multiplexing Systems. These assays will be performed on sera from hyperimmunization challenge experiments in rabbits, human serology standards for select viruses, and archival sera samples from wildlife surveillance studies in South Africa, Republic of Congo, Madagascar, and Thailand as well as human surveillance studies in Thailand. Calibration data, including measures from blank and mock samples, will also be generated.

The project will produce sample-level metadata for challenge experiments and standard dilutions. It will aggregate copies of metadata associated with archival samples from other research projects. The latter will include host species, traits, time and location of collection of animals sampled, and demographic information of humans sampled.

The Bio-Plex and MAGPIX systems will generate raw data in XML and XLSX files, with XML files being comprehensive logs of run metadata, machine calibration, and all measurements per sample, and XLSX being sample-level total measurements. Sample-level metadata will be collected in CSV and XSLX form.

Across experimental and archival samples, we expect to generate approximately 7,000 tests on 90 plates, totaling approximately 3.5MB of processed XLSX files and 440MB of raw XML files.

The project will also produce synthetic data from simulations and performance data from experiments. These will be generated in RDS (R Object files), and parts computationally intensive or difficult to reproduce will also be exported as CSV files. The project will produce computer code for both analyses and as a primary product in the form of reusable software packages. These will be in standard UTF-8 text of computer languages including R, Stan, and C++, as well as compiled executable binary files.

Scientific data that will be preserved and shared

Excepting identifiable data associated with human samples, all data produced in the course of this project will be publicly shared. Final sample-level cleaned and joined data and metadata will be shared as CSVs, as well as raw Bio-Plex or MAGPIX software XML data. All computer code created will be shared. Synthetic data and summaries of simulation experiments will be shared in summarized form, with raw data shared as reproducible code that can regenerate the exact results, excepting data that is computationally-intensive and therefore more efficient to share in raw form.

For data associated with human samples personally identifying information will not be shared. Personal individual-level data will be removed, demographic and location data will be binned to prevent re-identification, with location information binned to the province (ADM-2) level and age aggregated to bins of 10 years or more. Other fields (e.g. occupation) will be analyzed to determine potential for re-identification and removed or binned as necessary.

Metadata, other relevant data, and associated documentation

This project will also produce as primary outputs standard operating procedures and instructions for performing the assays under development, documentation to reproduce simulations and statistical analyses from provided code, as well as user documentation and tutorials for the statistical software that will be created. Descriptive and structural metadata will be included in deposits for each data set.

II. RELATED TOOLS, SOFTWARE AND/OR CODE

All produced data formats (CSV, JSON, XML, XLSX) can be read by multiple, widely available free and open-source tools, with only RDS files specifically requiring the free and open-source R language.

III. STANDARDS

In general, all data will be reported using the Frictionless data standard, as both an "umbrella" framework and a general approach to data sets without domain-specific standards. The Frictionless data standard provides a framework for consistently packaging data stored in most inoperable file formats. We will use accompanying Frictionless JSON files to describe CSV metadata, with additional standardized fields specific to the data repository used (e.g., Zenodo). Where applicable, we will use the NIH Common Data Elements (CDE, <https://cde.nlm.nih.gov>) for relevant fields.

Formal standards for non-target and quantitative serological data have not yet been widely adopted, and the development of essential reporting quantities is an anticipated output of this project. However, we will aim to ensure the data reported is, where applicable, compatible with standards for serological studies, notably the NIH ImmPort data model and its recommended ontologies for proteins and diseases.

Spatiotemporal and taxonomic metadata on wildlife samples will follow the Darwin Core Standard.

Computer code will be released using two standards. Software packages for reuse will be in the format of an R packages following the rOpenSci standards for statistical software implementations (<https://stats-devguide.ropensci.org/>) and CodeMeta standards for software descriptions (<https://codemeta.github.io/>), under an Open Source Initiative-compatible license. For computer code to reproduce simulations and statistical analyses, we will use git version controlled code repositories, the "Make" and "targets" frameworks to define dependencies between steps of analysis, the "renv" and "venv" frameworks for recording software dependencies, and Docker containers to capture the machine computing environments. Binary machine images of the containers will be stored alongside the source code.

IV. DATA PRESERVATION, ACCESS, AND ASSOCIATED TIMELINES

Repository where scientific data and metadata will be archived

We will archive all data and metadata generated, as well as all computer code, on the Zenodo archive. A subset of data generated is appropriate for NIH's ImmPort repository and will be cross-deposited there with appropriate semantic references to describe the relationships between data. Protocols will also be deposited on protocols.io.

How scientific data will be findable and identifiable

All data on Zenodo, NIH ImmPort, and protocols.io will be identifiable DOIs and have searchable metadata deposited with DataCite and indexed by search engines. In addition, we will mirror data on non-archival sites that are popular and accessible for their features and search optimization: DoITHub for data, GitHub for source code, and R-Universe for installable R software binaries.

When and how long the scientific data will be made available

Data associated with publications will be shared in its processed and cataloged form upon release of associated products (preprints, software, or publications upon acceptance), or the end of the period of performance (inclusive of any approved extensions), whichever comes first. The duration of preservation and sharing of the data will be a minimum of 10 years after the funding period.

V. ACCESS, DISTRIBUTION, OR REUSE CONSIDERATIONS

Factors affecting subsequent access, distribution, or reuse of scientific data

There are no anticipated factors or limitations that will affect the access, distribution or reuse of the scientific data generated by the proposal.

Whether access to scientific data will be controlled

All data generated by this project will be released in full excepting data aggregated from other projects with personally identifiable data.

Protections for privacy, rights, and confidentiality of human research participants

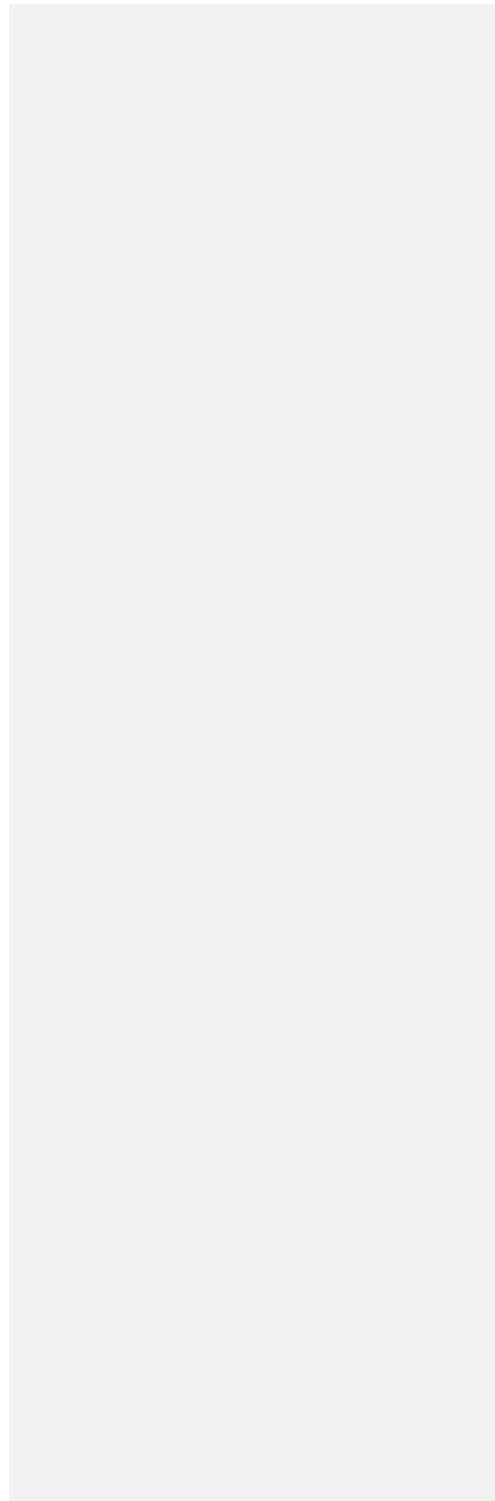

Where data used by this project from other projects is linked with personally identifiable information, only de-identified information will be released. Identifiable data will not be retained. Requests for the identifiable data will be referred to the original projects and institutions.

VI. OVERSIGHT OF DATA MANAGEMENT AND SHARING

PI Ross (ORCID 0000-0002-2136-0000) will be responsible for oversight of project data management and release of data. The project research assistant at EcoHealth Alliance will be responsible for management of the project database, maintenance of project metadata, aggregation of data from project partners, and releasing data to appropriate repositories under appropriate standards. A data librarian at EcoHealth Alliance will support this role and act as an organizational fallback for data maintenance. Data release will take place after agreement amongst PIs from all contributing institutions. State of data management and release will be a standing topic at project quarterly and annual meetings.

PROJECT NARRATIVE

This project develops new methods to identify emerging and zoonotic viruses by analyzing the virus-induced antibodies present in wildlife and human populations in contact with wildlife. It will create both new laboratory techniques to test for those antibodies as markers of infection and new mathematical models to analyze data to identify the trace of those viruses. It will test these methods in partnership with international virus surveillance projects in Bangladesh, Thailand, and South Africa.

PROJECT SUMMARY/ABSTRACT

Serology remains under-utilized as a reliable surveillance tool for the detection of emerging zoonotic viruses. Detection and estimation of Ebola virus spillovers is dependent on outbreak scale and thus may not be caught through early warning systems. The geographies at-risk for Nipah virus, and bat-borne and rodent-borne henipaviruses spill over across sub-Saharan Africa, Asia and Oceania remain under-surveyed. -Limitations of serosurveillance in addressing virus emergence ~~can be~~ found at both the front-end in serological assay design and development, and back-end in the statistical frameworks used to analyze data. Both of these need to be adapted to the unique challenges associated with known emergent viruses and novel unknown viruses not yet g-~~as opposed to known pathogenic viruses already g-~~genetically characterized. These challenges include cross-reactivity of antigens and antibodies and complex, nonbinary immune responses. The major goal of this proposal is to dramatically improve the utility of antigen-based serosurveillance for new viral discovery and epidemiology of emerging zoonotic ~~diseases~~ viruses by addressing the challenges of cross-reaction and statistical rigor. We will create discovery panels - qualified and optimized panels of multiplexed immunoassays designed to identify and characterize previously unknown viruses only detected through the ~~antibody response of~~serologically profiling wildlife and human hosts. We will develop new statistical approaches to extract the signals of novel viruses from those of known viruses or mixtures of virus-specific antibodies from complex histories multiple previous viral exposures, as well as integrate these into models into population-scale epidemiological models. Finally, we will partner with international viral surveillance projects to apply these techniques to identifying and characterizing filoviruses and henipaviruses in bat populations in South Africa and at-risk wildlife workers at-risk for exposure to wildlife viruses in Thailand, and to modeling immune-epidemiological dynamics of Nipah virus circulation in bats and people in Bangladesh.

Commented [MOU18]: 20 lines, no more than 30.

Commented [MOU19]: I think this is too much for the summary statement

FOREIGN JUSTIFICATION

This project concerns zoonotic infectious diseases found in wildlife and human populations globally and with the potential to spread and cause outbreaks in the United States. Study populations of interest – high animal-contact workers in Thailand, and known filovirus host bat species in South Africa – were selected because prior results indicated the presence of antibodies to novel viruses that could be better characterized using the methods developed in this proposal. In both cases, the systems are already being studied under U.S. federally-funded disease surveillance projects: The NIH CREID Emerging Infectious Diseases - South East Asia Research Collaboration Hub (U01 AI151797), the DTRA BTRP South Africa Bat Research Network (HDTRA12010025).

In the case of surveillance in Thailand, the lead expert in the disease ecology and epidemiology of the system of interest is Co-I Wacharapluesadee. Archival sera from study of this population are stored at her institution, King Chulalongkorn Memorial Hospital, and she and her team are best equipped to analyze these specimens and interpret the results. Dr. Wacharapluesadee and King Chulalongkorn Memorial Hospital have a history of collaboration with U.S. institutions under USAID and NIH programs.

In the case of surveillance in South Africa, the lead expert in the disease ecology and epidemiology of the system of interest is Co-I Markotter. Archival sera from study of this population are stored at her institution, University of Pretoria, and she and her team are best equipped to analyze these specimens and interpret the results. Dr. Markotter and University of Pretoria under DTRA and NIH programs.

CONSORTIUM/CONTRACTUAL ARRANGEMENTS

This project is a multi-institutional collaboration led by EcoHealth Alliance, New York (PI Ross, Co-I Epstein) that will subcontract funds in accordance to NIH Institutional guidelines to three other institution:

1. **Uniformed Services University of the Health Sciences, Bethesda, MD** (PI Laing)
2. **University of Pretoria** (Co-I Markotter)
3. **King Chulalongkorn Memorial Hospital, Thailand** (Co-I Wacharapluesadee)

The applicant organization (EcoHealth Alliance) is justified in taking the lead on this project because it specializes in understanding the ecological and virological processes underlying zoonotic disease emergence, and has conducted international, multi-disciplinary and multi-partner research around the world for more than 30 years, including joint projects with the listed institutions. EHA administers technological and data-management platforms used by partners as part of these project.

PI Ross oversees modeling, statistical design, and data systems at EcoHealth Alliance. Dr. Ross, a mathematical disease ecologist, is an expert in complex semiparametric modeling approaches and the role of host and pathogen heterogeneity in disease dynamics. He leads multiple multi-institution projects in scientific and statistical software development [80, 81], disease forecasting (Wellcome 226061/Z/22/Z). He has had core roles in quantitative methods for multi-institution projects under USAID, DTRA, and NIAID, including collaborations with all partner institutions on this project.

EcoHealth Alliance will be the lead for administrative components and oversight of this project, and also be the center of development and testing of quantitative methods, software development, data integration, and overall synthesis. Co-I Epstein at EcoHealth Alliance will provide expertise in the virology, disease ecology, and epidemiology of the populations of interest in Bangladesh.

The subcontract institutions will work on specific issues and areas in which they have proven expertise. These areas are:

- Wildlife virology and immunology, Novel serological and assay development; generation of reagents for novel assays; training and technology for serological and molecular protocol development, of Thailand and South Africa laboratory staff for technology transfer for serological and molecular protocol development (**Uniformed Services University of the Health Sciences, PI Laing**).
- Wildlife and human community surveillance and specimen collection, human clinical or hospital syndromic surveillance, screening of serum specimens using serological assays, disease ecology and epidemiology of zoonotic diseases specific to populations in Southern Africa (**University of Pretoria, Markotter**), and Thailand (**King Chulalongkorn Memorial Hospital, Wacharapluesadee**)

PROJECT LEADERSHIP PLAN

I. BACKGROUND AND MULTI-PI RATIONALE

This research program, *Characterizing unknown emerging viruses through targeted serological profiling*, is inherently interdisciplinary, jointly developing *in vitro* and *in silico* methods for serological viral discovery, drawing from the expertise, teams, networks, and resources of both PIs. This project will be co-led by PIs Dr. Noam Ross (EcoHealth Alliance, New York, NY), and Dr. Eric Laing (Department of Microbiology and Immunology, Uniformed Services University of the Health Sciences (USU), Bethesda, MD). The laboratory and computational components, as represented in Aim 1 and Aim 2, are complementary and co-equal. Each PI brings methodological expertise and experience to their component. Dr. Ross, a mathematical disease ecologist, is an expert in complex semiparametric modeling approaches and the role of host and pathogen heterogeneity in disease dynamics. He leads multiple projects in scientific and statistical software development [80, 81]. Dr. Laing, a virologist, is an experienced researcher in the field of infectious diseases, serological application and profiling, and cellular immunology. He is a co-investigator and associate investigator on multiple virus surveillance projects including Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EpiCC-EID), Prospective Assessment of SARS-CoV-Seroconversion, EID-SEARCH, SABRENET, and along with OSC Munster is a co-investigator on a pending project, Establishment of a Bat Resource for Infectious Disease Research. The PIs have a history of collaboration as part of multiple projects in disease surveillance, including serological surveillance of wildlife under DTRA-funded surveillance projects in Malaysia (HDTRA11710037) and South Africa (SABRENET, HDTRA12010025), and NIH-funded research on Nipah virus circulation in Bangladesh (U01 AI153420-01). In each they work(ed) jointly on interpretation of serological data and epidemiological models, serving as the methodological experts within those teams.

Co-Investigators Epstein, Markotter, and Wacharapluesadee all lead active federally funded projects in zoonotic viral surveillance and discovery that make use of serological methods developed by PI Laing. Each provide system-specific expertise in the ecology, epidemiology, and virology of the regions and species in those projects, which are the source of samples and data for our applications for Aim 3.

II. ROLES AND RESPONSIBILITIES

PI Ross will be the contact PI of the project, responsible for funder communication, budgeting, and reporting, and oversight of sub-awardees. He will be responsible for project data management, statistical methods and development under Aim 2, and analyses under Aim 3. Dr. Ross will be supported by EHA's administrative staff, including organizational-level finance and human resources directors, a federal grants administrator, a data librarian and computing cluster systems administrator. PI Laing will be the lead laboratory processes and development and site lead for USU. He will be responsible for protein and panel design, challenge experiments, and other laboratory experiments under Aim 1. Both PIs will participate equally in interpretation of analyses and manuscript writing.

Co-Is Markotter and Wacharapluesadee will be oversee the testing of samples from South Africa and Thailand at their institutions, respectively, and act as consortium leads for University of Pretoria and will liaise with PI Laing for logistics and implementation of protocols. SPs Epstein, Markotter, and Wacharapluesadee will all participate in the (re-)analyses and interpretation of results in Aim 3.

III. PROGRAM MANAGEMENT

COMMUNICATION

PIs will coordinate via monthly video calls. These calls will include other Co-Is quarterly, and more frequently as needed starting with Aim 3 activities in Year 3. At the discretion of PI and Co-Is, other laboratory staff from each institution and OSCs will participate in these meetings. The purpose of these meetings will be to keep all parties informed of the status, progress, and plans. Quarterly meetings will be extended to include presentation of preliminary results. Calls will be coordinated by PIs Ross and Laing with monthly rotation of leadership and responsibility of making agendas for and disseminating notes from each meeting.

PIs will use AirTable and GitHub project management boards, administered by PI Ross and EHA administrative staff, to track task status, including laboratory and computational experiments, testing, administrative tasks, manuscript preparation and publication. EHA's internal content sharing hub (secure.eha.io), will be used for sharing interim reports and preliminary results across project participants.

IN-PERSON MEETINGS

Project PIs will meet in-person at least annually at EHA, USU, or at jointly attended conferences in the last quarter of each project year. Following annual meetings PIs will generate annual reports, using this period to communicate and discuss program status and any possible changes to research directions should information indicate failure of certain directions or the possibility of new opportunities. Decision making will be made by all program's PIs. If issues/topics cannot be resolved at this level then PIs (unlikely) will consult with NIH program staff on future allocation of research funds pending any replacement or revision of the program's goals.

We have budgeted additional funds for laboratory exchanges of staff. The modeling Postdoc at EHA will travel to USU to train in Year 2 to train in laboratory methods to inform mathematical work. A USU graduate student will travel to EHA in Year 2-3 to study modeling and statistical methods. A PI or postdoc the project will travel to the University of Pretoria and Bangkok sites in Year 4 to work with other project members and staff on methods training and interpretation of results.

In addition, we will take advantage of existing collaborations to liaise with Co-Is. A USU project staff member is visiting scientist at the CKMH and PI Laing travels to CKMH under EID-SEARCH. PI Ross, PI Laing, and co-I Epstein travel regularly to UP for collaboration under other projects (HDTRA12010025, Wellcome 226061/Z/22/Z).

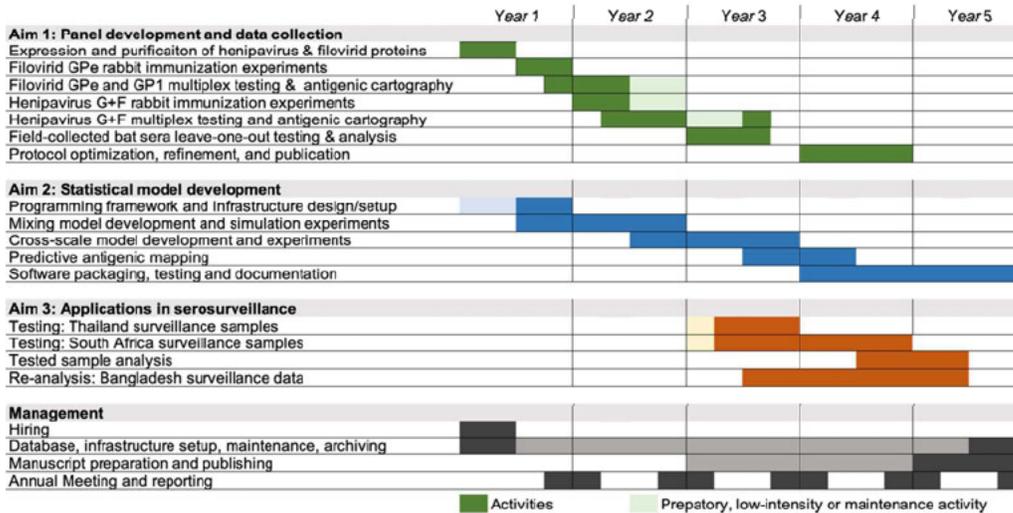

DATA MANAGEMENT

All data and code will be managed in a project database overseen by PI Ross and administered by the project research assistant. All other consortium members will upload data to this database and also maintain local copies in their local information management systems. See DATA MANAGEMENT AND SHARING PLAN for additional details on data dissemination.

COMPUTATIONAL RIGOR AND REPRODUCIBILITY

Development of model code will follow our framework of *deployment-ready research*, an approach to developing scientific code that can be integrated into reusable software with little additional effort. Code will be maintained in a version control system (git), with versions of models linked to the versions of data they were run against in a versioned database (dolt). Changes to model design or implementation will require code review by a team member. Review will include diagnostics of code quality and comparing output and performance of each version of models, implemented automatically by continuous integration (CI) on our code-sharing platform (GitHub).

PROJECT TIMELINE

COVER LETTER

National Institutes of Health (NIH)
9000 Rockville Pike
Bethesda, Maryland 20892

February 5, 2021

Application for the NIH Research Grant Program Announcement number PA-20-185, entitled NIH Research Project Grant (Parent R01 Clinical Trial Not Allowed), dated May 5, 2020

To whom it may concern:

We are pleased to submit our grant proposal titled “**Characterizing unknown emerging viruses through targeted serological profiling**” for consideration.

Please assign our proposal to the following:

Institutes/Centers: National Institute of Allergy and Infectious Diseases - NIAID

Scientific Review Groups: Transmission of Vector-Borne and Zoonotic Diseases (TVZ)

We know of no individuals (e.g. competitors) who should not review the application.

Our project is aligned with the mission of NIAID because it focuses on detection and characterization of pathogens with potential for emergence, including near neighbors of Ebola virus and Nipah virus, which are priority pathogens. This project addresses NIH’s priorities of Immunology and Assay Development, Reagents and Resources, and Epidemiology and Pathogen Discovery under the NIAID Pandemic Preparedness Plan (<https://www.niaid.nih.gov/sites/default/files/pandemic-preparedness-plan.pdf>).

Two of our subawards, for University of Pretoria (UP) and King Chulalongkorn Memorial Hospital (KCMH), are not active for the first two budget periods of the project. This grant concerns the development, testing, and validation of new methods, with initial development occurring at the main site, EcoHealth Alliance, and consortium partner Uniformed Services University. Testing and validation will involve all consortium partners and begin in Year 3 of the project.

Please note that the proposed work is NOT a Select Agent study because we work only with synthesized antigens and archived sera.

Thank you very much for your consideration.

Sincerely,

Noam Ross, Ph.D.

NOTES AND STUFF FROM OLD PROPOSALS

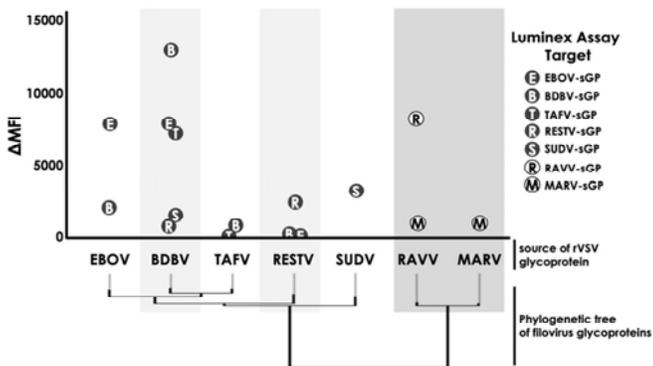

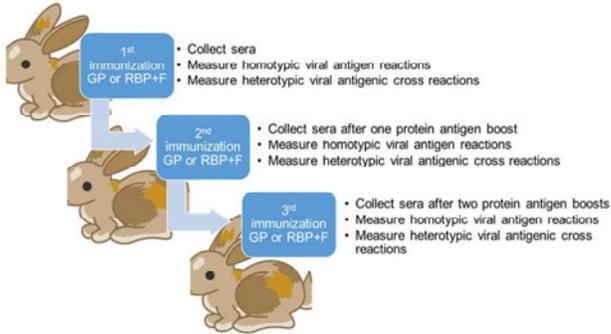

The majority of antibodies induced by virus infections are specific to conformational dependent epitopes found on virus proteins. Antibodies raised against envelope glycoprotein of henipaviruses and ebolaviruses undergo affinity maturation and are the targets of vaccine design and development. However, the confounding effects of cross-reactivity against native-like proteins expressed to retain quaternary structures, and a lack of true controls in understudied wildlife species or for yet-uncharacterized viruses stymies use of rich qualitative data that they produce.

Old World frugivorous bats have been largely considered the wildlife reservoirs of henipaviruses, the discovery of four Asiatic henipaviruses in rodents has come as a surprise [cite]. implies that serosurveillance measures thus far have been unable to appropriately detect the diverse serological profile of extant henipaviruses amongst wildlife, livestock, and human hosts. In fact, PI Laing's research team detected a unique serological profile in an archived sera bank of acutely febrile patients in Cambodia that were XX% (44/1400) seropositive for a henipavirus that is seemingly antigenically-distinct and -ancestral to Ghana, Hendra, and Cedar viruses (Figure JULIET).

The shape of this serological profile if protein antigens from LayV and the other rodent associated henipaviruses had been included will remain unknown, but the serologic data suggests that there are other serologic footprints left by unknown zoonotic henipaviruses in southeast Asia, the shadows of which can be measured through serological approaches.

Figure SECHO: Caption caption

IV. SIGNIFICANCE

Serological tests frequently viruses outside their known host range or geographic range (Filovirus, Singapore, etc.).

Serological surveys can capture usable info PCR cannot [11]. Serological screening can identify novel strains that would otherwise be missed, such as this Hendra virus variant [82].

Bayesian clustering approaches [83] are useful but have largely been applied to single-assay surveillance. At higher dimensions, the clustering in high/low expected values confounds with clustering of different viruses.

Outlier-based detection is inherently problematic for rare conditions. Rare values can occur at a rate less than statistically expected outliers.

V. INNOVATION

This project is innovative in its multi-scale approach, integrating laboratory method development and population-scale surveillance data through modeling to develop.

Estimate the probability of a multiplex panel response to represent exposure to novel coronaviruses. This approach has several statistical antecedents: spectral mixture analysis in remote imaging, antigenic cartography.

Paper on Nipah Panel: [84]

These measures will produce novel insights via *antigenic mapping*. The mixture of high- and low-specificity (RBD and IgG) will allow us to better understand the degree to which phylogenetic similarity between viral species is reflected in antigenic properties.

We will extend techniques of antigenic mapping,[66] using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential.

Model 1: mixed effects for unknown responses in wildlife species. Account for variation in wildlife, use phylogenetic information to inform immune response.

Model 2: "spectral mixing" / antigenic mapping approach. Determine the probability that an individual has an exposure to a single virus.

Experiments: test sera exposed to multiple viruses rather than single viruses only, determine additivity. Additive allow for straight spectral mixing, non-additivity requires models with covariance components.

Model 3: Multiple outcome (multivariate probit) models for joint seroprevalence.

In wildlife serological surveillance, we generally lack important controls, including PCR-based or symptom-based confirmation. We lack negative controls because we don't know the wild-caught status. In the few cases where there are captive-raised animals, these negative controls aren't representative of wild types that may have had other exposures. In any case the number of species of interests for serological monitoring far exceeds those it would be possible to establish captive models.

Many multi-species surveillance studies.

Analyses need to distinguish between *correlation in assay response*, which may be driven by cross reactions, and *correlation in exposure*, driven by epidemiological and ecological processes.

Pooling data from multiple studies can establish standardized responses for some species, while simultaneously giving a base of evidence for predicting to other species.

Pooling factors allow us to evaluate the level of species- or geography-level information incorporated into estimates

Making studies comparable by extracting raw data on machine calibration, sample dilution, etc.

Mixed models will allow us to estimate both intra- and interspecific variation in wild-type responses, and develop predictors of this using both phylogenetic and trait-based species data.

Phylogenetic models – assessing phylo-immuno relationship across the panels, allowing for prediction in phylogenetic space

Incorporate measures of variation by test

Benefits – quantitative and scalable interpretation, researchers don't all have access to the statistical or virological expertise which is required to interpret beyond specific recipes

Nonlinear relationship of cross-reactivity <https://link.springer.com/article/10.1007/s10875-021-00997-6>

We will screen serum from all subjects for IgG antibodies against Nipah and all other known henipaviruses (Hendra, Cedar, Ghanavirus & Mojiang) using a Luminex multiplexed sphere-based assay developed by the Broder lab and the CSIRO Australian Animal Health Laboratory in Geelong (10).

are acquiring new laboratory experimental data on titer-response curves and cross-reaction against non-target antibodies for Luminex assays.

The core of this proposal is the development of statistical models and the ability to test these models against field data from a variety of systems that has been collected, curated, and interpreted by our team.

Our team has been involved in 17+ years of research in host-pathogen dynamics and spillover processes for zoonotic viruses across continents including Hendra, Nipah, SARS-CoV, SARS-CoV-2, MERS-CoV, and Ebola viruses, as well as development of state-of-the-art multiplex assays for serological testing for these viruses. Our data from multiple NIH R01s, as well as other federally-funded work, includes paired individual data on both antibody levels and PCR detection of viral RNA, multiplex data from multiple systems, and serochip data. We will enable broader use of these models in epidemiology through the development of software for both model-fitting and visual diagnostics.

Our team has experience in turning research code into generalizable and sustainably maintained scientific software, including designing for user needs, recruiting open-source communities.

Our 3 specific aims are to:

- 1. Create procedures to detect signals of new viruses from multiplex serological assays.**
2. Discovering real signals in high-dimensional serochip data.

and .

Creation of a library of priors: While there are missing baselines for a wide array of serological assays, an accumulating body of evidence can provide input to future routines. We will use data accumulated from a series of projects to build a database of priors. This data will help us answer question such as: how applicable are thresholds and models across species? How consistent are immune responses within and

across families of viruses? How do distributions of responses, when normalized, compare across quantitative methods that are related but not linearly proportional with antibody titers?

We will use this database to identify laboratory calibrations that will provide the greatest ability to improve statistical discrimination among responses.

Cross calibration of methods: We have both Luminex data, serochip data, and a spectrum of VNT or pseudo-neutralization assays. All are related to antibody titer but have different mechanisms, and levels of specificity and nonlinearity in response. We will perform cross-calibrations. We will integrate these into our model designs so that mechanisms can be swapped out and serology can be made comparable across populations.

1. We will validate these models with a "leave-one-out" strategy – testing whether a novel virus is identified in sera from a population with a known exposures to a virus, with proteins specific to that protein removed. We will repeat this via both *in silico* and *in vitro* approaches. *In silico*, we will simply remove data from the target viral proteins from multiplex results from a full panel. *In vitro*, we will omit beads for the target viruses from the panel. Comparison of these two approaches will quantify the extent that competitive binding affects the validation technique.

BIOGRAPHICAL SKETCH

NAME: Brook, Cara E.

eRA COMMONS USER NAME (credential, e.g., agency login):

POSITION TITLE: Assistant Professor

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	END DATE MM/YYYY	FIELD OF STUDY
Stanford University, Stanford, CA	BS	06/2010	Earth Systems
Princeton University, Princeton, NJ	MS	09/2014	Ecology and Evolutionary Biology
Princeton University, Princeton, NJ	PHD	09/2017	Ecology and Evolutionary Biology
University of California, Berkeley, Berkeley, California	Postdoctoral Fellow	08/2020	Miller Postdoctoral Fellow
University of California, Berkeley, Berkeley, California	Postdoctoral Fellow	07/2021	Branco Weiss Fellowship

A. Personal Statement

My interdisciplinary research background spans the disciplines of field biology, molecular immunology, and mathematical modeling of infectious disease transmission. Across the course of my PhD and postdoc, I founded and developed a longitudinal field study deciphering the transmission dynamics of potentially zoonotic pathogens infecting wild fruit bats in Madagascar, which forms the backbone of the bulk of my research program. This work also highlights my commitment to scientific outreach, development, and capacity-building for Malagasy scientists in biology and medicine, most clearly manifest in the R-based programming workshop (E2M2: Ecological and Epidemiological Modeling in Madagascar), which I inaugurated and teach annually, and in the R-based mentoring program in quantitative ecology (C4C: Coding for Conservation), which I launched in 2022. In addition to my expertise in population-level transmission processes, from both an empirical and computational perspective, I also have extensive experience in developing within-host models to elucidate the role of the unique bat immune system in controlling viral infections, as well as a strong background in carrying out in vitro experiments to collect data against which to test the predictions of these models. Though just beginning my second year as an Assistant Professor in the Department of Ecology and Evolution at the University of Chicago, I have been independently funding my international research program since its inauguration with the start of my PhD in 2012. In total, I have amassed over \$5 million in grant money to support this work since its origination, resulting in 14 first-authored and 10 senior-authored peer-reviewed publications, in addition to a suite of co-authored papers, which span a range of subjects reflecting my wide-ranging interests in ecological theory, conservation, and public health. In addition to my own work, I have funded and mentored four Malagasy scientists in part with this research, including Dr. Hafaliana Christian Ranaivoson, a Malagasy biologist who is now a postdoctoral scholar in my lab at the University of Chicago. In addition, I have trained and mentored three other University of Chicago postdoctoral scholars, two University of Chicago PhD students, two University of Chicago undergraduates, and nine postbaccalaureate research scholars in my lab.

B. Positions, Scientific Appointments and Honors

Positions and Scientific Appointments

2021 -	Assistant Professor, Dept of Ecology & Evolution, University of Chicago, Chicago, IL
2020 -	Branco Weiss Fellow, Branco Weiss Society in Science Fellowship, ETH Zurich, Zurich
2017 - 2020	Miller Postdoctoral Fellow, Miller Institute for Basic Research, UC Berkeley, CA
2013 - 2017	NSF Graduate Research Fellow, Dept Ecology & Evol Biol, Princeton Univ, Princeton, NJ

Honors

2020 - 2025	Branco Weiss 'Society in Science' Fellowship, ETH-Zurich
2020 - 2021	L'Oréal USA For Women in Science Fellowship, AAAS
2017 - 2020	Miller Postdoctoral Fellowship, Miller Institute for Basic Research, UC Berkeley
2013 - 2017	Graduate Research Fellowship, National Science Foundation
2013	National Defense, Science, and Engineering Graduate Fellowship, Dept of Defense
2010	Firestone Medal for Undergraduate Research Excellence, Stanford University
2010	Earth Systems Award for Senior Thesis Excellence, Stanford University

C. Contribution to Science

- Population-level bat virus transmission dynamics:** At a broad scale, one major theme of my work seeks to decipher transmission mechanisms underpinning the persistence of potentially zoonotic pathogens circulating in bat reservoir hosts, with an eye towards addressing the drivers of seasonal pulses of virus shedding that, globally, coincide with zoonotic spillover. Across the course of my PhD and postdoc, I established a long-term field system dedicated to deciphering these mechanisms for disparate pathogen types infecting wild, fruit bats in Madagascar. Through this work, my research team and I undertake monthly capture and collection of biological samples from longitudinally-monitored roosts for three endemic fruit bat species. To date, we have successfully identified, described, and analyzed the ecology of potentially zoonotic bat-borne henipaviruses, filoviruses, and coronaviruses, *Babesia* spp. protozoa, and *Bartonella* spp. bacteria infecting these bats. Our work points to mechanisms of waning immunity and a role for viral recrudescence and reinfection in viral persistence in this system.

- Evolution of cross-species virulence in bat-borne zoonoses:** A second major theme of my work explores the within-host processes which enable bats to host pathogens that cause extreme pathology in other mammals without, themselves, experiencing significant disease. My work in this arena has demonstrated quantitatively that bats do source zoonotic viruses which cause higher case fatality rates in human populations than those derived from other mammalian hosts and also established an evolutionary mechanism to explain this phenomenon. Using a theoretical, within-host / population-level nested model, I

showed how unique anti-inflammatory mechanisms in bat physiology, believed to have evolved to mitigate the accumulation of oxidative stress incurred during flight, result in a high degree of bat tolerance to immunopathology. These mechanisms, in turn, lift the evolutionary cap on virus growth rates otherwise set by the classic virulence-transmission tradeoff, resulting in the evolution of faster-replicating pathogens that, while not pathological to a bat, cause extreme virulence in other mammals that lack unique bat physiology. My *in vitro* work infecting bat cells with virus in tissue culture offers an empirical validation of this phenomenon, suggesting that viruses replicating under constitutively antiviral innate bat immune conditions do, indeed, demonstrate faster growth rates than under more typical induced mammalian immune defenses.

3. **Expanding public health capacity in Madagascar:** An additional major theme of my research focuses on capacity-building for public health in Madagascar. I have continuously worked to support the quantitative training of Malagasy scientists in biology and medicine, co- and senior-authoring numerous publications with Malagasy collaborators to promote research into infectious disease dynamics. These initiatives have ranged in subject from guiding the roll-out of rubella vaccine, to deciphering the dynamics of COVID-19, to understanding the landscape for potential recombination in bat-borne and human-circulating coronaviruses. In addition, this work has resulted in the inauguration of the first-ever Illumina Next Generation Sequencing platform in Madagascar, used for SARS-CoV-2 genomic surveillance.

4. **Viral discovery:** Another scientific contribution of my work has revolved around viral discovery and characterization of novel, potentially zoonotic viruses of fruit bats in Madagascar. In recent studies, we have described and characterized novel genomes of important bat coronaviruses and henipaviruses which fill critical gaps in global phylogenetic trees. Additionally, we have work-in-progress characterizing novel picornaviruses and astroviruses from these bats, as well.

 5. **Conservation biology:** Finally, my work has helped shape an understanding of population viability for threatened taxa, mostly with a Madagascar focus. My early work demonstrated the life history traits that predispose threatened Malagasy lemurs to extinction or survival, highlighting the critical influence of the age of first reproduction and the adult lemur survival rate across each interbirth interval in safeguarding species into the future. Later studies recapitulated some of these predictions for Malagasy fruit bats, highlighting extreme population vulnerability in threatened *Pteropus rufus*, while others still demonstrated a role for population resilience to hunting pressure in rapidly-reproducing tenrecs.

SPECIFIC AIMS

Serosurveillance provides powerful measures of the infectome of wildlife and humans that can shed light on the disease ecology of zoonotic viruses. Yet **serological data is plagued with ambiguities that limit our ability to use it to identify zoonotic reservoirs or identify populations at risk from exposure to emerging viruses**. For example, the wildlife source of Ebola virus (EBOV), a continued ~~source~~cause of deadly outbreaks, has eluded researchers since the 1970s. Molecular surveillance has yielded extremely few detections, but serology paints a muddled picture as EBOV antisera are extensively cross-reactive with antigens from other filoviruses. Human seroprevalence estimates vary widely and positive EBOV detections in wildlife hosts are not distinguishable signals of other known or uncharacterized related filoviruses. Similarly, Nipah virus (NiV) a zoonotic henipavirus that has caused repeated outbreaks in Malaysia, Bangladesh and India with fatality rates greater than 70%, has a known host in flying foxes. Yet many other reservoir species test positive for NiV ~~antibodies~~ without neutralization or molecular confirmation. ~~Further, recent expansion description of of known henipaviral diversitys, such as~~ Langya virus in acutely ill patients and shrews, suggests ~~these serologic signals are footprints of other, the serologic footprints of~~ potentially zoonotic henipaviruses ~~have gone unnoticed by current serological testing strategies~~.

Our previous work has developed native-like antigens of filoviruses and henipaviruses for multiplex microsphere-based immunoassays, detected those viruses in humans and wildlife hosts, and used these data to model the circulation of zoonotic disease in wildlife and humans. **We propose to extend our methods into new laboratory and statistical techniques that can definitively identify the species of viruses from through serology, antibodies and characterize the properties and epidemiology of novel viruses only detectable by their antigenic signals — shadow viruses shadows.**

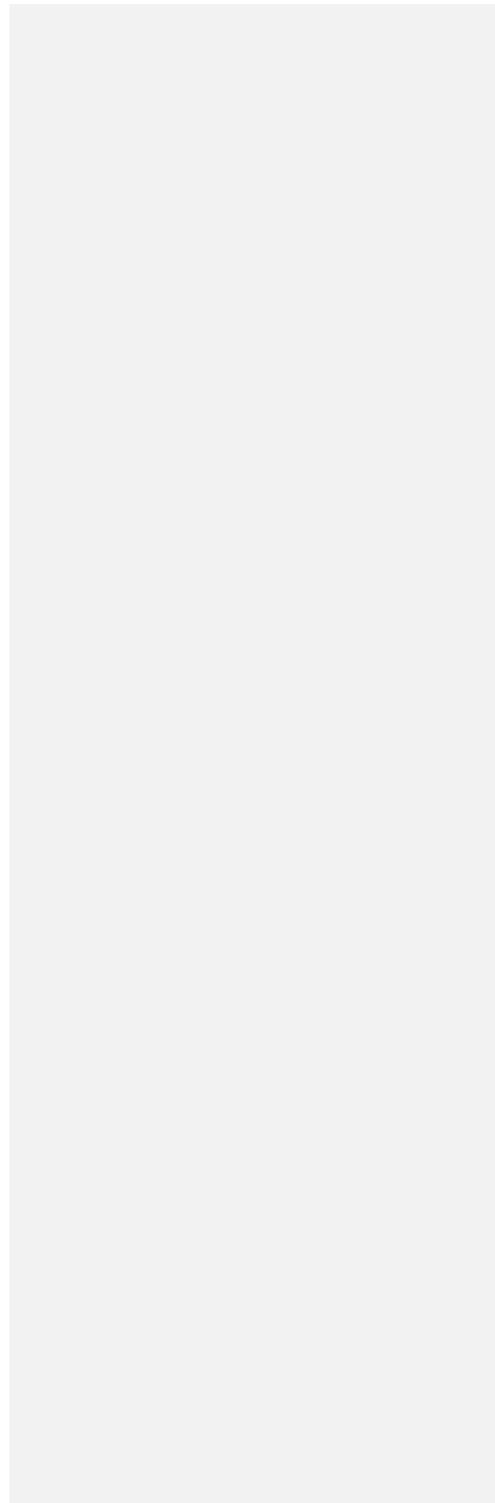

Our specific aims are to:

1. **Create multiplex serological panels optimized for discovery and characterization of novel viruses.** We will generate serological discovery panels of native-like filovirus and henipavirus proteins with mixtures of sensitive and specific antibody binding properties that collectively can distinguish between the signatures of target ed known viruses and unknown shadow virus shadows in antisera. We will measure their cross-reactive properties via experimental immunizations, including the effects of repeat exposure and multiple-virus interactions. We will test consistency of results in model organisms against reference sera for humans (NiV, EBOV, Marburg virus) and sera collected from bat species with serological profiles consistent with exposure to wild type samples with known specific serologic exposure to select viruses (NiV, Bundibugyo virus), yet the authenticity of this specificity being unclear, and that are reactive despite highly unlikely exposure.
2. **Develop novel statistical methods to extract viral signatures from discovery panel data and integrate rich multidimensional serology into epidemiology.** Will extend *spectral mixture* methods from image analysis to develop statistical models that use discovery panel data to disentangle the signals of multiple viruses and extract the antigenic signature of shadow viruses as well as quantify immune response. We will measure the discriminatory power of our models via simulation and validate them via a leave-one-out strategy, testing if we can identify viruses omitted from our panels. We will integrate these methods with cross-scale immuno-epidemiological models, improving the accuracy and precision of both individual- and population-level serology measures.
3. **Apply these methods to characterize novel and emerging viruses and their epidemiology in wildlife and humans.** We have identified wildlife and human populations demonstrating exposure to potentially novel but indeterminate filoviruses and henipaviruses. **This work will leverage investment from active NIH and DTRA-BTRP surveillance projects** in South Africa, Thailand, and Bangladesh by further testing and analyzing samples from these projects under our new protocols to antigenically characterize sera and distinguish known viruses from shadow viruses. We will use our cross-scale epidemiological models to determine the risk factors and spatiotemporal patterns of exposure and host-level immunological response to identify reservoirs and likely exposure interfaces.

This work has broad significance, addressing NIAID's Pandemic Preparedness Plan priorities of immunology and assay development, reagents and resources, and epidemiology and pathogen discovery.

RESEARCH STRATEGY

I. SIGNIFICANCE

Estimates of the cost of global virus discovery range in the billions of dollars [1]. One driving factor is the exceedingly low detection rate of viruses of concern, especially those in the *Ebolavirus*, *Marburgvirus*, and *Henipavirus* genera. The wildlife hosts of Ebola virus (EBOV), a continued source of deadly outbreaks in West and Central Africa, have eluded researchers since the 1970s despite considerable effort. In 2005, EBOV RNA was detected in three bat species [2]. Then in 2019 the USAID-funded Ebola Host Project sampled over 45,000 specimens from 10,000 bats discovering the complete genome of one novel ebolavirus (Bombali virus, BOMV), and a one-fifth genome of EBOV [3]. Wildlife reservoirs for related ebolaviruses, Sudan virus (SUDV), Bundibugyo (BDBV) virus, and Tai Forest virus (TAFV), have not been identified. Nipah virus (NiV), a zoonotic henipavirus that has caused repeated outbreaks in Malaysia, Bangladesh and India with fatality rates greater than 70% responsible for annual outbreak of fatal encephalitis in Bangladesh and southern India with some outbreak fatalities exceeding 90% [4-7], is known to circulate in flying foxes (*Pteropus* spp.). Even in a flying fox colony with known circulation, estimates of viremia are <2%, and a study of 3,600 bats over five years, including a period where an outbreak occurred, yielded only eight molecular detections [8]. The recent discovery of Langya virus (LayV) in patients with acute febrile illness and shrews in eastern China [9], indicates that unknown and undetected henipaviruses are also a global health concern [10].

In contrast to molecular surveillance, targeted and broad **serology can provide a more cost-effective approach to detecting emerging viruses in wildlife hosts and humans, and to measuring exposure rates** to identify at-risk populations [11-13]. Viral shedding occurs over a short window, with most shedding often occurring over a period of only days, while viral antibodies can last the lifetime of an organism. In the study of NiV circulation above, 3020% of individuals had NiV antibodies, and NiV seropositivity ranges from 11-40% across populations and species of flying foxes in South and Southeast Asia [PMID: 33139552, PMID: 31855143, PMID: 34218820, ERIC cite]. Using the adaptive humoral memory to indirectly measure prior infection and **identifying the serologic footprints left behind after virus infections has the potential to vastly improve our understanding of zoonotic virus diversity, distributions, and dynamics.**

Since serology is an indirect measurement of virus infection, wildlife and human zoonotic virus **serosurveillance faces limitations in the interpretation of data**, especially when attempting to identify natural hosts of viruses [14]. Expected and unexpected **antibody cross reactions frequently confound conclusions from single-antigen assays**. EBOV-positive antisera is extensively cross-reactive with protein antigens from heterotypic ebolaviruses [15]. Antisera from survivors infected with EBOV, BDBV, and RESTV is highly cross-reactive with heterotypic virus antigens; furthermore, RESTV antisera preferentially interacted with EBOV antigens [16]. This is likely the reason for many bewildering serologic observations: seroprevalence for EBOV was found in humans without a history of Ebola Virus Disease (EVD) [17]. In non-outbreak settings people who had contact with wildlife were found seropositive or indeterminate against EBOV, SUDV, BDBV [18, 19]. Community health volunteers with indirect contact of EVD patients were also ebolavirus seropositive [20]. Bush meat hunters sampled in Guinea had serologic evidence of infection by ebolaviruses, but seropositivity was detected by measuring immunoreactivity against several antigens and neutralization tests [21]. It is unclear whether assay performance are sensitive or specific enough to draw meaningful conclusions on the role of wildlife contact on human EBOV seropositivity. Antigen-based serosurveillance studies of fruit bats have also yielded ambiguous conclusions about wildlife reservoir statuses [22-24]. With >1200 species of bats and an unknown diversity of uncharacterized filoviruses the challenges of distinguishing EBOV-positive antisera from other ebolaviruses is daunting.

Similar challenges impede serosurveillance of henipaviruses. Since 1999, NiV surveillance has remained a top priority in south and southeast Asia. After the first documented cases of NiV emergence in Peninsular Malaysia, and an understanding of the factors that lead to transmission to humans [25, 26], government regulations on agricultural practices have limited further spillovers in Malaysia. The current epicenter of NiV disease is a region in western Bangladesh termed the *Nipah Belt*, where annual outbreaks are linked to the consumption of NiV contaminated unpasteurized date palm sap [27]. Flying foxes (*Pteropus* spp.)

Formatted: Not Highlight

Formatted: Highlight

are considered the wildlife reservoirs of NiV, and in south and southeast Asia, NiV has been detected and isolated from many species of pteropodid bats sampled in India, Bangladesh, Malaysia, Cambodia, and Thailand [28-33]. Despite isolation of NiV from flying foxes, detection of neutralizing NiV neutralizing antibodies, and experimental challenge models of NiV in flying foxes to confirm reservoir status, other bats across Asia test seropositive for NiV and their role in inter-species transmission remains unclear [34-36]. Rousettes and mouse-eared bats collected in China, Vietnam, and Kerala, India tested seropositive for NiV via a combination of nucleocapsid protein (NP), envelope receptor-binding glycoprotein (RBP) and cell lysate ELISA, but tested negative via neutralization tests. [37-39]. It is unclear whether seropositivity in these rousette bats is a factor of sensitivity and specificity issues with the immunoassay or the presence of another similar henipavirus. In sub-Saharan Africa, NiV-like neutralizing antibodies were detected in pigs in Ghana and Uganda, [40, 41] and humans sampled in Cameroon [42]. Genomic assemblages of two henipaviruses, Ghana virus and Angavokeely virus, were detected in closely related fruit bat species (genus *Eidolon*) [43, 44]. Recently ~~found~~ we found we genetic evidence of novel henipaviruses detected in Egyptian rousette bats [45], which adds to conclusions that rousette bats may be in fact harboring henipaviruses that cross-react with single antigen NiV ELISA.

Serology is also dependent on the quality and qualification of protein antigen. The Ebola virus envelope attachment glycoprotein (GP), ~~nucleocapsid protein (NP)~~, and matrix protein (VP40) have been utilized by several groups in antigen-based serology PMID: 2948188, PMID: 34748613, PMID: 33827978 [ERIC cite]. In one longitudinal study of Ebola virus disease survivors, seroconversion against GP and VP40 IgG occurred at XX/XX%, respectively, increased with days post-infection along with affinity maturation of GP-positive B cells [PMID: 32053790] [ERIC cite]. However, studies that detail the frequency of seroconversion against the the nucleocapsid protein (NP) after EBOV infection, or the frequency of seroconversion against GP, VP40, and NP with non-EBOV ebolaviruses have not been verified.

Most statistical approaches to interpreting serosurveillance data are limited to single antigen analysis and unrealistically simple models of host immunology and epidemiology. The state of the art approach to dealing with serological assay data in wildlife or with viruses without standardized controls has been clustering approaches [46] that assume seropositive and seronegative individuals separate into two distinct groups by a threshold antibody titer. Yet most real data is far less distinct, due a mix of processes including cross reactions, host heterogeneity, and antibody waning and nonlinearities in the physio-chemical processes of antibody assays [47] (Figure HOTEL). More sophisticated multi-antigen, multiplex, analyses [48] can account for cross reactions to distinguish amongst known viruses, but **fundamentally current serological laboratory and statistical approaches are not designed to deal with the challenges of detecting and characterizing novel viruses.**

The major goal of this proposal is to dramatically improve the utility of antigen-based serosurveillance for new viral discovery and epidemiology of emerging zoonotic diseases by addressing the challenges of cross-reaction and statistical rigor. We will create *discovery panels* - qualified and optimized panels of multiplexed immunoassays designed to detect and characterize shadow viruses, and distinguish known from novel viruses through mixtures of sensitive and specific binding properties. (Aim 1). We will develop new statistical approaches to extract the signals of novel viruses from those of known viruses or mixtures of multiple previous viral exposures, as well as integrating quantitative measures of immune response into epidemiological models (Aim 2). Finally, we will apply these techniques to identifying and characterizing filoviruses and henipaviruses in bat populations in South Africa and at-risk human populations in Thailand, and capturing immune-epidemiological dynamics of Nipah virus V circulation in Bangladesh (Aim 3).

This work has broad significance, addressing NIAID's Pandemic Preparedness Plan priorities of immunology and assay development, reagents and resources, and epidemiology and pathogen discovery. It will produce biological resources, published protocols, and reusable statistical software to enable the rapid dissemination and adoption of these methods.

Commented [EL2]: This is repeated from the Specific Aims.

II. INNOVATION

We propose a unique and innovative approach to characterizing antibodies induced by prior infections to discover the signals of novel viruses – *shadow viruses* – in wildlife and human hosts through antigen-based multiplex serology. While serology is an increasingly common technique in viral surveillance, multiplex panels have hitherto been composed of several proteins each designed specifically to bind antibodies of individual antigens, optimizing for specificity to individual viruses. We will instead design and test *discovery panels* composed of proteins with a mixture of sensitivities and specificities to a range of viral antigens within a family. This will simultaneously cover *antigenic space*, enabling detection of previously unknown viruses, and enable definitively ruling out or confirming the signal of known pathogens via their unique *antigenic signatures*. We will build these panels on a multiplex microsphere-based immunoassays (MMIA) platform [ERIC cite]. This enables cost-effective testing of dozens of antigens simultaneously and is easily updated with new reagents. We have successfully deployed this assay in laboratories for surveillance projects in low resource environments [PMID: 32034942, PMID: 31671094, PMID: 29260678] [ERIC cite]. Through the multiplex discovery approach, we can achieve accuracy far more readily adoptable than low-throughput panels such as indirect ELISA

[48], or neutralization tests requiring containment and virus isolates or verified pseudovirus systems.

We further innovate by adapting statistical methods from image-processing – nonlinear spectral unmixing models, implemented in a Bayesian framework [49-51] – to analyze multiplex serological data as joint rather than individual response signals. This flexible approach allows us to incorporate nonlinearities in the interaction of viruses and antigens, as well as those introduced in the physiochemical processes of the assay. It will enable us to disambiguate data that could represent a variety of exposure histories, including exposure to multiple viruses, known viruses with cross-reactions to multiple antigens, or novel viruses with an intermediate antigenic profile between known viruses, assigning probabilities to each hypothesis. This framework is applicable to serological methods beyond MMIA such quantitative LFIA and ELISA, as well as large-scale peptide multiplexing via PhIP-seq [52], which currently lacks unifying computational or analytical frameworks [53].

We will integrate our statistical framework with population-level epidemiological models to capture cross-scale immunological patterns and dynamics. The dominant threshold-based approach to seroepidemiology determines serostatus at the individual level from antibody titer or assay response, then describes population-level patterns as frequencies of seronegative/positive states. This discards the rich quantitative information on antibody levels and the role of processes such as individual immune variation, antibody waning, and inheritance that can be informative of population processes. By linking the estimation of individual- and population-level quantities, we increase the accuracy and precision of both. We will develop cross-scale statistical models that model individuals' complex binary and continuous immune state, and jointly model the variation of this complex serostatus across time, space, and groupings (species, populations, and demographic groups).

Finally, this proposal leverages active federal investments in global viral surveillance programs by partnering with them to rapidly validate these techniques. We will partner with an NIH Centers for Research in Emerging Infectious Disease (CREID) study of high wildlife-contact individuals in Thailand, a DTRA Biological Threat Reduction Program survey of bat virus diversity in Southern Africa, and an NIH NIAID research program on Nipah virus circulation and spillover in Bangladesh. In each, serosurveillance

Terms

shadow virus: a novel or unidentified virus only detected in a population via serology of infected individuals

discovery panel: a multiplexed immunoassay designed to detect shadow viruses and distinguish them from known viruses

antigenic space: the phenotypic range of antigens of known and unknown viruses in a family

antigenic signature: a combination of responses of an antiserum against a panel of antigens that identifies a virus

reaction/cross reaction matrix: the full combination of response curves of all antisera to all antigens in a multiplexed immunoassay

cross-binding interaction: the change in response of antisera to an antigen in the presence of another antigen due to preferential binding

has generated preliminary but ambiguous evidence of novel virus circulation. We will test archived samples to corroborate these data and characterize the suspected shadow viruses and their epidemiology.

III. APPROACH

RESEARCH TEAM AND MANAGEMENT

We have assembled a team with a unique combination of laboratory, analytic, and field expertise and a history of successful collaboration in zoonotic disease surveillance. Project PIs Laing and Ross are early-stage investigators with methodological expertise on laboratory and statistical methods for serological analysis, respectively. Other Co-Investigators lead viral discovery surveillance projects across Bangladesh (Epstein), Southern Africa (Markotter, Epstein), and Southeast Asia (Wacharapluesadee). PI Laing and other significant contributor (OSC), Brook, are collaborators on other surveillance projects; and OSC Munster is an established lab chief with a history of collaboration and whose research interests in virus ecology align with project PIs Laing and Ross.

The PIs began working together in 2017 on a project titled, Serological Biosurveillance for Spillover of Henipaviruses and Filoviruses at Agricultural and Hunting Human-Animal Interfaces in Peninsular Malaysia (HDTRA11710037). Both PIs remain respective methodological experts for active surveillance projects, Biosurveillance for Viral Zoonoses around Bat-Livestock-Human interfaces in Southern Africa (HDTRA12010025), and CREID EID-SEARCH.

We have designed our program so that laboratory and mathematical methods development are complementary but can proceed independently. Each benefit from data and innovations of the other. Statistical innovations enhance interpretation of discovery panel data and the data in turn can be used to parameterize and increase power of statistical techniques. However, we will be able to make progress on both in parallel, test their success on their own terms and apply outputs to the surveillance studies even if their success and completion time differ.

See the **MULTIPLE PD/PI LEADERSHIP PLAN** for additional team and project management detail.

AIM 1: OPTIMIZATION OF ANTIGEN-BASED MULTIPLEX SEROLOGY FOR DISCOVERY AND DETECTION

We have developed expressed, and purified envelope attachment glycoprotein (GP) of filoviruses GP and envelope receptor binding glycoprotein (RBP) of henipaviruses RBP antigens inexpressed in mammalian cell culture systems as native-like ectodomain trimers and tetramers, respectively, retaining conformation-dependent epitopes [54-58]. We have used these antigens to create MMIA focused on the detection of presently described ebolaviruses, marburgviruses, and henipaviruses. These have been successfully transferred to laboratories globally and used in completed and ongoing biosurveillance projects including DARPA PREEMPT, our CREID center EID-SEARCH (Co-I Wacharapluesadee), our DTRA BTRP-funded project in southern Africa at the University of Pretoria (Co-I Markotter), and for collaborative projects with OSCs Munster and Brook. Through these projects, these panels have been used to identify wildlife hosts of filoviruses and henipaviruses, and detect evidence of prior infection of high-risk human populations [59, 60]. The panels are continually expanding with each novel virus discovery, e.g., Bombali-virusBOMV and Langya-virusyV. However, without standardized protein antigens for antigen-based serosurveillance and sera standards for each virus, demonstrating specificity in wildlife reservoirs and human populations without outbreak histories remains a challenge. When screening samples collected from wildlife, it remains unclear if we are capturing antibodies induced by known virus infections or by antigenically related uncharacterized viruses. Here, we propose a strategy to overcome this fundamental limitation.

Designing the discovery panel with a two-protein approach

Preliminary Data: Cross reaction among filoviruses and henipaviruses. Antibodies induced by ebolavirus infections are cross-reactive with GP antigens, likely the result/result of several contributing factors such as amino acid sequence similarity, conserved epitoposepitopes, and glycoglycoepitoposepitopes or glycosylations in the glycan gap and mucin-like domain [61, 62]. Previous groups have attempted to distinguish homotypic and heterotypic known ebolavirus IgG binding to GP antigens by performing multiple ELISAs for each known ebolavirus [48]. This technique conferred specificity but at a great cost to throughput, and has unclear applications for the detection of unknown ebolaviruses.

Formatted: English (United States)

Commented [EL3]: Do we need a 3 panel figure to show the varying processes occurring, I don't know if there's space but I'll work on it more tomorrow.

In our GPe-based MMIA, the WHO EBOV antibody standard reacted equally against both EBOV and BDBV GPe antigens (Figure FOXTROT A).

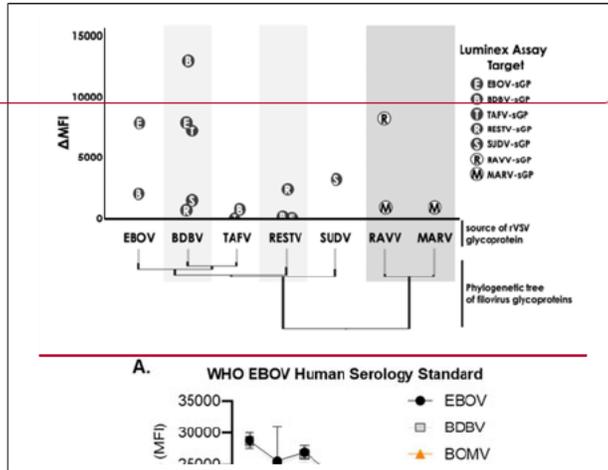

Although ebolavirus antisera are cross-reactive with heterotypic ebolaviruses, through a GPe-based multiplex approach we have been able to specifically identify the homotypic infecting ebolavirus after a single infection by a VSV-filoGP in a bat infection model despite observable cross reactions (preliminary data, not shown Figure 1). This indicated that pooled polyclonal antisera from human EVD survivors may include more cross-reactive antibodies than those generated after single infections in a putative wildlife host. Further, preliminary data from polyclonal antisera from rabbits hyperimmunized with EBOV GPe

corroborated data with the WHO EBOV serology standard that EBOV and BDBV specific antibodies are cross-reactive with GPe trimers, though preferential binding to the homotypic EBOV antigen was noted. However, the GP1 subunit protein improved specificity (Figure FOXTROT B Figure 2B).

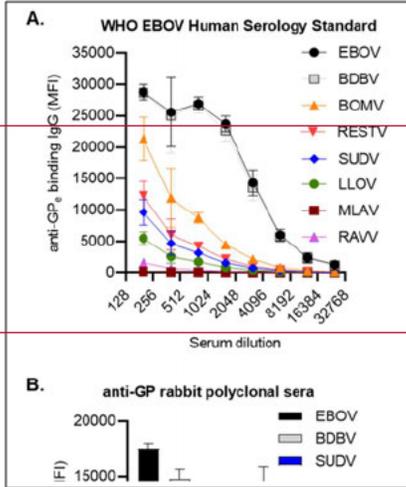

Cross-reaction among the other henipaviruses is less described. HeV antisera is known to display a fair degree of cross-reaction with NiV, however the inverse does not hold true. [PMID: 18556094, PMID: 22875827 CITE]. We have examined henipavirus cross-reactivity with polyclonal antisera from rabbits hyperimmunized with recombinant sGtet protein antigens and observed little cross-reactivity outside of HeV-positive antisera with NiV G (Figure CHARLIE Figure 3).

Approach: Protein development. Here, we propose to design antigen-based discovery panels that can distinguish between targeted and cross-reactive signals using a two-protein approach, selecting a highly specific (GP1) and a broadly sensitive (GPe trimer) antigen for each filovirus in the panel. This approach draws from our successful approach to large-scale COVID-19 serosurveillance, which used SARS-CoV S glycoprotein expressed as a trimeric prefusion stabilized spike ectodomain and a monomeric receptor-binding domain antigens, providing an optimal balance of assay sensitivity and specificity. We note this indicates that a similar strategy to succeed for surveillance and discovery of novel and zoonotic coronaviruses in the future.

Thus, our two-protein panel approach requires a sensitive protein antigen that could be the cross-reactive target for antibodies induced by shadow henipaviruses. Since the henipavirus RBP provides the specific antigen, we plan to develop the soluble native-like trimeric fusion (F) glycoproteins into the sensitive antigen. HeV and CedV RBP share ~2330% sequence identity while the F proteins share ~44% amino acid expressed, and purified and has been extensively studied as a target for monoclonal antibodies [57, 63-65]. In its role to mediate virus-cellular fusion, these F proteins share higher sequence identity and similarity across henipaviruses than the RBP sequence identity. The F protein has been similarly

Formatted: Font: Not Bold

Field Code Changed

designed. sequence identity. The F protein has been similarly designed, expressed, and purified and has been extensively studied as a target for monoclonal antibodies [57, 63-65]. In its role to mediate virus cellular fusion, these proteins share higher sequence identity and similarity across henipaviruses than the RBP. Thus, we plan to explore the ability of the henipavirus F protein as to function as a sensitive antigen for antigenic discovery of novel henipaviruses. We will develop GPe/GP1 antigen pairs for each of the filoviruses and RBP/F antigens comprising the range of currently known mammalian filoviruses and henipaviruses (Table ALPHA).

Filoviruses	Sensitive antigen	Specific antigen
Ebola-virus (EBOV)	GPe (trimer)	GP1-subunit
Bundibugyo-virus (BDBV)	GPe (trimer)	GP1-subunit
Tai Forest-virus (TAFV)	GPe (trimer)	GP1-subunit
Bombali-virus (BOMV)	GPe (trimer)	GP1-subunit
Gudon-virus (GUDV)	GPe (trimer)	GP1-subunit
Reston-virus (RESTV)	GPe (trimer)	GP1-subunit
Morburg-virus (MARV)	GPe (trimer)	GP1-subunit
Ravn-virus (RAVV)	GPe (trimer)	GP1-subunit
Lloviu-virus (LLOV)	GPe (trimer)	GP1-subunit
Mengla-virus (MLLV)	GPe (trimer)	GP1-subunit
Henipaviruses		
Hendra-virus (HeV)	RBP (tetramer)	F (trimer)
Nipah-virus (NiV)	RBP (tetramer)	F (trimer)
Cedar-virus (CedV)	RBP (tetramer)	F (trimer)
Ghana-virus (GhV)	RBP (tetramer)	F (trimer)
Angvokely-virus (AngV)	RBP (tetramer)	F (trimer)
Mejiang-virus (MejV)	RBP (tetramer)	F (trimer)
Lanyang-virus (LayV)	RBP (tetramer)	F (trimer)
Gomel-virus (GomV)	RBP (tetramer)	F (trimer)
Deeryang-virus (DerV)	RBP (tetramer)	F (trimer)

Commented [GU4]: I think this is too big of table and eats up space. maybe I can summarize this as a sentence or have i covered the 2 antigen approach enough?

Commented [NR5R4]: We are one page over right now so that's probably the way to go. It would be good to do this in maybe a four line table? One listing files, one listing henipas, One line for each of the two multiple interaction groups? Each saying 3 rabbits, 3 bleeds.... If you think it's all clear in the text that's fine, but this might be just as compact.

Formatted: Space Before: 6 pt

Formatted: Space Before: 6 pt

Approach: Quantifying cross-reactions: To optimize a discovery panel for discovery and detection, we first need to fully qualify the pairwise cross-reactions amongst proteins, generating a comprehensive reaction/cross reaction matrix via protein immunization experiments in rabbits. This will establish and qualify (a) the homotypic virus reactivity, (b) heterotypic cross-reactivity across other viruses in the family, and (c) how multiple immunogen exposures shape homotypic antigen binding and the cross-reactive breadth against heterotypic viruses. Since wildlife reservoirs are naturally exposed to these viruses throughout their lives, repeated exposures shape the magnitude, durability, and breadth of humoral responses. Data from (c) will support use be used to estimate time-from-infection and antigenic-relatedness. Using our filovirus GPe antigens and henipavirus RBP & F antigens, we will sequentially immunize rabbits (n = 3 rabbits per virus antigen) with up to two immunogen boosts (100 µg of protein antigen per injection), and whole blood will be collected 21 days after each immunization; followed by a terminal bleed after 84 days.

Sera will be tested against all antigens within the panel at a range of dilutions to find the optimal dilution factors within the range of the linear slope of the MMIA median fluorescence intensity (MFI) output signal. For the prototypical viruses, EBOV, NiV, and MARV, we will include WHO human serology standards developed by the National Institute for Standards and Control for interpolations of MFI into IgG concentrations. For each pair in the matrix, we will quantify cross-reaction by fitting logistic functions to the reactivity vs (log) dilution and estimating the slope parameter as the measure of reaction. Utilizing MFI values from optimal dilution factors, we will apply antigenic mapping [66], projecting the heterotypic cross-reactivity matrix into *antigenic space* for both filoviruses and henipaviruses, separately for the *specific* (GP1/RBP) and *sensitive* (GPe/F) antigen of each virus. We expect the mappings of sensitive antigens, e.g., filo GPe and henipa F, to cluster closely together and for some closely related viruses to broadly overlap as serogroups in antigenic space, while specific antigens, e.g., filo GP1 and henipa G will not. Gaps in antigenic space will indicate areas unlikely to be detected by the panel, while overlaps from specific antigens will indicate likely ambiguities. The *antigenic signature* data of viruses will serve as priors for our statistical models (Aim 2).

Determining how virus interactions shape antigenic signatures

The wildlife reservoirs of EBOV, BDBV, TAFV, and SUDV remain unknown. Outbreaks of Ebola-virus disease EVD caused by EBOV, SUDV, and BDBV have all occurred either in the Democratic Republic of Congo or nearby in Sudan and Uganda. The close spatial relationships of these outbreaks suggest the possibility that these viruses may co-circulate in certain bat species, populations, or multi-host communities. Furthermore, the degree of antigen-specific cross reactions between EBOV, BDBV, SUDV, TAFV may confound current serologic testing studies that rely on a single antigen or only investigate EBOV immunoreactivity. Thus, antibodies induced by BDBV or TAFV infections may seemingly be interpreted as evidence of prior EBOV infections. We aim to determine separate three distinct scenarios that may shape serological profiles, **(a) exposure to one virus and cross-reaction with the second, (b) independent exposures to both viruses, or (c) exposure to a third, uncharacterized virus with cross-reaction to both viruses.**

Approach: Multiple Immunization: As described above, we will sequentially immunize a-sets of rabbits with a GPe against-antigens from EBOV, BDBV, and TAFV; or BDBV and SUDV, two-viruses from the same family to simulate multiple exposures, determine the additivity of spectral signatures, and test our ability to extract theis signature of each via our statistical models (Aim 2). For example, rabbits will be first immunized with BDBV GPe (100 µg) then EBOV GPe (100 µg), EBOV then BDBV, or TAFV then EBOV. The immunization pairings simulate hypotheses of common circulation in wildlife such as ambiguous EBOV and BDBV serologies, and overlapping EVD outbreak regions where BDBV and SUDV are known to circulate. fe...

We will apply a similar approach to address these three scenarios for henipaviruses, focusing on the more recently described rodent-associated henipaviruses. Mojjiang virus (MojV)V was detected in the southern province of Yunnan, China, whereas LayV has been detected in easstern Shangdong and Henan provinces. Reports of shrew-associated henipaviruses in South Korea, Gamak virus and Daeryong virus, have contributed to an expansion of rodent-associated henipaviruses discovered since 2020. In Thailand we have detected serologic evidence infection by a MojV-like henipavirus (see Aim 3). As the field does not yet understand the antigenic-relationships among these rodent-associated henipaviruses we cannot confidently interpret serologic evidence of MojV-like in Southeast Asia. Thus, similar to the experiments described for the ebolaviruses, we will sequentially immunize rabbits with multiple Asiatic rodent-henipaviruses to examine how imprinted antibody memory and heterologous boosting shapes reaction and cross reactions to homotypic and heterotypic ebolavirus GPe and GP1, and henipavirus RBP and F antigens. The effects of heterologous boosts will be utilized to refine antigenic shape modeling in Aim 2.;

Approach: Measuring Cross-Binding Interactions: Antigen-antibody binding is context-dependent; the degree of binding may vary due to the presence of other antigens to which antibodies exhibit preferential binding. - We will measure the extent of this *cross-binding interaction* by conducting *in vitro* "leave-one-out" assays, where the virus-specific antigens matching each antiserum (both specific and sensitive), are removed from the panel and only-forcing only cross-reactions can-to occur. This simulates the detection conditions-of antibodies to-induced previously by uncharacterized viruses – shadow viruses – in the

Commented [EL6]: Noam – read over this.

Formatted: Not Highlight

Formatted: Not Highlight

Commented [EL7]: Noam....

antisera. We will measure the difference in cross-reaction strength **in the presence and absence of the with and without the** target antigen, and determine the dilution levels that minimize this effect.

Approach: Testing consistency in non-model organisms: To further test the consistency of cross-binding interactions beyond our **rabbit animal models organisms**, we will also conduct leave-one-out experiments **with** wild-type sera collected **from** bats and WHO polyclonal reference sera **for EBOV, MARV, and NiV**. Through a collaboration with Dr. Vincent Munster (~~other significant contributor~~, OSC; see Letter of Support), we identified BDBV-like ebolavirus immunoreactivity in populations of hammer-headed fruit bats (unpublished data). Hammer-headed fruit bats have been cited as putative EBOV reservoirs [PMID: 17848072, PMID: 31574111], yet in our GPe-based MMIA we detected greater immunoreactivity to BDBV. The distribution of these bats in southern Uganda is consistent with BDBV-driven EVD outbreaks. In addition, through ongoing research with Dr. Cara Brook (OSC; see Letter of Support), we identified 16% seroprevalence for a BDBV-like ebolavirus in populations of Madagascan rousette bats (Figure 5 ECHO). The result was surprising for two reasons, a) rousette bats are a reservoir of marburgviruses, not ebolaviruses [PMID: 19649327, PMID: 33219802] and b) Madagascar is >2500 km from Uganda where all confirmed BDBV outbreaks have been reported [PMID: 34467242, PMID: 21122234, PMID: 25910637].

These two bat species do not share overlapping geographic distribution, so how do we interpret seemingly similar serological profiles suggesting BDBV circulation? We propose to test the hammer-headed fruit bat and Madagascan rousette bat sera in multiplexes that leave-out the BDBV GP antigens, and to examine how the polyclonal antibodies shift binding patterns to other ebolavirus GP antigens. These shifts in serological profiles in the absence of BDBV GP antigens will be compared to the cross-reaction data established by the protein immunized rabbit antisera standards. We expect that the hammer-headed fruit bat sera would increase preferential binding to EBOV GP in the absence of BDBV GP, consistent with phylogenetic data, providing compelling data that these bats have a high probability of hosting BDBV. Whereas we may expect the Madagascan rousette bat sera to bind to ebolavirus GP in serologic pattern that was not predicted in polyclonal rabbit antisera standards. We anticipate that unexpected serological profiles, which break the ~~serological~~ standards, will help us to identify unique clusters of serogroups that would indicate unknown ebolaviruses.

Risks, limitations, and mitigating factors

We have proposed to establish antibody responses and antisera cross reactions via protein immunization and rabbits as our animal model. In the absence of WHO serology standard for all ebola-, marburg-, and henipaviruses, the development of antigen immunized rabbit polyclonal standards is a feasible goal. The uniqueness of the bat immune response among mammals has been an area of research interest for over a decade. The growing body of literature suggests that bats as an Order may have a uniquely adapted immune response including dampened inflammatory responses, and heavily favored innate immunity [67-70]. Thus, there may be distinctions unique to the bat humoral response to viral infections that we will not be reflected by protein immunizations in a rabbit model. However, outside of immunoglobulin (Ig) repertoire sequencing [PMID: 20816694, PMID: 20162414], the adaptive response has been less readily investigated, and questions about the functional role of cellular and humoral immunity for viral infection control remains. From field-collected bat sera, we observe robust virus-specific IgG responses, and do anticipate that conservation of humoral responses between rabbits and bats will reflect our ability to accurately determine serogroups through antigenic cartography. Further, we can verify selected rabbit-protein immunization results in a nascent bat infectious disease model being developed by **application OSC, Dr. Vincent Munster, r (see Letter of Support)-W-e** We have previously collaborated with Dr. Munster to investigate whether we can differentiate homotypic and heterotypic ebolavirus antibodies collected from captive Egyptian fruit bats experimentally infected with replication-competent vesicular stomatitis viruses expressing transmembrane bound ebola- and marburgvirus GP (Figure MIKE1).

AIM 2: NOVEL STATISTICAL MODELS FOR MULTIPLEX SEROLOGICAL ASSAYS

Preliminary data: We and others have used clustering approaches [46] to establish virus-specific seropositivity thresholds relying on our knowledge of confirmed virus-host interactions [8, 60, 71, 72]. However, we find that in many cases the required assumptions of this approach – that individuals separate out into distinct positive and negative groups, and that clusters conform to expected, usually symmetric distributions – break down.

Rather, large numbers of antibody responses fall into an indeterminate range without distinct breaks, and nonlinear assay response breaks down expectations at the high and low end of the response range (Fig. Figure 6HOTEL).

As a result, many results, are classified as indeterminate or assigned a serostatus with high uncertainty. On the other hand, we have extended these cluster methods to multidimensional panel data and found that they are more successful at disentangling groups of sera by their ratio of response to different antigens, indicating the kind of antigenic response had distinct differences, while magnitude of response was a more continuous measure (Fig. BOBure 7). This initial work indicates that clustering can detect distinct signals of samples that react to viral antigens in different ratios, indicating exposure to different viruses in intermediate antigenic space between known filoviruses. However, these multidimensional models conflate two components of these data – distinct reaction ratios as signals of exposure to different viruses, and clustering of the strength of serological response between seropositive and seronegative individuals. We propose a new class of multidimensional models for serology panel data that take a mechanistic approach to representing these two processes, disentangling the different types of clustering and deal with their separate complexities

Detecting shadow viruses in panel data via antigenic signatures

Model structure: Our minimal model of serological mixing is

$$R_i = \sum_{j=1}^M f_{ij}(t_j) + \epsilon_{ij}$$

Here R_i , the response (measured in as the \log_{10} mean fluorescent intensity), is the sum of the responses f_{ij} of assay i against each antibody titer t_j that binds to the antigens presented on that assay, plus measurement error ϵ_{ij} , for all M antigens present in the sample. If the response curve f_{ij} is linear this model resembles that of Schuh [48], as well as the structure of approaches to signal extraction from remote sensing imagery [49]. but due to saturation of the biochemical or instrument response, it is typically sigmoidal.

Cross-binding interactions in the multiplex assay, where antigens in the same solution attract the same antibodies, modify the additive framework of the spectral mixing model. In the absence of these

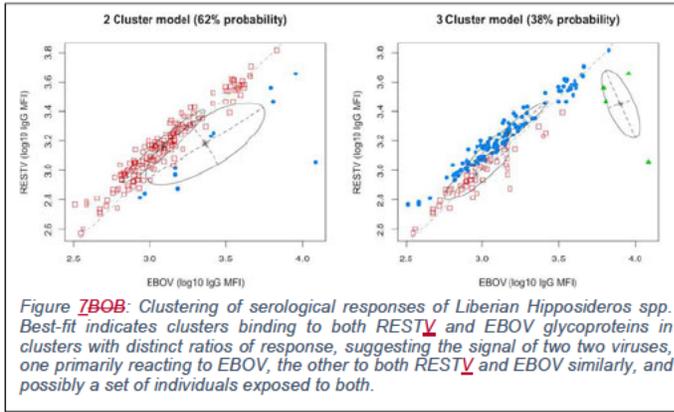

Figure 7BOB: Clustering of serological responses of Liberian *Hipposideros* spp. Best-fit indicates clusters binding to both RESTV and EBOV glycoproteins in clusters with distinct ratios of response, suggesting the signal of two viruses, one primarily reacting to EBOV, the other to both RESTV and EBOV similarly, and possibly a set of individuals exposed to both.

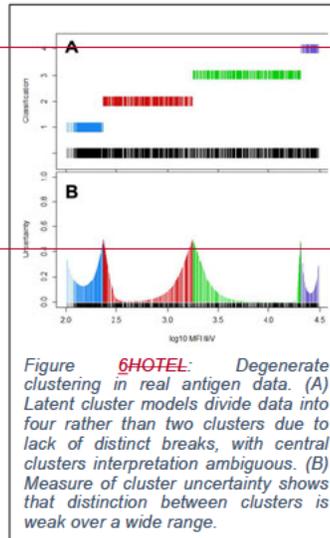

Figure 6HOTEL: Degenerate clustering in real antigen data. (A) Latent cluster models divide data into four rather than two clusters due to lack of distinct breaks, with central clusters interpretation ambiguous. (B) Measure of cluster uncertainty shows that distinction between clusters is weak over a wide range.

Formatted: Font: Not Italic

Formatted: Font: Not Italic

interactions, we could fully test the ability of the multiplex panel to identify the signal of a novel “shadow virus” *in silico* simply by removing the response data from one target antigen and determining if it could be identified via cross-reactions of antibodies against closely related viruses. However, with these interactions, the response of antigen j against antibody i depends on the presence of the other antigens present. We can decompose this effect in our model into the core titer-antibody-response function $f_{ij}(t_j)$ and an additional interaction term

$$R_i = \sum_{j=1}^J f_{ij}(t_j) + \sum_{j=1}^J \sum_{i=1}^I g_{ij}(t_i, t_j) + \varepsilon_{ij}$$

Fully estimating $g_{ij}(t_i, t_j)$, especially with nonlinearities in the response, would not be realistic. But nonlinear models from image processing provide reasonable approximations where these interactions take a set of reduced forms [50, 51]. Moreover, we can constrain the model with priors based on our experimental data. Our leave-one out experiments will estimate the size, consistency and linearity of the cross-binding interaction effects in both model and wild organisms and optimize our procedures to minimize it.

Experimental Approach: We will develop a Bayesian representation of this model and conduct simulation-based experiments to determine the conditions under which it can distinguish between different immunological conditions. We will test the ability to distinguish between a target virus and related shadow virus response as a function of antigenic distance, breadth of cross-reaction of both the target and shadow virus, sample and individual level variation, and sample size. We will use data from our challenge experiments to parameterize the models, initially using preliminary data so that we can conduct these aims in parallel. We will use the data from our experimental replicates to simulate sample-level variation and data from previous surveillance work (see Aim 3) to simulate individual variation in response within seropositive and seronegative groups. We will also simulate a range of scenarios for cross-reactive binding interactions, ranging from small, consistent effects to highly variable interactions amongst different viral pairings. We will conduct both *in silico* and *in vitro* validation tests to determine if the method can extract the antigenic signal of a shadow virus. We will create simulated leave-one-out tests by using data from our rabbit immunization experiments, with data from each virus in the panel removed in turn, and determine if the model identifies the signal of a non-target virus from cross-reactions alone. We will repeat this with the data from our *in vitro* leave-one-out experiments.

Cross-scale immuno-epidemiological modeling

Zoonotic serosurveillance, in wildlife and human populations, faces the challenge of a lack of controls. Surveillance requires testing many understudied host species, and by definition no standard controls can be created for novel viruses. Thus, standard cut-offs cannot be pre-determined and inference of individual immune states and population seroprevalence and risk factors is best conducted jointly, modeling individual serostatuses as continuous or probabilistic states informed by population measures.

Model structure: To build this cross-scale framework, we extend our mixing model above to the population scale. Titer t_j becomes t_{jk} , a sample k drawn from a population of individuals x . In this population with a seroprevalence $E(\omega_j)$, the distribution t_{jk} is a mixture of titer values ($F(\mu, \sigma)$) in both seronegative and seropositive individuals.

$$E(t_{jk}) \sim (1 - E(\omega_j))F(\mu_{j-}, \sigma_{j-}) + E(\omega_j)F(\mu_{j+}, \sigma_{j+})$$

Both the individual probability of seropositivity ω_{jk} and the distributions $F()$ of seronegative and seropositive distributions are affected by host traits, infectious dosage, and environmental factors. Immunological state has both binary (serostatus) and continuous (antigen-reactive IgG levels, concentrationstiter) components that are intertwined. In the simple case assuming $F()$ are normal distributions and those traits and risk factors have linear effects, these can be represented as the relationships

$$\rho \sim \text{Probit}(\beta_{\rho 0j} + \beta_{\rho j} x_k); \mu_{j-} \sim \text{Normal}(\beta_{\mu 0j-} + \beta_{\mu j-} x_k); \mu_{j+} \sim \text{Normal}(\beta_{\mu 0j+} + \beta_{\mu j+} x_k);$$

Formatted: Underline

Formatted: Underline

Formatted: Font: Italic

with seroprevalence ρ , seronegative titer-concentration μ_{j-} , and seropositive titer-concentration μ_{j+} modeled as a joint distribution, and the β values the marginal effect of risk factor on both seropositivity and antibody titer-concentration.

This allows us to integrate estimation of the factors affecting the probability of individual seropositivity (demographics, geography, host species), along with how those factors modify the titer-antibody concentration or response within seropositive or seronegative groups. For instance, if juvenile hosts have stronger responses than adults, but also are less likely to be exposed to the virus of interest, these will separate out under this approach. Under a traditional threshold-based approach these effects would mask each other.

One application of this joint modeling of the continuous and binary components is robust cross-species seroprevalence comparisons through combining mixed-effect structures [73] with this model framework. In many serosurveillance studies, large numbers of species are screened for evidence of antigen response to determine likely viral reservoirs, but species sample sizes vary due the difficulty of capture. This poses a challenge in comparing seroprevalence among species. Also, baseline or seropositive response binding levels may vary along with seroprevalence, and for some species sample numbers are not sufficient to establish species-level baselines. The joint approach will enable partial-pooling of species-level effects on both seroprevalence and titerantibody concentration, reducing noise from small size groups while capturing important differences.

Experimental Approach: We will simulate application of this model for two common surveillance inference problems. In each, we will compare this joint estimation approach to two-step threshold-based approaches based on outlier detection or simple clustering.

First, we simulate determining seroprevalence in a single group (species) of hosts, the probability of seropositivity and the strength of seropositive response are correlated. We will determine how seroprevalence, degree of correlation, sample size affect the accuracy of each method.

Second, we will perform studies of the case of sampling many species with mixed baseline and seropositive response rates to compare seroprevalence rates. Will simulate and fit from a mixed-effect model of the form

$$\begin{bmatrix} \mu_- \\ \mu_+ \\ \text{Probit}(\rho) \end{bmatrix} \sim \text{MVN}(\beta_0 + \beta_s \text{species}) + \epsilon; \beta_s \sim \text{MVN}(\mu_s, \sigma_s)$$

where the response distributions and seroprevalence vary as joint random effects by species. We will compare the mixed-model structure to a form where each species is evaluated independently and models where all species are pooled. In both cases we also compare two-step threshold-based approaches to the joint approach. We will use realistic sample and group sizes based on previous multispecies serosurveys [74], varying the size of interspecies differences and the evenness of sampling across groups to determine where the mixed-effect joint approach has the greatest differences from the alternatives.

Statistical approach and implementation:

All our simulation experiments will used a principled Bayesian framework [75] of simulating data from a structured model and testing the ability of the model as well as alternatives to retrieve the original parameters. We will implement models in the Stan probabilistic programming language [76], using Hamiltonian Markov Chain Monte Carlo to estimate model parameters. The R language [77] and will be used for data and model manipulation, workflows, and visualization.

Creating reusable software tools

We will develop an open-source software package for fitting, visualizing, and interpreting these models, written in the R computer language [77]. To maximize usability, we will test reduced-forms of all models, as well as multiple model-fitting algorithms including HMCMC, variational inference or maximum-likelihood optimization. For each we will measure model performance differences and model runtimes on both standard laptop on high-performance environments. The software package will include the ability to select amongst these options and include sensible defaults and guidance on trade-offs so that users can run tests in their compute environment. Reaction-cross reaction curve data and interaction will be packaged together with the software for users to use in their own model calibration.

Commented [EL9]: Virus or host?

Formatted: Underline

Software will follow community best practices for software usability, maintenance and algorithmic testing and correctness as developed under the rOpenSci Project [78, 79]. We expect to conduct training on software use for staff across all the cooperating surveillance projects as well as teach at least one workshop at an applicable conference in Year 4 or 5 of the projects. See RESOURCE SHARING PLAN and DATA MANAGEMENT AND SHARING PLAN for additional detail on software standards and dissemination.

Risks, limitations, and mitigating factors

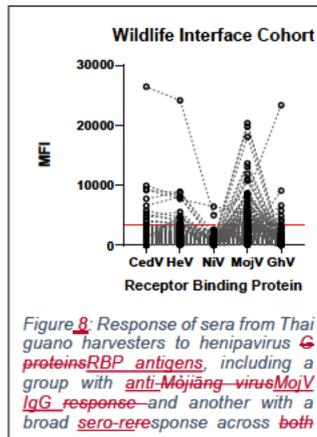

Several factors may limit the scope of applicability of these approaches. First, the high dimensionality and thus parameter size of these models may limit their use to large sample-size studies with moderate to high seroprevalence levels. Our pilot studies (Aim 3), have sample sizes of hundreds to thousands, with initial estimates of seroprevalence in the range of 15-20%. Second, if cross-binding interactions are strong between antigens in our panels as well as validation-verification tests in wild-type bat serum, it will make it difficult to distinguish cross-binding from a shadow virus signal within close antigenic distance. This will effectively increase the minimum antigenic distance needed to separate. However, even if strong, cross-binding is expected to predictably reduce with antigenic distance. That can be exploited to incorporate into explicit structures that predict associated uncertainty in the model structure or in model diagnostics.

AIM 3: APPLYING NOVEL METHODS TO OPEN QUESTIONS IN SPILLOVER IMMUNOLOGY

Our discovery panels and statistical models have direct applications to current open questions in serological surveillance. We will apply Aims 1 and 2 and leverage active serosurveillance projects where the identities of known or shadow viruses in sera from wildlife and humans could not be determined with current multiplex assays and statistical analyses. As testing will be conducted by and with local project teams, these projects will also serve as mechanisms for transfer and training and to refine protocols for publishing.

Henipaviruses in human community surveillance in Thailand

Preliminary Data: As part of the NIH CREID EID-SEARCH in Thailand, team members have been conducting clinical and community surveillance of humans in contact with wild bats via guano mining. We implemented our standard (non-discovery) filovirus and henipavirus glycoprotein antigen-based panels for MMIA testing. During these research activities, we identified that 19% (54/284) of study participants sampled near the Khao Chong Phran Non-hunting Area in Ratchaburi Province, were specifically immunoreactive with the MojV G (Figure 8XXX). We also identified one participant with a distinct serological pattern that had cross-reactive and preferential binding to GhV, HeV, and CedV antigens. These data provide preliminary evidence that study participants may have been infected with two serologically distinct henipaviruses, one that is MojV-like and one that is ancestral to HeV/CedV and GhV-like. However, their identities are indeterminate, and other hypotheses such as exposure to multiple viruses are plausible.

Formatted: Normal

Formatted: Normal

Approach: In Year 3 of this project, we will re-test sera from individuals with high wildlife contact currently being collected under the EID-SEARCH project using our full discovery 38plex antigen panels developed in Aim 1. With current archival sera and planned collection in the next two years, we estimate we will test 550 samples. Using the spectral mixture approach developed in Aim 2, we will fit models to determine (a) whether individuals with response to MojV were exposed to MojV or a closely henipavirus, and (b) whether individuals with response to GhV, CedV, and HeV were exposed one of these with cross-reaction to the other, multiple henipavirus with cross reaction to both or a new shadow virus. Using the antigenic mapping approaches, we will determine the relatedness of any shadow viruses to known henipaviruses. We will use our multi-scale models to determine how the presence and strength of response to each of these known or shadow viruses varies with sex, age, and occupational exposures.

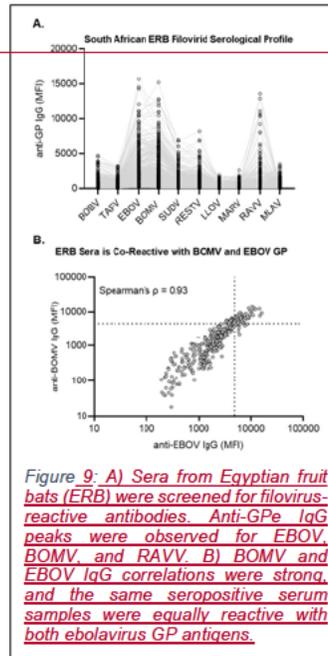

Formatted: Normal, Space Before: 0 pt

Expected results and limitations:.....

Filoviruses in Egyptian fruit bats in South Africa

Preliminary Data: Through ongoing research activities with co-investigator Dr. Wanda Markotter (University of Pretoria), our team has detected seroprevalances of 17.5% (77/440) for an unknown ebolavirus that is most antigenically-like EBOV/BOMV, as well a 4.5% (20/440) for RAVV marburgvirus (Figure K1LO-A) in *R. aegyptiacus* (Figure 9A-B). This degree of co-positivity is unexpected based on the WHO EBOV antisera, which favored preferential cross-reaction between EBOV and BDBV (Figure 2AFOXTRA-A). This data is highly suggestive of the existence of a novel intermediate ebolavirus that is antigenically equidistant from both EBOV and BOMV.

Approach: Years 3 and 4 of this project we propose to test *R. aegyptiacus* and other bat sera collected from across Southern Africa using our panel and methods. Under the SABRENET project, over 15,000 samples are expected to be collected via longitudinal and cross-sectional sampling across Southern Africa Based on current seropositive rates and planned sampling, we estimate 3,000 samples will have nonzero signals of a filovirus. Using a case-control approach we will select matching seronegative samples from collections for a total of approximately 6,000 samples. We will adapt our multi-scale models to a spatiotemporal framework to model the dynamics of these shadow viruses across different bat colonies.

Formatted: Font: Italic, Underline

Formatted: Normal, Space Before: 0 pt

Figure 9: A) Sera from Egyptian fruit bats (ERB) were screened for filovirus-reactive antibodies. Anti-GP_e IgG peaks were observed for EBOV, BOMV, and RAVV. B) BOMV and EBOV IgG correlations were strong, and the same seropositive serum samples were equally reactive with both ebolavirus GP antigens.

Expected results and limitations:

Linked serological-epidemiological models: Viral circulation in NiV reservoir Pteropus colonies

Preliminary data: In our previous and ongoing work studying NiV in Indian flying fox (*Pteropus medius*) colonies in Bangladesh, we found cyclical but non-seasonal patterns in seropositivity and viral shedding in a colony complex, a study we are now repeating across several colonies to understand geographic variation in seasonal shedding. We also found evidence of annual circulation of other filoviruses a, based on antibodies binding to EBOV and

Menangle virus (genus *Rubulavirus*) envelope protein antigens. Data collected in these serological studies was analyzed using a Bayesian cluster modeling to determine a threshold IgG level for serostatus, and threshold-based serostatus used as a binary variable in subsequent epidemiological analyses. However, this approach masks considerable complexity and uncertainty in the relationship between the individual binding levels in actual serostatus. For instance, for filovirus responses, the cluster of “baseline” responses of presumed seronegative bats increases with age, while in pre-weaned bats, an upper cluster of “seropositive” individuals has considerably weaker responses (Figure 10, publication in prep).

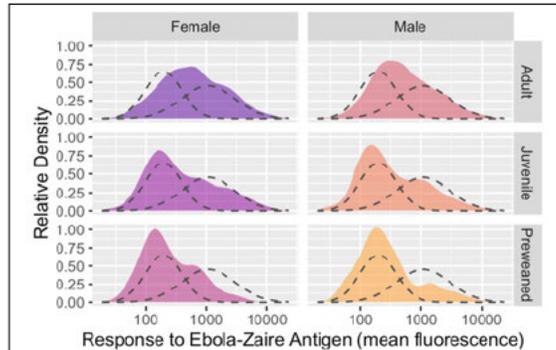

Figure 10: Clustering of binding response of Bangladeshi Pteropus sera to Ebola-Zaire antigen (filled densities), with clusters distributions from a Bayesian mixture model (dotted lines). Model thresholds do not capture within-cluster changes across demographic groups, which confound measures of seroprevalence.

Binding response also appears to change both seasonally and interannually.

Approach: We will use the antigenic relationships developed in Aim 1, and the cross-scale modeling approach developed in Aim 2, to re-analyze longitudinal and spatial extensive data on NiV, filo-, and rubulavirus binding response in *Pteropus* colonies. We will model the changes in baseline response binding (μ_-), seropositive response binding (μ_+), and seropositive binding probability (ρ , i.e. seroprevalence) as joint responses of a spatio-temporal model

$$\begin{bmatrix} \mu_- \\ \mu_+ \\ \rho \end{bmatrix} \sim \text{Multivariate}(f(\beta_0 + \beta_1 \text{sex} + \beta_2 \text{age} + s(\text{time}[\text{annual}, \text{seasonal}], \text{location}))) + \epsilon$$

Where Multivariate(...) is a joint multivariate normal-probit distribution representing the correlated response of all three outcomes, $f(\dots)$ is the pseudotiter-response relationship, and $s(\dots)$ is a term with a spatio-temporal correlation structure. We will test several joint hypotheses by determining the consistency of posterior model results: Does baseline serological response increase with age, and how much does this vary across viral types? Does average seropositive response (as well as seroprevalence) decline following peaks of seroprevalence, consistent with antibody decline following an outbreak? Do maternal traits determine the strength of vertical transmission of antibody titer?

Expected results and limitations:

RESOURCE SHARING PLAN

I. REAGENTS

Protein antigens and commercially sourced polyclonal rabbit antisera will be made available upon reasonable request.

II. PROTOCOLS

Protocols for generating reagents, performing assays, etc....will be published on <https://www.protocols.io/>

III. SOFTWARE

As part of activities in statistical model development we will create a software package to enable researchers to implement their methods. The program will be implemented in the R language (with Stan and C++ components as needed). It will be written to be compatible with Windows, macOS, and Linux platforms and tested on each. Algorithm implementation, code style, user and documentation will all follow rOpenSci standards for statistical software implementations (<https://stats-devguide.ropensci.org/>). It will be released under an Open Source Initiative-compatible license.

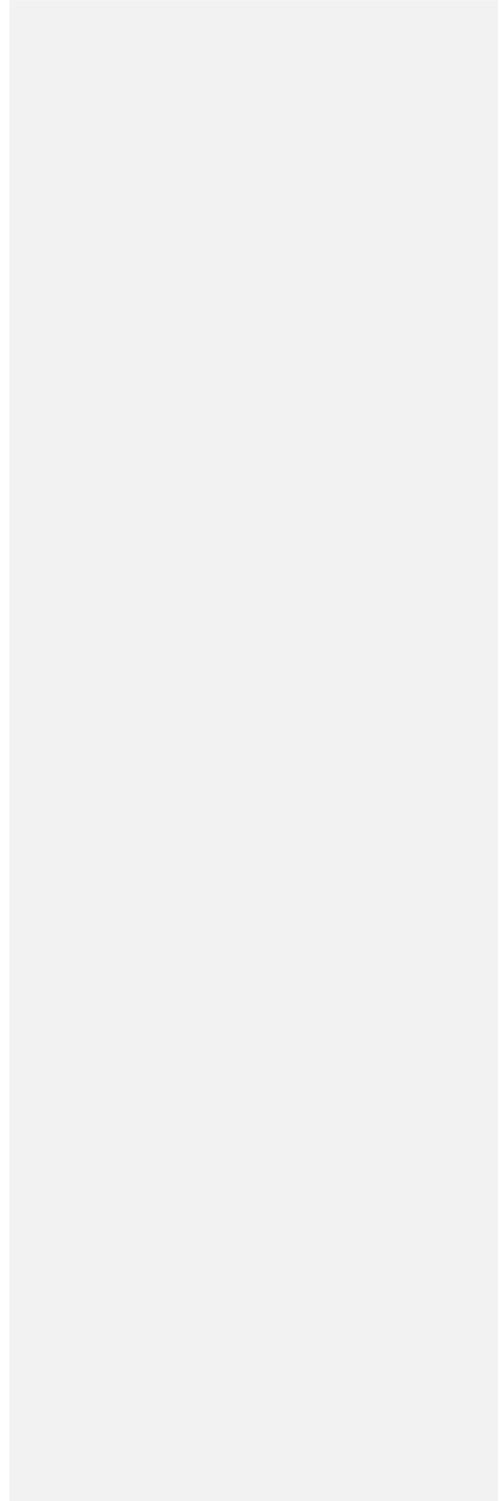

The software will include both reference documentation and tutorials on implementing the software on example data. We will test both software usability and documentation quality by distributing alpha versions to researcher, students, and postdoctoral scholars at PI and co-I institutions and collecting feedback. Beginning with alpha versions, the software will be publicly released on a platform inviting user reports.

The software will be published on several platforms allowing easy retrieval and installation (CRAN, R-Universe, GitHub, Zenodo). A project website will be created for documentation. We will maintain the software, including bug fixes, and updates to maintain compatibility with changing dependencies and platforms, for 5 years after the end of the funding period. Containerized versions of the software at any major release, packaged together with all dependencies and compute environment, will also be archived so that archival analyses using the software may be run even after the end of maintenance.

See DATA MANAGEMENT AND SHARING PLAN for further details on publication, archiving and standards.

Commented [NR10]: Eric. Expand/remove as appropriate.

VERTEBRATE ANIMALS

DATA MANAGEMENT AND SHARING PLAN

I. DATA TYPES

Types and amount of scientific data expected to be generated in the project

This project will produce data on antigen binding responses via multiplex bead array assays, as generated from Bio-Rad Bio-Pplex and Luminex MAGPIX multiplexing Systems. These assays will be performed on sera from hyperimmunization challenge experiments in rabbits, human serology standards for select viruses, and archival sera samples from wildlife surveillance studies in South Africa, Republic of Congo, Madagascar, and Thailand as well as human surveillance studies in Thailand. Calibration data, including measures from blank and mock samples, will also be generated.

The project will produce sample-level metadata for challenge experiments and standard dilutions. It will aggregate copies of metadata associated with archival samples from other research projects. The latter will include host species, traits, time and location of collection of animals sampled, and demographic information of humans sampled.

The Bio-Pplex and MAGPIX systems will generate raw data in XML and XLSX files, with XML files being comprehensive logs of run metadata, machine calibration, and all measurements per sample, and XLSX being sample-level total measurements. Sample-level metadata will be collected in CSV and XSLX form.

Across experimental and archival samples, we expect to generate approximately 7,000 tests on 90 plates, totaling approximately 3.5MB of processed XLSX files and 440MB of raw XML files.

The project will also produce synthetic data from simulations and performance data from experiments. These will be generated in RDS (R Object files), and parts computationally intensive or difficult to reproduce will also be exported as CSV files. The project will produce computer code for both analyses and as a primary product in the form of reusable software packages. These will be in standard UTF-8 text of computer languages including, R, Stan, and C++, as well as compiled executable binary files.

Scientific data that will be preserved and shared

Excepting identifiable data associated with human samples, all data produced in the course of this project will be publicly shared. Final sample-level cleaned and joined data and metadata will be shared as CSVs, as well as raw Bio-Pplex or MAGPIX software XML data. All computer code created will be shared. Synthetic data and summaries of simulation experiments will be shared in summarized form, with raw data shared as reproducible code that can regenerate the exact results, excepting data that is computationally-intensive and therefore more efficient to share in raw form.

For data associated with human samples personally identifying information will be not be shared. Personal individual-level data will be removed, demographic and location data will be binned to prevent re-identification, with location information binned to the province (ADM-2) level and age aggregated to bins of 10 years or more. Other fields (e.g. occupation) will be analyzed to determine potential for re-identification and removed or binned as necessary.

Metadata, other relevant data, and associated documentation

This project will also produce as primary outputs standard operating procedures and instructions for performing the assays under development, documentation to reproduce simulations and statistical analyses from provided code, as well as user documentation and tutorials for the statistical software that will be created. Descriptive and structural metadata will be included in deposits for each data set.

II. RELATED TOOLS, SOFTWARE AND/OR CODE

All produced data formats (CSV, JSON, XML, XLSX) can be read by multiple, widely available free and open-source tools, with only RDS files specifically requiring the free and open-source R language.

III. STANDARDS

In general, all data will be reported using the Frictionless data standard, as both an "umbrella" framework and a general approach to data sets without domain-specific standards. The Frictionless data standard provides a framework for consistently packaging data stored in most inoperable file formats. We will use accompanying Frictionless JSON files to describe CSV metadata, with additional standardized fields

specific to the data repository used (e.g., Zenodo). Where applicable, we will use the NIH Common Data Elements (CDE, <https://cde.nlm.nih.gov>) for relevant fields.

Formal standards for non-target and quantitative serological data have not yet been widely adopted, and the development of essential reporting quantities is an anticipated output of this project. However, we will aim to ensure the data reported is, where applicable, compatible with standards for serological studies, notably the NIH ImmPort data model and its recommended ontologies for proteins and diseases.

Spatiotemporal and taxonomic metadata on wildlife samples will follow the Darwin Core Standard.

Computer code will be released using two standards. Software packages for reuse will be in the format of an R packages following the rOpenSci standards for statistical software implementations (<https://stats-devguide.ropensci.org/>) and CodeMeta standards for software descriptions (<https://codemeta.github.io/>), under an Open Source Initiative-compatible license. For computer code to reproduce simulations and statistical analyses, we will use git version controlled code repositories, the “Make” and “targets” frameworks to define dependencies between steps of analysis, the “renv” and “venv” frameworks for recording software dependencies, and Docker containers to capture the machine computing environments. Binary machine images of the containers will be stored alongside the source code.

IV. DATA PRESERVATION, ACCESS, AND ASSOCIATED TIMELINES

Repository where scientific data and metadata will be archived

We will archive all data and metadata generated, as well as all computer code, on the Zenodo archive. A subset of data generated is appropriate for NIH’s ImmPort repository and will be cross-deposited there with appropriate semantic references to describe the relationships between data. Protocols will also be deposited on protocols.io.

How scientific data will be findable and identifiable

All data on Zenodo, NIH ImmPort, and protocols.io will be identifiable DOIs and have searchable metadata deposited with DataCite and indexed by search engines. In addition, we will mirror data on non-archival sites that are popular and accessible for their features and search optimization: DoltHub for data, GitHub for source code, and R-UNiverse for installable R software binaries.

When and how long the scientific data will be made available

Data associated with publications will be shared in its processed and cataloged form upon release of associated products (preprints, software, or publications upon acceptance), or the end of the period of performance (inclusive of any approved extensions), whichever comes first. The duration of preservation and sharing of the data will be a minimum of 10 years after the funding period.

V. ACCESS, DISTRIBUTION, OR REUSE CONSIDERATIONS

Factors affecting subsequent access, distribution, or reuse of scientific data

There are no anticipated factors or limitations that will affect the access, distribution or reuse of the scientific data generated by the proposal.

Whether access to scientific data will be controlled

All data generated by this project will be released in full excepting data aggregated from other projects with personally identifiable data.

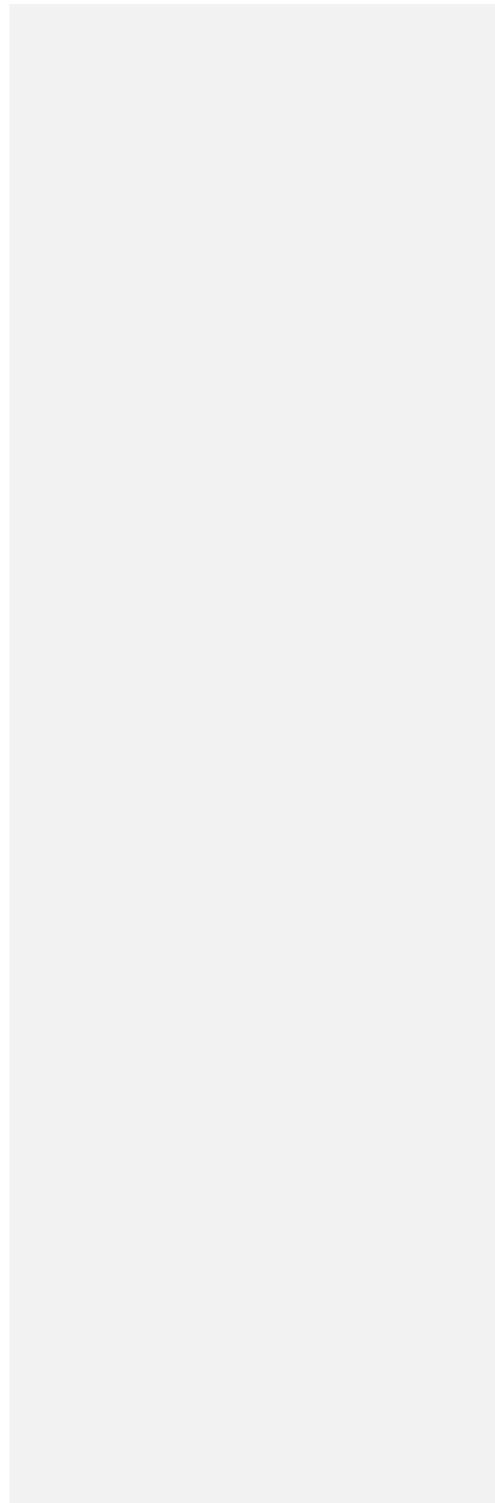

Protections for privacy, rights, and confidentiality of human research participants

Where data used by this project from other projects is linked with personally identifiable information, only de-identified information will be released. Identifiable data will not be retained. Requests for the identifiable data will be referred to the original projects and institutions.

VI. OVERSIGHT OF DATA MANAGEMENT AND SHARING

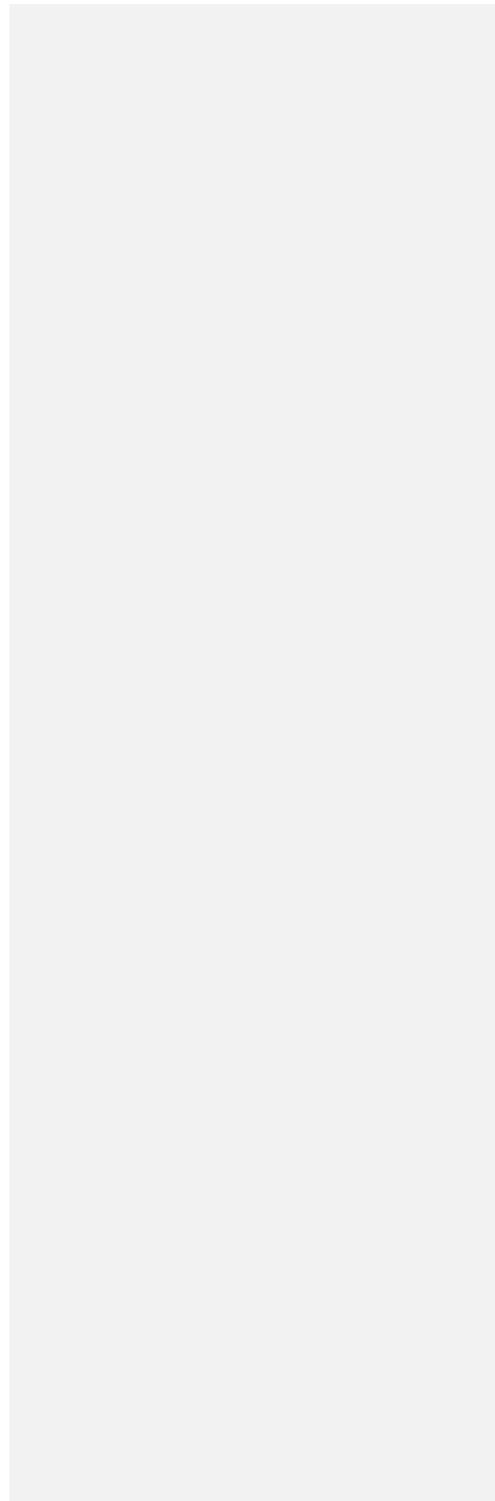

PI Ross (ORCID 0000-0002-2136-0000) will be responsible for oversight of project data management and release of data. The project research assistant at EcoHealth Alliance will be responsible for management of the project database, maintenance of project metadata, aggregation of data from project partners, and releasing data to appropriate repositories under appropriate standards. A data librarian at EcoHealth Alliance will support this role and act as an organizational fallback for data maintenance. Data release will

take place after agreement amongst PIs from all contributing institutions. State of data management and release will be a standing topic at project quarterly and annual meetings.

PROJECT NARRATIVE

This project develops new methods to identify emerging and zoonotic viruses by analyzing the virus-induced antibodies present in wildlife and human populations in contact with wildlife. It will create both new laboratory techniques to test for those antibodies and new mathematical models to analyze data to identify the trace of those viruses. It will test these methods in partnership with international virus surveillance projects in Bangladesh, Thailand, and South Africa.

PROJECT SUMMARY/ABSTRACT

Serosurveillance provides powerful measures of the infectome of wildlife and humans that can shed light on the disease ecology of zoonotic viruses. Yet serological data is plagued with ambiguities that limit our ability to use it to identify zoonotic disease reservoirs or identify populations at risk from exposure to emerging viruses. These issues include cross-reactivity of antigens and antibodies and complex, nonbinary immune responses. The major goal of this proposal is to dramatically improve the utility of antigen-based serosurveillance for new viral discovery and epidemiology of emerging zoonotic diseases by addressing the challenges of cross-reaction and statistical rigor. We will create discovery panels - qualified and optimized panels of multiplexed immunoassays designed to identify and characterize previously unknown viruses only detected through the antibody response of hosts. We will develop new statistical approaches to extract the signals of novel viruses from those of known viruses or mixtures of antibodies from complex histories multiple previous viral exposures, as well as integrate these into models into population-scale epidemiological models. Finally, we will partner with international viral surveillance projects to apply these techniques to identifying and characterizing filoviruses and henipaviruses in bat populations in South Africa and at-risk wildlife workers in Thailand, and to modeling immune-epidemiological dynamics of Nipah virus circulation in bats and people in Bangladesh.

Formatted: Highlight

Formatted: Highlight

FOREIGN JUSTIFICATION

This project concerns zoonotic infectious diseases found in wildlife and human populations globally and with the potential to spread and cause outbreaks in the United States. Study populations of interest – high animal-contact workers in Thailand, and known filovirus host bat species in South Africa – were selected because prior results indicated the presence of antibodies to novel viruses that could be better characterized using the methods developed in this proposal. In both cases, the systems are already being studied under U.S. federally-funded disease surveillance projects: The NIH CREID Emerging Infectious Diseases - South East Asia Research Collaboration Hub (U01 AI151797), the DTRA BTRP South Africa Bat Research Network (HDTRA12010025).

In the case of surveillance in Thailand, the lead expert in the disease ecology and epidemiology of the system of interest is Co-I Wacharapluesadee. Archival sera from study of this population are stored at her institution, King Chulalongkorn Memorial Hospital, and she and her team are best equipped to analyze these specimens and interpret the results. Dr. Wacharapluesadee and King Chulalongkorn Memorial Hospital have a history of collaboration with U.S. institutions under USAID and NIH programs.

In the case of surveillance in South Africa, the lead expert in the disease ecology and epidemiology of the system of interest is Co-I Markotter. Archival sera from study of this population are stored at her institution, University of Pretoria, and she and her team are best equipped to analyze these specimens and interpret the results. Dr. Markotter and University of Pretoria under DTRA and NIH programs.

CONSORTIUM/CONTRACTUAL ARRANGEMENTS

This project is a multi-institutional collaboration led by EcoHealth Alliance, New York (PI Ross, Co-I Epstein) that will subcontract funds in accordance to NIH Institutional guidelines to three other institution:

1. **Uniformed Services University of the Health Sciences, Bethesda, MD** (PI Laing)
2. **University of Pretoria** (Co-I Markotter)
3. **King Chulalongkorn Memorial Hospital, Thailand** (Co-I Wacharapluesadee)

The applicant organization (EcoHealth Alliance) is justified in taking the lead on this project because it specializes in understanding the ecological and virological processes underlying zoonotic disease emergence, and has conducted international, multi-disciplinary and multi-partner research around the world for more than 30 years, including joint projects with the listed institutions. EHA administers technological and data-management platforms used by partners as part of these project.

PI Ross oversees modeling, statistical design, and data systems at EcoHealth Alliance. Dr. Ross, a mathematical disease ecologist, is an expert in complex semiparametric modeling approaches and the role of host and pathogen heterogeneity in disease dynamics. He leads multiple multi-institution projects in scientific and statistical software development [80, 81], disease forecasting (Wellcome 226061/Z/22/Z). He has had core roles in quantitative methods for multi-institution projects under USAID, DTRA, and NIAID, including collaborations with all partner institutions on this project.

EcoHealth Alliance will be the lead for administrative components and oversight of this project, and also be the center of development and testing of quantitative methods, software development, data integration, and overall synthesis. Co-I Epstein at EcoHealth Alliance will provide expertise in the virology, disease ecology, and epidemiology of the populations of interest in Bangladesh.

The subcontract institutions will work on specific issues and areas in which they have proven expertise. These areas are:

- Wildlife virology and immunology, Novel serological and assay development; generation of reagents for novel assays; training and technology for serological and molecular protocol development, of Thailand and South Africa laboratory staff for technology transfer for serological and molecular protocol development (**Uniformed Services University of the Health Sciences**, PI Laing).
- Wildlife and human community surveillance and specimen collection, human clinical or hospital syndromic surveillance, screening of serum specimens using serological assays, disease ecology and epidemiology of zoonotic diseases specific to populations in Southern Africa (**University of Pretoria**, Markotter), and Thailand (**King Chulalongkorn Memorial Hospital**, Wacharapluesadee)

PROJECT LEADERSHIP PLAN

I. BACKGROUND AND MULTI-PI RATIONALE

This research program, *Characterizing unknown emerging viruses through targeted serological profiling*, is inherently interdisciplinary, jointly developing *in vitro* and *in silico* methods for serological viral discovery, drawing from the expertise, teams, networks, and resources of both PIs. This project will be co-led by PIs Dr. Noam Ross (EcoHealth Alliance, New York, NY), and Dr. Eric Laing (Department of Microbiology and Immunology, Uniformed Services University of the Health Sciences (USU), Bethesda, MD). The laboratory and computational components, as represented in Aim 1 and Aim 2, are complementary and co-equal. Each PI brings methodological expertise and experience to their component. Dr. Ross, a mathematical disease ecologist, is an expert in complex semiparametric modeling approaches and the role of host and pathogen heterogeneity in disease dynamics. He leads multiple projects in scientific and statistical software development [80, 81]. Dr. Laing, a virologist, is an experienced researcher in the field of infectious diseases, serological application and profiling, and cellular immunology. He is a co-investigator and associate investigator on multiple virus surveillance projects including [Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential \(EpiCC-EID\)](#), [EpiCC](#), [Prospective Assessment of SARS-CoV-SeroconversionPASS](#), [EID-SEARCH](#), [SABRENET](#), and along with OSC Munster is a co-investigator on a [pending project, Establishment of a Bat Resource for Infectious Disease Research](#). The PIs have a history of collaboration as part of multiple projects in disease surveillance, including serological surveillance of wildlife under DTRA-funded surveillance projects in Malaysia (HDTRA11710037) and South Africa ([SABRENET](#), HDTRA12010025), and NIH-funded research on Nipah virus circulation in Bangladesh (U01 AI153420-01). In each they work(ed) jointly on interpretation of serological data and epidemiological models, serving as the methodological experts within those teams.

Co-Investigators Epstein, Markotter, and Wacharapluesadee all lead active federally funded projects in zoonotic viral surveillance and discovery that make use of serological methods developed by PI Laing. Each provide system-specific expertise in the ecology, epidemiology, and virology of the regions and species in those projects, which are the source of samples and data for our applications for Aim 3.

II. ROLES AND RESPONSIBILITIES

PI Ross will be the lead of the project, responsible for funder communication, budgeting, and reporting, and oversight of sub-awardees. He will be responsible for project data management, statistical methods and development under Aim 2, and analyses under Aim 3. Dr. Ross will be supported by EHA's administrative staff, including organizational-level finance and human resources directors, a federal grants administrator, a data librarian and computing cluster systems administrator. PI Laing will be the lead laboratory processes and development and site lead for USU. He will be responsible for protein and panel design, challenge experiments, and other laboratory experiments under Aim 1. Both PIs will participate equally in interpretation of analyses and manuscript writing.

Co-Is Markotter and Wacharapluesadee will be oversee the testing of samples from South Africa and Thailand at their institutions, respectively, and act as consortium leads for University of Pretoria and will liaise with PI Laing for logistics and implementation of protocols. SPs Epstein, Markotter, and Wacharapluesadee will all participate in the (re-)analyses and interpretation of results in Aim 3.

III. PROGRAM MANAGEMENT

COMMUNICATION

PIs will coordinate via monthly video calls. These calls will include other Co-Is quarterly, and more frequently as needed starting with Aim 3 activities in Year 3. At the discretion of PI and Co-Is, other laboratory staff from each institution and OSCs will participate in these meetings. The purpose of these meetings will be to keep all parties informed of the status, progress, and plans. Quarterly meetings will be extended to include presentation of preliminary results. Calls will be coordinated by PIs Ross and Laing with monthly rotation of leadership and responsibility of making agendas for and disseminating notes from each meeting.

PIs will use AirTable and GitHub project management boards, administered by PI Ross and EHA administrative staff, to track task status, including laboratory and computational experiments, testing, administrative tasks, manuscript preparation and publication. EHA's internal content sharing hub (secure.eha.io), will be used for sharing interim reports and preliminary results across project participants.

Commented [NR11]: ERIC Add citations, grant numbers, and/or descriptions to make these understandable to reviewers.

Commented [EL12]: I think you should use "contact PI" that was the language I found in NIH examples.

IN-PERSON MEETINGS

Project PIs will meet in-person at least annually at EHA, USU, or at jointly attended conferences in the last quarter of each project year. Following annual meetings PIs will generate annual reports, using this period to communicate and discuss program status and any possible changes to research directions should information indicate failure of certain directions or the possibility of new opportunities. Decision making will be made by all program’s PIs. If issues/topics cannot be resolved at this level then PIs (unlikely) will consult with NIH program staff on future allocation of research funds pending any replacement or revision of the program’s goals.

We have budgeted additional funds for laboratory exchanges of staff between EHA and USU. The modeling Postdoc at EHA will travel to USU to train in laboratory methods in Year 1 inform mathematical work. A USU graduate student will travel to EHA to in Year 2-3 to study modeling and statistical methods. In addition, we will take advantage of existing collaborations to liaise with Co-Is. A USU project staff member is visiting scientist at the CKMH and PI Laing travels to CKMH under EID-SEARCH. PI Ross, PI Laing, and co-I Epstein travel regularly to UP for collaboration under other projects (HDTRA12010025, Wellcome 226061/Z/22/Z).

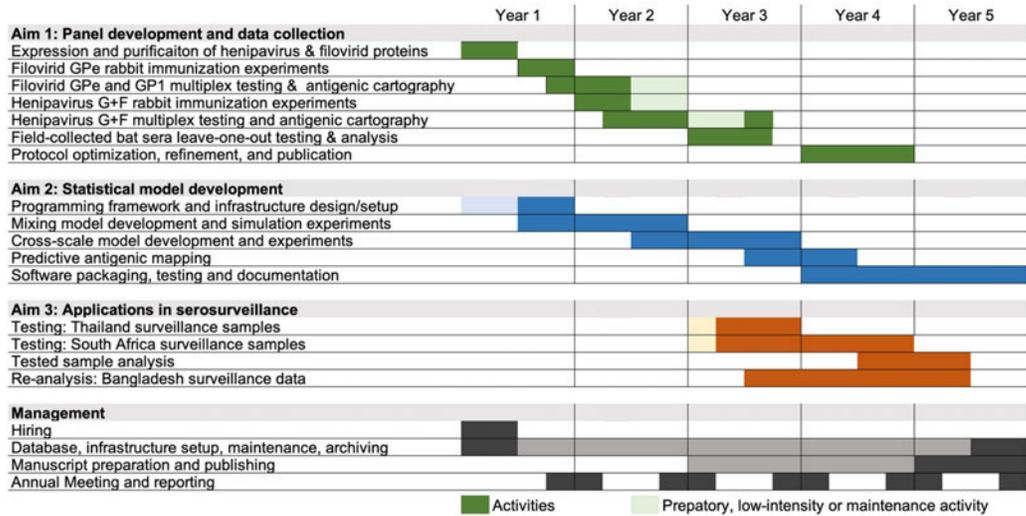

DATA MANAGEMENT

All data and code will be managed in a project database overseen by PI Ross and administered by the project research assistant. All other consortium members will upload data to this database and also maintain local copies in their local information management systems. See DATA MANAGEMENT AND SHARING PLAN for additional details on data dissemination.

COMPUTATIONAL RIGOR AND REPRODUCIBILITY

Development of model code will follow our framework of *deployment-ready research*, an approach to developing scientific code that can be integrated into reusable software with little additional effort. Code will be maintained in a version control system (git), with versions of models linked to the versions of data they were run against in a versioned database (dolt). Changes to model design or implementation will require code review by a team member. Review will include diagnostics of code quality and comparing output and performance of each version of models, implemented automatically by continuous integration (CI) on our code-sharing platform (GitHub).

PROJECT TIMELINE

COVER LETTER

National Institutes of Health (NIH)
9000 Rockville Pike
Bethesda, Maryland 20892

February 5, 2021

Application for the NIH Research Grant Program Announcement number PA-20-185, entitled NIH Research Project Grant (Parent R01 Clinical Trial Not Allowed), dated May 5, 2020

To whom it may concern:

We are pleased to submit our grant proposal titled “**Characterizing unknown emerging viruses through targeted serological profiling**” for consideration.

Please assign our proposal to the following:

Institutes/Centers: National Institute of Allergy and Infectious Diseases - NIAID

Scientific Review Groups: Transmission of Vector-Borne and Zoonotic Diseases (TVZ)

We know of no individuals (e.g. competitors) who should not review the application.

Our project is aligned with the mission of NIAID because it focuses on detection and characterization of pathogens with potential for emergence, including near neighbors of Ebola virus and Nipah virus, which are priority pathogens. This project addresses NIH’s priorities of Immunology and Assay Development, Reagents and Resources, and Epidemiology and Pathogen Discovery under the NIAID Pandemic Preparedness Plan (<https://www.niaid.nih.gov/sites/default/files/pandemic-preparedness-plan.pdf>).

Two of our subawards, for University of Pretoria (UP) and King Chulalongkorn Memorial Hospital (KCMH), are not active for the first two budget periods of the project. This grant concerns the development, testing, and validation of new methods, with initial development occurring at the main site, EcoHealth Alliance, and consortium partner Uniformed Services University. Testing and validation will involve all consortium partners and begin in Year 3 of the project.

Please note that the proposed work is NOT a Select Agent study because we work only with synthesized antigens and archived sera.

Thank you very much for your consideration.

Sincerely,

A black rectangular box containing the red text "(b) (6)", indicating a redacted signature.A black rectangular box containing the red text "(b) (6)", indicating a redacted signature.

NOTES AND STUFF FROM OLD PROPOSALS

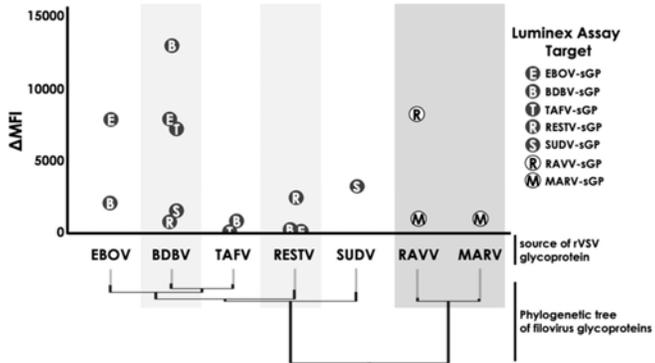

The majority of antibodies induced by virus infections are specific to conformational dependent epitopes found on virus proteins. Antibodies raised against envelope glycoprotein of henipaviruses and ebolaviruses undergo affinity maturation and are the targets of vaccine design and development. However, the confounding effects of cross-reactivity against native-like proteins expressed to retain quaternary structures, and a lack of true controls in understudied wildlife species or for yet-uncharacterized viruses stymies use of rich qualitative data that they produce.

Old World frugivorous bats have been largely considered the wildlife reservoirs of henipaviruses, the discovery of four Asiatic henipaviruses in rodents has come as a surprise [cite]. implies that serosurveillance measures thus far have been unable to appropriately detect the diverse serological profile of extant henipaviruses amongst wildlife, livestock, and human hosts. In fact, PI Laing's research team detected a unique serological profile in an archived sera bank of acutely febrile patients in Cambodia that were XX% (44/1400) seropositive for a henipavirus that is seemingly antigenically-distinct and -ancestral to Ghana, Hendra, and Cedar viruses (**Figure JULIET**).

The shape of this serological profile if protein antigens from LayV and the other rodent associated henipaviruses had been included will remain unknown, but the serologic data suggests that there are other serologic footprints left by unknown zoonotic henipaviruses in southeast Asia, the shadows of which can be measured through serological approaches.

IV. SIGNIFICANCE

Serological tests frequently viruses outside their known host range or geographic range (Filovirus, Singapore, etc.).

Serological surveys can capture usable info PCR cannot [11]. Serological screening can identify novel strains that would otherwise be missed, such as this Hendra virus variant [82].

Bayesian clustering approaches [83] are useful but have largely been applied to single-assay surveillance. At higher dimensions, the clustering in high/low expected values confounds with clustering of different viruses.

Outlier-based detection is inherently problematic for rare conditions. Rare values can occur at a rate less than statistically expected outliers.

V. INNOVATION

This project is innovative in its multi-scale approach, integrating laboratory method development and population-scale surveillance data through modeling to develop.

Estimate the probability of a multiplex panel response to represent exposure to novel coronaviruses. This approach has several statistical antecedents: spectral mixture analysis in remote imaging, antigenic cartography.

Paper on Nipah Panel: [84]

These measures will produce novel insights via *antigenic mapping*. The mixture of high- and low-specificity (RBD and IgG) will allow us to better understand the degree to which phylogenetic similarity between viral species is reflected in antigenic properties.

We will extend techniques of antigenic mapping,[66] using serological profiles to estimate phenotypic similarity of new viruses to known viral families, determine the correlation with phylogenetic relatedness, and use these measures to screen new viruses for pandemic potential.

Model 1: mixed effects for unknown responses in wildlife species. Account for variation in wildlife, use phylogenetic information to inform immune response.

Model 2: “spectral mixing” / antigenic mapping approach. Determine the probability that an individual has an exposure to a single virus.

Experiments: test sera exposed to multiple viruses rather than single viruses only, determine additivity. Additive allow for straight spectral mixing, non-additivity requires models with covariance components.

Model 3: Multiple outcome (multivariate probit) models for joint seroprevalence.

In wildlife serological surveillance, we generally lack important controls, including PCR-based or symptom-based confirmation. We lack negative controls because we don't know the wild-caught status. In the few cases where there are captive-raised animals, these negative controls aren't representative of wild types that may have had other exposures. In any case the number of species of interests for serological monitoring far exceeds those it would be possible to establish captive models.

Many multi-species surveillance studies.

Analyses need to distinguish between *correlation in assay response*, which may be driven by cross reactions, and *correlation in exposure*, driven by epidemiological and ecological processes.

Pooling data from multiple studies can establish standardized responses for some species, while simultaneously giving a base of evidence for predicting to other species.

Pooling factors allow us to evaluate the level of species- or geography-level information incorporated into estimates

Making studies comparable by extracting raw data on machine calibration, sample dilution, etc.

Mixed models will allow us to estimate both intra- and interspecific variation in wild-type responses, and develop predictors of this using both phylogenetic and trait-based species data.

Phylogenetic models – assessing phylo-immuno relationship across the panels, allowing for prediction in phylogenetic space

Incorporate measures of variation by test

Benefits – quantitative and scalable interpretation, researchers don't all have access to the statistical or virological expertise which is required to interpret beyond specific recipes

Nonlinear relationship of cross-reactivity <https://link.springer.com/article/10.1007/s10875-021-00997-6>

We will screen serum from all subjects for IgG antibodies against Nipah and all other known henipaviruses (Hendra, Cedar, Ghanavirus & Mojiang) using a Luminex multiplexed sphere-based assay developed by the Broder lab and the CSIRO Australian Animal Health Laboratory in Geelong (10).

are acquiring new laboratory experimental data on titer-response curves and cross-reaction against non-target antibodies for Luminex assays.

The core of this proposal is the development of statistical models and the ability to test these models against field data from a variety of systems that has been collected, curated, and interpreted by our team.

Our team has been involved in 17+ years of research in host-pathogen dynamics and spillover processes for zoonotic viruses across continents including Hendra, Nipah, SARS-CoV, SARS-CoV-2, MERS-CoV, and Ebola viruses, as well as development of state-of-the-art multiplex assays for serological testing for these viruses. Our data from multiple NIH R01s, as well as other federally-funded work, includes paired individual data on both antibody levels and PCR detection of viral RNA, multiplex data from multiple systems, and serochip data. We will enable broader use of these models in epidemiology through the development of software for both model-fitting and visual diagnostics.

Our team has experience in turning research code into generalizable and sustainably maintained scientific software, including designing for user needs, recruiting open-source communities.

Our 3 specific aims are to:

- 1. Create procedures to detect signals of new viruses from multiplex serological assays.**
2. Discovering real signals in high-dimensional serochip data.

and .

Creation of a library of priors: While there are missing baselines for a wide array of serological assays, an accumulating body of evidence can provide input to future routines. We will use data accumulated from a series of projects to build a database of priors. This data will help us answer question such as: how applicable are thresholds and models across species? How consistent are immune responses within and across families of viruses? How do distributions of responses, when normalized, compare across quantitative methods that are related but not linearly proportional with antibody titers?

We will use this database to identify laboratory calibrations that will provide the greatest ability to improve statistical discrimination among responses.

Cross calibration of methods: We have both Luminex data, serochip data, and a spectrum of VNT or pseudo-neutralization assays. All are related to antibody titer but have different mechanisms, and levels of specificity and nonlinearity in response. We will perform cross-calibrations. We will integrate these into our model designs so that mechanisms can be swapped out and serology can be made comparable across populations.

1. We will validate these models with a "leave-one-out" strategy – testing whether a novel virus is identified in sera from a population with a known exposures to a virus, with protiens specific to that protien removed. We will repeat this via both *in silica* and *in vitro* approaches. *In silica*, we will simply remove data from the target viral protiens from multiplex results from a full panel. *In vitro*, we will omit beads for the target viruses from the panel. Comparison of these two approaches will quantify the extent that competitive binding affects the validation technique.

Hi Noam,

Attached are very likely my final edits. Feel free to reach out. I added the vertebrate section language (it kicked down 2 blank pages) and also uploaded a doc to the folder "Other Documents."

I think it's there.

- Eric

Hi all,

Just sending a state-of-the submission of the serology grant with USU as we barrel to the end of the week and the Monday 5PM deadline.

Grant materials are in this folder: https://ecohealthalliance-my.sharepoint.com/personal/ross_ecohealthalliance_org/_layouts/15/onedrive.aspx?id=%2Fpersonal%2Fross%5Fecohealthalliance%5Forg%2FDocuments%2Fnih%2Dserostats

This includes a document tracker of development and upload status in the base folder. Note that several documents are all consolidated together in the research folder.

About 1/3 of documents and forms are filled out and uploaded in ASSIST (Application 1344425) . The plan is to spend Friday finishing the rest, including filling in the budget and writing the justification, pending any last-minute input from Joe. There is one outstanding administrative item Eric is tracking down for our vertebrate animal testing justification document, and a letter of support we are expecting. These should be done tomorrow, too.

The core research strategy is near-done, but Eric and I have decided to give ourselves a bit of breathing room to revise, taking a break to re-read then uploading and submitting from our end on Sunday. If all goes according to plan, Joe can give organizational approval Monday morning.

I am on a flight to California 6:30 AM on Monday morning and will pay for internet, but I will assume I'm incapable of doing anything. Should anything not go right with final submission, or an administrative document not arrive until Monday. Collin on my team has full edit capabilities for the proposal ASSIST. Collin please be on standby to liaise with Eric and Joe if something needs to be fixed.

Thank you all for your help!

Noam

EcoHealth Alliance develops science-based solutions to prevent pandemics and promote conservation.

SPECIFIC AIMS

Emerging infectious diseases—predominantly caused by zoonotic viruses—have become a major threat to individual and public health as well as the functioning of a global society. Even prior to the SARS-CoV-2 pandemic, outbreaks of consequential emerging pathogens including SARS-CoV, Pandemic influenza 2009, Zika virus, and Ebola virus disease tragically killed, disabled, and caused massive disruptions of regional and global economies and health care systems². The emergence of consequential zoonotic infections is accelerating due to anthropogenic drivers such as climate change, land-use change, intensification of livestock production, and wildlife trade, all of which increase opportunities for people and domestic animals to come into contact with wildlife reservoirs³⁻⁶. **To reduce the risk of infectious disease epidemics, there is a critical need to detect and prevent spillover of zoonotic pathogens from wildlife reservoirs^{3,7}.**

Illustrative of this need is the repeated spillover from wildlife reservoirs to human populations of groups of zoonotic viruses such as filoviruses (e.g., Ebola virus [EBOV]) and henipaviruses (e.g., Nipah virus [NIV]). Large-scale outbreaks or clusters of cases of these high-mortality zoonotic viruses have led to their **designation as high priority pathogens by the World Health Organization (WHO)**⁵. However, at present, the detection of outbreaks caused by these pathogens occurs only after the first human infections; a deadly, costly, and remediable failure in prevention². Identifying natural reservoirs of and measuring rates of human exposure to these zoonotic viruses is critical to assessing their potential threat and developing interventions that reduce spillover risk^{2,3}.

For the proposed study, we have assembled a team of leading experts in the ecology, epidemiology, virology, and immunology of bat-borne viral zoonoses such as filoviruses and henipaviruses, as well as experts in filovirus clinical care and research who are actively working in West Africa. Our study will provide much-needed empirical evidence to help answer the questions: **In a region that is an emerging disease hotspot, which has suffered the world's largest filovirus outbreak, and where there has been evidence of other consequential zoonotic viruses in animals and people, what is the natural reservoir for Ebola virus and how often does spillover of this and other high-consequence viruses happen?** To address these questions, we propose the following specific aims:

Aim 1. To determine the rates of filovirus and henipavirus exposure in people in rural Liberia. We have shown that certain bat species in Liberia may carry EBOV-Zaire, while others carry Marburg virus (MARV) and henipaviruses. Hunting bats is a common activity and we have detected high seroprevalence of Marburg and EBOV antibodies in residents of rural Liberia. Exposure to henipaviruses remains unknown. To test the hypothesis that spillover of both groups of viruses has occurred in this region, we will use an antigen-based multiplex serological assay to screen more than 1,900 archived blood specimens, collected in 2021 and again in 2023 from over 900 adults and children in rural central Liberia as part of a longitudinal study of Lassa fever seroprevalence and seroincidence, for antibodies against all known filoviruses and henipaviruses.

Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia. Our group detected EBOV-Zaire RNA and antibodies in *Miniopterus nimbae*, a cave- and mine-dwelling bat in northern Liberia found near the origin of the 2014 Ebola outbreak in Guinea. We also detected antibodies against EBOV and henipaviruses in *Hipposideros* bats that co-roost with *Miniopterus* in multiple locations in Liberia. *Rousettus aegyptiacus*, a common frugivorous bat in Liberia, carries MARV and henipaviruses. We will conduct a 3-year longitudinal study of populations of these bat species near the human cohort studied in **Aim 1**, to identify the reservoirs for Zaire ebolavirus and characterize the temporal dynamics of filovirus and henipavirus circulation in bats using multiplexed serological assays that test for specific IgG antibodies against all known filoviruses and henipaviruses, as well as molecular techniques to screen for Ebola, Marburg, and other filoviruses and henipaviruses.

Aim 3. To characterize factors associated with human exposure to filoviruses and henipaviruses. Combining the data collected in Aim 1 (humans) and Aim 2 (bats), we will identify the demographic, behavioral, and environmental factors associated with an individual's prior exposure to filoviruses and henipaviruses. Detailed animal exposure data collected from the adults and children (some born after the Ebola outbreak) who provided the Aim 1 blood specimens will be used to develop profiles of risk and inform public health and risk reduction communication tools in partnership with the Ministry of Health, Liberia.

RESEARCH STRATEGY

A. SIGNIFICANCE

Zoonotic viruses are responsible for the majority of emerging infectious disease outbreaks, which are occurring at an accelerating rate in global hotspots^{1,4,8}. Every outbreak begins with spillover—transmission of the virus from its animal reservoir either directly into human populations or into other animal hosts *en route* to humans (**Figure 1**). **Exactly how often spillover occurs is virtually unknown**, as surveillance systems are primarily designed to detect clusters or outbreaks, and often miss initial individual infections that result from animal contact. To reduce the risk of future epidemics, it will be necessary to limit opportunities for zoonotic virus spillover and to detect spillover at the earliest stages.^{2,9} Measuring the efficacy of any interventions designed to reduce spillover and spread of zoonotic pathogens will rely on measuring rates of exposure in at-risk human populations.

Filoviruses and henipaviruses are among the highest consequence zoonotic viruses and have greatly impacted public health. Each group contains zoonotic pathogens that cause significant disease in both people and animals, especially livestock, that have been associated with extremely high rates of morbidity and mortality. Ebola (EBOV) and related viruses, as well as Nipah virus (NIV), a henipavirus, and its related viruses have been listed by the World Health Organization (WHO) among the highest priority pathogens for the development of vaccines and therapeutics, as they represent zoonotic pathogens with high potential to threaten human health, with extremely high mortality rates and few or no therapeutics or vaccines currently available¹⁰⁻¹². These viruses share other important features which make them high priority: they are all associated with bat hosts that are abundant and widely distributed throughout Africa and Asia, living in close association with people and livestock in some of the most densely populated regions on Earth.

Spillover of these viruses has repeatedly occurred. Beyond the massive 2013-2016 outbreak in West Africa, EBOV outbreaks have occurred repeatedly in Central and East Africa, including a recent Sudan ebolavirus outbreak in Uganda in late 2022¹²⁻¹⁴. Marburg virus (MARV) and Ravn virus (RAVV) comprise the closely related genus *Marburgvirus* and have caused outbreaks in Central and East Africa and Europe with mortality and clinical presentation comparable to Ebola^{15,16}. MARV outbreaks were declared in Guinea in 2021, just across the border from the UNC-Liberia research site, and again in Ghana in 2022, marking the first time this virus was reported in either country^{17,18}. NIV is an emerging zoonotic paramyxovirus that causes nearly annual outbreaks in Bangladesh, including multiple in 2023, and sporadic outbreaks in India with mean case fatality rates over 70%^{13,19-21}. Despite the public health significance of Nipah and related viruses, little is known about their genetic diversity, natural reservoirs, or the frequency of spillover throughout their range, including Africa. Henipaviruses, and NIV in particular, have several characteristics that make them a global health priority: 1) Their bat reservoirs occur throughout Asia and Africa, overlapping human and livestock populations, giving them geographically broad opportunity to cause outbreaks²²; 2) henipaviruses can be transmitted to people directly from bats or via domestic animals²²; 3) NIV can be transmitted from person-to-person²³; 4) NIV spillover has and continues to occur in highly populous and internationally connected regions; 5) repeated spillovers of NIV strains with varying person-to-person transmission rates indicate the ability to evolve **with increased pandemic potential**^{24,25}; and 6) Nipah is associated with a high mortality rate in people and currently has no vaccine or treatment^{22,24}. While NIV has not been detected in Africa, closely related henipaviruses have been identified in Ghana and Madagascar, though their public health significance remains unknown²⁶⁻²⁸. In West Africa, where bats and

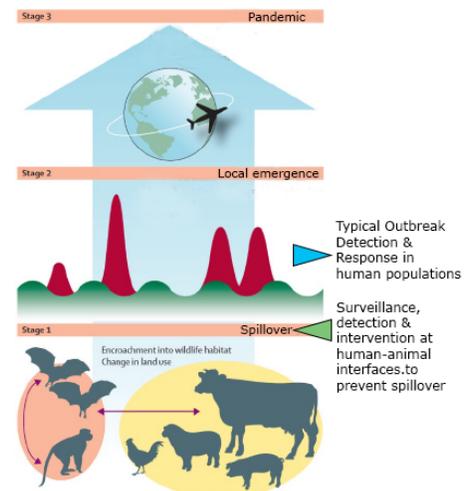

Figure 1. Most pandemics are caused by zoonotic viruses from animal reservoirs. Interventions that prevent spillover, rather than try to contain outbreaks, are needed. Adapted from 1.

associated henipaviruses occur but no human cases have been identified, **diagnostic testing and systematic surveillance is essentially non-existent**. The detection of antibodies against a Nipah-related virus in hunting communities in Central Africa suggests that cryptic spillover is occurring²⁹. **Repeated spillover of henipaviruses creates opportunity for more transmissible strains to emerge**³⁰.

While bats have been identified as potential hosts for filoviruses including EBOV, the natural reservoir for EBOV-Zaire Ebola in West Africa remains unknown. There is substantial evidence, both serological and molecular, that bat species host filoviruses; however, a definitive natural reservoir or set of reservoirs for EBOV-Zaire has not been identified³¹. Wildlife, including bats, represent a substantial source of animal protein for communities in Liberia³². People may be exposed to bat-borne viruses through hunting and butchering, eating food contaminated by bat excreta, or entering caves or mines inhabited by bats. Our group previously found that people living in rural areas of Liberia conduct activities which may increase their risk of contact with bats or their bodily fluids. In the 2013 Ebola outbreak, the index case was a child who was hypothesized to have had contact with bats, yet the exact species was never definitively identified³³. The route of spillover for most historical Ebola outbreaks remains a mystery. Despite broad efforts to determine the natural reservoirs of EBOV and related viruses, there continues to be a poor understanding of filovirus ecology, with the exception of MARV, whose host has been identified as Egyptian rousette bats (*Rousettus aegyptiacus*)³⁴⁻³⁶. Communities known to hunt bats in Cameroon and India have been found to have antibodies against henipaviruses and filoviruses, respectively, yet nothing is known about community exposure rates in Liberia, where bat hunting is common^{29,37}. Our preliminary data (see below) suggest that there is substantial exposure to EBOV as well as MARV among people in central Liberia. While the EBOV antibodies may indicate prior infection from another person such as during the West Africa outbreak, antibodies specific to other filoviruses may signal a localized exposure from animals. Even less is understood about henipaviruses in Africa; identifying antibodies against henipaviruses in people will be critical for understanding where, how, and how often spillover occurs.

The urgent need to develop interventions to prevent spillover of zoonotic high-consequence pathogens can only be met with a better understanding of their natural reservoirs, the rates of exposure in vulnerable human populations, and the ways in which people are exposed. Unrecognized outbreaks provide opportunities for viruses to emerge that may be more transmissible or more pathogenic than previously observed, and limiting these opportunities is an important component of pandemic prevention^{3,30}. Typically, by the time an outbreak is recognized in human populations, its containment and control are difficult, if not impossible, to achieve (e.g., HIV, SARS-CoV-2). Understanding the ecology of these viruses, including which species act as reservoirs as well as how and to what extent people are being exposed to filoviruses and henipaviruses, will inform intervention and surveillance strategies. Importantly, it will also provide baseline metrics against which one can measure the efficacy of interventions designed to reduce exposure, such as public health campaigns to promote avoidance of behaviors associated with infection among those most at risk (**Figure 1**).

This proposed study will be one of the most rigorous One Health investigations of spillover of high-consequence zoonotic viruses from bats to humans in an emerging disease hotspot. West Africa is known to be the source of prior outbreaks of emerging infectious diseases and future spillover events there are highly likely. Liberia is typical of this region and contains some of the largest tracts of pristine forest and wildlife biodiversity remaining in West Africa and has a population that depends on wildlife, including bats. Decades ago, a spillover event from a non-human primate to a human triggered an ongoing HIV pandemic that has led to the infection of over 60 million people and 25 million deaths. Only months ago, the orthopoxvirus mpox, which is found in rodents, spread to and within 110 countries across the globe and caused over 85,000 cases. Both originated from African wildlife. The proposed study will leverage the unique infrastructure and expertise we have developed in Liberia to undertake a comprehensive examination of filovirus and henipavirus spillover from bats to humans and provide evidence of previous and possibly on-going transmission events. Our findings will provide essential evidence of the presence and transmission dynamics of these bat-borne viruses and of the risks for infection in people living alongside them.

B. INNOVATION

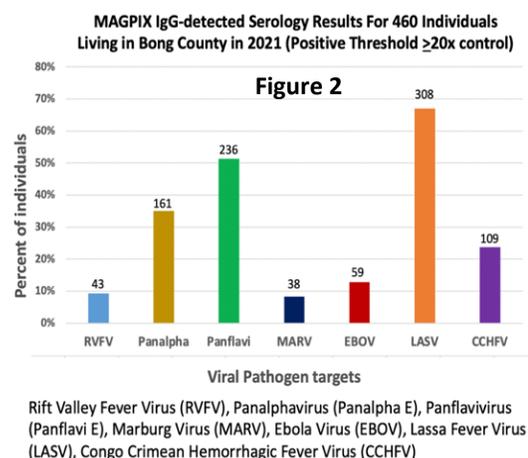

The proposed research is highly innovative in multiple ways, including: 1) Our use of a One Health approach to study the ecology and epidemiology of two groups of high-priority, high-consequence zoonotic viruses in both bats and people in West Africa – an emerging disease hotspot where spillover events have occurred (e.g. Ebola, Marburg, mpox, Lassa fever) and are highly likely to re-occur; 2) Our use of a novel and unique multiplexed serological platform, developed by our group, that will allow us to screen bat and human serum for IgG antibodies against each of the known filoviruses and henipaviruses, simultaneously in a single assay. Longitudinal comprehensive serological studies in bats and people **will provide unprecedented insight into the changes in rates of exposure to known as well as unknown, antigenically related viruses over time in both bats and people (e.g., what is the baseline rate of exposure to henipaviruses and filoviruses and is there evidence of recent exposure?)**; 3) We will couple serosurveillance with molecular testing to identify specific filoviruses and henipaviruses carried by bats; and 4) We will connect the bat and human epidemiological studies by analyzing questionnaire data from the human cohort to identify high-risk behaviors and other factors associated with viral exposure. **Results from this analysis will inform the development of public outreach and risk reduction campaigns by the Government of Liberia.**

C. APPROACH

C.1. Overview: **Aim 1** will test the hypothesis that spillover of filoviruses and henipaviruses, present in local bat populations, occurs regularly in rural Liberia by testing for IgG antibodies to all known filoviruses and henipaviruses (see **Table 1**) in archived serum samples from more than 900 people living in Bong County (central Liberia). These samples were collected between 2021-2023 at two time points 24 months apart as part of the Coalition for Epidemic Preparedness Innovations (CEPI)-sponsored **ENABLE Study**, an on-going longitudinal study of Lassa fever seroprevalence and seroincidence. Seroprevalence and seroincidence of filoviruses and henipaviruses will be assessed. In **Aim 2**, we will conduct a 36-month longitudinal study of three bat species which are putative reservoirs for EBOV and undescribed henipaviruses. Using a combination of longitudinal serology and molecular testing (PCR and whole genome sequencing) **we will determine the prevalence of filoviruses and henipaviruses in these key bats species associated with the rural human populations studied in Aims 1 and 3.** For **Aim 3**, we will analyze detailed questionnaire data developed collaboratively by our group (EHA and UNC) and collected in 2023 along with the blood samples to be screened in Aim 1. These data will allow us to identify factors associated with exposure to henipaviruses and filoviruses. We will use results from our exposure risk assessment to develop public risk reduction communication strategies with the National Public Health Institute, Liberia, using the results of this study to inform public health strategies. This application is a natural progression of our research activities, and our preliminary data speak to the feasibility of the proposed study.

C.2. Aim 1: To determine the rates of filovirus and henipavirus exposure in people in rural central Liberia.

C.2.1. Rationale and Preliminary Data. The primary goal of this aim is to be able to determine whether populations within Liberia who live in association with bats have evidence of exposure against one or multiple filoviruses and/or henipaviruses and to compare rates of exposure over time. Studies of human populations in Central and West Africa have found evidence of exposure to EBOV prior to the 2013 outbreak and in places not known to have had Ebola outbreaks^{38,39}. UNC Project-Liberia has previously assessed seropositivity to consequential viral pathogens including EBOV and MARV in a subset of ENABLE Study participants. Over 8% of participants had antibodies against MARV, using a conservative seropositivity threshold (**Figure 2**), suggesting

that unreported spillover events have previously occurred. Acute encephalitis is common in western sub-Saharan Africa, yet outbreaks of neurological disease are rarely reported and more than half of all cases are undiagnosed⁴⁰. Among the countries in western Africa reporting cases of meningitis or encephalitis, Liberia has reported the fewest, likely due to a lack of surveillance and capacity to diagnose neurological diseases⁴⁰. NIV encephalitis has never been reported in Africa; however, as described above, two Nipah-like henipaviruses have been described in bat hosts, including one in Ghana^{26,28}. Spillover of henipaviruses was reported in bat-hunting communities in Cameroon²⁹. In South Africa, we detected henipavirus sequences in *Rousettus aegyptiacus*, bats which also commonly occur in Liberia²⁷.

In Aim 1, we will test the hypothesis that spillover of both filoviruses and henipaviruses have occurred in rural populations in Liberia by measuring seropositivity to both groups of viruses within the ENABLE Study community cohort. We will also measure changes in exposure rates over a two-year period. While prior studies have provided cross-sectional snapshots of exposure, our longitudinal approach will provide data from the same cohort at two timepoints, 24 months apart, to determine both seroprevalence and seroincidence using a multiplexed serological assay to screen for IgG antibodies against all known filoviruses and henipaviruses.

Settings and Participants. To achieve this aim we will leverage a well characterized cohort of individuals in three rural communities located in Bong County, Liberia (**Figure 3**), which has a population of over 333,400. UNC Project-Liberia has been operating in Liberia since 2014 and established a research site at Phebe Hospital in Bong County, which includes a molecular laboratory that conducts daily qPCR testing for LASV, MARV, and EBOV as well as LASV serological assays using a MAGPIX (see RESOURCES AND FACILITIES). There, following extensive community engagement including meetings with key stakeholders, town hall meetings, and radio messaging, UNC launched the ENABLE Study, the largest passive and active surveillance program for Lassa fever in Liberia. Starting in 2021, 5,005 randomly selected participants 2 years of age and older in Phebe Airstrip, Suakoko, and Rubber Factory were enrolled over a period of 6 months, following informed consent/assent (mean age at enrollment is 22.2 years (range 2-97) and 54.2% are female). **Importantly, 7.7% of the cohort is under the age of 5 years, and therefore, were born after the 2013-14 Ebola outbreak.** Households were selected for recruitment following identification of rooftops by satellite photos and use of a program developed by Médecins Sans Frontières' (MSF) Epicenter to randomly select structures to approach sequentially for participation. The ENABLE Study includes baseline questionnaires and blood specimen collection from all participants with active follow-up by a study community health worker every 2 weeks to determine if a febrile event has occurred, which triggers drawing of blood for LASV, MARV, and EBOV PCR. Baseline blood is tested for Lassa fever virus (LASV) serology. A subset of 1,024 individuals (every 5th approached household is eligible) is also asked to provide blood samples routinely every 6 months for up to 24 months for repeat LASV serology. The blood samples from 0 and 24 months and the associated surveys will be used in Aims 1 and 3 of this proposal. Informed consent and assent documents include provisions for the use of collected specimens and data for infectious diseases research including for emerging pathogens (see PROTECTION OF HUMAN SUBJECTS).

C.2.2. Research Design. We will screen approximately **1,900 archived serum specimens** from participants in the ENABLE Study cohort at two time points ("baseline" at month 0 and again at month 24) for IgG antibodies against specific filoviruses and henipaviruses using the MAGPIX at the UNC molecular lab at Phebe Hospital to run the multiplexed *henipavirus / filovirus* platform to be provided by Co-I Laing in year 1 of the study. The multiplex platform will allow us to determine specifically which filoviruses and henipaviruses people have been exposed to and compare that to the filoviruses and antibodies we observe circulating in local bat populations in **Aim 2**.

Figure 3. Locations of UNC CEPI ENABLE study sites and proposed target county.

The bead-based multiplexed assay has tremendous advantage over traditional ELISAs in that it will identify up to 25 different antibodies against multiple viral agents in a single, 2uL serum sample and uses a high throughput format. The ability to look at reactivity across all serogroups simultaneously will allow us to differentiate among the viruses. Proteins A/G non-specifically bind IgG immunoglobulins, and weakly bind IgM, an immunoglobulin that is the first to be produced during the initial stages of infection. We will conduct a 1-week training at the UNC-Phebe lab for using the assay to detect filovirus and henipavirus antibodies as well as data management, bioinformatics, and analysis. **Table 1** shows the viral species and antigens that will be employed in this assay. The platform has been previously transferred to collaborating labs in the UK, South Africa, India, Bangladesh, Singapore, Thailand, and Malaysia. We have previously detected serological profiles of Asiatic ebolaviruses in fruit bats collected in Singapore⁴¹, and in fruits bats as well as humans actively engaged in bat hunting in northeast India³⁷.

C.2.3. Data Analysis. We will create a project database using Airtable, which will be hosted at EHA and will house all data from Aims 1 and 2 and will link to the REDCap server which stores questionnaire data from Aim 3. Database access will be secure and limited to key personnel (see DATA MANAGEMENT AND SHARING PLAN). Raw MFI values from the MAGPIX will be used to calculate reactivity to each viral antigen and, based on relative strength of reactivity and determinations of negative cutoffs based on reference sera, we will calculate prevalence rates for each time point and compare rates between the two timepoints. Serological profiling can be used to detect reactive antibodies against all specific filoviruses and henipaviruses in a sample and compare strength of reactivity and cross-reactivity against multiple antigens using a single sample⁴². We will compare the antibodies across all specific viral antigens to assess which virus or groups of viruses are responsible for the immunological response⁴³⁻⁴⁵. We will assess exposure to non-Zaire ebolavirus species, which may indicate spillover of filoviruses has occurred separate to the Ebola outbreak of 2013. We will also look at evidence for exposure to Nipah-like henipaviruses and compare exposure rates to both viral groups within and between our two sample collection time points.

C.2.4. Expected outcomes. We anticipate obtaining serological profiles of exposure to filoviruses and henipaviruses from each individual in our cohort. In previous studies we found antibodies against both EBOV and MARV. While the EBOV antibodies are attributable to the epidemic, MARV antibodies, in patients EBOV IgG negative, suggest possible exposure from an animal (e.g., bat) reservoir. We also anticipate seeing reactivity to

Bombali virus (BOMV), given the presence of the reservoir species in Liberia (*Mops condylurus*) and reactivity to the African henipaviruses (GhV and AngV), although this may represent reactivity to an antigenically related virus. Serological results from this and the bat study will inform our strategy for prioritizing which bat samples we test by PCR.

C.2.5. Potential problems and solutions. While our preliminary data suggest there will be detection of immune responses to filoviruses including EBOV-Zaire and, significantly, MARV, it is possible that evidence of exposure to other pathogens, including henipaviruses, will not be detected. This would be an important finding in this large cohort, especially if these viruses are detected in local bat species, that would warrant further investigation. It is also possible that there will be few or no seroconversion events among the cohort during the 24-month period of follow-up. This too would be reassuring but would suggest a need for longer follow-up of

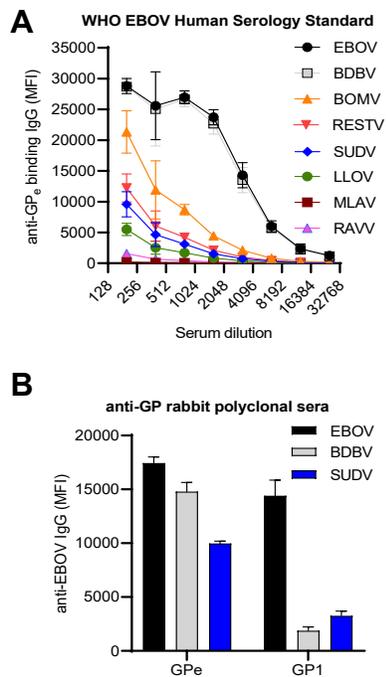

Figure 4. A) The WHO EBOV human serology standard was tested for immunoreactivity in a filovirid GP-trimer based multiplex assay. Filovirids are indicated along with sera dilution factors; data is the mean of three independent experiments. **B)** Antisera from EBOV GP-trimer immunized rabbits were tested in multiplex panels comprised of GP-trimer and GP1 subunit proteins. Anti-EBOV polyclonal IgG was less reactive with GP1 from BDBV and SUDV.

this cohort. To address the possibility that reactivity to EBOV-Zaire virus may be explained by infection during the 2013 Ebola epidemic, we will create a polyclonal sera reference standard utilizing WHO convalescent sera collected from human survivors of Ebola virus disease (EVD). This internal reference standard will be calibrated to the WHO EBOV human serology standard (**Figure 4A**) permitting direct interpolation of anti-EBOV IgG as an MFI to a standard antibody concentration (binding antibody units/mL). The internal reference standard will then be included in our human serology testing strategy allowing semi- or quantitative measurement of anti-EBOV IgG. These EBOV human serology standards will permit us to establish positive and negative predictive performance values for the

multiplex assay; furthermore, we will be able to investigate immunoreactivity of EVD survivors against heterotypic ebolaviruses. Our preliminary data indicates that EBOV+ sera IgG is highly cross-reactive with soluble native-like trimeric envelope glycoprotein (GP) antigens from both EBOV and BDBV (Figure 5A). EBOV GP, matrix protein (VP40), and nucleocapsid protein (NP) antigens have all been used in a variety of serological tests; however, the frequency of seroconversion against each antigen has not been fully described. In a longitudinal study of EVD survivors, high seroconversion against GP and VP40 was observed, with affinity maturation occurring overtime against GP⁴⁶. Antigens based on the GP are likely to provide an optimal intrinsic balance of sensitivity and specificity. To limit the degree of heterotypic ebolavirus cross reactions, we will test any anti-ebolavirus GP trimer antigen-seropositive samples with a pan-ebolavirus GP1 antigen-based panel. In preliminary studies, GP1 antigens improve specificity and differentiation of antibodies reactive with homotypic ebolaviruses in polyclonal antisera from rabbits immunized with GP trimer immunogens (**Figure 4B**).

C.3. Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia.

C.3.1 Rationale and Preliminary Data. Bats have been established as important hosts for filoviruses and henipaviruses in Africa and Asia, with combinations of viral isolation, molecular detection or serology providing substantial evidence^{31,47-50}. MARV was isolated from Egyptian rousette bats in Uganda, and RNA has since been detected in these bats in Sierra Leone, which borders Liberia⁵¹. To date, EBOV has never been isolated from bats, although molecular and serological evidence suggest that multiple frugivorous bats may carry EBOV in Central Africa^{51,52}. Prior to the 2014 epidemic, Zaire ebolavirus had not been reported in West Africa, and the animal reservoir remains unknown³³. From 2016-2019, our group (PI Epstein & KP Desmond)

implemented a large-scale effort under the USAID PREDICT Project to identify reservoirs for EBOV in West Africa⁵³. This led to the discovery of a new species of Ebola (Bombali virus)⁵⁴, the detection of MARV in Egyptian rousette bats in Sierra Leone³⁴, and **in 2018, we detected, for the first time in West Africa, EBOV RNA and anti-EBOV IgG antibodies in bats (Figure 5A-D).**

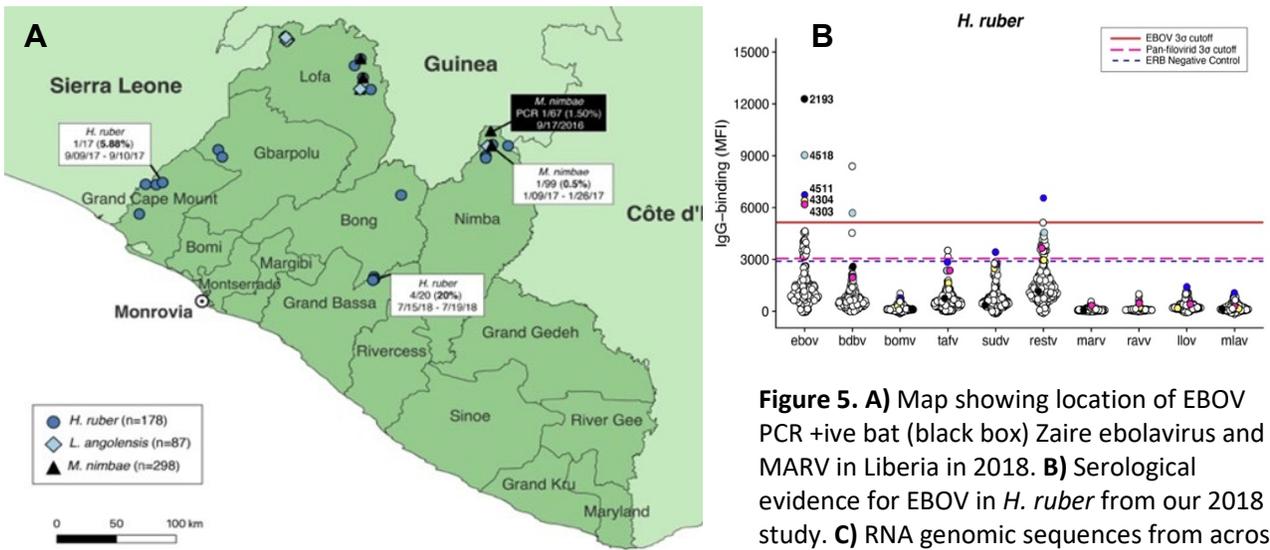

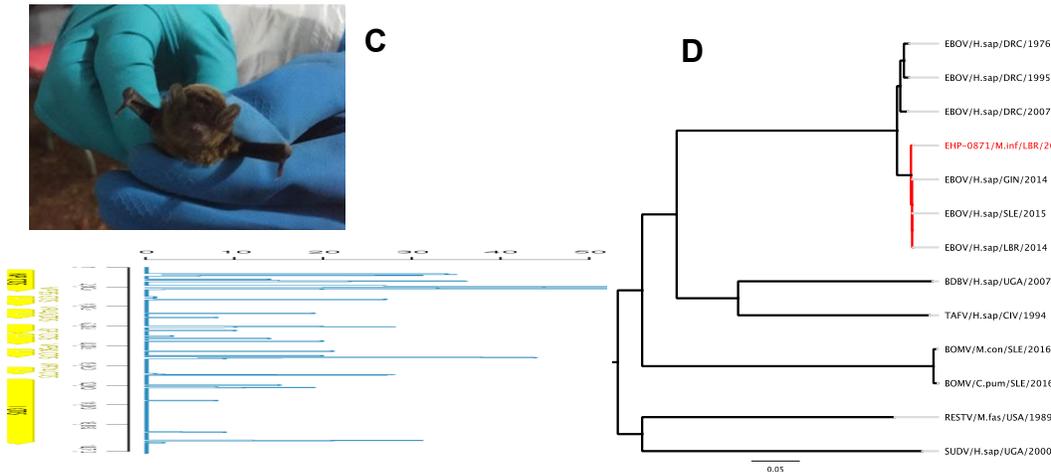

Figure 5. A) Map showing location of EBOV PCR +ive bat (black box) Zaire ebolavirus and MARV in Liberia in 2018. **B)** Serological evidence for EBOV in *H. ruber* from our 2018 study. **C)** RNA genomic sequences from across the *Zaire ebolavirus* genome detected in *Miniopterus nimbae*, Liberia in 2018. **D)** Phylogenetic analysis supports relatedness to 2013 EBOV epidemic virus.

We also detected antibodies reactive against multiple henipaviruses (NiV, Mojiang and GhV) in the same bats (Figure 6). While this finding generated the first evidence of which bats may be reservoirs for Zaire ebolavirus and unknown henipaviruses, longitudinal studies are required to more completely understand the role these species

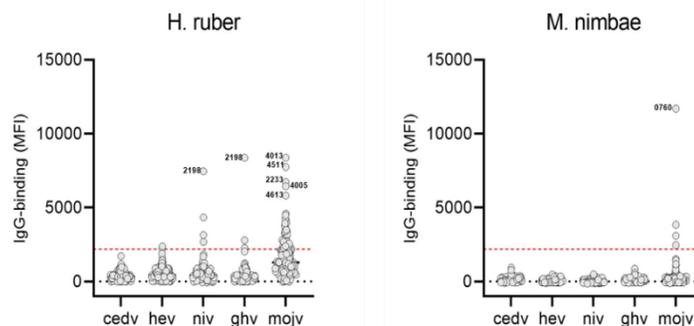

Figure 6. Detection of IgG antibodies reactive to multiple henipaviruses in the two bat species that may carry EBOV in Liberia.

play in EBOV and henipavirus circulation – either as reservoirs that maintain these viruses within a local population, or as incidental hosts, infected by an unknown bat species.

One-off, cross-sectional studies have a low probability of detecting any specific filovirus or henipavirus given their low prevalence and short viremic periods^{35,55}, and thus provide a poor characterization of viral diversity. The lack of understanding of **filovirus and henipavirus diversity and their natural reservoirs in West Africa significantly impedes risk-based public health interventions to prevent human outbreaks**. Longitudinal sampling is also needed to separate reservoir hosts from spillover hosts. For example, MARV has been isolated repeatedly from *R. aegyptiacus* in Uganda, which, when paired with experimental infection studies showing infection and shedding of MARV by *R. aegyptiacus*, strongly suggests that *R. aegyptiacus* is indeed a MARV reservoir^{36,56,57}. Similarly, our longitudinal studies of NIV in *Pteropus medius* bats in Bangladesh, which included the same multiplexed serological assay proposed here, confirmed them as a reservoir for NIV and identified important mechanisms driving viral circulation³⁰. **Understanding which species persistently carry filoviruses and henipaviruses will provide important insights into how they are maintained in nature and which species should be targeted for follow-up studies on bat habitat use and human-bat contact patterns.**

C.3.2. Sampling design. We will repeatedly sample three bat species associated with filoviruses or henipaviruses, based on our preliminary data: *M. nimbae* (EBOV), *H. ruber* (EBOV), and *R. aegyptiacus* (MARV & Henipaviruses). We will sample bats at roost sites in Bong County, as close as possible to the human study sites in Aim 1. In Y2-Y4, we will sample 40 individuals of each species every two months for 36 months and collect excreta using plastic tarps placed underneath bat roosts (details below and in C.3.3).

Bat capture and sampling. Briefly, we will use either harp traps or mist nets to capture bats, depending on the capture site. Personnel will wear appropriate personal protective equipment (e.g. Tyvek suits or dedicated long clothing; double nitrile gloves; an N95 respirator and safety glasses or a PAPR)⁵⁸. Traps and nets will be attended continuously during capture periods. Bats will be removed from mist nets immediately upon entanglement to avoid injury. Bats will be removed from harp traps after approximately 1 hour and placed in individual cloth bags until processed. Body measurements, blood, oropharyngeal swabs, and rectal swabs (or fecal pellets) will be collected from each bat. Swabs will be collected in duplicate; one swab will be placed in a cryovial containing Trizol lysis buffer and the other in viral transport medium (VTM). For bats <50g, blood will be collected in a microhematocrit tube and spun down using a portable centrifuge. A bulb will be used to expel serum from the tube into a cryovial. For larger bats >50g, a tuberculin syringe or 1ml syringe and 27g needle will be used to draw blood from the radial artery or vein⁵⁸. Blood will be placed into a conical vial and centrifuged. Serum will be aliquoted into a cryovial using a pipette. During site visits we will also lay out plastic tarps to collect pooled environmental excreta in Trizol and VTM to improve opportunity to detect viral RNA. All samples will be placed in a vapor phase liquid nitrogen dry shipper or portable battery-powered ultracold freezer immediately upon collection and then transferred to a -80C freezer at the Phebe lab until testing.

C.3.3. Testing plan, Data analysis, sample size, and power analysis.

Serology: At the end of Y3, we will screen all serum samples collected to date, at the UNC-Phebe lab, using the MAGPIX multiplex assay for IgG against filoviruses and henipaviruses. We will analyze temporal dynamics in seroprevalence using general additive models (GAMs), which are analyses that we have used successfully in many previous studies of similar design³⁰. These methods are well adapted for capturing long-term temporal fluctuations in prevalence and moderately sensitive at capturing short-term changes in seroprevalence which can be used to identify population-level disease outbreaks. For example, we estimated that, with 40 bats sampled every two months, we would be able to statistically detect an increase in seroprevalence (at a 95% CI limit) of greater than 25% between consecutive sampling events > 80% of the time, assuming a bat population seroprevalence of at least 10% in advance of a bat colony infection (estimated by, in brief, by simulating a fluctuating true seroprevalence value, simulating samples given this underlying seroprevalence, fitting a GAM to these samples, and then calculating if CI on true prevalence between the two sampling occasions over which the change in seroprevalence occurred were non-overlapping). While this is a large change, it is within a range to be

expected if infection were to sweep through a bat community³⁰. MAGPIX-positive bat sera will be sent to RML for serum neutralization assays using VSV pseudoviruses or viral isolates under BSL4 conditions.

VSV-pseudotype neutralization assays: Serological results will be confirmed using VSV-pseudotype neutralization assays for the following filoviruses EBOV, SUDV, BDBV, RESTV, BOMV, MARV and RAVN. If novel henipavirus sequences are detected, additional assays will be developed to test positive sera. Serum samples will be inactivated using γ -irradiation (4 MRad). Neutralization of irradiated and heat-inactivated serum samples will be assessed in Vero 352 E6 cells. Briefly, cells were seeded in 96-well round-bottom plates for 24 hours, serial dilutions of heat-inactivated serum samples will be performed in DMEM supplemented with 2% FBS, penicillin/streptomycin, and L-glutamine. Each plate will contain negative serum control, cell-only control, and virus-only control. VSV EBOV-GFP will be added to each well of the serum dilution plate and the serum-virus mix 357 was incubated at 37°C for 1 hour. The mix was added to the cells and incubated at 37°C for 24 hours. The cells will then be fixed with 4% paraformaldehyde at room temperature for 15 minutes and centrifuged at 600 x g for 5 minutes at room temperature. The supernatant will be discarded and FACS+EDTA buffer was added. Samples will be run on the FACSymphony A5 Cell Analyzer (BD Biosciences, Mississauga, ON, Canada) and FITC MFI 362 was measured. Data will be analyzed using FlowJo.

Molecular testing: We will use specific filovirus taqman real-time PCR assays to screen oropharyngeal, fecal, and environmental samples from bats for EBOV and MARV RNA at the UNC-Phebe lab^{54,56}. Testing bat samples by PCR may allow us to detect viral RNA during active infection, providing important information about the prevalence and timing of infection within target species. **Because we expect viral prevalence to be significantly lower than seroprevalence, estimated at <5%**^{26,28,50}, we developed a sampling scheme focused on maximizing our probability of detecting viral RNA with qPCR. To compare power under alternative sampling designs, we built simulation-based power analyses that estimated power to detect: 1) viral EBOV or MARV RNA in at least one bat; and 2) the expected number of positive cases, in each bat species. In brief, we estimated power for total sample sizes between 1500-3000 (500-1000 bats sampled per species) spread across a variable number of visits per year (2-6), while allowing for uncertainty in true infection dynamics in the bat populations, specifically: 1) prevalence during one three-week period (with unknown timing) per year of high prevalence ranging from 1-5%; and 2) an otherwise low background prevalence (0-1%). Given these estimates of yearly infection dynamics, these analyses showed that with 672 samples per species (minimum 32 individual bats per sampling event), spread across 6 sampling occasions per year, we would obtain a per-species probability of acquiring 0 positive samples of <4% (<1% at 40 bats per event – our target number) and an expectation of ~3-6 RNA positive results (~5-10 positives at 40 bats per event). Because henipaviruses have not been previously described in Liberia, we will focus our resources on filovirus testing by PCR. However, if henipavirus serology suggests active circulation, we may send a set of samples to RML for pathogen discovery (see RML LETTER OF SUPPORT).

Viral isolation: PCR-positive cDNA samples and their aliquot in VTM will be sent to RML for further sequencing and attempts at viral isolation under BSL4 conditions. If attempts to culture do not work, we will use next generation sequencing techniques to get whole genome sequence and further characterize the virus at RML. Novel viruses will be characterized and rescued (reverse engineered using a minigenome system to synthetically create infectious viral particles⁵⁹) at RML under secure, biosafety level 4 conditions, then used for serum neutralization assays in bat and human sera to determine more precise exposure rates. Sequences from the glycoproteins of any novel viruses discovered will be used by USU (Co-I Laing) to generate purified proteins and added to the Luminex assay, which will improve its specificity.

VirCapSeq-VERT and myBaits probe-based enrichment for recovery of full-length genome sequences of filoviruses: Although shotgun sequencing provides opportunities to analyze all host and virus genetic material, the larger average genome size of bacteria and hosts compared to viral genomes complicates a detailed analysis of the virome, particularly vertebrate viruses. We have established a positive selection probe capture-based system to enrich for viral sequences. Here, we will take advantage of these probe capture-based methods (VirCapSeq-VERT and myBaits probe library) to enrich for vertebrate viral sequences of interest. Sample libraries will be normalized and combined in 4- to 12-plex reactions for solution capture hybridization using either the

HyperExplore custom bait library version of VirCapSeq-VERT probe set or our custom myBaits probe library. For HyperExplore custom bait library probe set, libraires will be enriched for virus following the SeqCap EZ HyperCap Workflow User's Guide, version 2.3, while for custom myBaits probe library, the myBaits Hybridization Capture for Targeted NGS protocol, Version 4.01 will be used. Sequencing libraries will be normalized and sequenced as 2 X 150 bp fragments on Illumina's MiSeq or NextSeq sequencing platforms, following Illumina's standard procedure (Illumina, San Diego, CA). NGS data will be analyzed using metavirs (<https://openomics.github.io/metavirs/>), a comprehensive viral metagenomics pipeline to assemble, annotate, and classify viruses. It relies on technologies like Singularity¹ to maintain the highest-level of reproducibility. The pipeline consists of a series of data processing and quality-control steps orchestrated by Snakemake2, a flexible and scalable workflow management system, to submit jobs to a cluster. The pipeline is compatible with data generated from Illumina short-read sequencing technologies. As input, it accepts a set of FastQ files and will be run on-premises using the NIAID RML Big Sky supercomputing cluster.

C.3.4. Expected outcomes. Based on our prior work, our multifaceted analysis approach, and calculated power given our proposed temporal sampling strategy, we expect to be able to use temporal serological data to describe filovirus and henipavirus viral dynamics over time. Our molecular screening will primarily focus on filoviruses because we have known targets, and we expect to detect EBOV or MARV RNA, despite low prevalence and short-lived infections. Sequence data from positive samples will 1) provide substantial evidence for the identification of EBOV reservoirs and help explain which virus is responsible for the observed IgG response in bats (and possibly people); and 2) provide valuable information about viral diversity, about which little is known. Henipavirus serology, in the absence of sequence data, will allow us to identify potential bat reservoirs, analyze temporal trends, and generate hypotheses for future targeted studies.

C.3.5. Potential problems and solutions. Serological tests are greatly hindered by the inherent antibody cross-reactivity between antigens from known ebolaviruses, challenging data interpretations that antibodies are EBOV-specific or EBOV, BDBV, and SUDV cross-reactive⁴¹. This is also true for the henipaviruses in the panel. The advantage of the multiplexed platform is that we can simultaneously see relative MFI values for all the

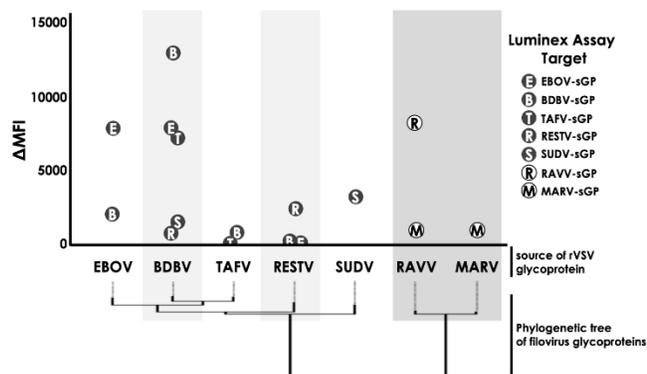

Figure 7. Captive-bred Egyptian rousette bats were experimentally challenged with VSV-filoGPs, the GP source is indicated on the x-axis. In a GP-trimer multiplex test the homotypic ebolavirus bat antisera were most reactive with the homotypic ebolavirus GP-trimer antigen.

filoviruses and henipaviruses. Glycoproteins from the homologous virus should cause the most intense reaction, particularly at higher dilutions. Co-Is Laing and Munster have demonstrated that homotypic and heterotypic ebolavirus-antibody reactions can be simultaneously measured and accounted for in ERBs challenged with replication-competent VSV-filoGP (**Figure 7**). Still, there is some cross reactivity, and we will use additional tools such as viral neutralization assays as a secondary test, and our statistical approach can correct for a portion of cross reactivity. Past studies have relied on individual ELISAs which had varying degrees of specificity depending on which test was used, but often couldn't rule out cross-reactivity. The Luminex filovirus multiplex assay has predictable patterns of cross-reactivity, but we will still be able to discern to which virus the serum is most reactive.

C.4. Aim 3: To characterize factors associated with human exposure to filoviruses and henipaviruses.

C.4.1 Background and rationale. As described above, there is substantial interaction between wildlife, domestic animals, and people living in rural Liberia. Our group collected questionnaire data from 585 people across Liberia as part of the USAID-funded Ebola Host Project between 2016 and 2019. When asked about animal exposures during the 2013-2016 Ebola outbreak, participants frequently reported contact with both domestic and wild

animals. Common types of animal contact included animals coming inside the dwelling (58%), cooking or handling animal meat (44%), and eating raw or undercooked meat (31%). Additionally, 26% reported slaughtering and 12% reported hunting or trapping an animal. Elsewhere in West Africa, EHA participated in the response to Ghana's 2022 cluster of MARV cases, working with local partners to administer a behavioral risk questionnaire characterizing bat exposures in three affected communities¹⁷. Many participants lived in close proximity to bats, with one fifth reporting exposure to bats inside a dwelling or other building in the previous four months. When asked about exposures more relevant to Egyptian rousette bats, a known MARV reservoir and a target species in this proposed study, participants commonly reported bats feeding on fruit trees on their home compound, eating fruit bearing bite marks, and exposure to bats inside a cave or mine. In the ENABLE Study of 5,005 residents of Bong County, which will be the source of preexisting survey data for our proposed study, baseline survey questions mainly focused on rodent exposures relevant to Lassa fever. 14% of participants reported hunting or preparing wild animal meat, but little is currently known about the prevalence and type of other potential bat exposures in this region of Liberia. However, EHA has collaborated with UNC to incorporate additional bat-specific exposure questions into the ENABLE Study's month 24 survey (to be conducted in 2023). These additional questions are based on EHA's experience in Ghana and with the Liberia Ebola Host Project, and the resulting data will provide a clearer picture of human-bat interactions in these communities.

C.4.2. Research design. As described in Aim 1, serum collected at baseline (in 2021) and at month 24 (in 2023) during the ENABLE Study will be screened for filoviruses and henipaviruses (analyses not included in the ENABLE Study protocol), enabling us to calculate seroprevalence at baseline and seroconversion over a two-year period. In addition to providing blood specimens, the 1,024 participants who initially enrolled responded to baseline questionnaires on demographics, healthcare-seeking behaviors, health status, and animal exposures. At month 24, the 921 participants still actively enrolled will be administered repeat questionnaires. This final survey includes additional items based on the Ghanaian questionnaire and asks specifically about bats including the respondents' activities in their habitats (entering forests, caves, and mines), direct contact (hunting, eating handling), indirect contact (presence in home or other used structure), and observed characteristics of bats encountered (fruit tree dwelling). By pairing this existing survey data with the new serology results generated from archived samples under Aim 1, as well as new data on nearby bat infection from Aim 2, we will be able to develop comprehensive risk profiles for exposure to filoviruses and henipaviruses in these communities.

C.4.3 Data analysis. The primary outcome for this analysis will be testing positive for IgG antibodies against any known filoviruses or henipaviruses. For both families of viruses, and for each species of virus within those families, we will use the serology results generated under Aim 1 to examine risk factors for seropositivity at baseline and for seroconversion between baseline and month 24. We plan to conduct a multivariate logistic regression, with appropriate weights applied to account for the single-stage cluster sampling design of the ENABLE Study, in which members of randomly selected households were surveyed and tested. We will use data from both the baseline and month 24 questionnaires to examine the effects of sampling site, participant demographics (e.g., age, gender, occupation), environmental exposures (e.g., animals present in and around the dwelling), and behavioral risks (e.g., direct contact with bats through hunting, preparing, or eating them, entering caves or mines where bats live).

Power analysis: To assess our power to identify risk metrics for seroconversion (or overall seropositivity), we built simulation-based power analyses that consisted of, in brief: 1) simulating survey responses for N (400-1000) individuals, while allowing for moderate unevenness in representation across five binary categories (as large as 80%-20%, for example); 2) examining a range of effect sizes (odds ratios ranging from 1-2.5) for these five binary categorical predictors (e.g., sex, encountered a bat, handled a bat, etc.). Summarizing across 1,200 simulations of surveys of 400-1000 individuals given joint uncertainty in the representation within these surveys and effect sizes, we estimated that we would have at least 80% power to detect significant effects for each predictor given an odds ratio of 1.65 or greater with 1,000 survey responses or ~1.80 (for example, with a rate just under 5% for Group1 = 0, just over 8% for Group1 = 1) with 750 responses.

C.4.4 Expected outcomes. By combining serology results with detailed questionnaire data on participant demographics and animal exposures, we will be able to use odds ratios to identify behaviors significantly associated with seropositivity (e.g., exposure to filoviruses or henipaviruses). We expect to be able to also identify age- and gender-based risk factors given our sample size. Based on previous experience conducting behavioral risk surveys, including a recent study in Ghana following a Marburg outbreak, we expect to be able to develop risk mitigation messaging that uses evidence from Aims 1 and 2 as well as results from this aim.

C.4.5 Potential problems and solutions. We anticipate that most IgG positive individuals for either set of viruses will be adults, with the likelihood of exposure and having antibodies increasing with age. Because we don't know how long IgG antibodies persist at detectable levels, it will not be possible to accurately determine when exposure occurred, with the exception being EBOV antibodies that most likely occurred as a result of contact with another infected person during the 2014-2016 outbreak. We will address this in two ways: by looking at respondents 2-6 years of age, we will know that any filovirus antibodies they have are most likely not due to the epidemic, and we will be able to determine whether there are any significant associations with particular behavior or other factor (e.g., household construction, domestic animal exposure) that promotes direct animal contact, consumption of contaminated fruit, or exposure to bat habitats (e.g., caves or mines). For adult respondents, we will focus on exposures (based on relative MFI values) specific to non-EBOV filoviruses and henipaviruses and see whether there are associations with specific behaviors.

D. Summary and Conclusions.

West Africa is a hotspot for emerging zoonotic viruses such as Ebola, Marburg, and potentially Nipah-related henipaviruses—groups that have been identified by WHO as among the most significant pathogens that threaten global health. Liberia is also a biodiversity hotspot, with some of the largest tracts of primary forest remaining in the region; its population relies on wildlife as a primary source of protein, creating continued risk of spillover of high consequence zoonotic pathogens. This project aims to comprehensively characterize the risk of filo- and henipavirus spillover events by measuring seroprevalence and seroincidence among a well characterized cohort of individuals in rural Liberia; identify bat reservoirs for Zaire ebolavirus, other filoviruses, and henipaviruses; and identify host, behavior, and environmental risk factors associated with exposure to these viruses. The results of this work will inform upstream interventions designed to prevent spillover and downstream interventions to facilitate early detection of human infections through implementation of pathogen-specific diagnostics. Our group comprises an unparalleled multidisciplinary group of leading experts in epidemiology, clinical medicine, virology, serology, and disease ecology all with deep experience working in Liberia and implementing zoonotic virus research, as well as strong partnerships with the Liberian public health institutions, giving this project a high likelihood of success in generating impactful results that will help prevent future epidemics in West Africa.

We did it!

Great job everyone! Thanks for all of your input, I think it came together nicely. Special thanks to Shannon and Madeline for all the hard work you did to keep us on track and make sure the proposal came together on time. Attached is the final version, as submitted.

I'll be interested to see what the reviewers think. I requested that it go to the TVZ study section which handles One Health and disease ecology type proposals. I believe it's a new study section, but it's really a good fit and I know several of the members.

Have a great weekend, everyone!

Cheers,
Jon

EcoHealth Alliance develops science-based solutions to prevent pandemics and promote conservation

Specific Aims

Emerging infectious diseases - predominantly caused by zoonotic viruses - have become a major threat to individual and public health as well as the functioning of a global society. Even prior to the SARS-CoV-2 pandemic, outbreaks of consequential high consequence emerging pathogens including SARS-CoV, Pandemic influenza 2009, Zika virus, and Ebola virus disease have not only caused significant morbidity and mortality but have also tragically killed and disabled and caused led to massive disruptions of regional and global economies and health care systems¹. The emergence-size and frequency of consequential high consequence zoonotic infections are increasingis accelerating, due to anthropogenic drivers such as climate change, land-use change, intensification of livestock production, and wildlife trade, all of which increase opportunity for people and domestic animals to come into contact with wildlife reservoirs²⁻⁵. **To reduce the risk of infectious disease epidemics, there is a critical need to detect and prevent spillover of zoonotic pathogens from wildlife reservoirs^{2,6}.**

Illustrative of this need is the repeated spillover from wildlife reservoirs to human populations of groups of zoonotic viruses such as filoviruses (e.g., Ebola virus [EBOV]) and henipaviruses (e.g., Nipah virus [NIV]). Large-scale outbreaks or clusters of cases with these high-mortality zoonotic viruses have led to their being **designated as high priority pathogens by the World Health Organization (WHO)**⁵. However, at present, the detection of outbreaks caused by these pathogens occurs only after clusters of the first human infections and deaths occur; a failure in prevention that is deadly, costly, and remediable¹. Identifying natural reservoirs of zoonotic viruses and measuring rates of exposure to these viruses in humans can inform both up and down-stream interventions to both are critical to assessing their potential threat and developing interventions that reduce the risk of spillover and accelerate early detection.^{1,2}

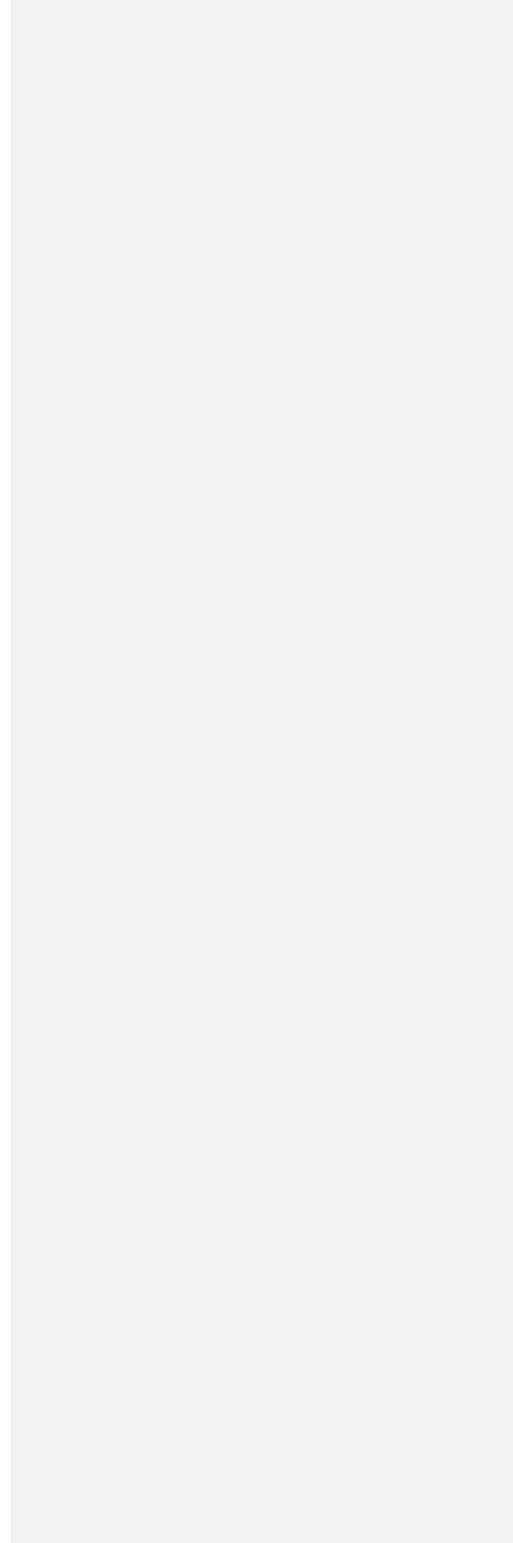

In the proposed study we have assembled a diverse team of experts in ecology, epidemiology, virology and immune response to bat-borne viral zoonoses such as filoviruses and henipaviruses; and filovirus clinical care and research who are actively working in West Africa to provide much needed empirical evidence to help answer the questions: **What is the natural reservoir for Ebola virus and how often does spillover of this and related viruses happen in a region that is an emerging disease hotspot, suffered the world's largest filovirus outbreak, and where there has been evidence of other consequential zoonotic viruses in animals and people?** To address these questions, we propose the following specific aims:

Aim 1. To determine the rates of filovirus and henipavirus exposure in people in rural Liberia. We have shown that certain bat species in Liberia carry EBOV-Zaire, while others carry Marburg virus and henipaviruses. Further, hunting bats is a common activity and we have detected high seroprevalence of Marburg and EBOV antibodies in residents of rural Liberia. Exposure to henipaviruses remains unknown. To test the hypothesis that spillover of both groups of viruses has occurred in this region, we will use an antigen-based multiplex serological assay to screen more than 1,9800 archived blood specimens, collected in 2021 and again in 2023 from over 900 adults and children in rural central Liberia as part of a longitudinal study of Lassa fever seroprevalence and seroincidence, for antibodies against all known filoviruses and henipaviruses.

Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia. Our group detected EBOV-Zaire RNA and antibodies in *Miniopterus nimbae*, a cave- and mine-dwelling bat in northern Liberia found near the origin of the 2014 Ebola outbreak in Guinea. We also detected antibodies against EBOV in *Hipposideros* bats that co-roost with *Miniopterus* in multiple locations in Liberia. *Rousettus aegyptiacus*, a common frugivorous bat in Liberia, carries Marburg virus and henipaviruses. We will conduct a 3-year longitudinal study of populations of these bat species near the human cohort studied in **Aim 1**, to determine whether they are reservoirs for Ebola or other filoviruses and henipaviruses and characterize the temporal dynamics of filoviruses and henipavirus circulation using multiplexed serological assays that test for IgG antibodies against all known filoviruses and henipaviruses, as well as molecular techniques to screen for Ebola, Marburg, Nipah virus, and related viruses.

Aim 3. To characterize behaviors associated with exposure to filoviruses and henipaviruses. Combining the data collected in Aim 1 (humans) and Aim 2 (bats) we will identify the demographic, behavioral, and environmental factors associated with an individual's prior exposure to filoviruses and henipaviruses. Detailed

animal exposure data collected from the adults and children (many born after the Ebola outbreak) who provided the Aim 1 blood specimens will be used to develop profiles of risk and inform public health & risk reduction communication tools in partnership with the Ministry of Health, Liberia.

RESEARCH STRATEGY
A. SIGNIFICANCE

Zoonotic viruses are responsible for the majority of emerging infectious disease outbreaks, which are occurring at an accelerating rate in global hotspots^{3,7}. Every outbreak begins with spillover – transmission of the virus from its animal reservoir either directly into human populations or into other animal hosts *en route* to humans (Figure 1). Exactly how often spillover occurs is virtually unknown, as surveillance systems are primarily designed to detect clusters or outbreaks, and often miss initial individual infections that result from animal contact. To reduce the risk of future epidemics, it will be necessary to limit opportunities for zoonotic viruses to spillover and to detect spillover at the earliest stages.^{1,8} Measuring the efficacy of any interventions designed to reduce spillover and spread of zoonotic pathogens will rely on measuring rates of exposure in at-risk human populations.

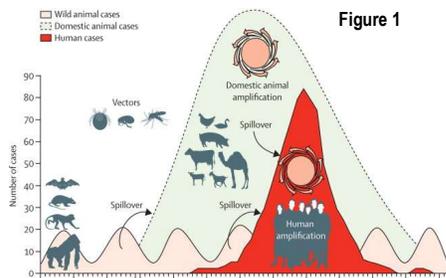

Figure 1

Filoviruses and henipaviruses are among the highest consequence zoonotic viruses and have greatly impacted public health. Each group contains zoonotic pathogens that cause significant disease in both people and animals, especially livestock, that have been associated with extremely high rates of morbidity and mortality. Ebola (EBOV) and related viruses, as well as Nipah virus (NIV), a henipavirus, and its related viruses have been listed by the World Health Organization (WHO) among the highest priority pathogens for the development of vaccines and therapeutics, as they represent zoonotic pathogens with high potential to threaten human health, with extremely high mortality rates and few or no therapeutics or vaccines currently available.⁹⁻¹¹ These viruses share other important features which make them high priority: they are all associated with bat hosts that are abundant and widely distributed throughout Africa and Asia, living in close association with people and livestock in some of the most densely populated regions on Earth.

Spillover of these viruses has repeatedly occurred. Beyond the massive outbreak in West Africa in 2013-16, EBOV outbreaks have occurred repeatedly in Central and East Africa; most recently Sudan ebolavirus caused an outbreak in Uganda in late 2022¹¹⁻¹³. Marburg virus (MARV) and Ravn virus (RAVV) comprise the closely related genus *Marburgvirus* and have caused outbreaks in Central and East Africa and Europe with mortality and clinical presentation comparable to Ebola^{14,15}. Marburg virus outbreaks were declared in Guinea, just across the border from the UNC-Liberia research site in 2021 and then again in Ghana in 2022 marking the first time this virus has been reported in either country^{16,17}. **Nipah-NIV virus** is an emerging zoonotic paramyxovirus that has caused nearly annual outbreaks in Bangladesh, including multiple outbreaks in 2023, and sporadically in India with mean case fatality rates greater than 70%^{12,18-20}. Despite the public health significance of Nipah and related viruses, little is known about its genetic diversity, natural reservoirs, or frequency of spillover throughout their range, including Africa. Henipaviruses, and **Nipah virus NIV** in particular - have several characteristics that make them a global health priority: 1) Their bat reservoirs occur throughout Asia and Africa, overlapping human and livestock populations, giving them geographically broad opportunity to cause outbreaks²¹; 2) henipaviruses can be transmitted to people directly from bats or via domestic animals²¹; 3) **Nipah virus NIV** can be transmitted from person to person²²; 4) **Nipah virus NIV** spillover has occurred and continues to occur in highly populous and internationally connected regions; 5) repeated spillovers of NIV strains with varying person-to-person transmission rates indicate the ability to evolve **with increased pandemic potential**^{23,24}, and 6) **Nipah-NIV** is associated with a high mortality rate in people and currently has no vaccine or treatment^{21,23}. While **Nipah virus NIV** has not been detected in Africa, closely related henipaviruses have been identified in Ghana and Madagascar, though their public health significance remains unknown²⁵⁻²⁷. In West Africa, **where bats and associated henipaviruses occur but where no human cases have been identified, diagnostic testing and systematic surveillance is essentially non-existent**. The detection of antibodies against a Nipah-related virus in hunting communities in Central Africa suggests that cryptic spillover is occurring²⁸. **Repeated spillover of henipaviruses creates opportunity for more transmissible strains to emerge**²⁹.

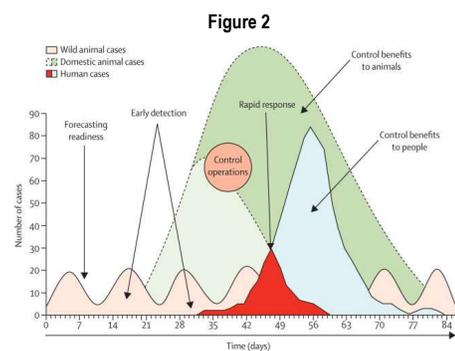

Commented [FWA11]: What do you mean “where bats and associated henipaviruses occur. I would included data here if you have found abs in bats

While bats have been identified as potential hosts for filoviruses including EBOV, the natural reservoir for EBOV-Zaire Ebola in West Africa remains unknown. There is substantial evidence, both serological and molecular, that bat species host filoviruses; however, a definitive natural reservoir or set of reservoirs for EBOV-Zaire has not been identified³⁰. Wildlife, including bats, represent a substantial source of animal protein for communities in Liberia³¹. People may be exposed to bat-borne viruses through hunting and butchering, eating food contaminated by bat excreta, or by entering caves or mines inhabited by bats. Our group previously found that people living in rural areas of Liberia ~~conduct engage in~~ activities ~~which may that~~ increase their risk of contact with bats or their bodily fluids. The index case, ~~a child,~~ in the 2013 Ebola outbreak, a child, was hypothesized to have had contact with bats, yet the exact species was never definitively identified³². The route of spillover for most historical Ebola outbreaks remains a mystery. Despite broad efforts to determine the natural reservoirs of EBOV and related viruses, there continues to be a poor understanding of filovirus ecology, with the exception of Marburg virus/MARV, whose host has been identified as Egyptian rousette bats (*Rousettus aegyptiacus*)³³⁻³⁵. Communities known to hunt bats in Cameroon and India have been found to have antibodies against henipaviruses and filoviruses, respectively, yet nothing is known about community exposure rates in Liberia, where bat hunting is common^{28,36}. Our preliminary data (see below) suggest that there is substantial exposure to EBOV as well as MARV among people in central Liberia. While the EBOV antibodies may indicate prior infection from another person such as during the West Africa outbreak, antibodies specific to other filoviruses may signal a localized exposure from animals. Even less is understood about henipaviruses in Africa, and Africa and identifying antibodies against henipaviruses in people will be critical for understanding where, how and how often spillover occurs.

The urgent need to develop interventions to prevent spillover of zoonotic high consequence pathogens can only be met with a better understanding of their natural reservoirs, the rates of exposure in vulnerable human populations, and the ways in which people are exposed. Unrecognized outbreaks provide opportunities for viruses to emerge that may be more transmissible or more pathogenic than previously observed, and limiting these opportunities is an important component of pandemic prevention^{2,29}. Typically, by the time an outbreak is recognized in human populations its containment and control are difficult, if not impossible to achieve (e.g., HIV, SARS-CoV-2). Understanding the ecology of these viruses, including which species act as reservoirs as well as how and to what extent people are being exposed to filoviruses and henipaviruses will inform intervention and surveillance strategies and provide baseline metrics against which one can measure the efficacy of interventions designed to reduce exposure, such as public health campaigns to promote avoidance of behaviors associated with infection among those most at risk (Figure 2).

This proposed study will be the largest and most rigorous One Health investigation of high-consequence zoonotic viruses in bats and humans in an emerging disease hotspot. West Africa is known to be the source of prior outbreaks of emerging infectious diseases and future spillover events there are highly likely. Liberia is typical of this region and contains some of the largest tracts of pristine forest and wildlife biodiversity

remaining in West Africa and has a population that depends on wildlife, including bats. Decades ago, a spillover event from a non-human primate to a human triggered an on-going HIV pandemic that has led to the infection of over 60 million people and 25 million deaths. Only months ago, the orthopoxvirus MPOX found in rodents spread to and within 110 countries across the globe causing over 85,000 cases. Both originated from African wildlife. The proposed study will leverage the unique infrastructure and expertise we have developed in Liberia to undertake a comprehensive examination of filovirus and henipavirus spillover from bats to humans and provide evidence of previous and possibly on-going transmission events. Our findings will provide essential

evidence of the presence and transmission dynamics of these bat-borne viruses and **identify** the risks for infection in people living alongside them.

B. INNOVATION

The proposed research is highly innovative in multiple ways, including: 1) Our use of a one Health approach to study the ecology and epidemiology of two groups of high-priority, high-consequence zoonotic viruses in both bats and people in West Africa – an emerging disease hotspot where spillover events have occurred (e.g. Ebola, Marburg, MPOX, Lassa fever) and are highly likely to re-occur; 2) Our use of a novel and unique multiplexed serological platform, developed by our group, that will allow us to screen bat and human serum for IgG antibodies against each of the known filoviruses and henipaviruses, simultaneously in a single assay. Longitudinal comprehensive serological studies in bats and people **will provide unprecedented insight into the changes in rates of exposure over time to known high consequence viruses in bats; and in people (e.g. what is the baseline rate of exposure to henipaviruses and filoviruses and is there evidence of recent exposure?); and exposure rates to unknown, antigenically related viruses;** 3) We will couple serosurveillance with molecular testing to identify specific filoviruses and henipaviruses carried by bats; and 4) We will connect the bat and human epidemiological studies by analyzing questionnaire data from the human cohort to identify **high risk behaviors associated with viral exposure. Results from this analysis will inform the development of public outreach and risk reduction campaigns by the Government of Liberia.**

C. APPROACH

C.1. Overview: Aim 1 will test the hypothesis that spillover of filoviruses and henipaviruses occur regularly in rural Liberia by testing for IgG antibodies to all known filoviruses and (see Table 13) in archived serum samples from **more than 900** people living in Bong county (central Liberia), collected **between 2021-23** at two time points 24 months apart **as part of the Coalition for Epidemic Preparedness Innovations (CEPI)-sponsored ENABLE Study, an on-going longitudinal study of Lassa fever seroprevalence and seroincidence.** Seroprevalence of filoviruses and henipaviruses will be assessed as will **changes seroincidence between the two collection timepoints.** In Aim 2, we will conduct a 36-month longitudinal study of three bat species which are putative reservoirs for EBOV and undescribed henipaviruses. Using a combination of longitudinal serology and molecular testing (PCR and whole genome sequencing) **we will determine the prevalence of filoviruses and henipaviruses in three these key bats species associated with the rural human populations studied in Aims 1 and 3.** For Aim 3, we will analyze detailed questionnaire data developed collaboratively by our group (EHA and UNC) and collected in 2023 along with blood samples to be screened in Aim 1. These data will allow us to identify **behaviors-factors** associated with exposure to henipaviruses and filoviruses. **We will use results from our behavioral and exposure risk assessment to develop public risk reduction communication strategies with the National Public Health Institute, Liberia, using the results of this study to inform public health strategies.** This application is a natural progression of our research activities, and our preliminary data speak to the feasibility of the proposed study.

C.2. Aim 1: To determine the rates of filovirus and henipavirus exposure in people in central rural Liberia.

C.2.1. Rationale and Preliminary Data. The primary goal of this aim is to be able to determine whether populations within Liberia who live in association with bats have evidence of exposure against one or multiple filoviruses and/or henipaviruses and to compare rates of exposure over time. Studies of human populations in Central and West Africa have found evidence of exposure to EBOV prior to the 2013 outbreak and in places not known to have had Ebola outbreaks^{37,38}. UNC Project-Liberia has previously assessed seropositivity to

Commented [FWAI2]: I would highlight the novelty of looking for henipaviruses in West Africa.

Formatted: Justified

Commented [FWAI3]: we are only looking at changes in exposure over time in humans; this reads as if we're doing it in bats as well.

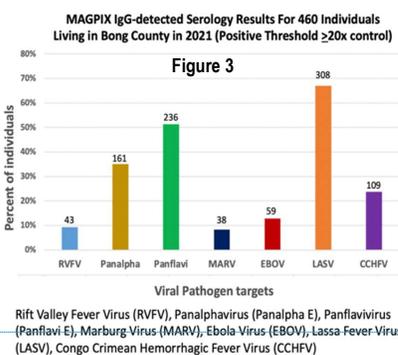

Formatted: Font: 11 pt

Commented [WDA4]: The conflation of filo and henipav makes Billy and my feet itch. We really don't know that henipav will pan out. Would turn this into a strength by saying this is our suspicion given the bats and that this will be the first-ever look to see. Finding these viruses in W Africa would be of great significance as could mean undiagnosed encephalitis or potential tinderbox for future spillover.

Formatted: Font: 11 pt

Formatted: Justified

Formatted: Font: Bold

Formatted: Tab stops: 0.5", Left + Not at 1.86"

Commented [WDA5]: The seroprevalence could have carried this alone. We are also adding possible seroincidence but this is limited by shortish follow up time. Could frame as am also an opportunity to assess exposure over time.

consequential-high consequence viral pathogens including EBOV and MARV in a subset of CEPI-ENABLE Study participants. About Over 810% of participants had antibodies against MARV using a conservative threshold for seropositivity (Figure 3), suggesting that unreported spillover events have previously occurred. Acute encephalitis is common in western sub-Saharan Africa, yet outbreaks of neurological disease are rarely reported and more than half of all cases are undiagnosed³⁹. Among the countries in western Africa reporting cases of meningitis or encephalitis, Liberia has reported the fewest, likely due to a lack of surveillance and capacity to diagnose neurological diseases³⁹. Nipah-virusNIV encephalitis has never been reported in Africa, however, as described above, two Nipah-like henipaviruses have been described in bat hosts, including one in Ghana^{25,27}. Spillover of henipaviruses was reported in bat-hunting communities in Cameroon²⁸. In South Africa, we detected henipavirus sequences in *Rousettus aegyptiacus*, bats which also commonly occur in Liberia²⁶.

In Aim 1, we will test the hypothesis that spillover of both filoviruses and henipaviruses have occurred in rural populations in Liberia by measuring seropositivity to both groups of viruses within the CEPI ENABLE Study community cohort. We will also measure changes in exposure rates over a two-year period. While prior studies have provided cross-sectional snapshots of exposure, our longitudinal approach will provide data from the same cohort at two timepoints, 24 months apart, to determine both seroprevalence and sero-incidence using a multiplexed serological assay to screen for IgG antibodies against all known filoviruses and henipaviruses.

Settings and Participants. To achieve this aim, we will leverage a well characterized cohort of individuals in three rural communities located in Bong County, Liberia (Figure 4), which has a population of over 333,400. UNC Project-Liberia has been operating in Liberia since 2014 and established a research site at Phebe Hospital in Bong County that includes a molecular laboratory that conducts daily qPCR testing for LASV, MARV, and EBOV as well as LASV serological assays using a MAGPIX (SEE RESOURCES AND FACILITIES). There, following extensive community engagement including meetings with key stakeholders, town hall meetings, and radio messaging, UNC launched the CEPI ENABLE Study, the largest passive and active

Figure 4. Map of Liberia with Bong County sites shown in inset.

surveillance program for Lassa fever in Liberia. Started in 2021⁹, 5,005 randomly selected participants 2 years of age and older in Phebe Airstrip, Suakoko, and Rubber Factory were enrolled over 6 months following informed consent/assent (mean age at enrollment is 22.2 years (range 2-97) and 54.2% are female). **Importantly, 7.7% of the cohort is under the age of 5 years, and therefore, were born after the 2013-14 Ebola outbreak (Table 1).** Households were selected for recruitment following identification of roof tops by satellite photos and use of a program developed by Médecins Sans Frontières' (MSF) Epicentre to randomly select structures to consecutively approach sequentially for participation. The ENABLE Study includes baseline questionnaires and blood specimen collection from all participants with active follow-up by a study community health worker every 2 weeks to determine ifs a febrile event has occurred, which triggers drawing of blood for LASV, MARV, and EBOV PCR. Baseline blood is tested for Lassa fever virus (LASV) serology. A subset of 1,024 individuals (every 5th approached household is eligible) is also asked to provide blood samples routinely every 6 months for up to 24 months for repeat LASV serology. The blood samples from 0 and 24 months and the associated surveys will be used in Aims 1 and 3 of this proposal. Informed consent and assent documents include provisions for the use of collected specimens and data for infectious diseases research including for emerging pathogens (see PROTECTION OF HUMAN SUBJECTS).

C.2.2. Research Design. We will screen approximately **1,900 archived serum specimens** from participants in the ENABLE Study cohort at two time points ("baseline" (Month 0) and (Month 24)) for IgG antibodies against specific filoviruses and henipaviruses using the MAGPIX at the UNC molecular lab at Phebe Hospital to run the multiplexed henipavirus / filovirus platform to be provided by Co-I Laing in year 1. The multiplex platform will allow us to determine specifically which filoviruses and henipaviruses people have been exposed to and compare that to the filoviruses and antibodies we observe circulating in local bat populations in

Commented [JE6]: @Billy or @Dave is this right?

Commented [WDA7R6]: 8% (38/460) by very conservative measure

Formatted: Font: Bold

Formatted: Font: Bold

Commented [JE8]: @Billy is this right?

Aim 2. The bead-based multiplexed assay has tremendous advantage over traditional ELISAs in that it will identify up to 25 different antibodies against multiple viral agents in a single, 2uL serum sample and uses a high through-put format. The ability to look at reactivity across all serogroups simultaneously will allow us to differentiate among the viruses. Proteins A/G non-specifically bind IgG immunoglobulins, and weakly bind IgM, an immunoglobulin that is the first to be produced during the initial stages of infection. We will conduct a 1-week training at the UNC-Phebe lab for using the assay to detect filovirus and henipavirus antibodies as well as data management, bioinformatics and analysis. **Table 13** shows the viral species and antigens that will be employed in this assay. The platform has been previously transferred to collaborating labs in the UK, South Africa, India, Bangladesh, Singapore, Thailand and Malaysia. We have previously detected serological profiles of Asiatic ebolaviruses in fruit bats collected in Singapore⁴⁰ and in fruits bats and humans actively engaged in bat hunting in northeast India³⁶.

Commented [FWAI9]: Need a stats section for AIM 1

C.2.3. Data Analysis. We will create a project database using Airtable, which will be hosted at EHA and will house all data from Aims 1 and 2 and will link to the RedCap server which stores questionnaire data from

Formatted: Justified, Indent: First line: 0.5", No widow/orphan control

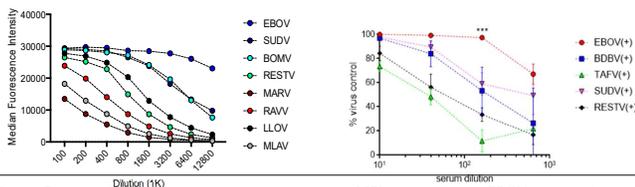

Figure 5. shows relative mean fluorescence index (MFI) values for an EBOV +ive control sera across serial dilutions. While there is cross reactivity, the EBOV MFI values are consistently greater than the other viral GPs and at higher dilutions the separation becomes significant.

Aim 3. Database access will be secure and limited to key personnel (see data management plan). Raw MFI values from the MAGPIX will be used to calculate reactivity to each viral antigen and based on relative strength of reactivity (Fig 5) and determinations of negative cutoffs based on

reference sera, we will calculate prevalence rates for each time point and compare rates between the two timepoints. Serological profiling can be used to detect reactive antibodies against all specific filoviruses and henipaviruses in a samples and compare strength of reactivity and cross-reactivity against multiple antigens

using a single sample⁴¹. We will compare the antibodies across all specific viral antigens to assess which virus or groups of viruses are responsible for the immunological response⁴²⁻⁴⁴. We will assess exposure to non-Zaire ebolavirus species, which may indicate spillover of filoviruses has occurred separate to the Ebola outbreak of 2013. We will also look at evidence for exposure to Nipah-like henipaviruses and compare exposure rates to both viral groups within and between our two sample collection time points.

C.2.4. Expected outcomes. We anticipate obtaining serological profiles of exposure to filoviruses and henipaviruses from each individual in our cohort. In previous studies we found antibodies against both **Ebola EBOV** and **Marburg-MARV** virus. While the **Ebola-EBOV** antibodies are attributable to the **2013-2016** epidemic, **Marburg-MARV** antibodies, in **patients-EBOV** IgG negative **patients**, suggest possible exposure from an animal (e.g. bat) reservoir. We also anticipate seeing reactivity to **Bombali virus (BOMV)**, given the presence of the reservoir species in Liberia (*Mops condylurus*) and reactivity to the African henipaviruses (GhV and AngV), although this may represent reactivity to an antigenically related virus. Serological results from this and the bat study will inform our strategy for prioritizing which bat samples we test by PCR.

C.2.5. Potential problems and solutions. While our preliminary data suggest there will be detection of immune responses to filoviruses including EBOV-Zaire and, significantly, MARV, it is possible that evidence of exposure to other pathogens, including henipaviruses will not be detected. This would be an important finding in this large cohort, especially if these viruses are detected in local bat species, that would warrant further investigation. It is also possible that there will be few or no seroconversion events among the cohort during the 24-month period of follow-up. This too would be reassuring but would suggest a need for longer follow-up of this cohort. To address the possibility that reactivity to EBOV-Zaire virus may be explained by infection during the 2013 Ebola epidemic, we will create a polyclonal sera reference standard utilizing **convalescent** sera collected from human survivors of EVD. This internal reference standard will be calibrated to the WHO EBOV human serology standard (Figure 6A) permitting direct interpolation of anti-EBOV IgG as \rightarrow MFI to a standard antibody concentration (binding antibody units/mL). The internal reference standard will then be included in our human serology testing strategy allowing semi- or quantitative measurement of anti-EBOV IgG. These EBOV human serology standards will permit us to establish positive and negative predictive performance values for the multiplex assay; furthermore, we will be able to investigate immunoreactivity of EVD survivors against heterotypic ebolaviruses. Our preliminary data indicates that EBOV+ sera IgG is highly cross-reactive with soluble native-like trimeric envelope glycoprotein (GP) antigens from both EBOV and BDBV (Figure 6A). EBOV GP, matrix protein (VP40), and nucleocapsid protein (NP) antigens have all been used in a variety of serological tests,

Formatted: Justified, No widow/orphan control

Commented [WDA10]: This may flag questions about sources for these sera.

Commented [WDA11]: Define: bundibugyo?

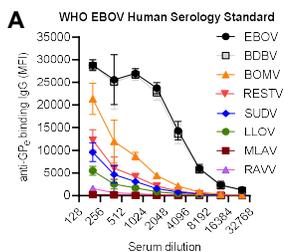

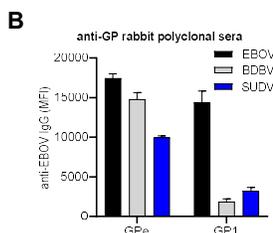

FIGURE 6A & B. A) The WHO EBOV human serology standard was tested using for immunoreactivity in a filovirid GP-trimer based multiplex assay. Filovirids are indicated along with sera dilution factors; data is the mean of three independent experiments.

B) Antisera from EBOV GP-trimer immunized rabbits were tested in multiplex panels comprised of GP-trimer and GP1 subunit proteins. Anti-EBOV polyclonal IgG was less reactive with GP1 from BDBV and SUDV.

however, the frequency of seroconversion against each antigen has not been fully described. In a longitudinal study of EVD survivors, high seroconversion against GP and VP40 was observed, with affinity maturation occurring overtime against GP⁴⁵. Antigens based on the GP are likely to provide an optimal intrinsic balance of sensitivity and specificity. To limit the degree of heterotypic ebolavirus cross reactions we will test any anti-ebolavirus GP trimer antigen-seropositive samples with a pan-ebolavirus GP1 antigen-based panel. In preliminary studies, GP1 antigens improve specificity and differentiation of antibodies reactive with homotypic ebolaviruses in polyclonal antisera from rabbits immunized with GP trimer immunogens (Figure 6B).

Commented [FWA112]: I would consider removing testing for antibodies against proteins other than GP

C.3. Aim 2. To identify reservoirs and

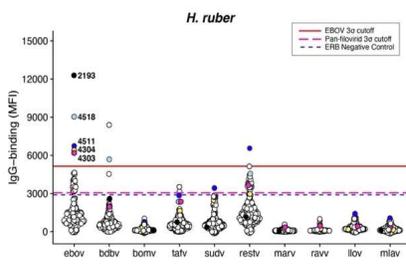

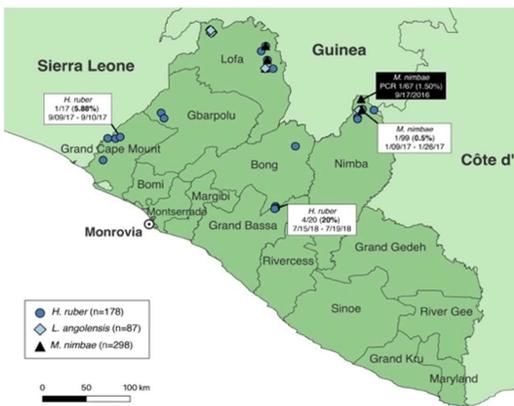

characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia.

C.3.1 *Rationale and Preliminary data.* Bats have been established as important hosts for filoviruses and henipaviruses in Africa and Asia, with combinations of viral isolation, molecular detection or serology providing substantial evidence^{30,46-49}. MARV was isolated from Egyptian rousette bats in Uganda, and RNA has since been detected in these bats in Sierra Leone, which borders Liberia⁵⁰. To date, **infectious** EBOV has never been isolated from bats, although molecular and serological evidence suggest that multiple frugivorous bats may carry EBOV in Central Africa^{50,51}. Prior to the 2014 epidemic, **Zaire ebolavirus had not been reported in West Africa**, and the animal reservoir remains unknown³². From 2016-2019, our group (PI Epstein & KP Desmond) implemented a large-scale project to identify reservoirs for EBOV in West Africa, under the USAID PREDICT Project⁵². This effort led to the discovery of a new species of Ebola (Bombali virus)⁵³, the detection of MARV in E **Egyptian rousette**

Formatted: Indent: First line: 0.5"

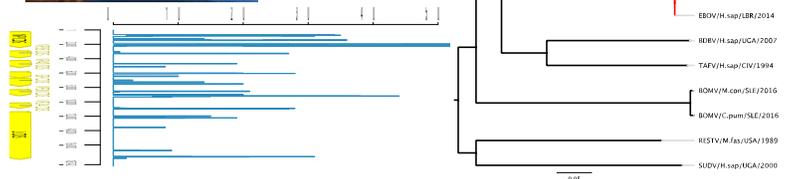

Commented [FWAI13]: or full length

Commented [FWAI14]: but there was evidence of seropositivity among humans

Formatted: Font: Bold

Figure 7: A. Map showing location of EBOV PCR +ve bat (black box) Zaire ebolavirus and MARV in Liberia in 2018. B. Serological evidence for EBOV in *H. ruber* from our 2018 study. C. bats in Sierra Leone³³, and in 2018, we detected, for the first time in West Africa, EBOV RNA and anti-EBOV IgG antibodies in bats (Figure 7A-D).

While this finding generated the first evidence of which bats

Formatted: Justified, No widow/orphan control

may be reservoirs for Zaire ebolavirus, longitudinal studies are required to more completely understand the role

Formatted: Justified, No widow/orphan control

these species play in EBOV circulation— either as reservoirs that maintain the virus within a local population, or as incidental hosts, infected by an unknown bat species. One-off, cross-sectional studies have a low probability of detecting any specific filovirus or henipavirus given their low prevalence and short viremic periods^{34,54}, and thus provide a poor characterization of viral diversity. The lack of understanding of **filovirus and henipavirus diversity and their natural reservoirs in West Africa significantly impedes risk-based public health interventions to prevent human outbreaks**. Longitudinal sampling is needed to separate reservoir hosts from spillover hosts. For example, MARV has been isolated repeatedly from *R. aegyptiacus* in Uganda, which, when paired with experimental infection studies showing infection and shedding of MARV by *R. aegyptiacus*, strongly suggests that *R. aegyptiacus* is indeed a Marburg-virus MARV reservoir^{35,55,56}. Similarly, our longitudinal studies of Nipah-virus NIV in *Pteropus medius* bats in Bangladesh, which included the same multiplexed serological assay proposed here, confirmed them as a reservoir for NIV and identified important mechanisms driving viral circulation²⁹. **Understanding which species persistently carry filoviruses and henipaviruses will provide important insights into how ~~they~~ these groups of viruses are maintained in nature and what species should be targeted for follow-up studies on bat habitat use and human-bat contact patterns.**

C.3.2. Sampling design. We will repeatedly sample three bat species associated with filoviruses or henipaviruses, based on our preliminary data: *M. nimbae* (EBOV), *H. ruber* (EBOV), and *R. aegyptiacus* (MARV & Henipaviruses). We will sample bats at roost sites in Bong county, as close as possible to the human study sites in Aim 1. In Y2-Y4, we will sample 40 individuals of each species every two months for 36 months and collect excreta using plastic tarps placed underneath bat roosts (details below and in C.3.3).

Bat capture and sampling. Briefly, we will use either harp traps or mist nets to capture bats, depending on the capture site. Personnel will wear appropriate personal protective equipment (e.g. Tyvek suits or dedicated long clothing; double nitrile gloves; an N95 respirator and safety glasses or a PAPR⁵⁷). Traps and nets will be attended continuously during capture periods. Bats will be removed from mist nets immediately upon entanglement to avoid injury. Bats will be removed from harp traps after approximately 1 hour and bats will be placed in individual cloth bags until processed. Body measurements, blood, oropharyngeal swabs, and rectal swabs (or fecal pellets) will be collected from each bat. Swabs will be collected in duplicate; one swab will be placed in a cryovial containing Trizol lysis buffer and the other in viral transport medium (VTM). For bats <50g, blood will be collected in a microhematocrit tube and spun down using a portable centrifuge. A bulb will be used to expel serum from the tube into a cryovial. For larger bats >50g, a tuberculin syringe or 1ml syringe and 27g needle will be used to draw blood from the radial artery or vein⁵⁷. Blood will be placed into a conical vial and centrifuged. Serum will be aliquoted into a cryovial using a pipette. During site visits we will also lay out plastic tarps to collect pooled environmental excreta in Trizol and VTM to improve opportunity to detect viral RNA. All samples will be placed in a vapor phase liquid nitrogen dry shipper or portable battery-powered ultracold freezer, immediately upon collection and then transferred to a -80C freezer at the Phebe lab until testing.

C.3.3. Testing plan, ~~d~~ata analysis, sample size, and power analysis. Serology: At the end of Y3, we will screen all serum samples collected to date using the MAGPIX multiplex assay for IgG against filoviruses and henipaviruses. We will analyze temporal dynamics in seroprevalence using general additive models (GAMs), which are analyses that we have used successfully in many previous studies of similar design²⁹. These methods are well adapted for capturing long-term temporal fluctuations in prevalence and moderately sensitive at capturing short-term changes in seroprevalence which can be used to identify population-level disease outbreaks. For example, we estimated that with 40 bats sampled every two months, we would be able to statistically detect an increase in seroprevalence (at a 95% CI limit) of greater than 25% between consecutive sampling events > 80% of the time, assuming a bat population seroprevalence of at least 10% in advance of a bat colony infection (estimated by, in brief, by simulating a fluctuating true seroprevalence value, simulating samples given this underlying seroprevalence, fitting a GAM to these samples, and then calculating if CI on true prevalence between the two sampling occasions over which the change in seroprevalence occurred were non-overlapping). While this is a large change, it is within a range to be expected if infection were to sweep through a bat community²⁹. MAGPIX-positive bat sera will be sent to RML for serum neutralization assays using viral isolates or VSV pseudoviruses under BSL4 conditions.

Formatted: Justified

Commented [WDA15]: Would indicate which laboratory is doing the individual testing to highlight in-country work for most.

Formatted: Font: Not Italic

VSV-pseudotype neutralization assays: Serological results will be confirmed using VSV-pseudotype neutralization assays for the following filoviruses EBOV, SUDV, BDBV, RETV, BOMV, MARV and RAVN. If novel henipavirus sequences are detected, additional assays will be developed to test positive sera. Serum samples will be inactivated using γ -irradiation (4 MRad). Neutralization of irradiated and heat-inactivated serum samples will be assessed in Vero 352 E6 cells. Briefly, cells were seeded in 96-well round-bottom plates for 24 hours, serial dilutions of heat-inactivated serum samples will be performed in DMEM supplemented with 2% FBS, penicillin/streptomycin, and L-glutamine. Each plate will contain negative serum control, cell-only control, and virus-only control. VSV EBOV-GFP will be added to each well of the serum dilution plate and the serum-virus mix 357 was incubated at 37°C for 1-hour. The mix was added to the cells and incubated at 37°C for 24 hours. The cells will then fixed with 4% paraformaldehyde at room temperature 359 for 15-minutes and centrifuged at 600 x g for 5-minutes at room temperature. The supernatant will be discarded and FACS+EDTA buffer was added. Samples will be run on the FACSymphony A5 Cell Analyzer (BD Biosciences, Mississauga, ON, Canada) and FITC MFI 362 was measured. Data will be analyzed using FlowJo.

Molecular testing: We will use specific **filovirus taqman real-time PCR** assays to screen oropharyngeal, fecal and environmental samples from bats for EBOV and MARV RNA at the UNC-Phebe lab^{55,58}. Testing bat samples by PCR may allow us to detect viral RNA during active infection, providing important information about the prevalence and timing of infection within target species. **Because we expect viral prevalence to be significantly lower than seroprevalence, estimated at <5%**^{25,27,49}, we developed a sampling scheme focused on maximizing our probability of detecting viral RNA with qPCR. To compare power under alternative sampling designs, we built simulation-based power analyses that estimated power to detect: 1) viral EBOV or MARV RNA in at least one bat; and 2) the expected number of positive cases, in each bat species. In brief, we estimated power for total sample sizes between 1500-3000 (between 500 and 1000 bats sampled per species) spread across a variable number of visits per year (2-6), while allowing for uncertainty in true infection dynamics in the bat populations, specifically: 1) prevalence during one three-week period (with unknown timing) per year of high prevalence ranging from 1-5%; and 2) an otherwise low background prevalence (0-1%). Given these estimates of yearly infection dynamics, these analyses showed with 672 samples per species (minimum 32 individual bats per sampling event), spread across 6 sampling occasions per year, we would obtain a per-species probability of acquiring 0 positive samples of <4% (<1% at 40 bats per event – our target number) and an expectation of ~3-6 RNA positive results (~5-10 positives at 40 bats per event). Because henipaviruses have not been previously described in Liberia, we will focus our resources on filovirus testing by PCR. However, if henipavirus serology suggests active circulation, we may send a set of samples to RML for pathogen discovery ([SEE RML LETTER OF SUPPORT](#)).

Viral isolation: PCR-positive cDNA samples and their aliquot in VTM will be sent to RML for further sequencing and attempts at viral isolation under BSL4 conditions. If attempts to culture do not work, we will use next generation sequencing techniques to get whole genome sequence and further characterize the virus at RML. Novel viruses will be characterized and rescued (reverse engineered using a minigenome system to synthetically create infectious viral particles⁵⁹) at RML under secure, biosafety level 4 conditions, then used for serum neutralization assays in bat and human sera to determine more precise exposure rates. Sequences from the glycoproteins of any novel viruses discovered will be used by USU (Co-I Laing) to generate purified proteins and added to the Luminex assay, which will improve its specificity.

VirCapSeq-VERT and myBaits probe-based enrichment for recovery of full-length genome sequences of filoviruses: Although shotgun sequencing provides opportunities to analyze all host and virus genetic material, the larger average genome size of bacteria and hosts compared to viral genomes complicates a detailed analysis of the virome, particularly vertebrate viruses. We have established a positive selection probe capture-based

Commented [FWAI16]: Altona filovirus kit

Formatted: Small caps

Formatted: Justified, Indent: First line: 0.5", Tab stops: Not at 1.86"

Formatted: Justified, Indent: First line: 0.5", Tab stops: Not at 1.86"

system to enrich for viral sequences. Here, we will take advantage of these probe capture-based methods (VirCapSeq-VERT and myBaits probe library) to enrich for vertebrate viral sequences of interest. Sample libraries will be normalized and combined in 4- to 12-plex reactions for solution capture hybridization using either the HyperExplore custom bait library version of VirCapSeq-VERT probe set or our custom myBaits probe library. For HyperExplore custom bait library probe set, libraries will be enriched for virus following the SeqCap EZ HyperCap Workflow User's Guide, version 2.3, while for custom myBaits probe library, the myBaits Hybridization Capture for Targeted NGS protocol, Version 4.01 will be used. Sequencing libraries will be normalized and sequenced as 2 X 150 bp fragments on Illumina's MiSeq or NextSeq sequencing platforms, following Illumina's standard procedure (Illumina, San Diego, CA). NGS data will be analyzed using metavirs (<https://openomics.github.io/metavirs/>), a comprehensive viral metagenomics pipeline to assemble, annotate, and classify viruses. It relies on technologies like Singularity1 to maintain the highest-level of reproducibility. The pipeline consists of a series of data processing and quality-control steps orchestrated by Snakemake2, a flexible and scalable workflow management system, to submit jobs to a cluster. The pipeline is compatible with data generated from Illumina short-read sequencing technologies. As input, it accepts a set of FastQ files and will be run on-premises using the NIAID RML Big Sky supercomputing cluster.

C.3.45. Expected outcomes. Based on our prior work, our multifaceted analysis approach, and calculated power given our proposed temporal sampling strategy, we expect to be able to use temporal serological data to describe filovirus and henipavirus viral dynamics over time. Our molecular screening will primarily focus on filoviruses because we have known targets, and we expect to detect EBOV or MARV RNA, despite low prevalence and short-lived infections. Sequence data from positive samples will: 1) provide substantial evidence for the identification of EBOV reservoirs and help explain which virus is responsible for the observed IgG response in bats (and possibly people); and 2) provide valuable information about viral diversity, about which little is known. Henipavirus serology, in the absence of sequence data, will allow us to identify potential bat reservoirs, analyze temporal trends, and generate hypotheses for future targeted studies.

C.3.56. Potential problems and solutions

Serological tests are greatly hindered by the inherent antibody cross-reactivity between antigens from known ebolaviruses, challenging data interpretations that antibodies are EBOV-specific or EBOV, BDBV, and SUDV cross-reactive⁴⁰. This is also true for the henipaviruses in the panel. The advantage of the multiplexed platform is that we can simultaneously see relative MFI values for all the filoviruses and henipaviruses. Glycoproteins from the

homologous virus should cause the most intense reaction, particularly at higher dilutions. Co-Is Laing and Munster have demonstrated that homotypic and heterotypic ebolavirus-antibody reactions can be simultaneously measured and accounted for in ERBs challenged with replication-competent VSV-filoGP (Figure 8). Still, there is some cross reactivity, and we will use additional tools such as viral neutralization assays as a secondary test, and our statistical approach can correct for a portion of cross reactivity. Past studies have relied on individual ELISAs which had varying degrees of specificity depending on which test was used, but often couldn't rule out cross-reactivity. The Luminex filovirus multiplex assay has predictable patterns of cross-reactivity, but we will still be able to discern to which virus the serum is most reactive.

Formatted: Justified, Indent: First line: 0.5"

Formatted: Justified

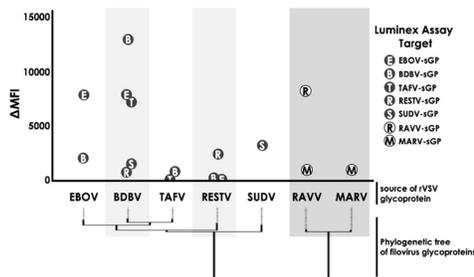

Figure 8. Captive-bred Egyptian rousette bats ERBs were experimentally challenged with VSV-filoGPs, the GP source is indicated on the x-axis. In a GP-trimer multiplex test the homotypic ebolavirus bat antisera were most reactive with the homotypic ebolavirus GP-trimer antigen.

Commented [WDA17]: What about not finding any henipaviruses at all?

C4. Aim 3: To characterize behaviors associated with exposure to filoviruses and henipaviruses.

C.4.1 Background and rationale. As described above, there is substantial interaction between wildlife, domestic animals, and people living in rural Liberia. Our group collected questionnaire data from 585 people across Liberia as part of the USAID-funded Ebola Host Project between 2016 and 2019. When asked about animal exposures during the 2013-2016 Ebola outbreak, participants frequently reported contact with both domestic and wild animals. Common types of animal contact included animals coming inside the dwelling (58%), cooking or handling animal meat (44%), and eating raw or undercooked meat (31%). Additionally, 26% reported slaughtering and 12% reported hunting or trapping an animal. In the ENABLE Study of 5,005 residents of Bong County, survey questions mainly focused on rodent exposures relevant to Lassa fever, but 12% of participants reported hunting or preparing wild animal meat. Little is known about the prevalence and type of other potential bat exposures in this region of Liberia. Elsewhere in West Africa, EcoHealth Alliance participated in the response to Ghana's 2022 cluster of MARV cases, working with local partners to administer a behavioral risk questionnaire characterizing bat exposures in three affected communities¹⁶. Many participants lived in close proximity to bats, with one fifth reported exposure to bats inside a dwelling or other building in the previous four months. When asked about exposures more relevant to Egyptian Rousette bats, a known MARV reservoir and a target species in this proposed study, participants commonly reported bats feeding on fruit trees on their home compound, eating fruit bearing bite marks, and exposure to bats inside a cave or mine.

Formatted: Justified

C.4.2. Research design. As described in Aim 1, serum collected at baseline (in 2021) and at month 24 (in 2023) during the ENABLE Study will be screened for filoviruses and henipaviruses antibodies (analyses not included in the ENABLE Study protocol), enabling us to calculate-determine both seroprevalence at baseline and seroconversion over a two-year period. In addition to providing blood specimens, the 1,024 participants who initially enrolled responded to baseline questionnaires on demographics, healthcare-seeking behaviors, health status, and animal exposures. At month 24, the 921 participants (90%) still actively enrolled are administered repeat questionnaires. This final survey includes additional items based on the Ghanaian questionnaire and asks specifically about bats including the respondents' activities in their habitats (entering forests, caves, and mines), direct contact (hunting, eating handling), indirect contact (presence in home or other used structure), and observed characteristics of bats encountered (fruit tree dwelling). By pairing this existing survey data with the new serology results generated from archived samples under Aim 1, as well as new data on nearby bat infection from Aim 2, we will be able to develop comprehensive risk profiles for exposure to filoviruses and henipaviruses in this community.

Formatted: Justified

C.4.3 Data analysis. The primary outcome for this analysis will be testing positive for IgG antibodies against any known filoviruses or henipaviruses. For both families of viruses, and for each species of virus within those families, we will use the serology results generated under Aim 1 to examine risk factors for seropositivity at baseline and for seroconversion between baseline and month 24. We plan to conduct a multivariate logistic regression, with appropriate weights applied to account for the single-stage cluster sampling design of the ENABLE Study, in which members of randomly selected households were surveyed and tested. We will use data from both the baseline and month 24 questionnaires to examine the effects of sampling site, participant demographics (e.g., age, gender, occupation), environmental exposures (e.g., animals present in and around the dwelling), and behavioral risks (e.g., direct contact with bats through hunting, preparing, or eating them, entering caves or mines where bats live).

Commented [FWA118]: the primary outcome for Aim 3 is really risk behavior associated with IgG positivity but NOT IgG positivity.

Formatted: Justified, Tab stops: Not at 1.86"

Power analysis: To assess our power to identify risk metrics for seroconversion (or overall seropositivity), we built simulation-based power analyses that consisted of, in brief: 1) simulating survey responses for N (400-1,000) individuals, while allowing for moderate unevenness in representation across five binary categories (as

great as 80%-20% for each); 2) examining a range of effect sizes (odds ratios ranging from 1-2.5) for these five binary categorical predictors (e.g., sex, encountered a bat, handled a bat, etc.). Summarizing across 1,200 simulations of surveys of 400-1,000 individuals given joint uncertainty in the representation within these surveys and effect sizes, we estimated that we would have at least 80% power to detect significant effects for each predictor given an odds ratio of 1.65 or greater with 1,000 survey responses or ~1.80 (for example, with a rate just under 5% for Group1 = 0, just over 8% -for Group1 = 1) -with 750 responses.

Formatted: Justified, Tab stops: Not at 1.86"

C.4.4 Expected outcomes. By combining serology results with detailed questionnaire data on participant demographics and animal exposures, we will be able to use odds ratios to identify behaviors significantly associated with seropositivity (e.g., exposure to filoviruses or henipaviruses). We expect to be able to also identify age and gender-based risk factors given our sample size. Based on previous experience conducting behavioral risk surveys, including a recent study in Ghana following a Marburg outbreak, we expect to be able to develop risk mitigation messaging that uses evidence from Aims 1 and 2 as well as results from this aim.

Formatted: Justified

C.4.5 Potential problems and solutions. We anticipate that most IgG positive individuals for either set of viruses will be adults, with the likelihood of exposure and having antibodies increasing with age. Because we don't know how long IgG antibodies persist at detectable levels, it will not be possible to accurately determine when exposure occurred, with the exception being EBOV antibodies that most likely occurred as a result of contact with another infected person during the 2014-2016 outbreak. We will address this in two ways: by looking at respondents 21-6 yrs-years old of age, we will know that any filovirus antibodies they have are most likely not due to the epidemic, and we will be able to determine whether there are any significant associations with particular behavior or other factor (household construction, domestic animal exposure) that promotes direct animal contact, consumption of contaminated fruit, or exposure to bat habitats (e.g., caves or mines). For adult respondents, we will focus on exposures (based on relative MFI values) specific to non-EBOV filoviruses and henipaviruses and see whether there are associations with specific behaviors.

D. Summary and Conclusions.

West Africa is a hotspot for emerging zoonotic viruses such as Ebola, Marburg and potentially Nipah-related henipaviruses – groups that have been identified by WHO as among the most significant pathogens that threaten global health. Liberia is also a biodiversity hotspot, with some of the largest tracts of primary forest remaining in the region, and its population relies on wildlife as a primary source of protein, creating continued risk of spillover of high consequence zoonotic pathogens. This study aims to comprehensively characterize the risk of filo- and Henipavirus cross over events by measuring seroprevalence and seroincidence among a well characterized cohort of individuals in rural Liberia, identify potential bat reservoirs for filoviruses and

Formatted: Justified

Henipaviruses, and identify host, behavior, and environmental risk factors associated with seroprevalence. The results of this work will inform upstream interventions designed to prevent spill over events from occurring and downstream interventions to facilitate early detection of human infections through implementation of pathogen-specific diagnostics. This project has the potential to determine the origins of Zaire ebolavirus in West Africa, characterize the circulation of Ebola and other filoviruses and henipaviruses in common bat species, identify background rates of spillover in rural human populations, and identify high risk behaviors associated with exposure to these bat borne zoonoses. Our group comprises an unparalleled multidisciplinary group of leading experts in epidemiology, clinical medicine, virology, serology, and disease ecology all with deep experience working in Liberia, [strong partnerships with the Liberian public health institutions](#), and implementing zoonotic virus research, giving this project a high chance of success in generating impactful results that will help prevent future epidemics in West Africa.

Specific Aims

Emerging infectious diseases - predominantly caused by zoonotic viruses - have become a major threat to individual and public health as well as the functioning of a global society. Even prior to the SARS-CoV-2 pandemic, outbreaks of consequential emerging pathogens including SARS-CoV, Pandemic influenza 2009, Zika virus, and Ebola virus disease tragically killed and disabled and caused massive disruptions of regional and global economies and health care systems¹. The emergence of consequential zoonotic infections is accelerating due to anthropogenic drivers such as climate change, land-use change, intensification of livestock production, and wildlife trade, all of which increase opportunity for people and domestic animals to come into contact with wildlife reservoirs²⁻⁵. **To reduce the risk of infectious disease epidemics, there is a critical need to detect and prevent spillover of zoonotic pathogens from wildlife reservoirs^{2,6}.**

Illustrative of this need is the repeated spillover from wildlife reservoirs to human populations of groups of zoonotic viruses such as filoviruses (e.g., Ebola virus [EBOV]) and henipaviruses (e.g., Nipah virus [NIV]). Large-scale outbreaks or clusters of cases with these high-mortality zoonotic viruses have led to their being **designated as high priority pathogens by the World Health Organization (WHO)**⁵. However, at present, the detection of outbreaks caused by these pathogens occurs only after the first human infections; a failure in prevention that is deadly, costly, and remediable¹. Identifying natural reservoirs of zoonotic viruses and measuring rates of exposure to these viruses in humans are critical to assessing their potential threat and developing interventions that reduce the risk of spillover.^{1,2}

In the proposed study we have assembled a diverse team of experts in ecology, epidemiology, virology and immune response to bat-borne viral zoonoses such as filoviruses and henipaviruses; and filovirus clinical care and research who are actively working in West Africa to provide much needed empirical evidence to help answer the questions: **What is the natural reservoir for Ebola virus and how often does spillover of this and related viruses happen in a region that is an emerging disease hotspot, suffered the world's largest filovirus outbreak, and where there has been evidence of other consequential zoonotic viruses in animals and people? To address these questions, we propose the following specific aims:**

Aim 1. To determine the rates of filovirus and henipavirus exposure in people in rural Liberia. We have shown that certain bat species in Liberia carry EBOV-Zaire, while others carry Marburg virus and henipaviruses. Further, hunting bats is a common activity and we have detected high seroprevalence of Marburg and EBOV antibodies in residents of rural Liberia. Exposure to henipaviruses remains unknown. To test the hypothesis that spillover of both groups of viruses has occurred in this region, we will use an antigen-based multiplex serological assay to screen more than 1,9800 archived blood specimens, collected in 2021 and again in 2023 from over 900 adults and children in rural central Liberia as part of a longitudinal study of Lassa fever seroprevalence and seroincidence, for antibodies against all known filoviruses and henipaviruses.

Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia. Our group detected EBOV-Zaire RNA and antibodies in *Miniopterus nimbae*, a cave- and mine-dwelling bat in northern Liberia found near the origin of the 2014 Ebola outbreak in Guinea. We also detected antibodies against EBOV in *Hipposideros* bats that co-roost with *Miniopterus* in multiple locations in Liberia. *Rousettus aegyptiacus*, a common frugivorous bat in Liberia, carries Marburg virus and henipaviruses. We will conduct a 3-year longitudinal study of populations of these bat species near the human cohort studied in **Aim 1**, to determine whether they are reservoirs for Ebola or other filoviruses and henipaviruses and characterize the temporal dynamics of filoviruses and henipavirus circulation using multiplexed serological assays that test for IgG antibodies against all known filoviruses and henipaviruses, as well as molecular techniques to screen for Ebola, Marburg, Nipah virus, and related viruses.

Aim 3. To characterize behaviors associated with exposure to filoviruses and henipaviruses. Combining the data collected in Aim 1 (humans) and Aim 2 (bats) we will identify the demographic, behavioral, and environmental factors associated with an individual's prior exposure to filoviruses and henipaviruses. Detailed animal exposure data collected from the adults and children (many born after the Ebola outbreak) who provided the Aim 1 blood specimens will be used to develop profiles of risk and inform public health & risk reduction communication tools in partnership with the Ministry of Health, Liberia.

RESEARCH STRATEGY

A. SIGNIFICANCE

Zoonotic viruses are responsible for the majority of emerging infectious disease outbreaks, which are occurring at an accelerating rate in global hotspots^{3,7}. Every outbreak begins with spillover – transmission of the virus from its animal reservoir either directly into human populations or into other animal hosts *en route* to humans (Figure 1). Exactly how often spillover occurs is virtually unknown, as surveillance systems are primarily designed to detect clusters or outbreaks, and often miss initial individual infections that result from animal contact. To reduce the risk of future epidemics, it will be necessary to limit opportunities for zoonotic viruses to spillover and to detect spillover at the earliest stages.^{1,8} Measuring the efficacy of any interventions designed to reduce spillover and spread of zoonotic pathogens will rely on measuring rates of exposure in at-risk human populations.

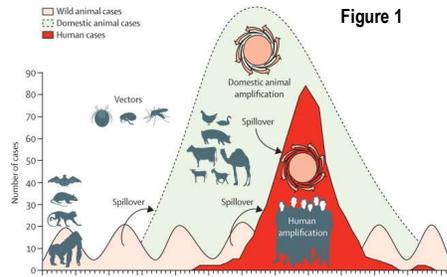

Figure 1

Filoviruses and henipaviruses are among the highest consequence zoonotic viruses and have greatly impacted public health. Each group contains zoonotic pathogens that cause significant disease in both people and animals, especially livestock, that have been associated with extremely high rates of morbidity and mortality. Ebola (EBOV) and related viruses, as well as Nipah virus (NIV), a henipavirus, and its related viruses have been listed by the World Health Organization (WHO) among the highest priority pathogens for the development of vaccines and therapeutics, as they represent zoonotic pathogens with high potential to threaten human health, with extremely high mortality rates and few or no therapeutics or vaccines currently available.⁹⁻¹¹ These viruses share other important features which make them high priority: they are all associated with bat hosts that are abundant and widely distributed throughout Africa and Asia, living in close association with people and livestock in some of the most densely populated regions on Earth.

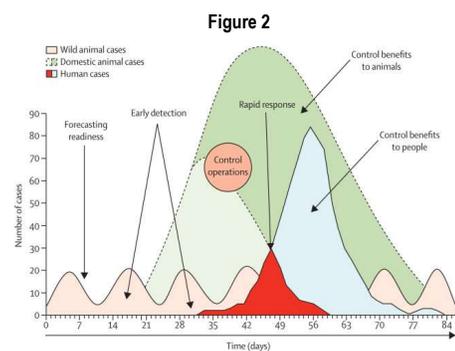

Spillover of these viruses has repeatedly occurred. Beyond the massive outbreak in West Africa in 2013-16, EBOV outbreaks have occurred repeatedly in Central and East Africa; most recently Sudan ebolavirus caused an outbreak in Uganda in late 2022¹¹⁻¹³. Marburg virus (MARV) and Ravn virus (RAVV) comprise the closely related genus *Marburgvirus* and have caused outbreaks in Central and East Africa and Europe with mortality and clinical presentation comparable to Ebola^{14,15}. Marburg virus outbreaks were declared in Guinea, just across the border from the UNC-Liberia research site in 2021 and then again in Ghana in 2022 marking the first time this virus has been reported in either country^{16,17}. **Nipah-NIV virus** is an emerging zoonotic paramyxovirus that has caused nearly annual outbreaks in Bangladesh, including multiple outbreaks in 2023, and sporadically in India with mean case fatality rates greater than 70%^{12,18-20}. Despite the public health significance of Nipah and related viruses, little is known about its genetic diversity, natural reservoirs, or frequency of spillover throughout their range, including Africa. Henipaviruses, and **Nipah virus NIV** in particular - have several characteristics that make them a global health priority: 1) Their bat reservoirs occur throughout Asia and Africa, overlapping human and livestock populations, giving them geographically broad opportunity to cause outbreaks²¹; 2) henipaviruses can be transmitted to people directly from bats or via domestic animals²¹; 3) **Nipah virus NIV** can be transmitted from person to person²²; 4) **Nipah virus NIV** spillover has occurred and continues to occur in highly populous and internationally connected regions; 5) repeated spillovers of NIV strains with varying person-to-person transmission rates indicate the ability to evolve **with increased pandemic potential**^{23,24}; and 6) Nipah is associated with a high mortality rate in people and currently has no vaccine or treatment^{21,23}. While **Nipah virus NIV** has not been detected in Africa, closely related henipaviruses have been identified in Ghana and Madagascar, though their public health significance remains unknown²⁵⁻²⁷. In West Africa, where bats and associated henipaviruses occur but where no human cases have been identified, **diagnostic testing and systematic surveillance is essentially non-existent**. The detection of antibodies against a Nipah-related virus in hunting communities in Central Africa suggests that cryptic spillover is occurring²⁸. **Repeated spillover of henipaviruses creates opportunity for more transmissible strains to emerge**²⁹.

While bats have been identified as potential hosts for filoviruses including EBOV, the natural reservoir for EBOV-Zaire Ebola in West Africa remains unknown. There is substantial evidence, both serological and molecular, that bat species host filoviruses; however, a definitive natural reservoir or set of reservoirs for EBOV-Zaire has not been identified³⁰. Wildlife, including bats, represent a substantial source of animal protein for communities in Liberia³¹. People may be exposed to bat-borne viruses through hunting and butchering, eating food contaminated by bat excreta, or by entering caves or mines inhabited by bats. Our group previously found that people living in rural areas of Liberia conduct activities which may increase their risk of contact with bats or their bodily fluids. The index case, a child, in the 2013 Ebola outbreak was hypothesized to have had contact with bats, yet the exact species was never definitely identified³². The route of spillover for most historical Ebola outbreaks remains a mystery. Despite broad efforts to determine the natural reservoirs of EBOV and related viruses, there continues to be a poor understanding of filovirus ecology, with the exception of **Marburg virus** MARV, whose host has been identified as Egyptian rousette bats (*Rousettus aegyptiacus*)³³⁻³⁵. Communities known to hunt bats in Cameroon and India have been found to have antibodies against henipaviruses and filoviruses, respectively, yet nothing is known about community exposure rates in Liberia, where bat hunting is common^{28,36}. Our preliminary data (see below) suggest that there is substantial exposure to EBOV as well as MARV among people in central Liberia. While the EBOV antibodies may indicate prior infection from another person such as during the West Africa outbreak, antibodies specific to other filoviruses may signal a localized exposure from animals. Even less is understood about henipaviruses in ~~Africa, and~~ **Africa and** identifying antibodies against henipaviruses in people will be critical for understanding where, how and how often spillover occurs.

The urgent need to develop interventions to prevent spillover of zoonotic high consequence pathogens can only be met with a better understanding of their natural reservoirs, the rates of exposure in vulnerable human populations, and the ways in which people are exposed. Unrecognized outbreaks provide opportunities for viruses to emerge that may be more transmissible or more pathogenic than previously observed, and limiting these opportunities is an important component of pandemic prevention^{2,29}. Typically, by the time an outbreak is recognized in human populations its containment and control are difficult, if not impossible to achieve (e.g., HIV, SARS-CoV-2). Understanding the ecology of these viruses, including which species act as reservoirs as well as how and to what extent people are being exposed to filoviruses and henipaviruses will inform intervention and surveillance strategies and provide baseline metrics against which one can measure the efficacy of interventions designed to reduce exposure, such as public health campaigns to promote avoidance of behaviors associated with infection among those most at risk (**Figure 2**).

This proposed study will be the largest and most rigorous One Health investigation of high-consequence zoonotic viruses in bats and humans in an emerging disease hotspot. West Africa is known to be the source of prior outbreaks of emerging infectious diseases and future spillover events there are highly likely. Liberia is typical of this region and contains some of the largest tracts of pristine forest and wildlife biodiversity

remaining in West Africa and has a population that depends on wildlife, including bats. Decades ago, a spillover event from a non-human primate to a human triggered an on-going HIV pandemic that has led to the infection of over 60 million people and 25 million deaths. Only months ago, the orthopoxvirus MPOX found in rodents spread to and within 110 countries across the globe causing over 85,000 cases. Both originated from African wildlife. The proposed study will leverage the unique infrastructure and expertise we have developed in Liberia to undertake a comprehensive examination of filovirus and henipavirus spillover from bats to humans and provide evidence of previous and possibly on-going transmission events. Our findings will provide essential

evidence of the presence and transmission dynamics of these bat-borne viruses and as the risks for infection in people living alongside them.

B. INNOVATION

The proposed research is highly innovative in multiple ways, including: 1) Our use of a one Health approach to study the ecology and epidemiology of two groups of high-priority, high-consequence zoonotic viruses in both bats and people in West Africa – an emerging disease hotspot where spillover events have occurred (e.g. Ebola, Marburg, MPOX, Lassa fever) and are highly likely to re-occur; 2) Our use of a novel and unique multiplexed serological platform, developed by our group, that will allow us to screen bat and human serum for IgG antibodies against each of the known filoviruses and henipaviruses, simultaneously in a single assay. Longitudinal comprehensive serological studies in bats and people **will provide unprecedented insight into the changes in rates of exposure over time to known viruses in bats; and in people (e.g. what is the baseline rate of exposure to henipaviruses and filoviruses and is there evidence of recent exposure?); and exposure rates to unknown, antigenically related viruses;** 3) We will couple serosurveillance with molecular testing to identify specific filoviruses and henipaviruses carried by bats; and 4) We will connect the bat and human epidemiological studies by analyzing questionnaire data from the human cohort to identifying high risk behaviors associated with viral exposure. **Results from this analysis will inform the development of public outreach and risk reduction campaigns by the Government of Liberia.**

Formatted: Justified

C. APPROACH

C.1. Overview: Aim 1 will test the hypothesis that spillover of filoviruses and henipaviruses occur regularly in rural Liberia by testing for IgG antibodies to all known filoviruses and (see [Table 13](#)) in [archived](#) serum samples from [more than 900](#) people living in Bong county (central Liberia), collected [between 2021-23](#) at two time points 24 months apart [as part of the Coalition for Epidemic Preparedness Innovations \(CEPI\)-sponsored ENABLE Study, an on-going longitudinal study of Lassa fever seroprevalence and seroincidence.](#) Seroprevalence of filoviruses and henipaviruses will be assessed as will ~~changes seroincidence between the two collection timepoints~~. In Aim 2, we will conduct a 36-month longitudinal study of three bat species which are putative reservoirs for EBOV and undescribed henipaviruses. Using a combination of longitudinal serology and molecular testing (PCR and whole genome sequencing) **we will determine the prevalence of filoviruses and henipaviruses in three these key bats species associated with the rural human populations studied in Aims 1 and 3.** For Aim 3, we will analyze detailed questionnaire data developed collaboratively by our group (EHA and UNC) and collected in 2023 along with blood samples to be screened in Aim 1. These data will allow us to identify ~~behaviors-factors~~ associated with exposure to henipaviruses and filoviruses. We will use results from our behavioral and exposure risk assessment to develop public risk reduction communication strategies with the National Public Health Institute, Liberia, using the results of this study to inform public health strategies. This application is a natural progression of our research activities, and our preliminary data speak to the feasibility of the proposed study.

Formatted: Font: 11 pt

Commented [WDA1]: The conflation of filo and henipav makes Billy and my feet itch. We really don't know that henipav will pan out. Would turn this into a strength by saying this is our suspicion given the bats and that this will be the first-ever look to see. Finding these viruses in W Africa would be of great significance as could mean undiagnosed encephalitis or potential tinderbox for future spillover.

C.2. Aim 1: To determine the rates of filovirus and henipavirus exposure in people in central rural Liberia.

C.2.1. Rationale and Preliminary Data.

The primary goal of this aim is to be able to determine whether populations within Liberia who live in association with bats have evidence of exposure against one or multiple filoviruses and/or henipaviruses and to compare rates of exposure over time. Studies of human populations in Central and West Africa have found evidence of exposure to EBOV prior to the 2013 outbreak and in places not known to have had Ebola outbreaks^{37,38}. UNC Project-Liberia has previously assessed seropositivity to

Formatted: Tab stops: 0.5", Left + Not at 1.86"

Commented [WDA2]: The seroprevalence could have carried this alone. We are also adding possible seroincidence but this is limited by shortish follow up time. Could frame as am also an opportunity to assess exposure over time.

consequential viral pathogens including EBOV and MARV in a subset of CEPI-ENABLE Study participants. **About Over 840%** of participants had antibodies against MARV **using a conservative threshold for seropositivity (Figure 3)**, suggesting that unreported spillover events have previously occurred. Acute encephalitis is common in western sub-Saharan Africa, yet outbreaks of neurological disease are rarely reported and more than half of all cases are undiagnosed³⁹. Among the countries in western Africa reporting cases of meningitis or encephalitis, Liberia has reported the fewest, likely due to a lack of surveillance and capacity to diagnose neurological diseases³⁹. **Nipah virus** NIV encephalitis has never been reported in Africa, however, as described above, two Nipah-like henipaviruses have been described in bat hosts, including one in Ghana^{25,27}. Spillover of henipaviruses was reported in bat-hunting communities in Cameroon²⁸. In South Africa, we detected henipavirus sequences in *Rousettus aegyptiacus*, bats which also commonly occur in Liberia²⁶.

In Aim 1, we will test the hypothesis that spillover of both filoviruses and henipaviruses have occurred in rural populations in Liberia by measuring seropositivity to both groups of viruses within the CEPI ENABLE Study community cohort. We will also measure changes in exposure rates over a two-year period. While prior studies have provided cross-sectional snapshots of exposure, our longitudinal approach will provide data from the same cohort at two timepoints, 24 months apart, to determine both seroprevalence and sero-incidence using a multiplexed serological assay to screen for IgG antibodies against all known filoviruses and henipaviruses.

Settings and Participants. To achieve this aim we will leverage a well characterized cohort of individuals in three rural communities located in Bong County, Liberia (**Figure 4**), which has a population of over 333,400. UNC Project-Liberia has been operating in Liberia since 2014 and established a research site at Phebe Hospital in Bong County that includes a molecular laboratory that conducts daily qPCR testing for LASV, MARV, and EBOV as well as LASV serological assays using a MAGPIX (SEE RESOURCES AND FACILITIES). There, following extensive community engagement including meetings with key stakeholders, town hall meetings, and radio messaging, UNC launched the CEPI **ENABLE Study**, the largest passive and active surveillance program for Lassa fever in Liberia. Started in 2021⁹, 5,005 randomly selected participants 2 years of age and older in Phebe Airstrip, Suakoko, and Rubber Factory were enrolled over 6 months following informed consent/assent (mean age at enrollment is 22.2 years (range 2-97) and 54.2% are female). **Importantly, 7.7% of the cohort is under the age of 5 years, and therefore, were born after the 2013-14 Ebola outbreak (Table 1).** Households were selected for recruitment following identification of roof tops by satellite photos and use of a program developed by Médecins Sans Frontières' (MSF) Epicentre to randomly selected structures to ~~consecutively~~ approach sequentially for participation. The ENABLE Study includes baseline questionnaires and blood specimen collection from all participants with active follow-up by a study community health worker every 2 weeks to determine if a febrile event has occurred, which triggers drawing of blood for LASV, MARV, and EBOV PCR. Baseline blood is tested for Lassa fever virus (LASV) serology. A subset of 1,024 individuals (every 5th approached household is eligible) is also asked to provide blood samples routinely every 6 months for up to 24 months for repeat LASV serology. The blood samples from 0 and 24 months and the associated surveys will be used in Aims 1 and 3 of this proposal. Informed consent and assent documents include provisions for the use of collected specimens and data for infectious diseases research including for emerging pathogens (see PROTECTION OF HUMAN SUBJECTS).

C.2.2. Research Design. We will screen approximately **1,900 archived serum specimens** from participants in the ENABLE Study cohort at two time points ("baseline" (Month 0) and (Month 24)) for IgG antibodies against specific filoviruses and henipaviruses using the MAGPIX at the UNC molecular lab at Phebe ~~H~~ospital to run the multiplexed *henipavirus / filovirus* platform to be provided by Co-I Laing in year 1. The multiplex platform will allow us to determine specifically which filoviruses and henipaviruses people have been exposed to and compare that to the filoviruses and antibodies we observe circulating in local bat populations in **Aim 2**. The bead-based multiplexed assay has tremendous advantage over traditional ELISAs in that it will

Figure 4. Map of Liberia with Bong County sites shown in inset.

identify up to 25 different antibodies against multiple viral agents in a single, 2uL serum sample and uses a high through-put format. The ability to look at reactivity across all serogroups simultaneously will allow us to differentiate among the viruses. Proteins A/G non-specifically bind IgG immunoglobulins, and weakly bind IgM, an immunoglobulin that is the first to be produced during the initial stages of infection. We will conduct a 1-week training at the UNC-Phebe lab for using the assay to detect filovirus and henipavirus antibodies as well as data management, bioinformatics and analysis. **Table 13** shows the viral species and antigens that will be employed in this assay. The platform has been previously transferred to collaborating labs in the UK, South Africa, India, Bangladesh, Singapore, Thailand and Malaysia. We have previously detected serological profiles of Asiatic ebolaviruses in fruit bats collected in Singapore⁴⁰ and in fruits bats and humans actively engaged in bat hunting in northeast India³⁶.

C.2.3. Data Analysis. We will create a project database using Airtable, which will be hosted at EHA and will house all data from Aims 1 and 2 and will link to the RedCap server which stores questionnaire data from Aim 3. Database access will be secure and limited to key personnel (see data management plan). Raw MFI values from the MAGPIX will be used to calculate reactivity to each viral antigen and based on relative strength of reactivity (**Fig 5**) and determinations of negative cutoffs based on

Commented [MOU6]: This figure is showing binding on the left and VSV-EBOV GP neuts on the right. Not sure what you want to highlight with this that isn't in Figure 6.

Formatted: Justified, Indent: First line: 0.5", No widow/orphan control

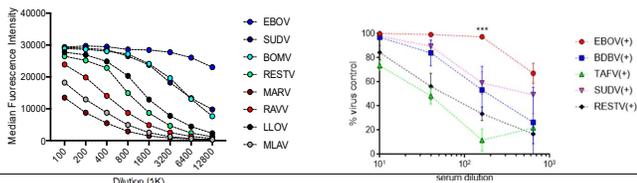

Figure 5. shows relative mean fluorescence index (MFI) values for an EBOV +ive control sera across serial dilutions. While there is cross reactivity, the EBOV MFI values are consistently greater than the other viral GPs and at higher dilutions the separation becomes significant.

reference sera, we will calculate prevalence rates for each time point and compare rates between the two timepoints. Serological profiling can be used to detect reactive antibodies against all specific filoviruses and henipaviruses in a samples and compare strength of reactivity and cross-reactivity against multiple antigens using a single sample⁴¹. We will compare the antibodies across all specific viral antigens to assess which virus or

groups of viruses are responsible for the immunological response⁴²⁻⁴⁴. We will assess exposure to non-Zaire ebolavirus species, which may indicate spillover of filoviruses has occurred separate to the Ebola outbreak of 2013. We will also look at evidence for exposure to Nipah-like henipaviruses and compare exposure rates to both viral groups within and between our two sample collection time points.

C.2.4. Expected outcomes. We anticipate obtaining serological profiles of exposure to filoviruses and henipaviruses from each individual in our cohort. In previous studies we found antibodies against both **Ebola-EBOV** and **Marburg-MARV** virus. While the **Ebola-EBOV** antibodies are attributable to the epidemic, **Marburg-MARV** antibodies, in patients EBOV IgG negative, suggest possible exposure from an animal (e.g. bat) reservoir. We also anticipate seeing reactivity to **to-Bombali virus (BOMV)**, given the presence of the reservoir species in Liberia (*Mops condylurus*) and reactivity to the African henipaviruses (GhV and AngV), although this may represent reactivity to an antigenically related virus. Serological results from this and the bat study will inform our strategy for prioritizing which bat samples we test by PCR.

C.2.5. Potential problems and solutions. While our preliminary data suggest there will be detection of immune responses to filoviruses including EBOV-Zaire and, significantly, MARV, it is possible that evidence of exposure to other pathogens, including henipaviruses will not be detected. This would be an important finding in this large cohort, especially if these viruses are detected in local bat species, that would warrant further investigation. It is also possible that there will be few or no seroconversion events among the cohort during the 24-month period of follow-up. This too would be reassuring but would suggest a need for longer follow-up of this cohort. To address the possibility that reactivity to EBOV-Zaire virus may be explained by infection during the 2013 Ebola epidemic, we will create a polyclonal sera reference standard utilizing convalescent sera collected from human survivors of EVD. This internal reference standard will be calibrated to the WHO EBOV human serology standard (**Fig 6A**) permitting direct interpolation of anti-EBOV IgG as a MFI to a standard antibody concentration (binding antibody units/mL). The internal reference standard will then be included in our human serology testing strategy allowing semi- or quantitative measurement of anti-EBOV IgG. These EBOV human serology standards will permit us to establish positive and negative predictive performance values for the multiplex assay; furthermore, we will be able to investigate immunoreactivity of EVD survivors against heterotypic ebolaviruses. Our preliminary data indicates that EBOV+ sera IgG is highly cross-reactive with soluble native-like trimeric envelope glycoprotein (GP) antigens from both EBOV and **BDBV** (Figure 6A). EBOV GP, matrix protein (VP40), and nucleocapsid protein (NP) antigens have all been used in a variety of serological tests,

Formatted: Justified, No widow/orphan control

Commented [WDA7]: This may flag questions about sources for these sera.

Commented [WDA8]: Define: bundibugyo?

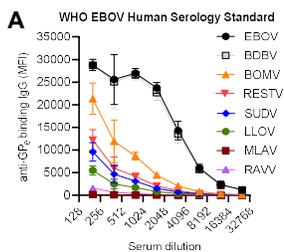

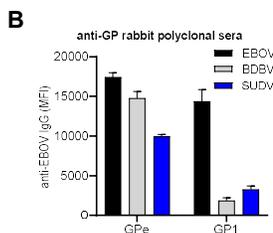

FIGURE 6A & B. A) The WHO EBOV human serology standard was tested for immunoreactivity in a filovirid GP-trimer based multiplex assay. Filovirids are indicated along with sera dilution factors; data is the mean of three independent experiments. B) Antisera from EBOV GP-trimer immunized rabbits were tested in multiplex panels comprised of GP-trimer and GP1 subunit proteins. Anti-EBOV polyclonal IgG was less reactive with GP1 from BDBV and SUDV.

however, the frequency of seroconversion against each antigen has not been fully described. In a longitudinal study of EVD survivors, high seroconversion against GP and VP40 was observed, with affinity maturation occurring overtime against GP⁴⁵. Antigens based on the GP are likely to provide an optimal intrinsic balance of sensitivity and specificity. To limit the degree of heterotypic ebolavirus cross reactions we will test any anti-ebolavirus GP trimer antigen-seropositive samples with a pan-ebolavirus GP1 antigen-based panel. In preliminary studies, GP1 antigens improve specificity and differentiation of antibodies reactive with homotypic ebolaviruses in polyclonal antisera from rabbits immunized with GP trimer immunogens (**Figure 6B**).

C.3. Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia.

C.3.1 Rationale and Preliminary data. Bats have been established as important hosts for filoviruses and henipaviruses in Africa and Asia, with combinations of viral isolation, molecular detection or serology providing substantial evidence^{30,46-49}. MARV was isolated from Egyptian rousette bats in Uganda, and RNA has since been detected in these bats in Sierra Leone, which borders Liberia⁵⁰. To date, EBOV has never been isolated from bats, although molecular and serological evidence suggest that multiple frugivorous bats may carry EBOV in Central Africa^{50,51}. Prior to the 2014 epidemic, Zaire ebolavirus had not been reported in West Africa, and the animal reservoir remains unknown³². From 2016-2019, our group (PI Epstein & KP Desmond) implemented a large-scale project to identify reservoirs for EBOV in West Africa, under the USAID PREDICT Project⁵². This effort led to the discovery of a new species of Ebola (Bombali virus)⁵³, the detection of MARV in *E. Egyptian rousette* bats⁵⁴ in Sierra Leone³³, and in 2018, we detected, for the first time in West Africa, EBOV RNA and anti-EBOV

Formatted: Indent: First line: 0.5"

IgG antibodies in bats (Figure 7A-D).

While this finding generated the first evidence of which bats

Formatted: Justified, No widow/orphan control

may be reservoirs for Zaire ebolavirus, longitudinal studies are required to more completely understand the role these species play in EBOV circulation— either as reservoirs that maintain the virus within a local population, or as incidental hosts, infected by an unknown bat species. One-off, cross-sectional studies have a low probability of detecting any specific filovirus or henipavirus given their low prevalence and short viremic periods^{34,54}, and thus provide a poor characterization of viral diversity. The lack of understanding of **filovirus and henipavirus diversity and their natural reservoirs in West Africa significantly impedes risk-based public health interventions to prevent human outbreaks**. Longitudinal sampling is needed to separate reservoir hosts from spillover hosts. For example, MARV has been isolated repeatedly from *R. aegyptiacus* in Uganda, which, when paired with experimental infection studies showing infection and shedding of MARV by *R. aegyptiacus*, strongly suggests that *R. aegyptiacus* is indeed a **Marburg-virus/MARV** reservoir^{35,55,56}. Similarly, our longitudinal studies of **Nipah-virus/NIV** in *Pteropus medius* bats in Bangladesh, which included the same multiplexed serological assay proposed here, confirmed them as a reservoir for NIV and identified important mechanisms driving viral circulation²⁹. **Understanding which species persistently carry filoviruses and henipaviruses will provide important insights into how they are maintained in nature and what species should be targeted for follow-up studies on bat habitat use and human-bat contact patterns.**

Formatted: Justified, No widow/orphan control

C.3.2. Sampling design. We will repeatedly sample three bat species associated with filoviruses or henipaviruses, based on our preliminary data: *M. nimbae* (EBOV), *H. ruber* (EBOV), and *R. aegyptiacus* (MARV & Henipaviruses). We will sample bats at roost sites in Bong county, as close as possible to the human study sites in Aim 1. In Y2-Y4, we will sample 40 individuals of each species every two months for 36 months and collect excreta using plastic tarps placed underneath bat roosts (details below and in C.3.3).

Formatted: Justified

Bat capture and sampling. Briefly, we will use either harp traps or mist nets to capture bats, depending on the capture site. Personnel will wear appropriate personal protective equipment (e.g. Tyvek suits or dedicated long clothing; double nitrile gloves; an N95 respirator and safety glasses or a PAPR⁵⁷). Traps and nets will be attended continuously during capture periods. Bats will be removed from mist nets immediately upon entanglement to avoid injury. Bats will be removed from harp traps after approximately 1 hour and bats will be placed in individual cloth bags until processed. Body measurements, blood, oropharyngeal swabs, and rectal swabs (or fecal pellets) will be collected from each bat. Swabs will be collected in duplicate; one swab will be placed in a cryovial containing Trizol lysis buffer and the other in viral transport medium (VTM). For bats <50g, blood will be collected in a microhematocrit tube and spun down using a portable centrifuge. A bulb will be used to expel serum from the tube into a cryovial. For larger bats >50g, a tuberculin syringe or 1ml syringe and 27g needle will be used to draw blood from the radial artery or vein⁵⁷. Blood will be placed into a conical vial and centrifuged. Serum will be aliquoted into a cryovial using a pipette. During site visits we will also lay out plastic tarps to collect pooled environmental excreta in Trizol and VTM to improve opportunity to detect viral RNA. All samples will be placed in a vapor phase liquid nitrogen dry shipper or portable battery-powered ultracold freezer, immediately upon collection and then transferred to a -80C freezer at the Phebe lab until testing.

C.3.3. Testing plan, ~~d~~Data analysis, sample size, and power analysis. Serology: At the end of Y3, we will screen all serum samples collected to date using the MAGPIX multiplex assay for IgG against filoviruses and henipaviruses. We will analyze temporal dynamics in seroprevalence using general additive models (GAMs), which are analyses that we have used successfully in many previous studies of similar design²⁹. These methods are well adapted for capturing long-term temporal fluctuations in prevalence and moderately sensitive at capturing short-term changes in seroprevalence which can be used to identify population-level disease outbreaks. For example, we estimated that with 40 bats sampled every two months, we would be able to statistically detect an increase in seroprevalence (at a 95% CI limit) of greater than 25% between consecutive sampling events > 80% of the time, assuming a bat population seroprevalence of at least 10% in advance of a bat colony infection (estimated by, in brief, by simulating a fluctuating true seroprevalence value, simulating samples given this underlying seroprevalence, fitting a GAM to these samples, and then calculating if CI on true prevalence between the two sampling occasions over which the change in seroprevalence occurred were non-overlapping). While this is a large change, it is within a range to be expected if infection were to sweep through a bat community²⁹. MAGPIX-positive bat sera will be sent to RML for serum neutralization assays using viral isolates or VSV pseudoviruses under BSL4 conditions.

Commented [WDA9]: Would indicate which laboratory is doing the individual testing to highlight in-country work for most.

Formatted: Font: Not Italic

Commented [MOU10]: Why the need for BSL4 containment?

VSV-pseudotype neutralization assays: Serological results will be confirmed using VSV-pseudotype neutralization assays for the following filoviruses EBOV, SUDV, BDBV, RESTV, BOMV, MARV and RAVN. If novel henipavirus sequences are detected, additional assays will be developed to test positive sera. Serum samples will be inactivated using γ -irradiation (4 MRad). Neutralization of irradiated and heat-inactivated serum samples will be assessed in Vero 352 E6 cells. Briefly, cells were seeded in 96-well round-bottom plates for 24 hours, serial dilutions of heat-inactivated serum samples will be performed in DMEM supplemented with 2% FBS, penicillin/streptomycin, and L-glutamine. Each plate will contain negative serum control, cell-only control, and virus-only control. VSV EBOV-GFP will be added to each well of the serum dilution plate and the serum-virus mix 357 was incubated at 37°C for 1-hour. The mix was added to the cells and incubated at 37°C for 24 hours. The cells will then fixed with 4% paraformaldehyde at room temperature 359 for 15-minutes and centrifuged at 600 x g for 5-minutes at room temperature. The supernatant will be discarded and FACS+EDTA buffer was added. Samples will be run on the FACSymphony A5 Cell Analyzer (BD Biosciences, Mississauga, ON, Canada) and FITC MFI 362 was measured. Data will be analyzed using FlowJo.

Molecular testing: We will use specific filovirus taqman real-time PCR assays to screen oropharyngeal, fecal and environmental samples from bats for EBOV and MARV RNA at the UNC-Phebe lab^{55,58}. Testing bat samples by PCR may allow us to detect viral RNA during active infection, providing important information about the prevalence and timing of infection within target species. **Because we expect viral prevalence to be significantly lower than seroprevalence, estimated at <5%**^{25,27,49}, we developed a sampling scheme focused on maximizing our probability of detecting viral RNA with qPCR. To compare power under alternative sampling designs, we built simulation-based power analyses that estimated power to detect: 1) viral EBOV or MARV RNA in at least one bat; and 2) the expected number of positive cases, in each bat species. In brief, we estimated power for total sample sizes between 1500-3000 (between 500 and 1000 bats sampled per species) spread across a variable number of visits per year (2-6), while allowing for uncertainty in true infection dynamics in the bat populations, specifically: 1) prevalence during one three-week period (with unknown timing) per year of high prevalence ranging from 1-5%; and 2) an otherwise low background prevalence (0-1%). Given these estimates of yearly infection dynamics, these analyses showed with 672 samples per species (minimum 32 individual bats per sampling event), spread across 6 sampling occasions per year, we would obtain a per-species probability of acquiring 0 positive samples of <4% (<1% at 40 bats per event – our target number) and an expectation of ~3-6 RNA positive results (~5-10 positives at 40 bats per event). Because henipaviruses have not been previously described in Liberia, we will focus our resources on filovirus testing by PCR. However, if henipavirus serology suggests active circulation, we may send a set of samples to RML for pathogen discovery (SEE RML LETTER OF SUPPORT).

Viral isolation: PCR-positive cDNA samples and their aliquot in VTM will be sent to RML for further sequencing and attempts at viral isolation under BSL4 conditions. If attempts to culture do not work, we will use next generation sequencing techniques to get whole genome sequence and further characterize the virus at RML. Novel viruses will be characterized and rescued (reverse engineered using a minigenome system to synthetically create infectious viral particles⁵⁹) at RML under secure, biosafety level 4 conditions, then used for serum neutralization assays in bat and human sera to determine more precise exposure rates. Sequences from the glycoproteins of any novel viruses discovered will be used by USU (Co-I Laing) to generate purified proteins and added to the Luminex assay, which will improve its specificity.

VirCapSeq-VERT and myBaits probe-based enrichment for recovery of full-length genome sequences of filoviruses: Although shotgun sequencing provides opportunities to analyze all host and virus genetic material, the larger average genome size of bacteria and hosts compared to viral genomes complicates a detailed analysis of the virome, particularly vertebrate viruses. We have established a positive selection probe capture-based

Formatted: Small caps

Formatted: Justified, Indent: First line: 0.5", Tab stops: Not at 1.86"

Formatted: Justified, Indent: First line: 0.5", Tab stops: Not at 1.86"

system to enrich for viral sequences. Here, we will take advantage of these probe capture-based methods (VirCapSeq-VERT and myBaits probe library) to enrich for vertebrate viral sequences of interest. Sample libraries will be normalized and combined in 4- to 12-plex reactions for solution capture hybridization using either the HyperExplore custom bait library version of VirCapSeq-VERT probe set or our custom myBaits probe library. For HyperExplore custom bait library probe set, libraries will be enriched for virus following the SeqCap EZ HyperCap Workflow User's Guide, version 2.3, while for custom myBaits probe library, the myBaits Hybridization Capture for Targeted NGS protocol, Version 4.01 will be used. Sequencing libraries will be normalized and sequenced as 2 X 150 bp fragments on Illumina's MiSeq or NextSeq sequencing platforms, following Illumina's standard procedure (Illumina, San Diego, CA). NGS data will be analyzed using metavirs (<https://openomics.github.io/metavirs/>), a comprehensive viral metagenomics pipeline to assemble, annotate, and classify viruses. It relies on technologies like Singularity1 to maintain the highest-level of reproducibility. The pipeline consists of a series of data processing and quality-control steps orchestrated by Snakemake2, a flexible and scalable workflow management system, to submit jobs to a cluster. The pipeline is compatible with data generated from Illumina short-read sequencing technologies. As input, it accepts a set of FastQ files and will be run on-premises using the NIAID RML Big Sky supercomputing cluster.

C.3.45. Expected outcomes. Based on our prior work, our multifaceted analysis approach, and calculated power given our proposed temporal sampling strategy, we expect to be able to use temporal serological data to describe filovirus and henipavirus viral dynamics over time. Our molecular screening will primarily focus on filoviruses because we have known targets, and we expect to detect EBOV or MARV RNA, despite low prevalence and short-lived infections. Sequence data from positive samples will: 1) provide substantial evidence for the identification of EBOV reservoirs and help explain which virus is responsible for the observed IgG response in bats (and possibly people); and 2) provide valuable information about viral diversity, about which little is known. Henipavirus serology, in the absence of sequence data, will allow us to identify potential bat reservoirs, analyze temporal trends, and generate hypotheses for future targeted studies.

C.3.56. Potential problems and solutions

Serological tests are greatly hindered by the inherent antibody cross-reactivity between antigens from known ebolaviruses, challenging data interpretations that antibodies are EBOV-specific or EBOV, BDBV, and SUDV cross-reactive⁴⁰. This is also true for the henipaviruses in the panel. The advantage of the multiplexed platform is that we can simultaneously see relative MFI values for all the filoviruses and henipaviruses. Glycoproteins from the

homologous virus should cause the most intense reaction, particularly at higher dilutions. Co-Is Laing and Munster have demonstrated that homotypic and heterotypic ebolavirus-antibody reactions can be simultaneously measured and accounted for in ERBs challenged with replication-competent VSV-filoGP (Figure 8). Still, there is some cross reactivity, and we will use additional tools such as viral neutralization assays as a secondary test, and our statistical approach can correct for a portion of cross reactivity. Past studies have relied on individual ELISAs which had varying degrees of specificity depending on which test was used, but often couldn't rule out cross-reactivity. The Luminex filovirus multiplex assay has predictable patterns of cross-reactivity, but we will still be able to discern to which virus the serum is most reactive.

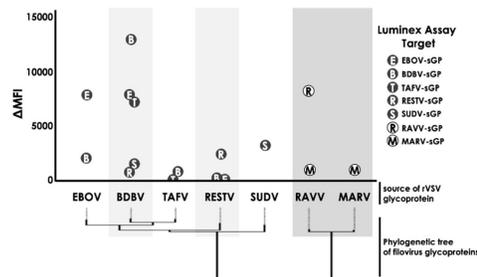

Figure 8. Captive-bred Egyptian rousette bats ERBs were experimentally challenged with VSV-filoGPs, the GP source is indicated on the x-axis. In a GP-trimer multiplex test the homotypic ebolavirus bat antisera were most reactive with the homotypic ebolavirus GP-trimer antigen.

Formatted: Justified

Commented [WDA11]: What about not finding any henipaviruses at all?

C4. Aim 3: To characterize behaviors associated with exposure to filoviruses and henipaviruses.

C.4.1 Background and rationale. As described above, there is substantial interaction between wildlife, domestic animals, and people living in rural Liberia. Our group collected questionnaire data from 585 people across Liberia as part of the USAID-funded Ebola Host Project between 2016 and 2019. When asked about animal exposures during the 2013-2016 Ebola outbreak, participants frequently reported contact with both domestic and wild animals. Common types of animal contact included animals coming inside the dwelling (58%), cooking or handling animal meat (44%), and eating raw or undercooked meat (31%). Additionally, 26% reported slaughtering and 12% reported hunting or trapping an animal. In the ENABLE Study of 5,005 residents of Bong County, survey questions mainly focused on rodent exposures relevant to Lassa fever, but 12% of participants reported hunting or preparing wild animal meat. Little is known about the prevalence and type of other potential bat exposures in this region of Liberia. Elsewhere in West Africa, EcoHealth Alliance participated in the response to Ghana's 2022 cluster of MARV cases, working with local partners to administer a behavioral risk questionnaire characterizing bat exposures in three affected communities¹⁶. Many participants lived in close proximity to bats, with one fifth reported exposure to bats inside a dwelling or other building in the previous four months. When asked about exposures more relevant to Egyptian Rousette bats, a known MARV reservoir and a target species in this proposed study, participants commonly reported bats feeding on fruit trees on their home compound, eating fruit bearing bite marks, and exposure to bats inside a cave or mine.

Formatted: Justified

C.4.2. Research design. As described in Aim 1, serum collected at baseline (in 2021) and at month 24 (in 2023) during the ENABLE Study will be screened for filoviruses and henipaviruses ([analyses not included in the ENABLE Study protocol](#)), enabling us to calculate seroprevalence at baseline and seroconversion over a two-year period. In addition to providing blood specimens, the 1,024 participants who initially enrolled responded to baseline questionnaires on demographics, healthcare-seeking behaviors, health status, and animal exposures. At month 24, the 921 participants still actively enrolled are administered repeat questionnaires. This final survey includes additional items based on the Ghanaian questionnaire and asks specifically about bats including the respondents' activities in their habitats (entering forests, caves, and mines), direct contact (hunting, eating handling), indirect contact (presence in home or other used structure), and observed characteristics of bats encountered (fruit tree dwelling). By pairing this existing survey data with the new serology results generated from archived samples under Aim 1, as well as new data on nearby bat infection from Aim 2, we will be able to develop comprehensive risk profiles for exposure to filoviruses and henipaviruses in this community.

Formatted: Justified

C.4.3 Data analysis. The primary outcome for this analysis will be testing positive for IgG antibodies against any known filoviruses or henipaviruses. For both families of viruses, and for each species of virus within those families, we will use the serology results generated under Aim 1 to examine risk factors for seropositivity at baseline and for seroconversion between baseline and month 24. We plan to conduct a multivariate logistic regression, with appropriate weights applied to account for the single-stage cluster sampling design of the ENABLE Study, in which members of randomly selected households were surveyed and tested. We will use data from both the baseline and month 24 questionnaires to examine the effects of sampling site, participant demographics (e.g., age, gender, occupation), environmental exposures (e.g., animals present in and around the dwelling), and behavioral risks (e.g., direct contact with bats through hunting, preparing, or eating them, entering caves or mines where bats live).

Formatted: Justified, Tab stops: Not at 1.86"

Power analysis: To assess our power to identify risk metrics for seroconversion (or overall seropositivity), we built simulation-based power analyses that consisted of, in brief: 1) simulating survey responses for N (400-1,000) individuals, while allowing for moderate unevenness in representation across five binary categories (as great as 80%-20% for each); 2) examining a range of effect sizes (odds ratios ranging from 1-2.5) for these five

binary categorical predictors (e.g., sex, encountered a bat, handled a bat, etc.). Summarizing across 1,200 simulations of surveys of 400-1,000 individuals given joint uncertainty in the representation within these surveys and effect sizes, we estimated that we would have at least 80% power to detect significant effects for each predictor given an odds ratio of 1.65 or greater with 1,000 survey responses or ~1.80 (for example, with a rate just under 5% for Group1 = 0, just over 8% for Group1 = 1) with 750 responses.

Formatted: Justified, Tab stops: Not at 1.86"

C.4.4 Expected outcomes. By combining serology results with detailed questionnaire data on participant demographics and animal exposures, we will be able to use odds ratios to identify behaviors significantly associated with seropositivity (e.g., exposure to filoviruses or henipaviruses). We expect to be able to also identify age and gender-based risk factors given our sample size. Based on previous experience conducting behavioral risk surveys, including a recent study in Ghana following a Marburg outbreak, we expect to be able to develop risk mitigation messaging that uses evidence from Aims 1 and 2 as well as results from this aim.

Formatted: Justified

C.4.5 Potential problems and solutions. We anticipate that most IgG positive individuals for either set of viruses will be adults, with the likelihood of exposure and having antibodies increasing with age. Because we don't know how long IgG antibodies persist at detectable levels, it will not be possible to accurately determine when exposure occurred, with the exception being EBOV antibodies that most likely occurred as a result of contact with another infected person during the 2014-2016 outbreak. We will address this in two ways: by looking at respondents ~~21-6 yrs-years old~~ of age, we will know that any filovirus antibodies they have are most likely not due to the epidemic, and we will be able to determine whether there are any significant associations with particular behavior or other factor (household construction, domestic animal exposure) that promotes direct animal contact, consumption of contaminated fruit, or exposure to bat habitats (e.g., caves or mines). For adult respondents, we will focus on exposures (based on relative MFI values) specific to non-EBOV filoviruses and henipaviruses and see whether there are associations with specific behaviors.

D. Summary and Conclusions.

West Africa is a hotspot for emerging zoonotic viruses such as Ebola, Marburg and potentially Nipah-related henipaviruses – groups that have been identified by WHO as among the most significant pathogens that threaten global health. Liberia is also a biodiversity hotspot, with some of the largest tracts of primary forest remaining in the region, and its population relies on wildlife as a primary source of protein, creating continued risk of spillover of high consequence zoonotic pathogens. This project has the potential to determine the origins of Zaire ebolavirus in West Africa, characterize the circulation of Ebola and other filoviruses and henipaviruses in common bat species, identify background rates of spillover in rural human populations, and identify high-risk behaviors associated with exposure to these bat-borne zoonoses. Our group comprises an unparalleled

multidisciplinary group of leading experts in epidemiology, clinical medicine, virology, serology, and disease ecology all with deep experience working in Liberia, [strong partnerships with the Liberian public health institutions](#), and implementing zoonotic virus research, giving this project a high chance of success in generating impactful results that will help prevent future epidemics in West Africa.

Specific Aims

Emerging infectious diseases - predominantly caused by zoonotic viruses - have become a major threat to individual and public health as well as the functioning of a global society. Even prior to the SARS-CoV-2 pandemic, outbreaks of consequential emerging pathogens including SARS-CoV, Pandemic influenza 2009, Zika virus, and Ebola virus disease tragically killed and disabled and caused massive disruptions of regional and global economies and health care systems¹. The emergence of consequential zoonotic infections is accelerating due to anthropogenic drivers such as climate change, land-use change, intensification of livestock production, and wildlife trade, all of which increase opportunity for people and domestic animals to come into contact with wildlife reservoirs²⁻⁵. **To reduce the risk of infectious disease epidemics, there is a critical need to detect and prevent spillover of zoonotic pathogens from wildlife reservoirs^{2,6}.**

Illustrative of this need is the repeated spillover from wildlife reservoirs to human populations of groups of zoonotic viruses such as filoviruses (e.g., Ebola virus [EBOV]) and henipaviruses (e.g., Nipah virus [NIV]). Large-scale outbreaks or clusters of cases with these high-mortality zoonotic viruses have led to their being **designated as high priority pathogens by the World Health Organization (WHO)**⁵. However, at present, the detection of outbreaks caused by these pathogens occurs only after the first human infections; a failure in prevention that is deadly, costly, and remediable¹. Identifying natural reservoirs of zoonotic viruses and measuring rates of exposure to these viruses in humans are critical to assessing their potential threat and developing interventions that reduce the risk of spillover.^{1,2}

In the proposed study we have assembled a diverse team of experts in ecology, epidemiology, virology and immune response to bat-borne viral zoonoses such as filoviruses and henipaviruses; and filovirus clinical care and research who are actively working in West Africa to provide much needed empirical evidence to help answer the questions: **What is the natural reservoir for Ebola virus and how often does spillover of this and related viruses happen in a region that is an emerging disease hotspot, suffered the world's largest filovirus outbreak, and where there has been evidence of other consequential zoonotic viruses in animals and people? To address these questions, we propose the following specific aims:**

Aim 1. To determine the rates of filovirus and henipavirus exposure in people in rural Liberia. We have shown that certain bat species in Liberia carry EBOV-Zaire, while others carry Marburg virus and henipaviruses. Further, hunting bats is a common activity and we have detected high seroprevalence of Marburg and EBOV antibodies in residents of rural Liberia. Exposure to henipaviruses remains unknown. To test the hypothesis that spillover of both groups of viruses has occurred in this region, we will use an antigen-based multiplex serological assay to screen more than 1,9800 archived blood specimens, collected in 2021 and again in 2023 from over 900 adults and children in rural central Liberia as part of a longitudinal study of Lassa fever seroprevalence and seroincidence, for antibodies against all known filoviruses and henipaviruses.

Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia. Our group detected EBOV-Zaire RNA and antibodies in *Miniopterus nimbae*, a cave- and mine-dwelling bat in northern Liberia found near the origin of the 2014 Ebola outbreak in Guinea. We also detected antibodies against EBOV in *Hipposideros* bats that co-roost with *Miniopterus* in multiple locations in Liberia. *Rousettus aegyptiacus*, a common frugivorous bat in Liberia, carries Marburg virus and henipaviruses. We will conduct a 3-year longitudinal study of populations of these bat species near the human cohort studied in **Aim 1**, to determine whether they are reservoirs for Ebola or other filoviruses and henipaviruses and characterize the temporal dynamics of filoviruses and henipavirus circulation using multiplexed serological assays that test for IgG antibodies against all known filoviruses and henipaviruses, as well as molecular techniques to screen for Ebola, Marburg, Nipah virus, and related viruses.

Aim 3. To characterize behaviors associated with exposure to filoviruses and henipaviruses. Combining the data collected in Aim 1 (humans) and Aim 2 (bats) we will identify the demographic, behavioral, and environmental factors associated with an individual's prior exposure to filoviruses and henipaviruses. Detailed animal exposure data collected from the adults and children (many born after the Ebola outbreak) who provided the Aim 1 blood specimens will be used to develop profiles of risk and inform public health & risk reduction communication tools in partnership with the Ministry of Health, Liberia.

RESEARCH STRATEGY

A. SIGNIFICANCE

Zoonotic viruses are responsible for the majority of emerging infectious disease outbreaks, which are occurring at an accelerating rate in global hotspots^{3,7}. Every outbreak begins with spillover – transmission of the virus from its animal reservoir either directly into human populations or into other animal hosts *en route* to humans (Figure 1). Exactly how often spillover occurs is virtually unknown, as surveillance systems are primarily designed to detect clusters or outbreaks, and often miss initial individual infections that result from animal contact. To reduce the risk of future epidemics, it will be necessary to limit opportunities for zoonotic viruses to spillover and to detect spillover at the earliest stages.^{1,8} Measuring the efficacy of any interventions designed to reduce spillover and spread of zoonotic pathogens will rely on measuring rates of exposure in at-risk human populations.

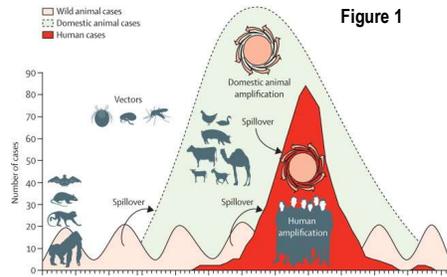

Figure 1

Filoviruses and henipaviruses are among the highest consequence zoonotic viruses and have greatly impacted public health. Each group contains zoonotic pathogens that cause significant disease in both people and animals, especially livestock, that have been associated with extremely high rates of morbidity and mortality. Ebola (EBOV) and related viruses, as well as Nipah virus (NIV), a henipavirus, and its related viruses have been listed by the World Health Organization (WHO) among the highest priority pathogens for the development of vaccines and therapeutics, as they represent zoonotic pathogens with high potential to threaten human health, with extremely high mortality rates and few or no therapeutics or vaccines currently available.⁹⁻¹¹ These viruses share other important features which make them high priority: they are all associated with bat hosts that are abundant and widely distributed throughout Africa and Asia, living in close association with people and livestock in some of the most densely populated regions on Earth.

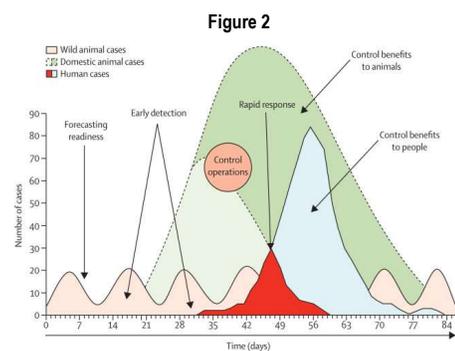

Spillover of these viruses has repeatedly occurred. Beyond the massive outbreak in West Africa in 2013-16, EBOV outbreaks have occurred repeatedly in Central and East Africa; most recently Sudan ebolavirus caused an outbreak in Uganda in late 2022¹¹⁻¹³. Marburg virus (MARV) and Ravn virus (RAVV) comprise the closely related genus *Marburgvirus* and have caused outbreaks in Central and East Africa and Europe with mortality and clinical presentation comparable to Ebola^{14,15}. Marburg virus outbreaks were declared in Guinea, just across the border from the UNC-Liberia research site in 2021 and then again in Ghana in 2022 marking the first time this virus has been reported in either country^{16,17}. **Nipah-NIV virus** is an emerging zoonotic paramyxovirus that has caused nearly annual outbreaks in Bangladesh, including multiple outbreaks in 2023, and sporadically in India with mean case fatality rates greater than 70%^{12,18-20}. Despite the public health significance of Nipah and related viruses, little is known about its genetic diversity, natural reservoirs, or frequency of spillover throughout their range, including Africa. Henipaviruses, and **Nipah virus NIV** in particular - have several characteristics that make them a global health priority: 1) Their bat reservoirs occur throughout Asia and Africa, overlapping human and livestock populations, giving them geographically broad opportunity to cause outbreaks²¹; 2) henipaviruses can be transmitted to people directly from bats or via domestic animals²¹; 3) **Nipah virus NIV** can be transmitted from person to person²²; 4) **Nipah virus NIV** spillover has occurred and continues to occur in highly populous and internationally connected regions; 5) repeated spillovers of NIV strains with varying person-to-person transmission rates indicate the ability to evolve **with increased pandemic potential**^{23,24}; and 6) Nipah is associated with a high mortality rate in people and currently has no vaccine or treatment^{21,23}. While **Nipah virus NIV** has not been detected in Africa, closely related henipaviruses have been identified in Ghana and Madagascar, though their public health significance remains unknown²⁵⁻²⁷. In West Africa, where bats and associated henipaviruses occur but where no human cases have been identified, **diagnostic testing and systematic surveillance is essentially non-existent**. The detection of antibodies against a Nipah-related virus in hunting communities in Central Africa suggests that cryptic spillover is occurring²⁸. **Repeated spillover of henipaviruses creates opportunity for more transmissible strains to emerge**²⁹.

While bats have been identified as potential hosts for filoviruses including EBOV, the natural reservoir for EBOV-Zaire Ebola in West Africa remains unknown. There is substantial evidence, both serological and molecular, that bat species host filoviruses; however, a definitive natural reservoir or set of reservoirs for EBOV-Zaire has not been identified³⁰. Wildlife, including bats, represent a substantial source of animal protein for communities in Liberia³¹. People may be exposed to bat-borne viruses through hunting and butchering, eating food contaminated by bat excreta, or by entering caves or mines inhabited by bats. Our group previously found that people living in rural areas of Liberia conduct activities which may increase their risk of contact with bats or their bodily fluids. The index case, a child, in the 2013 Ebola outbreak was hypothesized to have had contact with bats, yet the exact species was never definitely identified³². The route of spillover for most historical Ebola outbreaks remains a mystery. Despite broad efforts to determine the natural reservoirs of EBOV and related viruses, there continues to be a poor understanding of filovirus ecology, with the exception of **Marburg virus** MARV, whose host has been identified as Egyptian rousette bats (*Rousettus aegyptiacus*)³³⁻³⁵. Communities known to hunt bats in Cameroon and India have been found to have antibodies against henipaviruses and filoviruses, respectively, yet nothing is known about community exposure rates in Liberia, where bat hunting is common^{28,36}. Our preliminary data (see below) suggest that there is substantial exposure to EBOV as well as MARV among people in central Liberia. While the EBOV antibodies may indicate prior infection from another person such as during the West Africa outbreak, antibodies specific to other filoviruses may signal a localized exposure from animals. Even less is understood about henipaviruses in ~~Africa, and~~ **Africa** and identifying antibodies against henipaviruses in people will be critical for understanding where, how and how often spillover occurs.

The urgent need to develop interventions to prevent spillover of zoonotic high consequence pathogens can only be met with a better understanding of their natural reservoirs, the rates of exposure in vulnerable human populations, and the ways in which people are exposed. Unrecognized outbreaks provide opportunities for viruses to emerge that may be more transmissible or more pathogenic than previously observed, and limiting these opportunities is an important component of pandemic prevention^{2,29}. Typically, by the time an outbreak is recognized in human populations its containment and control are difficult, if not impossible to achieve (e.g., HIV, SARS-CoV-2). Understanding the ecology of these viruses, including which species act as reservoirs as well as how and to what extent people are being exposed to filoviruses and henipaviruses will inform intervention and surveillance strategies and provide baseline metrics against which one can measure the efficacy of interventions designed to reduce exposure, such as public health campaigns to promote avoidance of behaviors associated with infection among those most at risk (**Figure 2**).

This proposed study will be the largest and most rigorous One Health investigation of high-consequence zoonotic viruses in bats and humans in an emerging disease hotspot. West Africa is known to be the source of prior outbreaks of emerging infectious diseases and future spillover events there are highly likely. Liberia is typical of this region and contains some of the largest tracts of pristine forest and wildlife biodiversity

remaining in West Africa and has a population that depends on wildlife, including bats. Decades ago, a spillover event from a non-human primate to a human triggered an on-going HIV pandemic that has led to the infection of over 60 million people and 25 million deaths. Only months ago, the orthopoxvirus MPOX found in rodents spread to and within 110 countries across the globe causing over 85,000 cases. Both originated from African wildlife. The proposed study will leverage the unique infrastructure and expertise we have developed in Liberia to undertake a comprehensive examination of filovirus and henipavirus spillover from bats to humans and provide evidence of previous and possibly on-going transmission events. Our findings will provide essential

evidence of the presence and transmission dynamics of these bat-borne viruses and as the risks for infection in people living alongside them.

B. INNOVATION

The proposed research is highly innovative in multiple ways, including: 1) Our use of a one Health approach to study the ecology and epidemiology of two groups of high-priority, high-consequence zoonotic viruses in both bats and people in West Africa – an emerging disease hotspot where spillover events have occurred (e.g. Ebola, Marburg, MPOX, Lassa fever) and are highly likely to re-occur; 2) Our use of a novel and unique multiplexed serological platform, developed by our group, that will allow us to screen bat and human serum for IgG antibodies against each of the known filoviruses and henipaviruses, simultaneously in a single assay. Longitudinal comprehensive serological studies in bats and people **will provide unprecedented insight into the changes in rates of exposure over time to known viruses in bats; and in people (e.g. what is the baseline rate of exposure to henipaviruses and filoviruses and is there evidence of recent exposure?); and exposure rates to unknown, antigenically related viruses;** 3) We will couple serosurveillance with molecular testing to identify specific filoviruses and henipaviruses carried by bats; and 4) We will connect the bat and human epidemiological studies by analyzing questionnaire data from the human cohort to identifying high risk behaviors associated with viral exposure. **Results from this analysis will inform the development of public outreach and risk reduction campaigns by the Government of Liberia.**

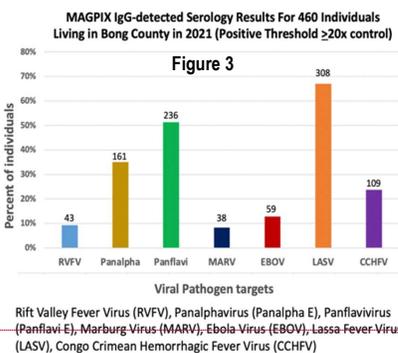

C. APPROACH

C.1. Overview: Aim 1 will test the hypothesis that spillover of filoviruses and henipaviruses occur regularly in rural Liberia by testing for IgG antibodies to all known filoviruses and (see [Table 13](#)) in [archived](#) serum samples from [more than 900](#) people living in Bong county (central Liberia), collected [between 2021-23](#) at two time points 24 months apart [as part of the Coalition for Epidemic Preparedness Innovations \(CEPI\)-sponsored ENABLE Study, an on-going longitudinal study of Lassa fever seroprevalence and seroincidence.](#) Sero-prevalence of filoviruses and henipaviruses will be assessed as will ~~changes sero-incidence between the two collection timepoints~~. In Aim 2, we will conduct a 36-month longitudinal study of three bat species which are putative reservoirs for EBOV and undescribed henipaviruses. Using a combination of longitudinal serology and molecular testing (PCR and whole genome sequencing) **we will determine the prevalence of filoviruses and henipaviruses in three these key bats species associated with the rural human populations studied in Aims 1 and 3.** For Aim 3, we will analyze detailed questionnaire data developed collaboratively by our group (EHA and UNC) and collected in 2023 along with blood samples to be screened in Aim 1. These data will allow us to identify ~~behaviors-factors~~ associated with exposure to henipaviruses and filoviruses. We will use results from our behavioral and exposure risk assessment to develop public risk reduction communication strategies with the National Public Health Institute, Liberia, using the results of this study to inform public health strategies. This application is a natural progression of our research activities, and our preliminary data speak to the feasibility of the proposed study.

C.2. Aim 1: To determine the rates of filovirus and henipavirus exposure in people in central rural Liberia.

C.2.1. Rationale and Preliminary Data.

The primary goal of this aim is to be able to determine whether populations within Liberia who live in association with bats have evidence of exposure against one or multiple filoviruses and/or henipaviruses and to compare rates of exposure over time. Studies of human populations in Central and West Africa have found evidence of exposure to EBOV prior to the 2013 outbreak and in places not known to have had Ebola outbreaks^{37,38}. UNC Project-Liberia has previously assessed seropositivity to

Formatted: Justified

Formatted: Font: 11 pt

Commented [WDA1]: The conflation of filo and henipav makes Billy and my feet itch. We really don't know that henipav will pan out. Would turn this into a strength by saying this is our suspicion given the bats and that this will be the first-ever look to see. Finding these viruses in W Africa would be of great significance as could mean undiagnosed encephalitis or potential tinderbox for future spillover.

Formatted: Font: 11 pt

Formatted: Justified

Formatted: Font: Bold

Formatted: Tab stops: 0.5", Left + Not at 1.86"

Commented [WDA2]: The seroprevalence could have carried this alone. We are also adding possible sero-incidence but this is limited by shortish follow up time. Could frame as am also an opportunity to assess exposure over time.

consequential viral pathogens including EBOV and MARV in a subset of CEPI-ENABLE Study participants. **About Over 840%** of participants had antibodies against MARV **using a conservative threshold for seropositivity (Figure 3)**, suggesting that unreported spillover events have previously occurred. Acute encephalitis is common in western sub-Saharan Africa, yet outbreaks of neurological disease are rarely reported and more than half of all cases are undiagnosed³⁹. Among the countries in western Africa reporting cases of meningitis or encephalitis, Liberia has reported the fewest, likely due to a lack of surveillance and capacity to diagnose neurological diseases³⁹. **Nipah virus** NIV encephalitis has never been reported in Africa, however, as described above, two Nipah-like henipaviruses have been described in bat hosts, including one in Ghana^{25,27}. Spillover of henipaviruses was reported in bat-hunting communities in Cameroon²⁸. In South Africa, we detected henipavirus sequences in *Rousettus aegyptiacus*, bats which also commonly occur in Liberia²⁶.

In Aim 1, we will test the hypothesis that spillover of both filoviruses and henipaviruses have occurred in rural populations in Liberia by measuring seropositivity to both groups of viruses within the CEPI ENABLE Study community cohort. We will also measure changes in exposure rates over a two-year period. While prior studies have provided cross-sectional snapshots of exposure, our longitudinal approach will provide data from the same cohort at two timepoints, 24 months apart, to determine both seroprevalence and sero-incidence using a multiplexed serological assay to screen for IgG antibodies against all known filoviruses and henipaviruses.

Settings and Participants. To achieve this aim we will leverage a well characterized cohort of individuals in three rural communities located in Bong County, Liberia (**Figure 4**), which has a population of over 333,400. UNC Project-Liberia has been operating in Liberia since 2014 and established a research site at Phebe Hospital in Bong County that includes a molecular laboratory that conducts daily qPCR testing for LASV, MARV, and EBOV as well as LASV serological assays using a MAGPIX (SEE RESOURCES AND FACILITIES). There, following extensive community engagement including meetings with key stakeholders, town hall meetings, and radio messaging, UNC launched the CEPI **ENABLE Study**, the largest passive and active surveillance program for Lassa fever in Liberia. Started in 2021⁹, 5,005 randomly selected participants 2 years of age and older in Phebe Airstrip, Suakoko, and Rubber Factory were enrolled over 6 months following informed consent/assent (mean age at enrollment is 22.2 years (range 2-97) and 54.2% are female). **Importantly, 7.7% of the cohort is under the age of 5 years, and therefore, were born after the 2013-14 Ebola outbreak (Table 1).** Households were selected for recruitment following identification of roof tops by satellite photos and use of a program developed by Médecins Sans Frontières' (MSF) Epicentre to randomly selected structures to ~~consecutively~~ approach sequentially for participation. The ENABLE Study includes baseline questionnaires and blood specimen collection from all participants with active follow-up by a study community health worker every 2 weeks to determine ifs a febrile event has occurred, which triggers drawing of blood for LASV, MARV, and EBOV PCR. Baseline blood is tested for Lassa fever virus (LASV) serology. A subset of 1,024 individuals (every 5th approached household is eligible) is also asked to provide blood samples routinely every 6 months for up to 24 months for repeat LASV serology. The blood samples from 0 and 24 months and the associated surveys will be used in Aims 1 and 3 of this proposal. Informed consent and assent documents include provisions for the use of collected specimens and data for infectious diseases research including for emerging pathogens (see PROTECTION OF HUMAN SUBJECTS).

C.2.2. Research Design. We will screen approximately **1,900 archived serum specimens** from participants in the ENABLE Study cohort at two time points ("baseline" (Month 0) and (Month 24)) for IgG antibodies against specific filoviruses and henipaviruses using the MAGPIX at the UNC molecular lab at Phebe ~~H~~ospital to run the multiplexed *henipavirus / filovirus* platform to be provided by Co-I Laing in year 1. The multiplex platform will allow us to determine specifically which filoviruses and henipaviruses people have been exposed to and compare that to the filoviruses and antibodies we observe circulating in local bat populations in **Aim 2**. The bead-based multiplexed assay has tremendous advantage over traditional ELISAs in that it will

Figure 4. Map of Liberia with Bong County sites shown in inset.

Commented [JE5]: @Billy is this right?

identify up to 25 different antibodies against multiple viral agents in a single, 2uL serum sample and uses a high through-put format. The ability to look at reactivity across all serogroups simultaneously will allow us to differentiate among the viruses. Proteins A/G non-specifically bind IgG immunoglobulins, and weakly bind IgM, an immunoglobulin that is the first to be produced during the initial stages of infection. We will conduct a 1-week training at the UNC-Phebe lab for using the assay to detect filovirus and henipavirus antibodies as well as data management, bioinformatics and analysis. **Table 13** shows the viral species and antigens that will be employed in this assay. The platform has been previously transferred to collaborating labs in the UK, South Africa, India, Bangladesh, Singapore, Thailand and Malaysia. We have previously detected serological profiles of Asiatic ebolaviruses in fruit bats collected in Singapore⁴⁰ and in fruits bats and humans actively engaged in bat hunting in northeast India³⁶.

C.2.3. Data Analysis. We will create a project database using Airtable, which will be hosted at EHA and will house all data from Aims 1 and 2 and will link to the RedCap server which stores questionnaire data from Aim 3. Database access will be secure and limited to key personnel (see data management plan). Raw MFI values from the MAGPIX will be used to calculate reactivity to each viral antigen and based on relative strength of reactivity (**Fig 5**) and determinations of negative cutoffs based on reference sera, we will calculate prevalence rates for each time point and compare rates between the two timepoints. Serological profiling can be used to detect reactive antibodies against all specific filoviruses and henipaviruses in a samples and compare strength of reactivity and cross-reactivity against multiple antigens using a single sample⁴¹. We will compare the antibodies across all specific viral antigens to assess which virus or

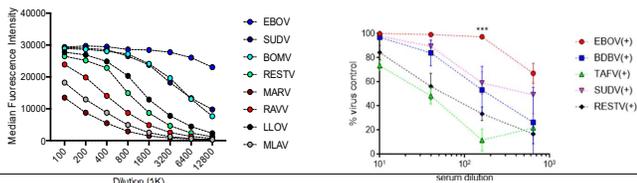

Figure 5. shows relative mean fluorescence index (MFI) values for an EBOV +ive control sera across serial dilutions. While there is cross reactivity, the EBOV MFI values are consistently greater than the other viral GPs and at higher dilutions the separation becomes significant.

reference sera, we will calculate prevalence rates for each time point and compare rates between the two timepoints. Serological profiling can be used to detect reactive antibodies against all specific filoviruses and henipaviruses in a samples and compare strength of reactivity and cross-reactivity against multiple antigens using a single sample⁴¹. We will compare the antibodies across all specific viral antigens to assess which virus or

Formatted Table

Formatted: Indent: First line: 0"

Formatted: Justified, Indent: First line: 0.5", No widow/orphan control

groups of viruses are responsible for the immunological response⁴²⁻⁴⁴. We will assess exposure to non-Zaire ebolavirus species, which may indicate spillover of filoviruses has occurred separate to the Ebola outbreak of 2013. We will also look at evidence for exposure to Nipah-like henipaviruses and compare exposure rates to both viral groups within and between our two sample collection time points.

C.2.4. Expected outcomes. We anticipate obtaining serological profiles of exposure to filoviruses and henipaviruses from each individual in our cohort. In previous studies we found antibodies against both **Ebola-EBOV** and **Marburg-MARV** virus. While the **Ebola-EBOV** antibodies are attributable to the epidemic, **Marburg-MARV** antibodies, in patients EBOV IgG negative, suggest possible exposure from an animal (e.g. bat) reservoir. We also anticipate seeing reactivity to **to-Bombali virus (BOMV)**, given the presence of the reservoir species in Liberia (*Mops condylurus*) and reactivity to the African henipaviruses (GhV and AngV), although this may represent reactivity to an antigenically related virus. Serological results from this and the bat study will inform our strategy for prioritizing which bat samples we test by PCR.

C.2.5. Potential problems and solutions. While our preliminary data suggest there will be detection of immune responses to filoviruses including EBOV-Zaire and, significantly, MARV, it is possible that evidence of exposure to other pathogens, including henipaviruses will not be detected. This would be an important finding in this large cohort, especially if these viruses are detected in local bat species, that would warrant further investigation. It is also possible that there will be few or no seroconversion events among the cohort during the 24-month period of follow-up. This too would be reassuring but would suggest a need for longer follow-up of this cohort. To address the possibility that reactivity to EBOV-Zaire virus may be explained by infection during the 2013 Ebola epidemic, we will create a polyclonal sera reference standard utilizing convalescent sera collected from human survivors of EVD. This internal reference standard will be calibrated to the WHO EBOV human serology standard (Fig 6A) permitting direct interpolation of anti-EBOV IgG as a MFI to a standard antibody concentration (binding antibody units/mL). The internal reference standard will then be included in our human serology testing strategy allowing semi- or quantitative measurement of anti-EBOV IgG. These EBOV human serology standards will permit us to establish positive and negative predictive performance values for the multiplex assay; furthermore, we will be able to investigate immunoreactivity of EVD survivors against heterotypic ebolaviruses. Our preliminary data indicates that EBOV+ sera IgG is highly cross-reactive with soluble native-like trimeric envelope glycoprotein (GP) antigens from both EBOV and BDBV (Figure 6A). EBOV GP, matrix protein (VP40), and nucleocapsid protein (NP) antigens have all been used in a variety of serological tests,

Formatted: Justified, No widow/orphan control

Commented [WDA6]: This may flag questions about sources for these sera.

Commented [WDA7]: Define: bundibugyo?

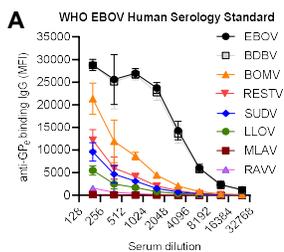

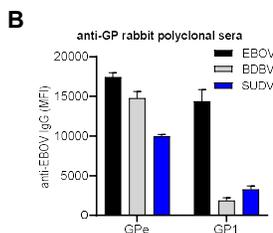

FIGURE 6A & B. A) The WHO EBOV human serology standard was tested for immunoreactivity in a filovirid GP-trimer based multiplex assay. Filovirids are indicated along with sera dilution factors; data is the mean of three independent experiments. B) Antisera from EBOV GP-trimer immunized rabbits were tested in multiplex panels comprised of GP-trimer and GP1 subunit proteins. Anti-EBOV polyclonal IgG was less reactive with GP1 from BDBV and SUDV.

however, the frequency of seroconversion against each antigen has not been fully described. In a longitudinal study of EVD survivors, high seroconversion against GP and VP40 was observed, with affinity maturation occurring overtime against GP⁴⁵. Antigens based on the GP are likely to provide an optimal intrinsic balance of sensitivity and specificity. To limit the degree of heterotypic ebolavirus cross reactions we will test any anti-ebolavirus GP trimer antigen-seropositive samples with a pan-ebolavirus GP1 antigen-based panel. In preliminary studies, GP1 antigens improve specificity and differentiation of antibodies reactive with homotypic ebolaviruses in polyclonal antisera from rabbits immunized with GP trimer immunogens (Figure 6B).

C.3. Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia.

C.3.1 Rationale and Preliminary data. Bats have been established as important hosts for filoviruses and henipaviruses in Africa and Asia, with combinations of viral isolation, molecular detection or serology providing substantial evidence^{30,46-49}. MARV was isolated from Egyptian rousette bats in Uganda, and RNA has since been detected in these bats in Sierra Leone, which borders Liberia⁵⁰. To date, EBOV has never been isolated from bats, although molecular and serological evidence suggest that multiple frugivorous bats may carry EBOV in Central Africa^{50,51}. Prior to the 2014 epidemic, Zaire ebolavirus had not been reported in West Africa, and the animal reservoir remains unknown³². From 2016-2019, our group (PI Epstein & KP Desmond) implemented a large-scale project to identify reservoirs for EBOV in West Africa, under the USAID PREDICT Project⁵². This effort led to the discovery of a new species of Ebola (Bombali virus)⁵³, the detection of MARV in *Egyptian rousette bats* in Sierra Leone³³, and in 2018, we detected, for the first time in West Africa, EBOV RNA and anti-EBOV

Formatted: Indent: First line: 0.5"

IgG antibodies in bats (Figure 7A-D).

While this finding generated the first evidence of which bats

Formatted: Justified, No widow/orphan control

may be reservoirs for Zaire ebolavirus, longitudinal studies are required to more completely understand the role these species play in EBOV circulation— either as reservoirs that maintain the virus within a local population, or as incidental hosts, infected by an unknown bat species. One-off, cross-sectional studies have a low probability of detecting any specific filovirus or henipavirus given their low prevalence and short viremic periods^{34,54}, and thus provide a poor characterization of viral diversity. The lack of understanding of **filovirus and henipavirus diversity and their natural reservoirs in West Africa significantly impedes risk-based public health interventions to prevent human outbreaks**. Longitudinal sampling is needed to separate reservoir hosts from spillover hosts. For example, MARV has been isolated repeatedly from *R. aegyptiacus* in Uganda, which, when paired with experimental infection studies showing infection and shedding of MARV by *R. aegyptiacus*, strongly suggests that *R. aegyptiacus* is indeed a **Marburg-virus** MARV reservoir^{35,55,56}. Similarly, our longitudinal studies of **Nipah-virus** NIV in *Pteropus medius* bats in Bangladesh, which included the same multiplexed serological assay proposed here, confirmed them as a reservoir for NIV and identified important mechanisms driving viral circulation²⁹. **Understanding which species persistently carry filoviruses and henipaviruses will provide important insights into how they are maintained in nature and what species should be targeted for follow-up studies on bat habitat use and human-bat contact patterns.**

Formatted: Justified, No widow/orphan control

C.3.2. Sampling design. We will repeatedly sample three bat species associated with filoviruses or henipaviruses, based on our preliminary data: *M. nimbae* (EBOV), *H. ruber* (EBOV), and *R. aegyptiacus* (MARV & Henipaviruses). We will sample bats at roost sites in Bong county, as close as possible to the human study sites in Aim 1. In Y2-Y4, we will sample 40 individuals of each species every two months for 36 months and collect excreta using plastic tarps placed underneath bat roosts (details below and in C.3.3).

Formatted: Justified

Bat capture and sampling. Briefly, we will use either harp traps or mist nets to capture bats, depending on the capture site. Personnel will wear appropriate personal protective equipment (e.g. Tyvek suits or dedicated long clothing; double nitrile gloves; an N95 respirator and safety glasses or a PAPR⁵⁷). Traps and nets will be attended continuously during capture periods. Bats will be removed from mist nets immediately upon entanglement to avoid injury. Bats will be removed from harp traps after approximately 1 hour and bats will be placed in individual cloth bags until processed. Body measurements, blood, oropharyngeal swabs, and rectal swabs (or fecal pellets) will be collected from each bat. Swabs will be collected in duplicate; one swab will be placed in a cryovial containing Trizol lysis buffer and the other in viral transport medium (VTM). For bats <50g, blood will be collected in a microhematocrit tube and spun down using a portable centrifuge. A bulb will be used to expel serum from the tube into a cryovial. For larger bats >50g, a tuberculin syringe or 1ml syringe and 27g needle will be used to draw blood from the radial artery or vein⁵⁷. Blood will be placed into a conical vial and centrifuged. Serum will be aliquoted into a cryovial using a pipette. During site visits we will also lay out plastic tarps to collect pooled environmental excreta in Trizol and VTM to improve opportunity to detect viral RNA. All samples will be placed in a vapor phase liquid nitrogen dry shipper or portable battery-powered ultracold freezer, immediately upon collection and then transferred to a -80C freezer at the Phebe lab until testing.

C.3.3. Testing plan, data analysis, sample size, and power analysis. Serology: At the end of Y3, we will screen all serum samples collected to date using the MAGPIX multiplex assay for IgG against filoviruses and henipaviruses. We will analyze temporal dynamics in seroprevalence using general additive models (GAMs), which are analyses that we have used successfully in many previous studies of similar design²⁹. These methods are well adapted for capturing long-term temporal fluctuations in prevalence and moderately sensitive at capturing short-term changes in seroprevalence which can be used to identify population-level disease outbreaks. For example, we estimated that with 40 bats sampled every two months, we would be able to statistically detect an increase in seroprevalence (at a 95% CI limit) of greater than 25% between consecutive sampling events > 80% of the time, assuming a bat population seroprevalence of at least 10% in advance of a bat colony infection (estimated by, in brief, by simulating a fluctuating true seroprevalence value, simulating samples given this underlying seroprevalence, fitting a GAM to these samples, and then calculating if CI on true prevalence between the two sampling occasions over which the change in seroprevalence occurred were non-overlapping). While this is a large change, it is within a range to be expected if infection were to sweep through a bat community²⁹. MAGPIX-positive bat sera will be sent to RML for serum neutralization assays using viral isolates or VSV pseudoviruses under BSL4 conditions.

Commented [WDA8]: Would indicate which laboratory is doing the individual testing to highlight in-country work for most.

Formatted: Font: Not Italic

VSV-pseudotype neutralization assays: Serological results will be confirmed using VSV-pseudotype neutralization assays for the following filoviruses EBOV, SUDV, BDBV, RETV, BOMV, MARV and RAVN. If novel henipavirus sequences are detected, additional assays will be developed to test positive sera. Serum samples will be inactivated using γ -irradiation (4 MRad). Neutralization of irradiated and heat-inactivated serum samples will be assessed in Vero 352 E6 cells. Briefly, cells were seeded in 96-well round-bottom plates for 24 hours, serial dilutions of heat-inactivated serum samples will be performed in DMEM supplemented with 2% FBS, penicillin/streptomycin, and L-glutamine. Each plate will contain negative serum control, cell-only control, and virus-only control. VSV EBOV-GFP will be added to each well of the serum dilution plate and the serum-virus mix 357 was incubated at 37°C for 1-hour. The mix was added to the cells and incubated at 37°C for 24 hours. The cells will then fixed with 4% paraformaldehyde at room temperature 359 for 15-minutes and centrifuged at 600 x g for 5-minutes at room temperature. The supernatant will be discarded and FACS+EDTA buffer was added. Samples will be run on the FACSymphony A5 Cell Analyzer (BD Biosciences, Mississauga, ON, Canada) and FITC MFI 362 was measured. Data will be analyzed using FlowJo.

Molecular testing: We will use specific filovirus taqman real-time PCR assays to screen oropharyngeal, fecal and environmental samples from bats for EBOV and MARV RNA at the UNC-Phebe lab^{55,58}. Testing bat samples by PCR may allow us to detect viral RNA during active infection, providing important information about the prevalence and timing of infection within target species. **Because we expect viral prevalence to be significantly lower than seroprevalence, estimated at <5%**^{25,27,49}, we developed a sampling scheme focused on maximizing our probability of detecting viral RNA with qPCR. To compare power under alternative sampling designs, we built simulation-based power analyses that estimated power to detect: 1) viral EBOV or MARV RNA in at least one bat; and 2) the expected number of positive cases, in each bat species. In brief, we estimated power for total sample sizes between 1500-3000 (between 500 and 1000 bats sampled per species) spread across a variable number of visits per year (2-6), while allowing for uncertainty in true infection dynamics in the bat populations, specifically: 1) prevalence during one three-week period (with unknown timing) per year of high prevalence ranging from 1-5%; and 2) an otherwise low background prevalence (0-1%). Given these estimates of yearly infection dynamics, these analyses showed with 672 samples per species (minimum 32 individual bats per sampling event), spread across 6 sampling occasions per year, we would obtain a per-species probability of acquiring 0 positive samples of <4% (<1% at 40 bats per event – our target number) and an expectation of ~3-6 RNA positive results (~5-10 positives at 40 bats per event). Because henipaviruses have not been previously described in Liberia, we will focus our resources on filovirus testing by PCR. However, if henipavirus serology suggests active circulation, we may send a set of samples to RML for pathogen discovery (SEE RML LETTER OF SUPPORT).

Viral isolation: PCR-positive cDNA samples and their aliquot in VTM will be sent to RML for further sequencing and attempts at viral isolation under BSL4 conditions. If attempts to culture do not work, we will use next generation sequencing techniques to get whole genome sequence and further characterize the virus at RML. Novel viruses will be characterized and rescued (reverse engineered using a minigenome system to synthetically create infectious viral particles⁵⁹) at RML under secure, biosafety level 4 conditions, then used for serum neutralization assays in bat and human sera to determine more precise exposure rates. Sequences from the glycoproteins of any novel viruses discovered will be used by USU (Co-I Laing) to generate purified proteins and added to the Luminex assay, which will improve its specificity.

VirCapSeq-VERT and myBaits probe-based enrichment for recovery of full-length genome sequences of filoviruses: Although shotgun sequencing provides opportunities to analyze all host and virus genetic material, the larger average genome size of bacteria and hosts compared to viral genomes complicates a detailed analysis of the virome, particularly vertebrate viruses. We have established a positive selection probe capture-based

Formatted: Small caps

Formatted: Justified, Indent: First line: 0.5", Tab stops: Not at 1.86"

Formatted: Justified, Indent: First line: 0.5", Tab stops: Not at 1.86"

system to enrich for viral sequences. Here, we will take advantage of these probe capture-based methods (VirCapSeq-VERT and myBaits probe library) to enrich for vertebrate viral sequences of interest. Sample libraries will be normalized and combined in 4- to 12-plex reactions for solution capture hybridization using either the HyperExplore custom bait library version of VirCapSeq-VERT probe set or our custom myBaits probe library. For HyperExplore custom bait library probe set, libraries will be enriched for virus following the SeqCap EZ HyperCap Workflow User's Guide, version 2.3, while for custom myBaits probe library, the myBaits Hybridization Capture for Targeted NGS protocol, Version 4.01 will be used. Sequencing libraries will be normalized and sequenced as 2 X 150 bp fragments on Illumina's MiSeq or NextSeq sequencing platforms, following Illumina's standard procedure (Illumina, San Diego, CA). NGS data will be analyzed using metavirs (<https://openomics.github.io/metavirs/>), a comprehensive viral metagenomics pipeline to assemble, annotate, and classify viruses. It relies on technologies like Singularity1 to maintain the highest-level of reproducibility. The pipeline consists of a series of data processing and quality-control steps orchestrated by Snakemake2, a flexible and scalable workflow management system, to submit jobs to a cluster. The pipeline is compatible with data generated from Illumina short-read sequencing technologies. As input, it accepts a set of FastQ files and will be run on-premises using the NIAID RML Big Sky supercomputing cluster.

C.3.45. Expected outcomes. Based on our prior work, our multifaceted analysis approach, and calculated power given our proposed temporal sampling strategy, we expect to be able to use temporal serological data to describe filovirus and henipavirus viral dynamics over time. Our molecular screening will primarily focus on filoviruses because we have known targets, and we expect to detect EBOV or MARV RNA, despite low prevalence and short-lived infections. Sequence data from positive samples will: 1) provide substantial evidence for the identification of EBOV reservoirs and help explain which virus is responsible for the observed IgG response in bats (and possibly people); and 2) provide valuable information about viral diversity, about which little is known. Henipavirus serology, in the absence of sequence data, will allow us to identify potential bat reservoirs, analyze temporal trends, and generate hypotheses for future targeted studies.

C.3.56. Potential problems and solutions

Serological tests are greatly hindered by the inherent antibody cross-reactivity between antigens from known ebolaviruses, challenging data interpretations that antibodies are EBOV-specific or EBOV, BDBV, and SUDV cross-reactive⁴⁰. This is also true for the henipaviruses in the panel. The advantage of the multiplexed platform is that we can simultaneously see relative MFI values for all the filoviruses and henipaviruses. Glycoproteins from the

homologous virus should cause the most intense reaction, particularly at higher dilutions. Co-Is Laing and Munster have demonstrated that homotypic and heterotypic ebolavirus-antibody reactions can be simultaneously measured and accounted for in ERBs challenged with replication-competent VSV-filoGP (Figure 8). Still, there is some cross reactivity, and we will use additional tools such as viral neutralization assays as a secondary test, and our statistical approach can correct for a portion of cross reactivity. Past studies have relied on individual ELISAs which had varying degrees of specificity depending on which test was used, but often couldn't rule out cross-reactivity. The Luminex filovirus multiplex assay has predictable patterns of cross-reactivity, but we will still be able to discern to which virus the serum is most reactive.

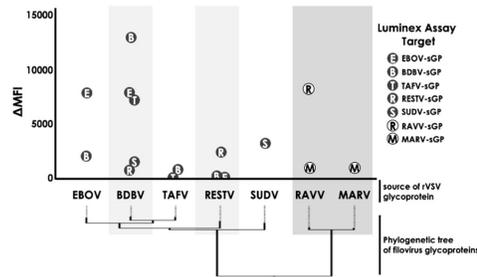

Figure 8. Captive-bred Egyptian rousette bats ERBs were experimentally challenged with VSV-filoGPs, the GP source is indicated on the x-axis. In a GP-trimer multiplex test the homotypic ebolavirus bat antisera were most reactive with the homotypic ebolavirus GP-trimer antigen.

Commented [WDA9]: What about not finding any henipaviruses at all?

C4. Aim 3: To characterize behaviors associated with exposure to filoviruses and henipaviruses.

C.4.1 Background and rationale. As described above, there is substantial interaction between wildlife, domestic animals, and people living in rural Liberia. Our group collected questionnaire data from 585 people across Liberia as part of the USAID-funded Ebola Host Project between 2016 and 2019. When asked about animal exposures during the 2013-2016 Ebola outbreak, participants frequently reported contact with both domestic and wild animals. Common types of animal contact included animals coming inside the dwelling (58%), cooking or handling animal meat (44%), and eating raw or undercooked meat (31%). Additionally, 26% reported slaughtering and 12% reported hunting or trapping an animal. In the ENABLE Study of 5,005 residents of Bong County, survey questions mainly focused on rodent exposures relevant to Lassa fever, but 12% of participants reported hunting or preparing wild animal meat. Little is known about the prevalence and type of other potential bat exposures in this region of Liberia. Elsewhere in West Africa, EcoHealth Alliance participated in the response to Ghana's 2022 cluster of MARV cases, working with local partners to administer a behavioral risk questionnaire characterizing bat exposures in three affected communities¹⁶. Many participants lived in close proximity to bats, with one fifth reported exposure to bats inside a dwelling or other building in the previous four months. When asked about exposures more relevant to Egyptian Rousette bats, a known MARV reservoir and a target species in this proposed study, participants commonly reported bats feeding on fruit trees on their home compound, eating fruit bearing bite marks, and exposure to bats inside a cave or mine.

Formatted: Justified

C.4.2. Research design. As described in Aim 1, serum collected at baseline (in 2021) and at month 24 (in 2023) during the ENABLE Study will be screened for filoviruses and henipaviruses ([analyses not included in the ENABLE Study protocol](#)), enabling us to calculate seroprevalence at baseline and seroconversion over a two-year period. In addition to providing blood specimens, the 1,024 participants who initially enrolled responded to baseline questionnaires on demographics, healthcare-seeking behaviors, health status, and animal exposures. At month 24, the 921 participants still actively enrolled are administered repeat questionnaires. This final survey includes additional items based on the Ghanaian questionnaire and asks specifically about bats including the respondents' activities in their habitats (entering forests, caves, and mines), direct contact (hunting, eating handling), indirect contact (presence in home or other used structure), and observed characteristics of bats encountered (fruit tree dwelling). By pairing this existing survey data with the new serology results generated from archived samples under Aim 1, as well as new data on nearby bat infection from Aim 2, we will be able to develop comprehensive risk profiles for exposure to filoviruses and henipaviruses in this community.

Formatted: Justified

C.4.3 Data analysis. The primary outcome for this analysis will be testing positive for IgG antibodies against any known filoviruses or henipaviruses. For both families of viruses, and for each species of virus within those families, we will use the serology results generated under Aim 1 to examine risk factors for seropositivity at baseline and for seroconversion between baseline and month 24. We plan to conduct a multivariate logistic regression, with appropriate weights applied to account for the single-stage cluster sampling design of the ENABLE Study, in which members of randomly selected households were surveyed and tested. We will use data from both the baseline and month 24 questionnaires to examine the effects of sampling site, participant demographics (e.g., age, gender, occupation), environmental exposures (e.g., animals present in and around the dwelling), and behavioral risks (e.g., direct contact with bats through hunting, preparing, or eating them, entering caves or mines where bats live).

Formatted: Justified, Tab stops: Not at 1.86"

Power analysis: To assess our power to identify risk metrics for seroconversion (or overall seropositivity), we built simulation-based power analyses that consisted of, in brief: 1) simulating survey responses for N (400-1,000) individuals, while allowing for moderate unevenness in representation across five binary categories (as great as 80%-20% for each); 2) examining a range of effect sizes (odds ratios ranging from 1-2.5) for these five

binary categorical predictors (e.g., sex, encountered a bat, handled a bat, etc.). Summarizing across 1,200 simulations of surveys of 400-1,000 individuals given joint uncertainty in the representation within these surveys and effect sizes, we estimated that we would have at least 80% power to detect significant effects for each predictor given an odds ratio of 1.65 or greater with 1,000 survey responses or ~1.80 (for example, with a rate just under 5% for Group1 = 0, just over 8% for Group1 = 1) with 750 responses.

Formatted: Justified, Tab stops: Not at 1.86"

C.4.4 Expected outcomes. By combining serology results with detailed questionnaire data on participant demographics and animal exposures, we will be able to use odds ratios to identify behaviors significantly associated with seropositivity (e.g., exposure to filoviruses or henipaviruses). We expect to be able to also identify age and gender-based risk factors given our sample size. Based on previous experience conducting behavioral risk surveys, including a recent study in Ghana following a Marburg outbreak, we expect to be able to develop risk mitigation messaging that uses evidence from Aims 1 and 2 as well as results from this aim.

Formatted: Justified

C.4.5 Potential problems and solutions. We anticipate that most IgG positive individuals for either set of viruses will be adults, with the likelihood of exposure and having antibodies increasing with age. Because we don't know how long IgG antibodies persist at detectable levels, it will not be possible to accurately determine when exposure occurred, with the exception being EBOV antibodies that most likely occurred as a result of contact with another infected person during the 2014-2016 outbreak. We will address this in two ways: by looking at respondents ~~21-6 yrs-years old~~ of age, we will know that any filovirus antibodies they have are most likely not due to the epidemic, and we will be able to determine whether there are any significant associations with particular behavior or other factor (household construction, domestic animal exposure) that promotes direct animal contact, consumption of contaminated fruit, or exposure to bat habitats (e.g., caves or mines). For adult respondents, we will focus on exposures (based on relative MFI values) specific to non-EBOV filoviruses and henipaviruses and see whether there are associations with specific behaviors.

D. Summary and Conclusions.

West Africa is a hotspot for emerging zoonotic viruses such as Ebola, Marburg and potentially Nipah-related henipaviruses – groups that have been identified by WHO as among the most significant pathogens that threaten global health. Liberia is also a biodiversity hotspot, with some of the largest tracts of primary forest remaining in the region, and its population relies on wildlife as a primary source of protein, creating continued risk of spillover of high consequence zoonotic pathogens. This project has the potential to determine the origins of Zaire ebolavirus in West Africa, characterize the circulation of Ebola and other filoviruses and henipaviruses in common bat species, identify background rates of spillover in rural human populations, and identify high-risk behaviors associated with exposure to these bat-borne zoonoses. Our group comprises an unparalleled

Formatted: Justified

multidisciplinary group of leading experts in epidemiology, clinical medicine, virology, serology, and disease ecology all with deep experience working in Liberia, [strong partnerships with the Liberian public health institutions](#), and implementing zoonotic virus research, giving this project a high chance of success in generating impactful results that will help prevent future epidemics in West Africa.

Specific Aims

Emerging infectious diseases - predominantly caused by zoonotic viruses - have become a major threat to individual and public health as well as the functioning of a global society. Even prior to the SARS-CoV-2 pandemic, outbreaks of consequential emerging pathogens including SARS-CoV, Pandemic influenza 2009, Zika virus, and Ebola virus disease tragically killed and disabled and caused massive disruptions of regional and global economies and health care systems¹. The emergence of consequential zoonotic infections is accelerating due to anthropogenic drivers such as climate change, land-use change, intensification of livestock production, and wildlife trade, all of which increase opportunity for people and domestic animals to come into contact with wildlife reservoirs²⁻⁵. **To reduce the risk of infectious disease epidemics, there is a critical need to detect and prevent spillover of zoonotic pathogens from wildlife reservoirs^{2,6}.**

Illustrative of this need is the repeated spillover from wildlife reservoirs to human populations of groups of zoonotic viruses such as filoviruses (e.g., Ebola virus [EBOV]) and henipaviruses (e.g., Nipah virus [NIV]). Large-scale outbreaks or clusters of cases with these high-mortality zoonotic viruses have led to their being **designated as high priority pathogens by the World Health Organization (WHO)**⁵. However, at present, the detection of outbreaks caused by these pathogens occurs only after the first human infections; a failure in prevention that is deadly, costly, and remediable¹. Identifying natural reservoirs of zoonotic viruses and measuring rates of exposure to these viruses in humans are critical to assessing their potential threat and developing interventions that reduce the risk of spillover.^{1,2}

In the proposed study we have assembled a diverse team of experts in ecology, epidemiology, virology and immune response to bat-borne viral zoonoses such as filoviruses and henipaviruses; and filovirus clinical care and research who are actively working in West Africa to provide much needed empirical evidence to help answer the questions: **What is the natural reservoir for Ebola virus and how often does spillover of this and related viruses happen in a region that is an emerging disease hotspot, suffered the world's largest filovirus outbreak, and where there has been evidence of other consequential zoonotic viruses in animals and people? To address these questions, we propose the following specific aims:**

Aim 1. To determine the rates of filovirus and henipavirus exposure in people in rural Liberia. We have shown that certain bat species in Liberia carry EBOV-Zaire, while others carry Marburg virus and henipaviruses. Further, hunting bats is a common activity and we have detected high seroprevalence of Marburg and EBOV antibodies in rural Liberia. Exposure to henipaviruses remains unknown. To test the hypothesis that spillover of both groups of viruses has occurred in this region, we will use an antigen-based multiplex serological assay to screen more than 1,800 archived blood specimens, collected in 2021 and again in 2023 from over 900 adults and children in rural central Liberia, for antibodies against all known filoviruses and henipaviruses.

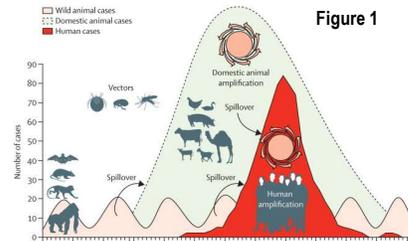

Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia. Our group detected EBOV-Zaire RNA and antibodies in *Miniopterus nimbae*, a cave- and mine-dwelling bat in northern Liberia found near the origin of the 2014 Ebola outbreak in Guinea. We also detected antibodies against EBOV in *Hipposideros* bats that co-roost with *Miniopterus* in multiple locations in Liberia. *Rousettus aegyptiacus*, a common frugivorous bat in Liberia, carries Marburg virus and henipaviruses. We will conduct a 3-year longitudinal study of populations of these bat species near the human cohort studied in **Aim 1**, to determine whether they are reservoirs for Ebola or other filoviruses and henipaviruses and characterize the temporal dynamics of filoviruses and henipavirus circulation using multiplexed serological assays that test for IgG antibodies against all known filoviruses and henipaviruses, as well as molecular techniques to screen for Ebola, Marburg, Nipah virus, and related viruses.

Aim 3. To characterize behaviors associated with exposure to filoviruses and henipaviruses. Combining the data collected in Aim 1 (humans) and Aim 2 (bats) we will identify the demographic, behavioral, and environmental factors associated with an individual's prior exposure to filoviruses and henipaviruses. Detailed animal exposure data collected from the adults and children (many born after the Ebola outbreak) who provided the Aim 1 blood specimens will be used to develop profiles of risk and inform public health & risk reduction communication tools in partnership with the Ministry of Health, Liberia.

RESEARCH STRATEGY

A. SIGNIFICANCE

Zoonotic viruses are responsible for the majority of emerging infectious disease outbreaks, which are occurring at an accelerating rate in global hotspots^{3,7}. Every outbreak begins with spillover – transmission of the virus from its animal reservoir either directly into human populations or into other animal populations or into other animal hosts *en route* to humans (Figure 1). Exactly how often spillover occurs is virtually unknown, as surveillance systems are primarily designed to detect clusters or outbreaks, and often miss initial individual infections that result from animal contact. To reduce the risk of future epidemics, it will be necessary to limit opportunities for zoonotic viruses to spillover and to detect spillover at the earliest stages.^{1,8} Measuring the efficacy of any interventions designed to reduce spillover and spread of zoonotic pathogens will rely on measuring rates of exposure in at-risk human populations.

Filoviruses and henipaviruses are among the highest consequence zoonotic viruses and have greatly impacted public health. Each group contains zoonotic pathogens that cause significant disease in both people and animals, especially livestock, that have been associated with extremely high rates of morbidity and mortality. Ebola (EBOV) and related viruses, as well as Nipah virus (NIV), a henipavirus, and its related viruses have been listed by the World Health Organization (WHO) among the highest priority pathogens for the development of vaccines and therapeutics, as they represent zoonotic pathogens with high potential to threaten human health, with extremely high mortality rates and few or no therapeutics or vaccines currently available.⁹⁻¹¹ These viruses share other important features which make them high priority: they are all associated with bat hosts that are abundant and widely distributed throughout Africa and Asia, living in close association with people and livestock in some of the most densely populated regions on Earth.

Spillover of these viruses has repeatedly occurred. Beyond the massive outbreak in West Africa in 2013-16, EBOV outbreaks have occurred repeatedly in Central and East Africa; most recently Sudan ebolavirus caused an outbreak in Uganda in late 2022¹¹⁻¹³. Marburg virus (MARV) and Ravn virus (RAVV) comprise the closely related genus *Marburgvirus* and have caused outbreaks in Central and East Africa and Europe with mortality and clinical presentation comparable to Ebola^{14,15}. Marburg virus outbreaks were declared in Guinea, just across the border from the UNC-Liberia research site in 2021 and then again in Ghana in 2022 marking the first time this virus has been reported in either country^{16,17}. Nipah virus is an emerging zoonotic paramyxovirus that has caused nearly annual outbreaks in Bangladesh, including multiple outbreaks in 2023, and sporadically in India with mean case fatality rates greater than 70%^{12,18-20}. Despite the public health significance of Nipah and related viruses, little is known about its genetic diversity, natural reservoirs, or frequency of spillover throughout their range, including Africa. Henipaviruses, and Nipah virus in particular - have several characteristics that make them a global health priority: 1) Their bat reservoirs occur throughout Asia and Africa, overlapping human and livestock populations, giving them geographically broad opportunity to cause outbreaks²¹; 2) henipaviruses can be transmitted to people directly from bats or via domestic animals²¹; 3) Nipah virus can be transmitted from person to person²²; 4) Nipah virus spillover has occurred and continues to occur in highly populous and internationally connected regions; 5) repeated spillovers of NIV strains with varying person-to-person transmission rates indicate the ability to evolve **with increased pandemic potential**^{23,24}; and 6) Nipah is associated with a high mortality rate in people and currently has no vaccine or treatment^{21,23}. While Nipah virus has not been detected in Africa, closely related henipaviruses have been identified in Ghana and Madagascar, though their public health significance remains unknown²⁵⁻²⁷. In West Africa, where bats and associated henipaviruses occur but where no human cases have been identified, **diagnostic testing and systematic surveillance is essentially non-existent**. The detection of antibodies against a Nipah-related virus in hunting communities in Central Africa suggests that cryptic spillover is occurring²⁸. **Repeated spillover of henipaviruses creates opportunity for more transmissible strains to emerge**²⁹.

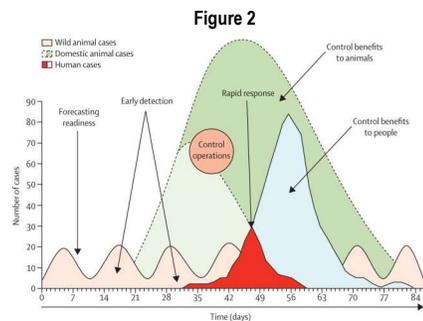

While bats have been identified as potential hosts for filoviruses including EBOV, the natural reservoir for EBOV-Zaire Ebola in West Africa remains unknown. There is substantial evidence, both serological and molecular, that bat species host filoviruses; however, a definitive natural reservoir or set of reservoirs for EBOV-Zaire has not been identified³⁰. Wildlife, including bats, represent a substantial source of animal protein for communities in Liberia³¹. People may be exposed to bat-borne viruses through hunting and butchering, eating food contaminated by bat excreta, or by entering caves or mines inhabited by bats. Our group previously found that people living in rural areas of Liberia conduct activities which may increase their risk of contact with bats or their bodily fluids. The index case, a child, in the 2013 Ebola outbreak was hypothesized to have had contact with bats, yet the exact species was never definitely identified³². The route of spillover for most historical Ebola outbreaks remains a mystery. Despite broad efforts to determine the natural reservoirs of EBOV and related viruses, there continues to be a poor understanding of filovirus ecology, with the exception of Marburg virus, whose host has been identified as Egyptian rousette bats (*Rousettus aegyptiacus*)³³⁻³⁵. Communities known to hunt bats in Cameroon and India have been found to have antibodies against henipaviruses and filoviruses, respectively, yet nothing is known about community exposure rates in Liberia, where bat hunting is common^{28,36}. Our preliminary data (see below) suggest that there is substantial exposure to EBOV as well as MARV among people in central Liberia. While the EBOV antibodies may indicate prior infection from another person such as during the West Africa outbreak, antibodies specific to other filoviruses may signal a localized exposure from animals. Even less is understood about henipaviruses in Africa, and identifying antibodies against henipaviruses in people will be critical for understanding where, how and how often spillover occurs.

The urgent need to develop interventions to prevent spillover of zoonotic high consequence pathogens can only be met with a better understanding of their natural reservoirs, the rates of exposure in vulnerable human populations, and the ways in which people are exposed. Unrecognized outbreaks provide opportunities for viruses to emerge that may be more transmissible or more pathogenic than previously observed, and limiting these opportunities is an important component of pandemic prevention^{2,29}. Typically, by the time an outbreak is recognized in human populations its containment and control are difficult, if not impossible to achieve (e.g., HIV, SARS-CoV-2). Understanding the ecology of these viruses, including which

species act as reservoirs as well as how and to what extent people are being exposed to filoviruses and henipaviruses will inform intervention and surveillance strategies and provide baseline metrics against which one can measure the efficacy of interventions designed to reduce exposure, such as public health campaigns to promote avoidance of behaviors associated with infection among those most at risk (Figure 2).

This proposed study will be the largest and most rigorous One Health investigation of high-consequence zoonotic viruses in bats and humans in an emerging disease hotspot. West Africa is known to be the source of prior outbreaks of emerging infectious diseases and future

spillover events there are highly likely. Liberia is typical of this region and contains some of the largest tracts of pristine forest and wildlife biodiversity remaining in West Africa and has a population that depends on wildlife, including bats. Decades ago, a spillover event from a non-human primate to a human triggered an on-going HIV pandemic that has led to the infection of over 60 million people and 25 million deaths. Only months ago, the orthopoxvirus MPOX found in rodents spread to and within 110 countries across the globe causing over 85,000 cases. Both originated from African wildlife. The proposed study will leverage the unique infrastructure and expertise we have developed in Liberia to undertake a comprehensive examination of filovirus and henipavirus spillover from bats to humans and provide evidence of previous and possibly on-going transmission events. Our findings will provide essential evidence of the presence and transmission dynamics of these bat-borne viruses and as the risks for infection in people living alongside them.

B. INNOVATION

The proposed research is highly innovative in multiple ways, including: 1) Our use of a one Health approach to study the ecology and epidemiology of two groups of high-priority, high-consequence zoonotic viruses in both bats and people in West Africa – an emerging disease hotspot where spillover events have occurred (e.g. Ebola, Marburg, MPOX, Lassa fever) and are highly likely to re-occur; 2) Our use of a novel and unique multiplexed serological platform, developed by our group, that will allow us to screen bat and human serum for IgG antibodies against each of the known filoviruses and henipaviruses, simultaneously in a single assay. Longitudinal comprehensive serological studies in bats and people **will provide unprecedented insight into the changes in rates of exposure over time to known viruses in bats; and in people (e.g. what is the baseline rate of exposure to henipaviruses and filoviruses and is there evidence of recent exposure?); and exposure rates to unknown, antigenically related viruses;** 3) We will couple serosurveillance with molecular testing to identify specific filoviruses and henipaviruses carried by bats; and 4) We will connect the bat and human epidemiological studies by analyzing questionnaire data from the human cohort to identifying high risk behaviors associated with viral exposure. **Results from this analysis will inform the development of public outreach and risk reduction campaigns by the Government of Liberia.**

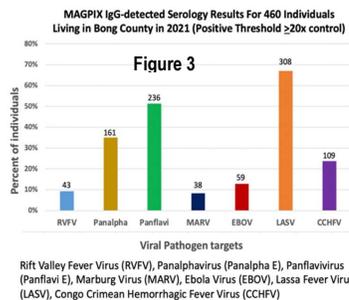

C. APPROACH

C.1. Overview: **Aim 1** will test the hypothesis that spillover of filoviruses and henipaviruses occur regularly in rural Liberia by testing for IgG antibodies to all known filoviruses and (see table 3) in archived serum samples from 900 people living in Bong county (central Liberia), collected at two time points 24 months apart. Seroprevalence of filoviruses and henipaviruses will be assessed as will changes between the two collection timepoints. In **Aim 2**, we will conduct a 36-month longitudinal study of three bat species which are putative reservoirs for EBOV and undescribed henipaviruses. Using a combination of longitudinal serology and molecular testing (PCR and whole genome sequencing) **we will determine the prevalence of filoviruses and henipaviruses in three key bats species associated with the rural human populations studied in Aims 1 and 3.** For **Aim 3**, we will analyze detailed questionnaire data developed collaboratively by our group (EHA and UNC) and collected in 2023 along with blood samples to be screened in Aim 1. These data will allow us to identify behaviors associated with exposure to henipaviruses and filoviruses. We will use results from our behavioral risk assessment to develop public risk reduction communication strategies with the National Public Health Institute, Liberia, using the results of this study to inform public health strategies. This application is a natural progression of our research activities, and our preliminary data speak to the feasibility of the proposed study.

C.2. Aim 1: To determine the rates of filovirus and henipavirus

exposure in people in central rural Liberia. C.2.1. Rationale and Preliminary Data.

The primary goal of this aim is to be able to determine whether populations within Liberia who live in association with bats have evidence of exposure against one or multiple filoviruses and/or henipaviruses and to compare rates of exposure over time. Studies of human populations in Central and West Africa have found evidence of exposure to EBOV prior to the 2013 outbreak and in places not known to have had Ebola outbreaks^{37,38}. UNC Project-Liberia has previously assessed seropositivity to consequential viral pathogens including EBOV and MARV in a subset of CEPI ENABLE Study participants. About 10% of participants had antibodies against MARV (Figure 3), suggesting that unreported spillover events have previously occurred. Acute encephalitis is common in western sub-Saharan Africa, yet outbreaks of neurological disease are rarely reported and more than half of all cases are undiagnosed³⁹. Among the countries in western Africa reporting cases of meningitis or encephalitis, Liberia has reported the fewest, likely due to a lack of surveillance

Commented [JE1]: @Billy or @Dave is this right?

and capacity to diagnose neurological diseases³⁹. Nipah virus encephalitis has never been reported in Africa, however, as described above, two Nipah-like henipaviruses have been described in bat hosts, including one in Ghana^{25,27}. Spillover of henipaviruses was reported in bat-hunting communities in Cameroon²⁸. In South Africa, we detected henipavirus sequences in *Rousettus aegyptiacus*, bats which also commonly occur in Liberia²⁶.

In Aim 1, we will test the hypothesis that spillover of both filoviruses and henipaviruses have occurred in rural populations in Liberia by measuring seropositivity to both groups of viruses within the CEPI ENABLE Study community cohort. We will also measure changes in exposure rates over a two-year period. While prior studies have provided cross-sectional snapshots of exposure, our longitudinal approach will provide data from the same cohort at two timepoints, 24 months apart, to determine both seroprevalence and sero-incidence using a multiplexed serological assay to screen for IgG antibodies against all known filoviruses and henipaviruses.

Settings and Participants. To achieve this aim we will leverage a well characterized cohort of individuals in three rural communities located in Bong County, Liberia (**Figure 4**), which has a population of over 333,400. UNC Project-Liberia has been operating in Liberia since 2014 and established a research site at Phebe Hospital in Bong County that includes a molecular laboratory that conducts daily qPCR testing for LASV, MARV, and EBOV as well as LASV serological assays using a MAGPIX (SEE RESOURCES AND FACILITIES). There, following extensive community engagement including meetings with key stakeholders, town hall meetings, and radio messaging, UNC launched the CEPI ENABLE Study, the largest passive and active surveillance program for Lassa fever in Liberia. Started in 2020, 5,005 randomly selected participants 2 years of age and older in Phebe Airstrip, Suakoko, and Rubber Factory were enrolled over 6 months following informed consent/assent (mean age at enrollment is 22.2 years (range 2-97) and 54.2% are female). **Importantly, 7.7% of the cohort is under the age of 5 years, and therefore, were born after the 2013-14 Ebola outbreak (Table 1).**

Figure 4. Map of Liberia with Bong County sites shown in inset.

Households were selected for recruitment following identification of roof tops by satellite photos and use of a program developed by Médecins Sans Frontières' (MSF) Epicentre to randomly selected structures to consecutively approach. The ENABLE Study includes baseline questionnaires and blood specimen collection from all participants with active follow-up by a study community health worker every 2 weeks to determine if a febrile event has occurred, which triggers drawing of blood for LASV, MARV, and EBOV PCR. A subset of 1,024 individuals is also asked to provide blood samples routinely every 6 months for up to 24 months. The blood samples from 0 and 24 months and the associated surveys will be used in Aims 1 and 3 of this proposal. Informed consent and assent documents include provisions for the use of collected specimens and data for infectious diseases research including for emerging pathogens (see PROTECTION OF HUMAN SUBJECTS).

C.2.2. Research Design. We will screen approximately **1,900 archived serum specimens** from participants in the ENABLE Study cohort at two time points ("baseline" (Month 0) and (Month 24)) for IgG antibodies against specific filoviruses and henipaviruses using the MAGPIX at the UNC molecular lab at Phebe hospital to run the multiplexed *henipavirus / filovirus* platform to be provided by Co-I Laing in year 1. The multiplex platform will allow us to determine specifically which filoviruses and henipaviruses people have been exposed to and compare that to the filoviruses and antibodies we observe circulating in local bat populations in **Aim 2**. The bead-based multiplexed assay has tremendous advantage over traditional ELISAs in that it will identify up to 25 different antibodies against multiple viral agents in a single, 2uL serum sample and uses a high through-put format. The ability to look at reactivity across all serogroups simultaneously will allow us to differentiate among the viruses. Proteins A/G non-specifically bind IgG immunoglobulins, and weakly bind IgM, an immunoglobulin that is the first to be produced during the initial stages of infection. We will conduct a 1-week training at the UNC-Phebe lab for using the assay to detect filovirus and henipavirus antibodies as well as data management, bioinformatics and analysis. **Table 3** shows the viral species and antigens that will be employed in this assay. The platform has been previously transferred to collaborating labs in the UK, South

Commented [JE2]: @Billy is this right?

Africa, India, Bangladesh, Singapore, Thailand and Malaysia. We have previously detected serological profiles of Asiatic ebolaviruses in fruit bats collected in Singapore⁴⁰ and in fruits bats and humans actively engaged in bat hunting in northeast India³⁶.

C.2.3. Data Analysis. We will create a project database using Airtable, which will be hosted at EHA and will house all data from Aims 1 and 2 and will link to the RedCap server which stores questionnaire data from Aim

3. Database access will be secure and limited to key personnel (see data management plan). Raw MFI values from the MAGPIX will be used to calculate reactivity to each viral antigen and based on relative strength of reactivity (Fig 5) and determinations of negative cutoffs based on

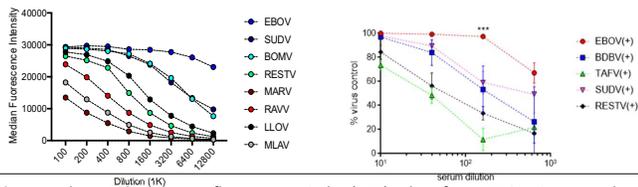

Figure 5. shows relative mean fluorescence index (MFI) values for an EBOV +ive control sera across serial dilutions. While there is cross reactivity, the EBOV MFI values are consistently greater than the other viral GPs and at higher dilutions the separation becomes significant.

reference sera, we will calculate prevalence rates for each time point and compare rates between the two timepoints. Serological profiling can be used to detect reactive antibodies against all specific filoviruses and henipaviruses in a samples and compare strength of reactivity and cross-reactivity against multiple antigens using a single sample⁴¹. We will compare the antibodies across all specific viral antigens to assess which virus or groups of viruses are responsible for the immunological response⁴²⁻⁴⁴. We will assess exposure to non-Zaire ebolavirus species, which may indicate spillover of filoviruses has occurred separate to the Ebola outbreak of 2013. We will also look at evidence for exposure to Nipah-like henipaviruses and compare exposure rates to both viral groups within and between our two sample collection time points.

C.2.4. Expected outcomes. We anticipate obtaining serological profiles of exposure to filoviruses and henipaviruses from each individual in our cohort. In previous studies we found antibodies against both Ebola and Marburg virus. While the Ebola antibodies are attributable to the epidemic, Marburg antibodies, in

patients EBOV IgG negative, suggest possible exposure from an animal (e.g. bat) reservoir. We also anticipate seeing reactivity to Bombali virus (BOMV), given the presence of the reservoir species in Liberia (*Mops condylurus*) and reactivity to the African henipaviruses (GhV and AngV), although this may represent reactivity to an antigenically related virus. Serological results from this and the bat study will inform our strategy for prioritizing which bat samples we test by PCR.

C.2.5. Potential problems and solutions. While our preliminary data suggest there will be detection of immune responses to filoviruses including EBOV-Zaire and, significantly, MARV, it is possible that evidence of exposure to other pathogens, including henipaviruses will not be detected. This would be an important finding in this large cohort, especially if these viruses are detected in local bat species, that would warrant further investigation. It is also possible that there will be few or no seroconversion events among the cohort during the 24-month period of follow-up. This too would be reassuring but would suggest a need for longer follow-up

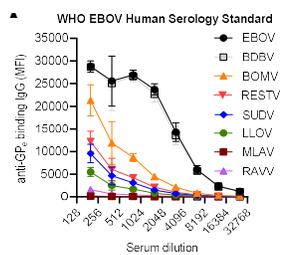

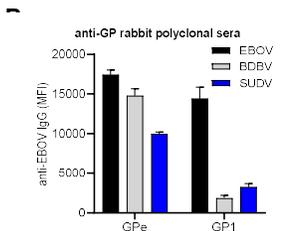

FIGURE 6A & B. A) The WHO EBOV human serology standard was testing for immunoreactivity in a filovirid GP-trimer based multiplex assay. Filovirids are indicated along with sera dilution factors; data is the mean of three independent experiments. B) Antisera from EBOV GP-trimer immunized rabbits were tested in multiplex panels comprised of GP-trimer and GP1 subunit proteins. Anti-EBOV polyclonal IgG was less reactive with GP1 from BDBV and SUDV.

of this cohort. To address the possibility that reactivity to EBOV-Zaire virus may be explained by infection during the 2013 Ebola epidemic, we will create a polyclonal sera reference standard utilizing convalescent sera collected from human survivors of EVD. This internal reference standard will be calibrated to the WHO EBOV human serology standard (Fig 6A) permitting direct interpolation of anti-EBOV IgG as a MFI to a standard antibody concentration (binding antibody units/mL). The internal reference standard will then be included in our human serology testing strategy allowing semi- or quantitative measurement of anti-EBOV IgG. These EBOV human serology standards will permit us to establish positive and negative predictive performance values for the multiplex assay, furthermore, we will be able to

investigate immunoreactivity of EVD survivors against heterotypic ebolaviruses. Our preliminary data indicates that EBOV+ sera IgG is highly cross-reactive with soluble native-like trimeric envelope glycoprotein (GP) antigens from both EBOV and BDBV (Figure 6A). EBOV GP, matrix protein (VP40), and nucleocapsid protein (NP) antigens have all been used in a variety of serological tests, however, the frequency of seroconversion against each antigen has not been fully described. In a longitudinal study of EVD survivors, high seroconversion against GP and VP40 was observed, with affinity maturation occurring overtime against GP⁴⁵. Antigens based on the GP are likely to provide an optimal intrinsic balance of sensitivity and specificity. To limit the degree of heterotypic ebolavirus cross reactions we will test any anti-ebolavirus GP trimer antigen-seropositive samples with a pan-ebolavirus GP1 antigen-based panel. In preliminary studies, GP1 antigens improve specificity and differentiation of antibodies reactive with homotypic ebolaviruses in polyclonal antisera from rabbits immunized with GP trimer immunogens (Figure 6B).

C.3. Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia. C3.1 *Rationale and preliminary data.* Bats have been established as important hosts for filoviruses and henipaviruses in Africa and Asia, with combinations of viral isolation, molecular detection or serology providing substantial evidence^{30,46-49}. MARV was isolated from Egyptian rousette bats in Uganda, and RNA has since been detected in these bats in Sierra Leone, which borders Liberia⁵⁰. To date, EBOV has never been isolated from bats, although molecular and serological evidence suggest that multiple frugivorous bats may carry EBOV in Central Africa^{50,51}. Prior to the 2014 epidemic, Zaire ebolavirus had not been reported in West Africa, and the animal reservoir remains unknown³². From 2016-2019, our group (PI Epstein & KP Desmond) implemented a large-scale project to identify reservoirs for EBOV in West Africa, under the USAID PREDICT Project⁵². This effort led to the discovery of a new species of Ebola (Bombali virus)⁵³, the detection of MARV in ERBs in Sierra Leone³³, and **in 2018, we detected, for the first time in West Africa, EBOV RNA and anti-EBOV IgG antibodies in bats (Figure 7A-D)**. While this finding generated the first evidence of which bats

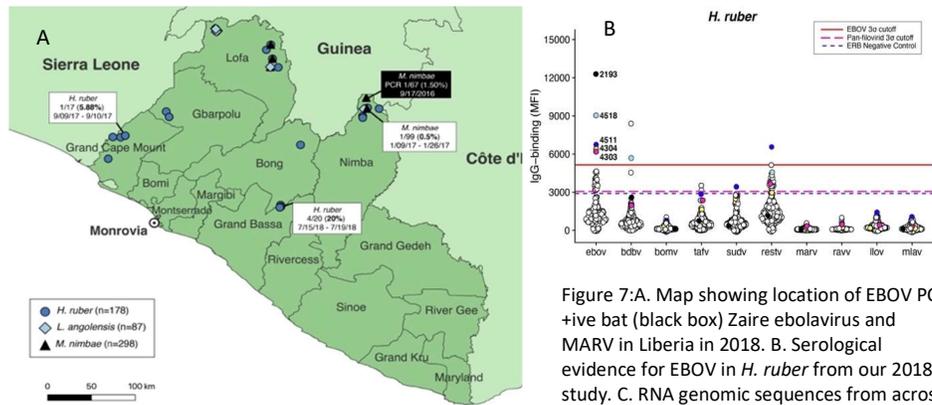

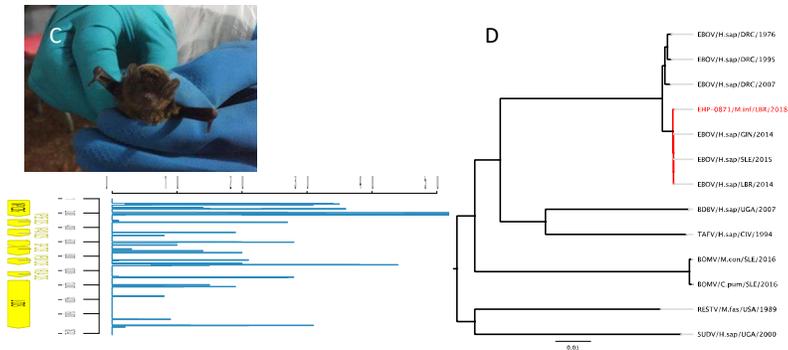

Figure 7:A. Map showing location of EBOV PCR +ve bat (black box) Zaire ebolavirus and MARV in Liberia in 2018. B. Serological evidence for EBOV in *H. ruber* from our 2018 study. C. RNA genomic sequences from across the Zaire ebolavirus genome detected in *Miniopterus nimbae*, Liberia in 2018. D. Phylogenetic analysis supports relatedness to 2013 EBOV epidemic virus.

may be reservoirs for Zaire ebolavirus, longitudinal studies are required to more completely understand the role these species play in EBOV circulation— either as reservoirs that maintain the virus within a local population, or as incidental hosts, infected by an unknown bat species. One -off, cross-sectional studies have a

low probability of detecting any specific filovirus or henipavirus given their low prevalence and short viremic periods^{34,54}, and thus provide a poor characterization of viral diversity. The lack of understanding of **filovirus and henipavirus diversity and their natural reservoirs in West Africa significantly impedes risk-based public health interventions to prevent human outbreaks**. Longitudinal sampling is needed to separate reservoir hosts from spillover hosts. For example, MARV has been isolated repeatedly from *R. aegyptiacus* in Uganda, which, when paired with experimental infection studies showing infection and shedding of MARV by *R. aegyptiacus*, strongly suggests that *R. aegyptiacus* is indeed a Marburg virus reservoir^{35,55,56}. Similarly, our longitudinal studies of Nipah virus in *Pteropus medius* bats in Bangladesh, which included the same multiplexed serological assay proposed here, confirmed them as a reservoir for NIV and identified important mechanisms driving viral circulation²⁹. **Understanding which species persistently carry filoviruses and henipaviruses will provide important insights into how they are maintained in nature and what species should be targeted for follow-up studies on bat habitat use and human-bat contact patterns.**

3.2. *Sampling design*. We will repeatedly sample three bat species associated with filoviruses or henipaviruses, based on our preliminary data: *M. nimbae* (EBOV), *H. ruber* (EBOV), and *R. aegyptiacus* (MARV & Henipaviruses). We will sample bats at roost sites in Bong county, as close as possible to the human study sites in Aim 1. In Y2-Y4, we will sample 40 individuals of each species every two months for 36 months and collect excreta using plastic tarps placed underneath bat roosts (details below and in C3.3).

Bat capture and sampling. Briefly, we will use either harp traps or mist nets to capture bats, depending on the capture site. Personnel will wear appropriate personal protective equipment (e.g. Tyvek suits or dedicated long clothing; double nitrile gloves; an N95 respirator and safety glasses or a PAPR⁵⁷). Traps and nets will be attended continuously during capture periods. Bats will be removed from mist nets immediately upon entanglement to avoid injury. Bats will be removed from harp traps after approximately 1 hour and bats will be placed in individual cloth bags until processed. Body measurements, blood, oropharyngeal swabs, and rectal swabs (or fecal pellets) will be collected from each bat. Swabs will be collected in duplicate; one swab will be placed in a cryovial containing Trizol lysis buffer and the other in viral transport medium (VTM). For bats <50g, blood will be collected in a microhematocrit tube and spun down using a portable centrifuge. A bulb will be used to expel serum from the tube into a cryovial. For larger bats >50g, a tuberculin syringe or 1ml syringe and 27g needle will be used to draw blood from the radial artery or vein⁵⁷. Blood will be placed into a conical vial and centrifuged. Serum will be aliquoted into a cryovial using a pipette. During site visits we will also lay out plastic tarps to collect pooled environmental excreta in Trizol and VTM to improve opportunity to detect viral RNA. All samples will be placed in a vapor phase liquid nitrogen dry shipper or portable battery-powered ultracold freezer, immediately upon collection and then transferred to a -80C freezer at the Phebe lab until testing.

C3.3. *Testing plan, Data analysis, sample size, and power analysis*. Serology: At the end of Y3, we will screen all serum samples collected to date using the MAGPIX multiplex assay for IgG against filoviruses and henipaviruses. We will analyze temporal dynamics in seroprevalence using general additive models (GAMs), which are analyses that we have used successfully in many previous studies of similar design²⁹. These methods are well adapted for capturing long-term temporal fluctuations in prevalence and moderately sensitive at capturing short-term changes in seroprevalence which can be used to identify population-level disease outbreaks. For example, we estimated that with 40 bats sampled every two months, we would be able to statistically detect an increase in seroprevalence (at a 95% CI limit) of greater than 25% between consecutive sampling events > 80% of the time, assuming a bat population seroprevalence of at least 10% in advance of a bat colony infection (estimated by, in brief, by simulating a fluctuating true seroprevalence value, simulating samples given this underlying seroprevalence, fitting a GAM to these samples, and then calculating if CI on true prevalence between the two sampling occasions over which the change in seroprevalence occurred were non-overlapping). While this is a large change, it is within a range to be expected if infection were to sweep through a bat community²⁹. MAGPIX-positive bat sera will be sent to RML for serum neutralization assays using viral isolates or VSV pseudoviruses under BSL4 conditions.

VSV-pseudotype neutralization assays: Serological results will be confirmed using VSV-pseudotype neutralization assays for the following filoviruses EBOV, SUDV, BDBV, RETV, BOMV, MARV and RAVN. If novel

henipavirus sequences are detected, additional assays will be developed to test positive sera. Serum samples will be inactivated using γ -irradiation (4 MRad). Neutralization of irradiated and heat-inactivated serum samples will be assessed in Vero 352 E6 cells. Briefly, cells were seeded in 96-well round-bottom plates for 24 hours, serial dilutions of heat-inactivated serum samples will be performed in DMEM supplemented with 2% FBS, penicillin/streptomycin, and L-glutamine. Each plate will contain negative serum control, cell-only control, and virus-only control. VSV EBOV-GFP will be added to each well of the serum dilution plate and the serum-virus mix 357 was incubated at 37°C for 1-hour. The mix was added to the cells and incubated at 37°C for 24 hours. The cells will then fixed with 4% paraformaldehyde at room temperature 359 for 15-minutes and centrifuged at 600 x g for 5-minutes at room temperature. The supernatant will be discarded and FACS+EDTA buffer was added. Samples will be run on the FACSymphony A5 Cell Analyzer (BD Biosciences, Mississauga, ON, Canada) and FITC MFI 362 was measured. Data will be analyzed using FlowJo.

Molecular testing: We will use specific filovirus taqman real-time PCR assays to screen oropharyngeal, fecal and environmental samples from bats for EBOV and MARV RNA at the UNC-Phebe lab^{55,58}. Testing bat samples by PCR may allow us to detect viral RNA during active infection, providing important information about the prevalence and timing of infection within target species. **Because we expect viral prevalence to be significantly lower than seroprevalence, estimated at <5%**^{25,27,49}, we developed a sampling scheme focused on maximizing our probability of detecting viral RNA with qPCR. To compare power under alternative sampling designs, we built simulation-based power analyses that estimated power to detect: 1) viral EBOV or MARV RNA in at least one bat; and 2) the expected number of positive cases, in each bat species. In brief, we estimated power for total sample sizes between 1500-3000 (between 500 and 1000 bats sampled per species) spread across a variable number of visits per year (2-6), while allowing for uncertainty in true infection dynamics in the bat populations, specifically: 1) prevalence during one three-week period (with unknown timing) per year of high prevalence ranging from 1-5%; and 2) an otherwise low background prevalence (0-1%). Given these estimates of yearly infection dynamics, these analyses showed with 672 samples per species (minimum 32 individual bats per sampling event), spread across 6 sampling occasions per year, we would obtain a per-species probability of acquiring 0 positive samples of <4% (<1% at 40 bats per event – our target number) and an expectation of ~3-6 RNA positive results (~5-10 positives at 40 bats per event). Because henipaviruses have not been previously described in Liberia, we will focus our resources on filovirus testing by PCR. However, if henipavirus serology suggests active circulation, we may send a set of samples to RML for pathogen discovery (see RML letter of support).

Viral isolation: PCR-positive cDNA samples and their aliquot in VTM will be sent to RML for further sequencing and attempts at viral isolation under BSL4 conditions. If attempts to culture do not work, we will use next generation sequencing techniques to get whole genome sequence and further characterize the virus at RML. Novel viruses will be characterized and rescued (reverse engineered using a minigenome system to synthetically create infectious viral particles⁵⁹) at RML under secure, biosafety level 4 conditions, then used for serum neutralization assays in bat and human sera to determine more precise exposure rates. Sequences from the glycoproteins of any novel viruses discovered will be used by USU (Co-I Laing) to generate purified proteins and added to the Luminex assay, which will improve its specificity.

VirCapSeq-VERT and myBaits probe-based enrichment for recovery of full-length genome sequences of filoviruses: Although shotgun sequencing provides opportunities to analyze all host and virus genetic material, the larger average genome size of bacteria and hosts compared to viral genomes complicates a detailed analysis of the virome, particularly vertebrate viruses. We have established a positive selection probe capture-based system to enrich for viral sequences. Here, we will take advantage of these probe capture-based methods (VirCapSeq-VERT and myBaits probe library) to enrich for vertebrate viral sequences of interest. Sample libraries will be normalized and combined in 4- to 12-plex reactions for solution capture hybridization using either the HyperExplore custom bait library version of VirCapSeq-VERT probe set or our custom myBaits probe library. For HyperExplore custom bait library probe set, libraries will be enriched for virus following the

SeqCap EZ HyperCap Workflow User's Guide, version 2.3, while for custom myBaits probe library, the myBaits Hybridization Capture for Targeted NGS protocol, Version 4.01 will be used. Sequencing libraries will be normalized and sequenced as 2 X 150 bp fragments on Illumina's MiSeq or NextSeq sequencing platforms, following Illumina's standard procedure (Illumina, San Diego, CA). NGS data will be analyzed using metavirs (<https://openomics.github.io/metavirs/>), a comprehensive viral metagenomics pipeline to assemble, annotate, and classify viruses. It relies on technologies like Singularity1 to maintain the highest-level of reproducibility. The pipeline consists of a series of data processing and quality-control steps orchestrated by Snakemake2, a flexible and scalable workflow management system, to submit jobs to a cluster. The pipeline is compatible with data generated from Illumina short-read sequencing technologies. As input, it accepts a set of FastQ files and will be run on-premises using the NIAID RML Big Sky supercomputing cluster.

C3.5. Expected outcomes. Based on our prior work, our multifaceted analysis approach, and calculated power given our proposed temporal sampling strategy, we expect to be able to use temporal serological data to describe filovirus and henipavirus viral dynamics over time. Our molecular screening will primarily focus on filoviruses because we have known targets, and we expect to detect EBOV or MARV RNA, despite low prevalence and short-lived infections. Sequence data from positive samples will 1) provide substantial evidence for the identification of EBOV reservoirs and help explain which virus is responsible for the observed IgG response in bats (and possibly people); and 2) provide valuable information about viral diversity, about which little is known. Henipavirus serology, in the absence of sequence data, will allow us to identify potential bat reservoirs, analyze temporal trends, and generate hypotheses for future targeted studies.

C3.6. Potential problems and solutions

Serological tests are greatly hindered by the inherent antibody cross-reactivity between antigens from known ebolaviruses, challenging data interpretations that antibodies are EBOV-specific or EBOV, BDBV, and SUDV cross-reactive⁴⁰. This is also true for the henipaviruses in the panel. The advantage of the multiplexed platform

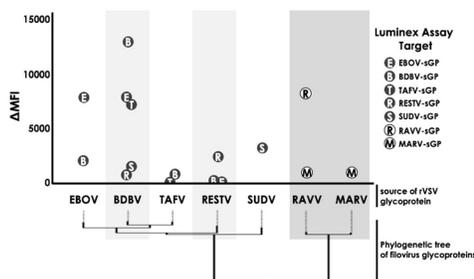

Figure 8. Captive-bred ERBs were experimentally challenged with VSV-filoGPs, the GP source is indicated on the x-axis. In a GP-trimer multiplex test the homotypic ebolavirus bat antisera were most reactive with the homotypic ebolavirus GP-trimer antigen.

is that we can simultaneously see relative MFI values for all the filoviruses and henipaviruses. Glycoproteins from the homologous virus should cause the most intense reaction, particularly at higher dilutions. Co-Is Laing and Munster have demonstrated that homotypic and heterotypic ebolavirus-antibody reactions can be simultaneously measured and accounted for in ERBs challenged with replication-competent VSV-filoGP (**Figure 8**). Still, there is some cross reactivity, and we will use additional tools such as viral neutralization assays as a secondary test, and our statistical approach can correct for a portion of cross reactivity. Past studies have relied on individual ELISAs which had varying degrees of specificity depending on which test was used, but often couldn't rule out cross-reactivity. The Luminex filovirus multiplex assay has predictable

patterns of cross-reactivity, but we will still be able to discern to which virus the serum is most reactive.

C4. Aim 3: To characterize behaviors associated with exposure to filoviruses and henipaviruses. C4.1

Background and rationale. As described above, there is substantial interaction between wildlife, domestic animals, and people living in rural Liberia. Our group collected questionnaire data from 585 people across Liberia as part of the USAID-funded Ebola Host Project between 2016 and 2019. When asked about animal exposures during the 2013-2016 Ebola outbreak, participants frequently reported contact with both domestic

and wild animals. Common types of animal contact included animals coming inside the dwelling (58%), cooking or handling animal meat (44%), and eating raw or undercooked meat (31%). Additionally, 26% reported slaughtering and 12% reported hunting or trapping an animal. In the ENABLE Study of 5,005 residents of Bong County, survey questions mainly focused on rodent exposures relevant to Lassa fever, but 12% of participants reported hunting or preparing wild animal meat. Little is known about the prevalence and type of other potential bat exposures in this region of Liberia. Elsewhere in West Africa, EcoHealth Alliance participated in the response to Ghana's 2022 cluster of MARV cases, working with local partners to administer a behavioral risk questionnaire characterizing bat exposures in three affected communities¹⁶. Many participants lived in close proximity to bats, with one fifth reported exposure to bats inside a dwelling or other building in the previous four months. When asked about exposures more relevant to Egyptian Rousette bats, a known MARV reservoir and a target species in this proposed study, participants commonly reported bats feeding on fruit trees on their home compound, eating fruit bearing bite marks, and exposure to bats inside a cave or mine.

C4.2. Research design. As described in Aim 1, serum collected at baseline (in 2021) and at month 24 (in 2023) during the ENABLE Study will be screened for filoviruses and henipaviruses, enabling us to calculate seroprevalence at baseline and seroconversion over a two-year period. In addition to providing blood specimens, the 1,024 participants who initially enrolled responded to baseline questionnaires on demographics, healthcare-seeking behaviors, health status, and animal exposures. At month 24, the 921 participants still actively enrolled are administered repeat questionnaires. This final survey includes additional items based on the Ghanaian questionnaire and asks specifically about bats including the respondents' activities in their habitats (entering forests, caves, and mines), direct contact (hunting, eating handling), indirect contact (presence in home or other used structure), and observed characteristics of bats encountered (fruit tree dwelling). By pairing this existing survey data with the new serology results generated from archived samples under Aim 1, as well as new data on nearby bat infection from Aim 2, we will be able to develop comprehensive risk profiles for exposure to filoviruses and henipaviruses in this community.

C4.3 Data analysis. The primary outcome for this analysis will be testing positive for IgG antibodies against any known filoviruses or henipaviruses. For both families of viruses, and for each species of virus within those families, we will use the serology results generated under Aim 1 to examine risk factors for seropositivity at baseline and seroconversion between baseline and month 24. We plan to conduct a multivariate logistic regression, with appropriate weights applied to account for the single-stage cluster sampling design of the ENABLE Study, in which members of randomly selected households were surveyed and tested. We will use data from both the baseline and month 24 questionnaires to examine the effects of sampling site, participant demographics (e.g., age, gender, occupation), environmental exposures (e.g. animals present in and around the dwelling), and behavioral risks (e.g. direct contact with bats through hunting, preparing, or eating them, entering caves or mines where bats live).

Power analysis: To assess our power to identify risk metrics for seroconversion (or overall seropositivity), we built simulation-based power analyses that consisted of, in brief: 1) simulating survey responses for N (400-1000) individuals, while allowing for moderate unevenness in representation across five binary categories (as great as 80%-20% for each); 2) examining a range of effect sizes (odds ratios ranging from 1-2.5) for these five binary categorical predictors (e.g., sex, encountered a bat, handled a bat, etc.). Summarizing across 1,200 simulations of surveys of 400-1000 individuals given joint uncertainty in the representation within these surveys and effect sizes, we estimated that we would have at least 80% power to detect significant effects for each predictor given an odds ratio of 1.65 or greater with 1,000 survey responses or ~1.80 (for example, with a rate just under 5% for Group1 = 0, just over 8% for Group1 = 1) with 750 responses.

C4.4 Expected outcomes. By combining serology results with detailed questionnaire data on participant demographics and animal exposures, we will be able to use odds ratios to identify behaviors significantly associated with seropositivity (e.g. exposure to filoviruses or henipaviruses). We expect to be able to also

identify age and gender-based risk factors given our sample size. Based on previous experience conducting behavioral risk surveys, including a recent study in Ghana following a Marburg outbreak, we expect to be able to develop risk mitigation messaging that uses evidence from Aims 1 and 2 as well as results from this aim.

C4.5 Potential problems and solutions. We anticipate that most IgG positive individuals for either set of viruses will be adults, with the likelihood of exposure and having antibodies increasing with age. Because we don't know how long IgG antibodies persist at detectable levels, it will not be possible to accurately determine when exposure occurred, with the exception being EBOV antibodies that most likely occurred as a result of contact with another infected person during the 2014-2016 outbreak. We will address this in two ways: by looking at respondents 1-6 yrs old, we will know that any filovirus antibodies they have are most likely not due to the epidemic, and we will be able to determine whether there are any significant associations with particular behavior that promotes direct animal contact, consumption of contaminated fruit, or exposure to bat habitats (e.g. caves or mines). For adult respondents, we will focus on exposures (based on relative MFI values) specific to non-EBOV filoviruses and henipaviruses and see whether there are associations with specific behaviors.

D. Summary and Conclusions.

West Africa is a hotspot for emerging zoonotic viruses such as Ebola, Marburg and potentially Nipah-related henipaviruses – groups that have been identified by WHO as among the most significant pathogens that threaten global health. Liberia is also a biodiversity hotspot, with some of the largest tracts of primary forest remaining in the region, and its population relies on wildlife as a primary source of protein, creating continued risk of spillover of high consequence zoonotic pathogens. This project has the potential to determine the origins of Zaire ebolavirus in West Africa, characterize the circulation of Ebola and other filoviruses and henipaviruses in common bat species, identify background rates of spillover in rural human populations, and identify high-risk behaviors associated with exposure to these bat-borne zoonoses. Our group comprises an unparalleled multidisciplinary group of leading experts in epidemiology, clinical medicine, virology, serology, and disease ecology all with deep experience working in Liberia and implementing zoonotic virus research, giving this project a high chance of success in generating impactful results that will help prevent future epidemics in West Africa.

Well done – see attached for minor edits and suggestions.

I know we're tight on space but a figure triangulating seroprevalence in humans, PCR positivity in bats, and host/behavior/environmental risk factors might be helpful to tie the three aims together.

Thanks for everyone's work on this!!

I think I get why you're sticking with "Nipah-like henipavirus," but it seems odd to me. Is every henipavirus, "Nipah-like." Why not just call out Ghana virus, or shrew-associated Langya virus that causes acute febrile illness in humans.

The manuscript write-up was EBOV focused but when my student rant the multiplex we included henipaviruses. This prelim you should use that would address the henipavirus concern. I'd drop Figure 5 and use this

Hi Jon,

See attached. Looks solid.

Main issues to consider:

The conflating of filoviruses and henipaviruses makes me nervous (as Jean DeMarco often says). We have good rationale for expecting filoviruses in bats and humans. For henipaviruses, not so much. This could be shifted to a strength if acknowledged not just at the end but earlier and make clear that this is an opportunity to look for these viruses given the bat species and limited ability to detect encephalitis in Liberia – we could detect the tinderbox for a future outbreak.

I do think in the limitations section we need to address more explicitly that not finding henipavirus exposure in bats or people is possible and is ok in that this is an important negative finding given the potential. I am concerned reviewers will be attracted to henipavirus and unclear if their reaction will be sweet or sour.

Less of an issue is the seroincidence. I am of two minds about this. We can double down and take our chances that reviewers won't ding us for placing bets on a 24 month follow-up period by going the route selected. Alternatively, we could acknowledge that incidence is less certain but that we hypothesize is not uncommon. Given hours left to submit, doubling down makes sense.

For Aim 3, I agree could be clearer about putative factors for infection/exposure. It is not just behavior but also structural (literally and figuratively). Environment plays a role too as does super poverty among the impoverished. Could list hypotheses regarding risks including men>women, hunters vs non, having domestic animals vs not, less sturdy housing vs more, etc.

Let us know if you need anything else.

Thanks for leading the charge.

Subject: Complete draft 7 for rapid review

Hi all,

I've compiled a near final draft, incorporating the text you each provided and then cutting it down to fit within the 13 page (1 page specific aims and 12 page research strategy) limit. Thank you all for excellent contributions to this. I'm sure it's not perfect, but I think it's solid.

If you're able to go through it today and check it for overall readability and accuracy where you have preliminary data, that would be fantastic. Please do use track changes and change the file name to add your initials when you edit, and please do not add too much text, as there's not much space at the end.

I do think Aim 3 might be a little thin, so if Shannon, Dave and Billy could look through that and see if you think it's missing anything, there's space for a few extra lines there.

Please return your edits to me by 7pm, if possible, so I can finalize the draft. Our plan is to submit at noon tomorrow and deal with any errors that may pop up.

While you're reviewing this, I'll work on the summary and narrative, and other peripheral pieces.

Thanks again. We're in the home stretch!

Cheers,
Jon

EcoHealth Alliance develops science-based solutions to prevent pandemics and promote conservation

Specific Aims

Emerging infectious diseases - predominantly caused by zoonotic viruses - have become a major threat to individual and public health as well as the functioning of a global society. Even prior to the SARS-CoV-2 pandemic, outbreaks of consequential emerging pathogens including SARS-CoV, Pandemic influenza 2009, Zika virus, and Ebola virus disease tragically killed ~~and~~ disabled, and caused massive disruptions of regional and global economies and health care systems¹. The emergence of consequential zoonotic infections is accelerating due to anthropogenic drivers such as climate change, land-use change, intensification of livestock production, and wildlife trade, all of which increase opportunity for people and domestic animals to come into contact with wildlife reservoirs²⁻⁵. **To reduce the risk of infectious disease epidemics, there is a critical need to detect and prevent spillover of zoonotic pathogens from wildlife reservoirs^{2,6}.**

Illustrative of this need is the repeated spillover from wildlife reservoirs to human populations of groups of zoonotic viruses such as filoviruses (e.g., Ebola virus [EBOV]) and henipaviruses (e.g., Nipah virus [NIV]). Large-scale outbreaks or clusters of cases with these high-mortality zoonotic viruses have led to their being **designated as high priority pathogens by the World Health Organization (WHO)**⁵. However, at present, the detection of outbreaks caused by these pathogens occurs only after the first human infections; a failure in prevention that is deadly, costly, and remediable¹. Identifying natural reservoirs of zoonotic viruses and measuring rates of **human** exposure to these viruses ~~in humans~~ are critical to assessing their potential threat and developing interventions that reduce ~~the risk of spillover risk~~.^{1,2}

In the proposed study we have assembled a diverse team of experts in the ecology, epidemiology, virology, ~~and immune response immunology of~~ bat-borne viral zoonoses such as filoviruses and henipaviruses, as well as; experts in and filovirus clinical care and research who are actively working in West Africa. With this team, our study will ~~te~~ provide much needed empirical evidence to help answer the questions: **What is the natural reservoir for Ebola virus and how often does spillover of this and related viruses happen in a region that is an emerging disease hotspot, suffered the world's largest filovirus outbreak, and where there has been evidence of other consequential zoonotic viruses in animals and people?**

To address these questions, we propose the following specific aims:

Aim 1. To determine the rates of filovirus and henipavirus exposure in people in rural Liberia. ~~We have shown~~ that certain bat species in Liberia carry EBOV-Zaire, while others carry Marburg virus and henipaviruses. Further, hunting bats is a common activity and we have detected high seroprevalence of Marburg and EBOV antibodies in rural Liberia. Exposure to henipaviruses remains unknown. To test the hypothesis that spillover of both groups of viruses has occurred in this region, we will use an antigen-based multiplex serological assay to screen more than 1,800 archived blood specimens, collected in 2021 and again in 2023 from over 900 adults and children in rural central Liberia, for antibodies against all known filoviruses and henipaviruses.

Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia. ~~Our group detected~~ EBOV-Zaire RNA and antibodies in *Miniopterus nimbae*, a cave- and mine-dwelling bat in northern Liberia found near the origin of the 2014 Ebola outbreak in Guinea. We also detected antibodies against EBOV in *Hipposideros* bats that co-roost with *Miniopterus* in multiple locations in Liberia. *Rousettus aegyptiacus*, a common frugivorous bat in Liberia, carries Marburg virus and henipaviruses. We will conduct a 3-year longitudinal study of populations of these bat species near the human cohort studied in **Aim 1**, to determine whether they are reservoirs for Ebola or other filoviruses and henipaviruses and characterize the temporal dynamics of filoviruses and henipavirus circulation using multiplexed serological assays that test for IgG antibodies against all known filoviruses and henipaviruses, as well as molecular techniques to screen for Ebola, Marburg, Nipah virus, and related viruses.

Aim 3. To characterize behaviors associated with exposure to filoviruses and henipaviruses. Combining the data collected in Aim 1 (humans) and Aim 2 (bats) we will identify the demographic, behavioral, and environmental factors associated with an individual's prior exposure to filoviruses and henipaviruses. Detailed animal exposure data collected from the adults and children (many born after the Ebola outbreak) who provided the Aim 1 blood specimens will be used to develop profiles of risk and inform public health & risk reduction communication tools in partnership with the Ministry of Health, Liberia.

Formatted: Indent: First line: 0"

Commented [MK1]: Reads slightly odd to me given the bolded aim of "people". Maybe flip this paragraph around?

Commented [MV([2]): Is this correct? Which henipavirus comes from Rousettus?

Commented [MV([3]): Wouldn't you say this stronger, to link it o our initial work detecting EBOV? More like identification of the exact reservoir?

RESEARCH STRATEGY

A. SIGNIFICANCE

Zoonotic viruses are responsible for the majority of emerging infectious disease outbreaks, which are occurring at an accelerating rate in global hotspots^{3,7}. Every outbreak begins with spillover – transmission of the virus from its animal reservoir either directly into human populations or into other animal hosts *en route* to humans (Figure 1). Exactly how often spillover occurs is virtually unknown, as surveillance systems are primarily designed to detect clusters or outbreaks; thus current surveillance – and often misses initial individual infections that result from animal contact. To reduce the risk of future epidemics, it will be necessary to limit opportunities for zoonotic viruses to spillover and to detect spillover at the earliest stages.^{1,8} Measuring the efficacy of any interventions designed to reduce spillover and spread of zoonotic pathogens will rely on measuring rates of exposure in at-risk human populations.

Filoviruses and henipaviruses are among the highest consequence zoonotic viruses and have greatly impacted public health. Each group contains zoonotic pathogens that cause significant disease in both people and animals, especially livestock, that have been associated with extremely high rates of morbidity and mortality. Ebola (EBOV) and related viruses, as well as Nipah virus (NIV), a henipavirus, and its related viruses have been listed by the World Health Organization (WHO) among the highest priority pathogens for the development of vaccines and therapeutics, as they represent zoonotic pathogens with high potential to threaten human health, with extremely high mortality rates and few or no therapeutics or vaccines currently available.⁹⁻¹¹ These viruses share other important features which make them high priority: they are all associated with bat hosts that are abundant and widely distributed throughout Africa and Asia, living in close association with people and livestock in some of the most densely populated regions on Earth.

Spillover of these viruses has repeatedly occurred. Beyond the massive outbreak in West Africa in 2013-16, EBOV outbreaks have occurred repeatedly in Central and East Africa; most recently Sudan ebolavirus caused an outbreak in Uganda in late 2022¹¹⁻¹³. Marburg virus (MARV) and Ravn virus (RAVV) comprise the closely related genus *Marburgvirus* and have caused outbreaks in Central and East Africa and Europe with mortality and clinical presentation comparable to Ebola^{14,15}. Marburg virus outbreaks were declared in Guinea in 2021, just across the border from the UNC-Liberia research site, in 2021 and then again in Ghana in 2022 marking the first time this virus has been reported in either country^{16,17}. Nipah virus is an emerging zoonotic paramyxovirus that has caused nearly annual outbreaks in Bangladesh, including multiple outbreaks in 2023, and sporadically in India with mean case fatality rates greater than 70%^{12,18-20}. Despite the public health significance of Nipah and related viruses, little is known about its genetic diversity, natural reservoirs, or frequency of spillover throughout their range, including Africa. Henipaviruses, and Nipah virus in particular - have several characteristics that make them a global health priority: 1) Their bat reservoirs occur throughout Asia and Africa, overlapping human and livestock populations, giving them geographically broad opportunity to cause outbreaks²¹; 2) henipaviruses can be transmitted to people directly from bats or via domestic animals²¹; 3) Nipah virus can be transmitted from person to person²²; 4) Nipah virus spillover has occurred and continues to occur in highly populous and internationally connected regions; 5) repeated spillovers of NIV strains with varying person-to-person transmission rates indicate the ability to evolve with increased pandemic potential^{23,24}; and 6) Nipah is associated with a high mortality rate in people and currently has no vaccine or treatment^{21,23}. While Nipah virus has not been detected in Africa, closely related henipaviruses have been identified in Ghana and Madagascar, though their public health significance remains unknown²⁵⁻²⁷. In West Africa, where bats and associated henipaviruses occur but where no human cases have been identified, diagnostic testing and systematic surveillance is essentially non-existent. The detection of antibodies against a Nipah-related virus in hunting communities in Central Africa suggests that cryptic spillover is occurring²⁸. Repeated spillover of henipaviruses creates opportunity for more transmissible strains to emerge²⁹.

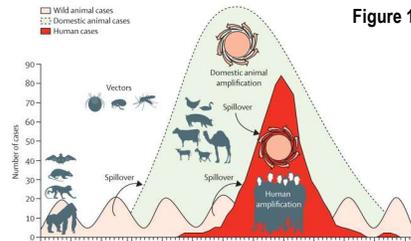

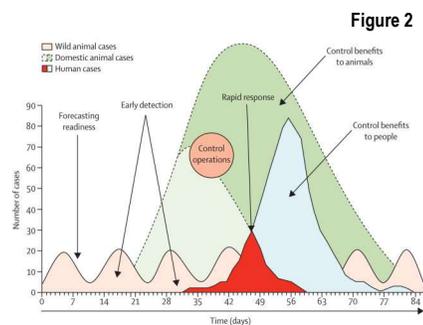

Figure 1

Commented [MK4]: This figure seems overly complicated to me for the sentence in which it is referenced, especially without any caption. Do you expect a reviewer to stop and parse this figure and continue reading with a stronger understanding of what is going on? I feel a reviewer could just get annoyed...

While bats have been identified as potential hosts for filoviruses including EBOV, the natural reservoir for EBOV-Zaire Ebola in West Africa remains unknown. There is substantial evidence, both serological and molecular, that bat species host filoviruses; however, a definitive natural reservoir or set of reservoirs for EBOV-Zaire has not been identified³⁰. Wildlife, including bats, represent a substantial source of animal protein for communities in Liberia³¹. People may be exposed to bat-borne viruses through hunting and butchering, eating food contaminated by bat excreta, or by entering caves or mines inhabited by bats. Our group previously found that people living in rural areas of Liberia conduct activities which may increase their risk of contact with bats or their bodily fluids. The index case, a child, in the 2013 Ebola outbreak was hypothesized to have had contact with bats, yet the exact species was never definitely identified³². The route of spillover for most historical Ebola outbreaks remains a mystery. Despite broad efforts to determine the natural reservoirs of EBOV and related viruses, there continues to be a poor understanding of filovirus ecology, with the exception of Marburg virus, whose host has been identified as Egyptian rousette bats (*Rousettus aegyptiacus*)³³⁻³⁵. Communities known to hunt bats in Cameroon and India have been found to have antibodies against henipaviruses and filoviruses, respectively, yet nothing is known about community exposure rates in Liberia, where bat hunting is common^{28,36}. Our preliminary data (see below) suggest that there is substantial exposure to EBOV as well as MARV among people in central Liberia. While the EBOV antibodies may indicate prior infection from another person such as during the West Africa outbreak, antibodies specific to other filoviruses may signal a localized exposure from animals. Even less is understood about henipaviruses in Africa, and identifying antibodies against henipaviruses in people will be critical for understanding where, how, and how often spillover occurs.

The urgent need to develop interventions to prevent spillover of zoonotic high consequence pathogens can only be met with a better understanding of their natural reservoirs, the rates of exposure in vulnerable human populations, and the ways in which people are exposed. Unrecognized outbreaks provide opportunities for viruses to emerge that may be more transmissible or more pathogenic than previously observed, and limiting these opportunities is an important component of pandemic prevention^{2,29}. Typically, by the time an outbreak is recognized in human populations its containment and control are difficult, if not impossible to achieve (e.g., HIV, SARS-CoV-2). Understanding the ecology of these viruses, including which

species act as reservoirs as well as how and to what extent people are being exposed to filoviruses and henipaviruses will inform intervention and surveillance strategies and provide baseline metrics against which one can measure the efficacy of interventions designed to reduce exposure, such as public health campaigns to promote avoidance of behaviors associated with infection among those most at risk (Figure 2).

This proposed study will be the largest and most rigorous One Health investigation of high-consequence zoonotic viruses in bats and humans in an emerging disease hotspot. West Africa is known to be the source of prior outbreaks of emerging infectious diseases and future

spillover events there are highly likely. Liberia is typical of this region and contains some of the largest tracts of pristine forest and wildlife biodiversity remaining in West Africa and has a population that depends on wildlife, including bats. Decades ago, a spillover event from a non-human primate to a human triggered an on-going HIV pandemic that has led to the infection of over 60 million people and 25 million deaths. Only months ago, the orthopoxvirus MPOX [virus found in originating from](#) rodents spread to and within 110 countries across the globe causing over 85,000 cases. Both originated from African wildlife. The proposed study will leverage the unique infrastructure and expertise we have developed in Liberia to undertake a comprehensive examination of filovirus and henipavirus spillover from bats to humans and provide evidence of previous and possibly on-going transmission events. Our findings will provide essential evidence of the presence and transmission dynamics of these bat-borne viruses and as the risks for infection in people living alongside them.

B. INNOVATION

The proposed research is highly innovative in multiple ways, including: 1) Our use of a One Health approach to study the ecology and epidemiology of two groups of high-priority, high-consequence zoonotic viruses in both bats and people in West Africa – an emerging disease hotspot where spillover events have occurred (e.g. Ebola, Marburg, MPOX, Lassa fever) and are highly likely to re-occur; 2) Our use of a novel and unique multiplexed serological platform, developed by our group, that will allow us to screen bat and human serum for IgG antibodies against each of the known filoviruses and henipaviruses, simultaneously in a single assay. Longitudinal comprehensive serological studies in bats and people **will provide unprecedented insight into the changes in rates of exposure over time to known viruses in both bats; and in people (e.g., what is the baseline rate of exposure to henipaviruses and filoviruses and is there evidence of recent exposure?), as well as ; and exposure rates to unknown, antigenically related viruses;** 3) We will couple serosurveillance with molecular testing to identify specific filoviruses and henipaviruses carried by bats; and 4) We will connect the bat and human epidemiological studies by analyzing questionnaire data from the human cohort to identifying high risk behaviors associated with viral exposure. **Results from this analysis will inform the development of public outreach and risk reduction campaigns by the Government of Liberia.**

Formatted: Font: 11 pt

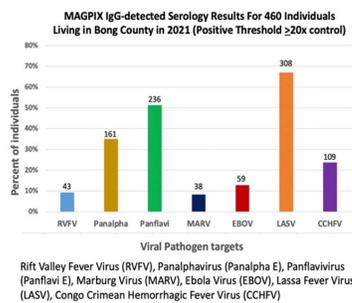

C. APPROACH

C.1. Overview: **Aim 1** will test the hypothesis that spillover of filoviruses and henipaviruses occur regularly in rural Liberia by testing for IgG antibodies to all known filoviruses and (see table 3) in archived serum samples from 900 people living in Bong county (central Liberia), collected at two time points 24 months apart. Seroprevalence of filoviruses and henipaviruses will be assessed as will changes between the two collection timepoints. In **Aim 2**, we will conduct a 36-month longitudinal study of three bat species which are putative reservoirs for EBOV and undescribed henipaviruses. Using a combination of longitudinal serology and molecular testing (PCR and whole genome sequencing) **we will determine the prevalence of filoviruses and henipaviruses in three key bats species associated with the rural human populations studied in Aims 1 and 3.** For **Aim 3**, we will analyze detailed questionnaire data developed collaboratively by our group (EHA and UNC) and collected in 2023 along with blood samples to be screened in Aim 1. These data will allow us to identify behaviors associated with exposure to henipaviruses and filoviruses. We will use results from our behavioral risk assessment to develop public risk reduction communication strategies with the National Public Health Institute, Liberia, using the results of this study to inform public health strategies. This application is a natural progression of our research activities, and our preliminary data speak to the feasibility of the proposed study.

C.2. Aim 1: To determine the rates of filovirus and henipavirus exposure in people in central rural Liberia.

C.2.1. Rationale and Preliminary Data. The primary goal of this aim is to be able to determine whether populations within Liberia who live in association with bats have evidence of exposure against one or multiple filoviruses and/or henipaviruses and to compare rates of exposure over time. Studies of human populations in Central and West Africa have found evidence of exposure to EBOV prior to the 2013 outbreak and in places not known to have had Ebola outbreaks^{37,38}. UNC Project-Liberia has previously assessed seropositivity to consequential viral pathogens including EBOV and MARV in a subset of CEPI ENABLE Study participants. About 10% of participants had antibodies against MARV (Figure 3), suggesting that unreported spillover events have previously occurred. Acute encephalitis is common in western sub-Saharan Africa, yet outbreaks of neurological disease are rarely reported and more than half of all cases are undiagnosed³⁹. Among the countries in western Africa reporting cases of meningitis or encephalitis, Liberia has reported the fewest, likely due to a lack of surveillance and capacity to diagnose neurological diseases³⁹. Nipah

Figure 3

Commented [JES]: @Billy or @Dave is this right?

virus encephalitis has never been reported in Africa, however, as described above, two Nipah-like henipaviruses have been described in bat hosts, including one in Ghana^{25,27}. Spillover of henipaviruses was reported in bat-hunting communities in Cameroon²⁸. In South Africa, we detected henipavirus sequences in *Rousettus aegyptiacus*, bats which also commonly occur in Liberia²⁶.

In Aim 1, we will test the hypothesis that spillover of both filoviruses and henipaviruses have occurred in rural populations in Liberia by measuring seropositivity to both groups of viruses within the CEPI ENABLE Study community cohort. We will also measure changes in exposure rates over a two-year period. While prior studies have provided cross-sectional snapshots of exposure, our longitudinal approach will provide data from the same cohort at two timepoints, 24 months apart, to determine both seroprevalence and sero-incidence using a multiplexed serological assay to screen for IgG antibodies against all known filoviruses and henipaviruses.

Settings and Participants. To achieve this aim, we will leverage a well characterized cohort of individuals in three rural communities located in Bong County, Liberia (Figure 4), which has a population of over 333,400. UNC Project-Liberia has been operating in Liberia since 2014 and established a research site at Phebe Hospital in Bong County that includes a molecular laboratory that conducts daily qPCR testing for LASV, MARV, and EBOV as well as LASV serological assays using a MAGPIX (SEE RESOURCES AND FACILITIES). There, following extensive community engagement including meetings with key stakeholders, town hall meetings, and radio messaging, UNC launched the CEPI ENABLE Study, the largest passive and active surveillance program for Lassa fever in Liberia. Started in 2020, 5,005 randomly selected participants 2 years of age and older in Phebe Airstrip, Suakoko, and Rubber Factory were enrolled over 6 months following informed consent/assent (mean age at enrollment is 22.2 years (range 2-97) and 54.2% are female). **Importantly, 7.7% of the cohort is under the age of 5 years, and therefore, were born after the 2013-14 Ebola outbreak (Table 1).**

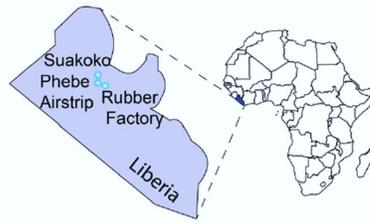

Figure 4. Map of Liberia with Bong County sites shown in inset.

Households were selected for recruitment following identification of roof tops by satellite photos and use of a program developed by Médecins Sans Frontières' (MSF) Epicentre to randomly selected structures to consecutively approach. The ENABLE Study includes baseline questionnaires and blood specimen collection from all participants with active follow-up by a study community health worker every 2 weeks to determine if a febrile event has occurred, which triggers drawing of blood for LASV, MARV, and EBOV PCR. A subset of 1,024 individuals is also asked to provide blood samples routinely every 6 months for up to 24 months. The blood samples from 0 and 24 months and the associated surveys will be used in Aims 1 and 3 of this proposal. Informed consent and assent documents include provisions for the use of collected specimens and data for infectious diseases research including for emerging pathogens (see PROTECTION OF HUMAN SUBJECTS).

C.2.2. Research Design. We will screen approximately **1,900 archived serum specimens** from participants in the ENABLE Study cohort at two time points ("baseline" [(Month 0)] and [(Month 24)]) for IgG antibodies against specific filoviruses and henipaviruses using the MAGPIX at the UNC molecular lab at Phebe hospital to run the multiplexed *henipavirus / filovirus* platform to be provided by Co-I Laing in year 1. The multiplex platform will allow us to determine specifically which filoviruses and henipaviruses people have been exposed to and compare that to the filoviruses and antibodies we observe circulating in local bat populations in **Aim 2**. The bead-based multiplexed assay has tremendous advantage over traditional ELISAs in that it will identify up to 25 different antibodies against multiple viral agents in a single, 2 μ l serum sample and uses a high through-put format. The ability to look at reactivity across all serogroups simultaneously will allow us to differentiate among the viruses. Proteins A/G non-specifically bind IgG immunoglobulins, and weakly bind IgM, an immunoglobulin that is the first to be produced during the initial stages of infection. We will conduct a 1-week training at the UNC-Phebe lab for using the assay to detect filovirus and henipavirus antibodies as well as data management, bioinformatics, and analysis. **Table 3** shows the viral species and antigens that will be employed in this assay. The platform has

Formatted: Font: 11 pt

Formatted: Indent: First line: 0"

Commented [JE6]: @Billy is this right?

been previously transferred to collaborating labs in the UK, South Africa, India, Bangladesh, Singapore, Thailand, and Malaysia. We have previously detected serological profiles of Asiatic ebolaviruses in fruit bats collected in Singapore⁴⁰ and in fruits bats and humans actively engaged in bat hunting in northeast India³⁶.

Commented [MK7]: Feels odd to just have a number here. Add "Cuevavirus" in front of the number? [Cuevavirus 86]

C.2.3. Data Analysis. We will create a project database using **Airtable**, which will be hosted at EHA and will house all data from Aims 1 and 2 and will link to the RedCap server which stores questionnaire data from Aim

Commented [MK8]: Would advocate dropping the box from the caption

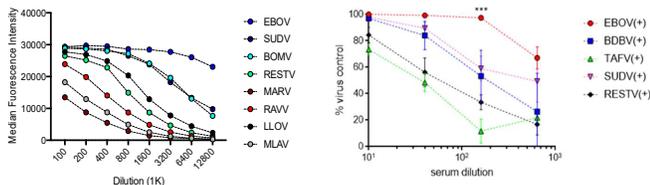

Figure 5. shows relative mean fluorescence index (MFI) values for an EBOV +ive control sera across serial dilutions. While there is cross reactivity, the EBOV MFI values are consistently greater than the other viral GPs and at higher dilutions the separation becomes significant.

3. Database access will be secure and limited to key personnel (see data management plan). Raw MFI values from the MAGPIX will be used to calculate reactivity to each viral antigen and based on relative strength of reactivity (Fig 5) and determinations of negative cutoffs based on

reference sera, we will calculate prevalence rates for each time point and compare rates between the two timepoints. Serological profiling can be used to detect reactive antibodies against all specific filoviruses and henipaviruses in a samples and compare strength of reactivity and cross-reactivity against multiple antigens using a single sample⁴¹. We will compare the antibodies across all specific viral antigens to assess which virus or groups of viruses are responsible for the immunological response⁴²⁻⁴⁴. We will assess exposure to non-Zaire ebolavirus species, which may indicate spillover of filoviruses has occurred separate to the Ebola outbreak of 2013. We will also look at evidence for exposure to Nipah-like henipaviruses and compare exposure rates to both viral groups within and between our two sample collection time points.

C.2.4. Expected outcomes. We anticipate obtaining serological profiles of exposure to filoviruses and henipaviruses from each individual in our cohort. In previous studies we found antibodies against both Ebola and Marburg virus. While the Ebola antibodies are attributable to the epidemic, Marburg antibodies, in

Commented [MK9]: I get the purpose of this structure, but the variety in how new sections start (left justify with a paragraph break or tabbed without a paragraph break) despite equivalent nestedness (e.g., C.2.3. vs C.2.4) is moderately noticeable to me

patients EBOV IgG negative, suggest possible exposure from an animal (e.g., bat) reservoir. We also anticipate seeing reactivity to Bombali virus (BOMV), given the presence of the reservoir species in Liberia (*Mops condylurus*) and reactivity to the African henipaviruses (GhV and AngV), although this may represent reactivity to an antigenically related virus. Serological results from this and the bat study will inform our strategy for prioritizing which bat samples we test by PCR.

C.2.5. Potential problems and solutions. -While our preliminary data suggest there will be detection of immune responses to filoviruses including EBOV-Zaire and, significantly, MARV, it is possible that evidence of exposure to other pathogens, including henipaviruses will not be detected. This would be an important finding in this large cohort, especially if these viruses are detected in local bat species, that would warrant further investigation. It is also possible that there will be few or no seroconversion events among the cohort during the 24-month period of follow-up. This too would be reassuring but would suggest a need for longer follow-up

of this cohort. To address the possibility that reactivity to EBOV-Zaire virus may be explained by infection during the 2013 Ebola epidemic, we will create a polyclonal sera reference standard utilizing convalescent sera collected from human survivors of EVD. This internal reference standard will be calibrated to the WHO EBOV human serology standard (Fig 6A) permitting direct interpolation of anti-EBOV IgG as an MFI to a standard antibody concentration (binding antibody units/mL). The internal reference standard will then be included in our human serology testing strategy allowing semi- or quantitative measurement of anti-EBOV IgG. These EBOV human serology standards will permit us to establish positive and negative predictive performance values for the multiplex assay, furthermore, we will be able to

Commented [MK10]: A and B were hidden

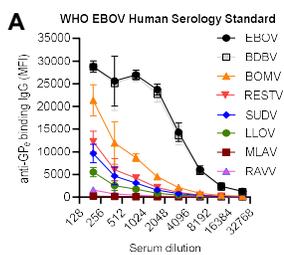

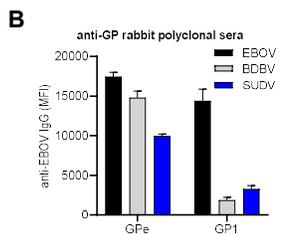

Figure 6A & B. A) The WHO EBOV human serology standard was testing for immunoreactivity in a filovirid GP-trimer based multiplex assay. Filovirids are indicated along with sera dilution factors; data is the mean of three independent experiments. **B)** Antisera from EBOV GP-trimer immunized rabbits were tested in multiplex panels comprised of GP-trimer and GP1 subunit proteins. Anti-EBOV polyclonal IgG was less reactive with GP1 from BDBV and SUDV.

investigate immunoreactivity of EVD survivors against heterotypic ebolaviruses. Our preliminary data indicates that EBOV+ sera IgG is highly cross-reactive with soluble native-like trimeric envelope glycoprotein (GP) antigens from both EBOV and BDBV (Figure 6A). EBOV GP, matrix protein (VP40), and nucleocapsid protein (NP) antigens have all been used in a variety of serological tests, however, the frequency of seroconversion against each antigen has not been fully described. In a longitudinal study of EVD survivors, high seroconversion against GP and VP40 was observed, with affinity maturation occurring overtime against GP⁴⁵. Antigens based on the GP are likely to provide an optimal intrinsic balance of sensitivity and specificity. To limit the degree of heterotypic ebolavirus cross reactions we will test any anti-ebolavirus GP trimer antigen-seropositive samples with a pan-ebolavirus GP1 antigen-based panel. In preliminary studies, GP1 antigens improve specificity and differentiation of antibodies reactive with homotypic ebolaviruses in polyclonal antisera from rabbits immunized with GP trimer immunogens (Figure 6B).

C.3. Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia.

C.3.1 Rationale and preliminary data. Bats have been established as important hosts for filoviruses and henipaviruses in Africa and Asia, with combinations of viral isolation, molecular detection or serology providing substantial evidence^{30,46-49}. MARV was isolated from Egyptian rousette bats in Uganda, and RNA has since been detected in these bats in Sierra Leone, which borders Liberia⁵⁰. To date, EBOV has never been isolated from bats, although molecular and serological evidence suggest that multiple frugivorous bats may carry EBOV in Central Africa^{50,51}. Prior to the 2014 epidemic, Zaire ebolavirus had not been reported in West Africa, and the animal reservoir remains unknown³². From 2016-2019, our group (PI Epstein & KP Desmond) implemented a large-scale project to identify reservoirs for EBOV in West Africa, under the USAID PREDICT Project⁵². This effort led to the discovery of a new species of Ebola (Bombali virus)⁵³, the detection of MARV in ERBs in Sierra Leone³³, and in 2018, we detected, for the first time in West Africa, EBOV RNA and anti-EBOV IgG antibodies in bats (Figure 7A-D).

While this finding generated the first evidence of which bats

may be reservoirs for Zaire ebolavirus, longitudinal studies are required to more completely understand the role these species play in EBOV circulation— either as reservoirs that maintain the virus within a local population, or as incidental hosts, infected by an unknown bat species. One-off, cross-sectional studies have a low probability of detecting any specific filovirus or henipavirus given their low prevalence and short viremic periods^{34,54}, and thus provide a poor characterization of viral diversity. The lack of understanding of **filovirus and henipavirus diversity and their natural reservoirs in West Africa significantly impedes risk-based public health interventions to prevent human outbreaks**. Longitudinal sampling is also needed to separate reservoir hosts from spillover hosts. For example, MARV has been isolated repeatedly from *R. aegyptiacus* in Uganda, which, when paired with experimental infection studies showing infection and shedding of MARV by *R. aegyptiacus*, strongly suggests that *R. aegyptiacus* is indeed a Marburg virus reservoir^{35,55,56}. Similarly, our longitudinal studies of Nipah virus in *Pteropus medius* bats in Bangladesh, which included the same multiplexed serological assay proposed here, confirmed them as a reservoir for NIV and identified important mechanisms driving viral circulation²⁹. **Understanding which species persistently carry filoviruses and henipaviruses will provide important insights into how they are maintained in nature and what species should be targeted for follow-up studies on bat habitat use and human-bat contact patterns.**

C.3.2. Sampling design. We will repeatedly sample three bat species associated with filoviruses or henipaviruses, based on our preliminary data: *M. nimbae* (EBOV), *H. ruber* (EBOV), and *R. aegyptiacus* (MARV & Henipaviruses). We will sample bats at roost sites in Bong county, as close as possible to the human study sites in Aim 1. In Y2-Y4, we will sample 40 individuals of each species every two months for 36 months and collect excreta using plastic tarps placed underneath bat roosts (details below and in C.3.3).

Bat capture and sampling. Briefly, we will use either harp traps or mist nets to capture bats, depending on the capture site. Personnel will wear appropriate personal protective equipment (e.g., Tyvek suits or dedicated long clothing; double nitrile gloves; an N95 respirator and safety glasses or a PAPR)⁵⁷. Traps and nets will be attended continuously during capture periods. Bats will be removed from mist nets immediately upon entanglement to avoid injury. Bats will be removed from harp traps after approximately 1 hour and ~~bats will be~~ placed in individual cloth bags until processed. Body measurements, blood, oropharyngeal swabs, and rectal swabs (or fecal pellets) will be collected from each bat. Swabs will be collected in duplicate; one swab will be placed in a cryovial containing Trizol lysis buffer and the other in viral transport medium (VTM). For bats <50g, blood will be collected in a microhematocrit tube and spun down using a portable centrifuge. A bulb will be used to expel serum from the tube into a cryovial. For larger bats >50g, a tuberculin syringe or 1ml syringe and 27g needle will be used to draw blood from the radial artery or vein⁵⁷. Blood will be placed into a conical vial and centrifuged. Serum will be aliquoted into a cryovial using a pipette. During site visits we will also lay out plastic tarps to collect pooled environmental excreta in Trizol and VTM to improve opportunity to detect viral RNA. All samples will be placed in a vapor phase liquid nitrogen dry shipper or portable battery-powered ultracold freezer, immediately upon collection and then transferred to a -80C freezer at the Phebe lab until testing.

C.3.3. Testing plan, Data analysis, sample size, and power analysis.

Serology: At the end of Y3, we will screen all serum samples collected to date using the **MAGPIX** multiplex assay for IgG against filoviruses and henipaviruses. We will analyze temporal dynamics in seroprevalence using general additive models (GAMs), which are analyses that we have used successfully in many previous studies of similar design²⁹. These methods are well adapted for capturing long-term temporal fluctuations in prevalence and moderately sensitive at capturing short-term changes in seroprevalence which can be used to identify population-level disease outbreaks. For example, we estimated that with 40 bats sampled every two months, we would be able to statistically detect an increase in seroprevalence (at a 95% CI limit) of greater than 25% between consecutive sampling events > 80% of the time, assuming a bat population seroprevalence of at least 10% in advance of a bat colony infection (estimated by, in brief, by simulating a fluctuating true seroprevalence value, simulating samples given this underlying seroprevalence, fitting a GAM to these samples, and then calculating if CI on true prevalence between the two sampling occasions over which the change in seroprevalence occurred were non-overlapping). While this is a large change, it is within a range to

Commented [MK11]: I think Eric made some comment about this phrasing? Maybe I am misremembering the specific context...

Formatted: Indent: First line: 0"

be expected if infection were to sweep through a bat community²⁹. MAGPIX-positive bat sera will be sent to RML for serum neutralization assays using viral isolates or VSV pseudoviruses under BSL4 conditions.

VSV-pseudotype neutralization assays: Serological results will be confirmed using VSV-pseudotype neutralization assays for the following filoviruses EBOV, SUDV, BDBV, RETV, BOMV, MARV and RAVN. If novel henipavirus sequences are detected, additional assays will be developed to test positive sera. Serum samples will be inactivated using γ -irradiation (4 MRad). Neutralization of irradiated and heat-inactivated serum samples will be assessed in Vero 352 E6 cells. Briefly, cells were seeded in 96-well round-bottom plates for 24 hours, serial dilutions of heat-inactivated serum samples will be performed in DMEM supplemented with 2% FBS, penicillin/streptomycin, and L-glutamine. Each plate will contain negative serum control, cell-only control, and virus-only control. VSV EBOV-GFP will be added to each well of the serum dilution plate and the serum-virus mix 357 was incubated at 37°C for 1-hour. The mix was added to the cells and incubated at 37°C for 24 hours. The cells will then fixed with 4% paraformaldehyde at room temperature 359 for 15-minutes and centrifuged at 600 x g for 5-minutes at room temperature. The supernatant will be discarded and FACS+EDTA buffer was added. Samples will be run on the FACSymphony A5 Cell Analyzer (BD Biosciences, Mississauga, ON, Canada) and FITC MFI 362 was measured. Data will be analyzed using FlowJo.

Formatted: Font: No underline, Font color: Black

Molecular testing: We will use specific filovirus taqman real-time PCR assays to screen oropharyngeal, fecal and environmental samples from bats for EBOV and MARV RNA at the UNC-Phebe lab^{55,58}. Testing bat samples by PCR may allow us to detect viral RNA during active infection, providing important information about the prevalence and timing of infection within target species. **Because we expect viral prevalence to be significantly lower than seroprevalence, estimated at <5%^{25,27,49}**, we developed a sampling scheme focused on maximizing our probability of detecting viral RNA with qPCR. To compare power under alternative sampling designs, we built simulation-based power analyses that estimated power to detect: 1) viral EBOV or MARV RNA in at least one bat; and 2) the expected number of positive cases, in each bat species. In brief, we estimated power for total sample sizes between 1500-3000 (between 500 and 1000 bats sampled per species) spread across a variable number of visits per year (2-6), while allowing for uncertainty in true infection dynamics in the bat populations, specifically: 1) prevalence during one three-week period (with unknown timing) per year of high prevalence ranging from 1-5%); and 2) an otherwise low background prevalence (0-1%). Given these estimates of yearly infection dynamics, these analyses showed that with 672 samples per species (minimum 32 individual bats per sampling event), spread across 6 sampling occasions per year, we would obtain a per-species probability of acquiring 0 positive samples of <4% (<1% at 40 bats per event – our target number) and an expectation of ~3-6 RNA positive results (~5-10 positives at 40 bats per event). Because henipaviruses have not been previously described in Liberia, we will focus our resources on filovirus testing by PCR. –However, if henipavirus serology suggests active circulation, we may send a set of samples to RML for pathogen discovery (see RML letter of support).

Commented [MK12]: Just trying to get a bit more consistency among equivalently nested sections

Formatted: Underline

Viral isolation: PCR-positive cDNA samples and their aliquot in VTM will be sent to RML for further sequencing and attempts at viral isolation under BSL4 conditions. If attempts to culture do not work, we will use next generation sequencing techniques to get whole genome sequence and further characterize the virus at RML. Novel viruses will be characterized and rescued (reverse engineered using a minigenome system to synthetically create infectious viral particles⁵⁹) at RML under secure, biosafety level 4 conditions, then used for serum neutralization assays in bat and human sera to determine more precise exposure rates. –Sequences from the glycoproteins of any novel viruses discovered will be used by USU (Co-I Laing) to generate purified proteins and added to the Luminex assay, which will improve its specificity.

Commented [MK13]: Same comment about consistency (compared to above section on "serology"). Maybe this bothers others much less :)

VirCapSeq-VERT and myBaits probe-based enrichment for recovery of full-length genome sequences of filoviruses: Although shotgun sequencing provides opportunities to analyze all host and virus genetic material, the larger average genome size of bacteria and hosts compared to viral genomes complicates a detailed analysis of the virome, particularly vertebrate viruses. We have established a positive selection probe capture-

Formatted: Indent: First line: 0.5"

based system to enrich for viral sequences. Here, we will take advantage of these probe capture-based methods (VirCapSeq-VERT and myBaits probe library) to enrich for vertebrate viral sequences of interest. Sample libraries will be normalized and combined in 4- to 12-plex reactions for solution capture hybridization using either the HyperExplore custom bait library version of VirCapSeq-VERT probe set or our custom myBaits probe library. For HyperExplore custom bait library probe set, libraries will be enriched for virus following the SeqCap EZ HyperCap Workflow User's Guide, version 2.3, while for custom myBaits probe library, the myBaits Hybridization Capture for Targeted NGS protocol, Version 4.01 will be used. Sequencing libraries will be normalized and sequenced as 2 X 150 bp fragments on Illumina's MiSeq or NextSeq sequencing platforms, following Illumina's standard procedure (Illumina, San Diego, CA). NGS data will be analyzed using metavirs (<https://openomics.github.io/metavirs/>), a comprehensive viral metagenomics pipeline to assemble, annotate, and classify viruses. It relies on technologies like Singularity1 to maintain the highest-level of reproducibility. The pipeline consists of a series of data processing and quality-control steps orchestrated by Snakemake2, a flexible and scalable workflow management system, to submit jobs to a cluster. The pipeline is compatible with data generated from Illumina short-read sequencing technologies. As input, it accepts a set of FastQ files and will be run on-premises using the NIAID RML Big Sky supercomputing cluster.

C.3.5. Expected outcomes. -Based on our prior work, our multifaceted analysis approach, and calculated power given our proposed temporal sampling strategy, we expect to be able to use temporal serological data to describe filovirus and henipavirus viral dynamics over time. Our molecular screening will primarily focus on filoviruses because we have known targets, and we expect to detect EBOV or MARV RNA, despite low prevalence and short-lived infections. Sequence data from positive samples will 1) provide substantial evidence for the identification of EBOV reservoirs and help explain which virus is responsible for the observed IgG response in bats (and possibly people); and 2) provide valuable information about viral diversity, about which little is known. Henipavirus serology, in the absence of sequence data, will allow us to identify potential bat reservoirs, analyze temporal trends, and generate hypotheses for future targeted studies.

C.3.6. Potential problems and solutions.

Serological tests are greatly hindered by the inherent antibody cross-reactivity between antigens from known ebolaviruses, challenging data interpretations that antibodies are EBOV-specific or EBOV, BDBV, and SUDV cross-reactive⁴⁰. This is also true for the henipaviruses in the panel. The advantage of the multiplexed platform is that we can simultaneously see relative MFI values for all the filoviruses and henipaviruses. Glycoproteins

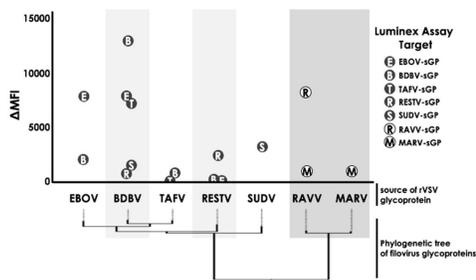

Figure 8. Captive-bred ERBs were experimentally challenged with VSV-filoGPs, the GP source is indicated on the x-axis. In a GP-trimer multiplex test the homotypic ebolavirus bat antisera were most reactive with the homotypic ebolavirus GP-trimer antigen.

from the homologous virus should cause the most intense reaction, particularly at higher dilutions. Co-Is Laing and Munster have demonstrated that homotypic and heterotypic ebolavirus-antibody reactions can be simultaneously measured and accounted for in ERBs challenged with replication-competent VSV-filoGP (**Figure 8**). Still, there is some cross reactivity, and we will use additional tools such as viral neutralization assays as a secondary test, and our statistical approach can correct for a portion of cross reactivity. Past studies have relied on individual ELISAs which had varying degrees of specificity depending on which test was used, but often couldn't rule out cross-reactivity. The Luminex filovirus multiplex assay has predictable patterns of cross-reactivity, but we will still be able to discern to which virus the serum is most reactive.

C4. Aim 3: To characterize behaviors associated with exposure to filoviruses and henipaviruses.

C.4.1 Background and rationale. As described above, there is substantial interaction between wildlife, domestic animals, and people living in rural Liberia. -Our group collected questionnaire data from 585 people across Liberia as part of the USAID-funded Ebola Host Project between 2016 and 2019. -When asked about animal exposures during the 2013-2016 Ebola outbreak, participants frequently reported contact with both domestic and wild animals. Common types of animal contact included animals coming inside the dwelling (58%), cooking or handling animal meat (44%), and eating raw or undercooked meat (31%). Additionally, 26% reported slaughtering and 12% reported hunting or trapping an animal. In the ENABLE Study of 5,005 residents of Bong County, survey questions mainly focused on rodent exposures relevant to Lassa fever, but 12% of participants reported hunting or preparing wild animal meat. Little is known about the prevalence and type of other potential bat exposures in this region of Liberia. Elsewhere in West Africa, EcoHealth Alliance participated in the response to Ghana's 2022 cluster of MARV cases, working with local partners to administer a behavioral risk questionnaire characterizing bat exposures in three affected communities¹⁶. Many participants lived in close proximity to bats, with one fifth reported exposure to bats inside a dwelling or other building in the previous four months. When asked about exposures more relevant to Egyptian Rousette bats, a known MARV reservoir and a target species in this proposed study, participants commonly reported bats feeding on fruit trees on their home compound, eating fruit bearing bite marks, and exposure to bats inside a cave or mine.

C.4.2. Research design. As described in Aim 1, serum collected at baseline (in 2021) and at month 24 (in 2023) during the ENABLE Study will be screened for filoviruses and henipaviruses, enabling us to calculate seroprevalence at baseline and seroconversion over a two-year period. In addition to providing blood specimens, the 1,024 participants who initially enrolled responded to baseline questionnaires on demographics, healthcare-seeking behaviors, health status, and animal exposures. At month 24, the 921 participants still actively enrolled are administered repeat questionnaires. This final survey includes additional items based on the Ghanaian questionnaire and asks specifically about bats including the respondents' activities in their habitats (entering forests, caves, and mines), direct contact (hunting, eating handling), indirect contact (presence in home or other used structure), and observed characteristics of bats encountered (fruit tree dwelling). By pairing this existing survey data with the new serology results generated from archived samples under Aim 1, as well as new data on nearby bat infection from Aim 2, we will be able to develop comprehensive risk profiles for exposure to filoviruses and henipaviruses in this community.

C.4.3. Data analysis. The primary outcome for this analysis will be testing positive for IgG antibodies against any known filoviruses or henipaviruses. For both families of viruses, and for each species of virus within those families, we will use the serology results generated under Aim 1 to examine risk factors for seropositivity at baseline and seroconversion between baseline and month 24. We plan to conduct a multivariate logistic regression, with appropriate weights applied to account for the single-stage cluster sampling design of the ENABLE Study, in which members of randomly selected households were surveyed and tested. We will use data from both the baseline and month 24 questionnaires to examine the effects of sampling site, participant demographics (e.g., age, gender, occupation), environmental exposures (e.g., animals present in and around the dwelling), and behavioral risks (e.g., direct contact with bats through hunting, preparing, or eating them, entering caves or mines where bats live).

Power analysis: To assess our power to identify risk metrics for seroconversion (or overall seropositivity), we built simulation-based power analyses that consisted of, in brief: 1) simulating survey responses for N (400-1000) individuals, while allowing for moderate unevenness in representation across five binary categories (as **largegreat** as 80%-20,% for **eachexample**); 2) examining a range of effect sizes (odds ratios ranging from 1-2.5) for these five binary categorical predictors (e.g., sex, encountered a bat, handled a bat, etc.). Summarizing across 1,200 simulations of surveys of 400-1000 individuals given joint uncertainty in the representation within these surveys and effect sizes, we estimated that we would have at least 80% power

Formatted: Indent: First line: 0.5"

to detect significant effects for each predictor given an odds ratio of 1.65 or greater with 1,000 survey responses or ~1.80 (for example, with a rate just under 5% for Group1 = 0, just over 8% for Group1 = 1) -with 750 responses.

C.4.4. Expected outcomes. By combining serology results with detailed questionnaire data on participant demographics and animal exposures, we will be able to use odds ratios to identify behaviors significantly associated with seropositivity (e.g., exposure to filoviruses or henipaviruses). We expect to be able to also identify age and gender-based risk factors given our sample size. Based on previous experience conducting behavioral risk surveys, including a recent study in Ghana following a Marburg outbreak, we expect to be able to develop risk mitigation messaging that uses evidence from Aims 1 and 2 as well as results from this aim.

C.4.5. Potential problems and solutions. We anticipate that most IgG positive individuals for either set of viruses will be adults, with the likelihood of exposure and having antibodies increasing with age. Because we don't know how long IgG antibodies persist at detectable levels, it will not be possible to accurately determine when exposure occurred, with the exception being EBOV antibodies that most likely occurred as a result of contact with another infected person during the 2014-2016 outbreak. We will address this in two ways: by looking at respondents 1-6 yrs old, we will know that any filovirus antibodies they have are most likely not due to the epidemic, and we will be able to determine whether there are any significant associations with particular behavior that promotes direct animal contact, consumption of contaminated fruit, or exposure to bat habitats (e.g. caves or mines). For adult respondents, we will focus on exposures (based on relative MFI values) specific to non-EBOV filoviruses and henipaviruses and see whether there are associations with specific behaviors.

D. Summary and Conclusions.

West Africa is a hotspot for emerging zoonotic viruses such as Ebola, Marburg and potentially Nipah-related henipaviruses – groups that have been identified by WHO as among the most significant pathogens that threaten global health. Liberia is also a biodiversity hotspot, with some of the largest tracts of primary forest remaining in the region, and its population relies on wildlife as a primary source of protein, creating continued risk of spillover of high consequence zoonotic pathogens. This project has the potential to determine the origins of Zaire ebolavirus in West Africa, characterize the circulation of Ebola and other filoviruses and henipaviruses in common bat species, identify background rates of spillover in rural human populations, and identify high-risk behaviors associated with exposure to these bat-borne zoonoses. Our group comprises an unparalleled multidisciplinary group of leading experts in epidemiology, clinical medicine, virology, serology, and disease ecology all with deep experience working in Liberia and implementing zoonotic virus research, giving this project a high chance of success in generating impactful results that will help prevent future epidemics in West Africa.

Couple of very minor comments,

I agree with David on the henipa's as you are coupling a clear direct public health threat (Filos's – EBOV and MARV) with a history of large outbreaks, with a group of viruses for which there is no direct evidence of causing any morbidity and mortality in Africa. It makes complete sense to do exactly what we are proposing, but i think it would be stronger to argue that the risk of henipa's is currently unknown. Particularly tying this back to the human data, you know that most filo's will have direct zoonotic potential, for anything you find in the bats that will remain clear unless you can isolate said virus from a human case.

Other than that, cool proposal, great team!

Subject: [EXTERNAL] Re: Complete draft 7 for rapid review

Hi Jon,

See attached. Looks solid.

Main issues to consider:

The conflating of filoviruses and henipaviruses makes me nervous (as Jean DeMarco often says). We have good rationale for expecting filoviruses in bats and humans. For henipaviruses, not so much. This could be shifted to a strength if acknowledged not just at the end but earlier and make clear that this is an opportunity to look for these viruses given the bat species and limited ability to detect encephalitis in Liberia – we could detect the tinderbox for a future outbreak.

I do think in the limitations section we need to address more explicitly that not finding henipavirus exposure in bats or people is possible and is ok in that this is an important negative finding given the potential. I am concerned reviewers will be attracted to henipavirus and unclear if their reaction will be sweet or sour.

Less of an issue is the seroincidence. I am of two minds about this. We can double down and take our chances that reviewers won't ding us for placing bets on a 24 month follow-up period by going the route selected. Alternatively, we could acknowledge that incidence is less certain but that we hypothesize is not uncommon. Given hours left to submit, doubling down makes sense.

For Aim 3, I agree could be clearer about putative factors for infection/exposure. It is not just behavior but also structural (literally and figuratively). Environment plays a role too as does super poverty among the impoverished. Could list hypotheses regarding risks including men>women, hunters vs non, having domestic animals vs not, less sturdy housing vs more, etc.

Let us know if you need anything else.

Thanks for leading the charge.

D

Subject: Complete draft 7 for rapid review

Hi all,

I've compiled a near final draft, incorporating the text you each provided and then cutting it down to fit within the 13 page (1 page specific aims and 12 page research strategy) limit. Thank you all for excellent contributions to this. I'm sure it's not perfect, but I think it's solid.

If you're able to go through it today and check it for overall readability and accuracy where you have preliminary data, that would be fantastic. Please do use track changes and change the file name to add your initials when you edit, and please do not add too much text, as

there's not much space at the end.

I do think Aim 3 might be a little thin, so if Shannon, Dave and Billy could look through that and see if you think it's missing anything, there's space for a few extra lines there.

Please return your edits to me by 7pm, if possible, so I can finalize the draft. Our plan is to submit at noon tomorrow and deal with any errors that may pop up.

While you're reviewing this, I'll work on the summary and narrative, and other peripheral pieces.

Thanks again. We're in the home stretch!

Cheers,
Jon

Specific Aims

Emerging infectious diseases - predominantly caused by zoonotic viruses - have become a major threat to individual and public health as well as the functioning of a global society. Even prior to the SARS-CoV-2 pandemic, outbreaks of consequential emerging pathogens including SARS-CoV, Pandemic influenza 2009, Zika virus, and Ebola virus disease tragically killed ~~and~~ disabled, and caused massive disruptions of regional and global economies and health care systems¹. The emergence of consequential zoonotic infections is accelerating due to anthropogenic drivers such as climate change, land-use change, intensification of livestock production, and wildlife trade, all of which increase opportunity for people and domestic animals to come into contact with wildlife reservoirs²⁻⁵. **To reduce the risk of infectious disease epidemics, there is a critical need to detect and prevent spillover of zoonotic pathogens from wildlife reservoirs^{2,6}.**

Illustrative of this need is the repeated spillover from wildlife reservoirs to human populations of groups of zoonotic viruses such as filoviruses (e.g., Ebola virus [EBOV]) and henipaviruses (e.g., Nipah virus [NIV]). Large-scale outbreaks or clusters of cases with these high-mortality zoonotic viruses have led to their being **designated as high priority pathogens by the World Health Organization (WHO)**⁵. However, at present, the detection of outbreaks caused by these pathogens occurs only after the first human infections; a failure in prevention that is deadly, costly, and remediable¹. Identifying natural reservoirs of zoonotic viruses and measuring rates of **human** exposure to these viruses ~~in humans~~ are critical to assessing their potential threat and developing interventions that reduce ~~the risk of spillover risk~~.^{1,2}

In the proposed study we have assembled a diverse team of experts in the ecology, epidemiology, virology, and immune response immunology of bat-borne viral zoonoses such as filoviruses and henipaviruses, as well as; experts in and filovirus clinical care and research who are actively working in West Africa. With this team, our study will ~~te~~ provide much needed empirical evidence to help answer the questions: **What is the natural reservoir for Ebola virus and how often does spillover of this and related viruses happen in a region that is an emerging disease hotspot, suffered the world's largest filovirus outbreak, and where there has been evidence of other consequential zoonotic viruses in animals and people?**

To address these questions, we propose the following specific aims:

Aim 1. To determine the rates of filovirus and henipavirus exposure in people in rural Liberia. ~~We have shown~~ that certain bat species in Liberia carry EBOV-Zaire, while others carry Marburg virus and henipaviruses. Further, hunting bats is a common activity and we have detected high seroprevalence of Marburg and EBOV antibodies in rural Liberia. Exposure to henipaviruses remains unknown. To test the hypothesis that spillover of both groups of viruses has occurred in this region, we will use an antigen-based multiplex serological assay to ~~screen~~ more than 1,800 archived blood specimens, collected in 2021 and again in 2023 from over 900 adults and children in rural central Liberia, for antibodies against all known filoviruses and henipaviruses.

Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia. Our group detected EBOV-Zaire RNA and antibodies in *Miniopterus nimbae*, a cave- and mine-dwelling bat in northern Liberia found near the origin of the 2014 Ebola outbreak in Guinea. We also detected antibodies against EBOV in *Hipposideros* bats that co-roost with *Miniopterus* in multiple locations in Liberia. *Rousettus aegyptiacus*, a common frugivorous bat in Liberia, carries Marburg virus and henipaviruses. We will conduct a 3-year longitudinal study of populations of these bat species near the human cohort studied in **Aim 1**, to determine whether they are reservoirs for Ebola or other filoviruses and henipaviruses and characterize the temporal dynamics of filoviruses and henipavirus circulation using multiplexed serological assays that test for IgG antibodies against all known filoviruses and henipaviruses, as well as molecular techniques to screen for Ebola, Marburg, Nipah virus, and related viruses.

Aim 3. To characterize behaviors associated with exposure to filoviruses and henipaviruses. Combining the data collected in Aim 1 (humans) and Aim 2 (bats) we will identify the demographic, behavioral, and environmental factors associated with an individual's prior exposure to filoviruses and henipaviruses. Detailed animal exposure data collected from the adults and children (many born after the Ebola outbreak) who provided the Aim 1 blood specimens will be used to develop profiles of risk and inform public health & risk reduction communication tools in partnership with the Ministry of Health, Liberia.

Commented [MK1]: Reads slightly odd to me given the bolded aim of "people". Maybe flip this paragraph around?

RESEARCH STRATEGY
A. SIGNIFICANCE

Zoonotic viruses are responsible for the majority of emerging infectious disease outbreaks, which are occurring at an accelerating rate in global hotspots^{3,7}. Every outbreak begins with spillover – transmission of the virus from its animal reservoir either directly into human populations or into other animal hosts *en route* to humans (Figure 1). Exactly how often spillover occurs is virtually unknown, as surveillance systems are primarily designed to detect clusters or outbreaks; thus current surveillance – and often misses initial individual infections that result from animal contact. To reduce the risk of future epidemics, it will be necessary to limit opportunities for zoonotic viruses to spillover and to detect spillover at the earliest stages.^{1,8} Measuring the efficacy of any interventions designed to reduce spillover and spread of zoonotic pathogens will rely on measuring rates of exposure in at-risk human populations.

Filoviruses and henipaviruses are among the highest consequence zoonotic viruses and have greatly impacted public health. Each group contains zoonotic pathogens that cause significant disease in both people and animals, especially livestock, that have been associated with extremely high rates of morbidity and mortality. Ebola (EBOV) and related viruses, as well as Nipah virus (NIV), a henipavirus, and its related viruses have been listed by the World Health Organization (WHO) among the highest priority pathogens for the development of vaccines and therapeutics, as they represent zoonotic pathogens with high potential to threaten human health, with extremely high mortality rates and few or no therapeutics or vaccines currently available.⁹⁻¹¹ These viruses share other important features which make them high priority: they are all associated with bat hosts that are abundant and widely distributed throughout Africa and Asia, living in close association with people and livestock in some of the most densely populated regions on Earth.

Spillover of these viruses has repeatedly occurred. Beyond the massive outbreak in West Africa in 2013-16, EBOV outbreaks have occurred repeatedly in Central and East Africa; most recently Sudan ebolavirus caused an outbreak in Uganda in late 2022¹¹⁻¹³. Marburg virus (MARV) and Ravn virus (RAVV) comprise the closely related genus *Marburgvirus* and have caused outbreaks in Central and East Africa and Europe with mortality and clinical presentation comparable to Ebola^{14,15}. Marburg virus outbreaks were declared in Guinea in 2021, just across the border from the UNC-Liberia research site, in 2021 and then again in Ghana in 2022 marking the first time this virus has been reported in either country^{16,17}. Nipah virus is an emerging zoonotic paramyxovirus that has caused nearly annual outbreaks in Bangladesh, including multiple outbreaks in 2023, and sporadically in India with mean case fatality rates greater than 70%^{12,18-20}. Despite the public health significance of Nipah and related viruses, little is known about its genetic diversity, natural reservoirs, or frequency of spillover throughout their range, including Africa. Henipaviruses, and Nipah virus in particular - have several characteristics that make them a global health priority: 1) Their bat reservoirs occur throughout Asia and Africa, overlapping human and livestock populations, giving them geographically broad opportunity to cause outbreaks²¹; 2) henipaviruses can be transmitted to people directly from bats or via domestic animals²¹; 3) Nipah virus can be transmitted from person to person²²; 4) Nipah virus spillover has occurred and continues to occur in highly populous and internationally connected regions; 5) repeated spillovers of NIV strains with varying person-to-person transmission rates indicate the ability to evolve with increased pandemic potential^{23,24}; and 6) Nipah is associated with a high mortality rate in people and currently has no vaccine or treatment^{21,23}. While Nipah virus has not been detected in Africa, closely related henipaviruses have been identified in Ghana and Madagascar, though their public health significance remains unknown²⁵⁻²⁷. In West Africa, where bats and associated henipaviruses occur but where no human cases have been identified, diagnostic testing and systematic surveillance is essentially non-existent. The detection of antibodies against a Nipah-related virus in hunting communities in Central Africa suggests that cryptic spillover is occurring²⁸. Repeated spillover of henipaviruses creates opportunity for more transmissible strains to emerge²⁹.

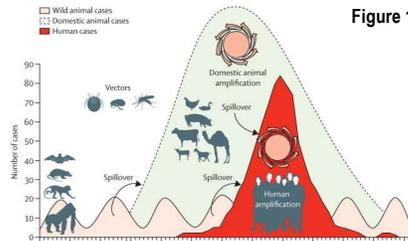

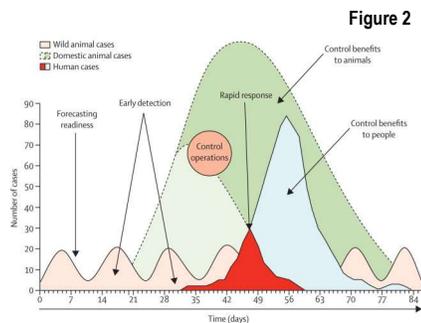

Figure 1

Commented [MK2]: This figure seems overly complicated to me for the sentence in which it is referenced, especially without any caption. Do you expect a reviewer to stop and parse this figure and continue reading with a stronger understanding of what is going on? I feel a reviewer could just get annoyed...

While bats have been identified as potential hosts for filoviruses including EBOV, the natural reservoir for EBOV-Zaire Ebola in West Africa remains unknown. There is substantial evidence, both serological and molecular, that bat species host filoviruses; however, a definitive natural reservoir or set of reservoirs for EBOV-Zaire has not been identified³⁰. Wildlife, including bats, represent a substantial source of animal protein for communities in Liberia³¹. People may be exposed to bat-borne viruses through hunting and butchering, eating food contaminated by bat excreta, or by entering caves or mines inhabited by bats. Our group previously found that people living in rural areas of Liberia conduct activities which may increase their risk of contact with bats or their bodily fluids. The index case, a child, in the 2013 Ebola outbreak was hypothesized to have had contact with bats, yet the exact species was never definitely identified³². The route of spillover for most historical Ebola outbreaks remains a mystery. Despite broad efforts to determine the natural reservoirs of EBOV and related viruses, there continues to be a poor understanding of filovirus ecology, with the exception of Marburg virus, whose host has been identified as Egyptian rousette bats (*Rousettus aegyptiacus*)³³⁻³⁵. Communities known to hunt bats in Cameroon and India have been found to have antibodies against henipaviruses and filoviruses, respectively, yet nothing is known about community exposure rates in Liberia, where bat hunting is common^{28,36}. Our preliminary data (see below) suggest that there is substantial exposure to EBOV as well as MARV among people in central Liberia. While the EBOV antibodies may indicate prior infection from another person such as during the West Africa outbreak, antibodies specific to other filoviruses may signal a localized exposure from animals. Even less is understood about henipaviruses in Africa, and identifying antibodies against henipaviruses in people will be critical for understanding where, how, and how often spillover occurs.

The urgent need to develop interventions to prevent spillover of zoonotic high consequence pathogens can only be met with a better understanding of their natural reservoirs, the rates of exposure in vulnerable human populations, and the ways in which people are exposed. Unrecognized outbreaks provide opportunities for viruses to emerge that may be more transmissible or more pathogenic than previously observed, and limiting these opportunities is an important component of pandemic prevention^{2,29}. Typically, by the time an outbreak is recognized in human populations its containment and control are difficult, if not impossible to achieve (e.g., HIV, SARS-CoV-2). Understanding the ecology of these viruses, including which

species act as reservoirs as well as how and to what extent people are being exposed to filoviruses and henipaviruses will inform intervention and surveillance strategies and provide baseline metrics against which one can measure the efficacy of interventions designed to reduce exposure, such as public health campaigns to promote avoidance of behaviors associated with infection among those most at risk (Figure 2).

This proposed study will be the largest and most rigorous One Health investigation of high-consequence zoonotic viruses in bats and humans in an emerging disease hotspot. West Africa is known to be the source of prior outbreaks of emerging infectious diseases and future

spillover events there are highly likely. Liberia is typical of this region and contains some of the largest tracts of pristine forest and wildlife biodiversity remaining in West Africa and has a population that depends on wildlife, including bats. Decades ago, a spillover event from a non-human primate to a human triggered an on-going HIV pandemic that has led to the infection of over 60 million people and 25 million deaths. Only months ago, the orthopoxvirus MPOX found in rodents spread to and within 110 countries across the globe causing over 85,000 cases. Both originated from African wildlife. The proposed study will leverage the unique infrastructure and expertise we have developed in Liberia to undertake a comprehensive examination of filovirus and henipavirus spillover from bats to humans and provide evidence of previous and possibly on-going transmission events. Our findings will provide essential evidence of the presence and transmission dynamics of these bat-borne viruses and as the risks for infection in people living alongside them.

B. INNOVATION

The proposed research is highly innovative in multiple ways, including: 1) Our use of a One Health approach to study the ecology and epidemiology of two groups of high-priority, high-consequence zoonotic viruses in both bats and people in West Africa – an emerging disease hotspot where spillover events have occurred (e.g. Ebola, Marburg, MPOX, Lassa fever) and are highly likely to re-occur; 2) Our use of a novel and unique multiplexed serological platform, developed by our group, that will allow us to screen bat and human serum for IgG antibodies against each of the known filoviruses and henipaviruses, simultaneously in a single assay. Longitudinal comprehensive serological studies in bats and people **will provide unprecedented insight into the changes in rates of exposure over time to known viruses in both bats; and in people (e.g., what is the baseline rate of exposure to henipaviruses and filoviruses and is there evidence of recent exposure?), as well as ; and exposure rates to unknown, antigenically related viruses**; 3) We will couple serosurveillance with molecular testing to identify specific filoviruses and henipaviruses carried by bats; and 4) We will connect the bat and human epidemiological studies by analyzing questionnaire data from the human cohort to identifying high risk behaviors associated with viral exposure. **Results from this analysis will inform the development of public outreach and risk reduction campaigns by the Government of Liberia.**

Formatted: Font: 11 pt

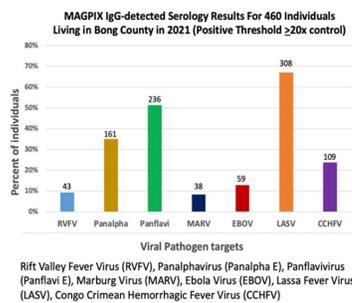

C. APPROACH

C.1. Overview: **Aim 1** will test the hypothesis that spillover of filoviruses and henipaviruses occur regularly in rural Liberia by testing for IgG antibodies to all known filoviruses and (see table 3) in archived serum samples from 900 people living in Bong county (central Liberia), collected at two time points 24 months apart. Seroprevalence of filoviruses and henipaviruses will be assessed as will changes between the two collection timepoints. In **Aim 2**, we will conduct a 36-month longitudinal study of three bat species which are putative reservoirs for EBOV and undescribed henipaviruses. Using a combination of longitudinal serology and molecular testing (PCR and whole genome sequencing) **we will determine the prevalence of filoviruses and henipaviruses in three key bats species associated with the rural human populations studied in Aims 1 and 3.** For **Aim 3**, we will analyze detailed questionnaire data developed collaboratively by our group (EHA and UNC) and collected in 2023 along with blood samples to be screened in Aim 1. These data will allow us to identify behaviors associated with exposure to henipaviruses and filoviruses. We will use results from our behavioral risk assessment to develop public risk reduction communication strategies with the National Public Health Institute, Liberia, using the results of this study to inform public health strategies. This application is a natural progression of our research activities, and our preliminary data speak to the feasibility of the proposed study.

C.2. Aim 1: To determine the rates of filovirus and henipavirus exposure in people in central rural Liberia.

C.2.1. Rationale and Preliminary Data. The primary goal of this aim is to be able to determine whether populations within Liberia who live in association with bats have evidence of exposure against one or multiple filoviruses and/or henipaviruses and to compare rates of exposure over time. Studies of human populations in Central and West Africa have found evidence of exposure to EBOV prior to the 2013 outbreak and in places not known to have had Ebola outbreaks^{37,38}. UNC Project-Liberia has previously assessed seropositivity to consequential viral pathogens including EBOV and MARV in a subset of CEPI ENABLE Study participants. About 10% of participants had antibodies against MARV (Figure 3), suggesting that unreported spillover events have previously occurred. Acute encephalitis is common in western sub-Saharan Africa, yet outbreaks of neurological disease are rarely reported and more than half of all cases are undiagnosed³⁹. Among the countries in western Africa reporting cases of meningitis or encephalitis, Liberia has reported the fewest, likely due to a lack of surveillance and capacity to diagnose neurological diseases³⁹. Nipah

Figure 3

Commented [JE3]: @Billy or @Dave is this right?

virus encephalitis has never been reported in Africa, however, as described above, two Nipah-like henipaviruses have been described in bat hosts, including one in Ghana^{25,27}. Spillover of henipaviruses was reported in bat-hunting communities in Cameroon²⁸. In South Africa, we detected henipavirus sequences in *Rousettus aegyptiacus*, bats which also commonly occur in Liberia²⁶.

In Aim 1, we will test the hypothesis that spillover of both filoviruses and henipaviruses have occurred in rural populations in Liberia by measuring seropositivity to both groups of viruses within the CEPI ENABLE Study community cohort. We will also measure changes in exposure rates over a two-year period. While prior studies have provided cross-sectional snapshots of exposure, our longitudinal approach will provide data from the same cohort at two timepoints, 24 months apart, to determine both seroprevalence and sero-incidence using a multiplexed serological assay to screen for IgG antibodies against all known filoviruses and henipaviruses.

Settings and Participants. To achieve this aim, we will leverage a well characterized cohort of individuals in three rural communities located in Bong County, Liberia (Figure 4), which has a population of over 333,400. UNC Project-Liberia has been operating in Liberia since 2014 and established a research site at Phebe Hospital in Bong County that includes a molecular laboratory that conducts daily qPCR testing for LASV, MARV, and EBOV as well as LASV serological assays using a MAGPIX (SEE RESOURCES AND FACILITIES). There, following extensive community engagement including meetings with key stakeholders, town hall meetings, and radio messaging, UNC launched the CEPI ENABLE Study, the largest passive and active surveillance program for Lassa fever in Liberia. Started in 2020, 5,005 randomly selected participants 2 years of age and older in Phebe Airstrip, Suakoko, and Rubber Factory were enrolled over 6 months following informed consent/assent (mean age at enrollment is 22.2 years (range 2-97) and 54.2% are female). **Importantly, 7.7% of the cohort is under the age of 5 years, and therefore, were born after the 2013-14 Ebola outbreak (Table 1).**

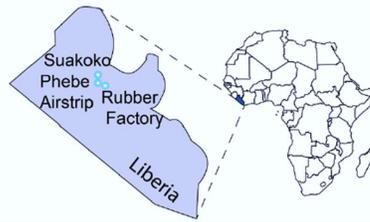

Figure 4. Map of Liberia with Bong County sites shown in inset.

Households were selected for recruitment following identification of roof tops by satellite photos and use of a program developed by Médecins Sans Frontières' (MSF) Epicentre to randomly selected structures to consecutively approach. The ENABLE Study includes baseline questionnaires and blood specimen collection from all participants with active follow-up by a study community health worker every 2 weeks to determine if a febrile event has occurred, which triggers drawing of blood for LASV, MARV, and EBOV PCR. A subset of 1,024 individuals is also asked to provide blood samples routinely every 6 months for up to 24 months. The blood samples from 0 and 24 months and the associated surveys will be used in Aims 1 and 3 of this proposal. Informed consent and assent documents include provisions for the use of collected specimens and data for infectious diseases research including for emerging pathogens (see PROTECTION OF HUMAN SUBJECTS).

C.2.2. Research Design. We will screen approximately **1,900 archived serum specimens** from participants in the ENABLE Study cohort at two time points ("baseline" [(Month 0)] and [(Month 24)]) for IgG antibodies against specific filoviruses and henipaviruses using the MAGPIX at the UNC molecular lab at Phebe hospital to run the multiplexed *henipavirus / filovirus* platform to be provided by Co-I Laing in year 1. The multiplex platform will allow us to determine specifically which filoviruses and henipaviruses people have been exposed to and compare that to the filoviruses and antibodies we observe circulating in local bat populations in **Aim 2**. The bead-based multiplexed assay has tremendous advantage over traditional ELISAs in that it will identify up to 25 different antibodies against multiple viral agents in a single, 2 μ l serum sample and uses a high through-put format. The ability to look at reactivity across all serogroups simultaneously will allow us to differentiate among the viruses. Proteins A/G non-specifically bind IgG immunoglobulins, and weakly bind IgM, an immunoglobulin that is the first to be produced during the initial stages of infection. We will conduct a 1-week training at the UNC-Phebe lab for using the assay to detect filovirus and henipavirus antibodies as well as data management, bioinformatics, and analysis. **Table 3** shows the viral species and antigens that will be employed in this assay. The platform has

Formatted: Font: 11 pt

Formatted: Indent: First line: 0"

Commented [JE4]: @Billy is this right?

been previously transferred to collaborating labs in the UK, South Africa, India, Bangladesh, Singapore, Thailand, and Malaysia. We have previously detected serological profiles of Asiatic ebolaviruses in fruit bats collected in Singapore⁴⁰ and in fruits bats and humans actively engaged in bat hunting in northeast India³⁶.

Commented [MK5]: Feels odd to just have a number here. Add "Cuevavirus" in front of the number? [Cuevavirus 86]

C.2.3. Data Analysis. We will create a project database using Airtable, which will be hosted at EHA and will house all data from Aims 1 and 2 and will link to the RedCap server which stores questionnaire data from Aim

Commented [MK6]: Would advocate dropping the box from the caption

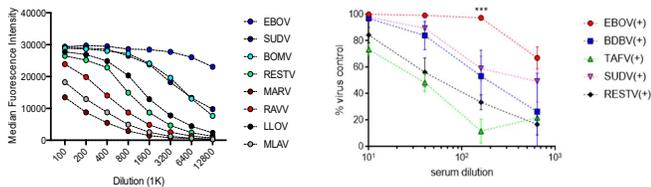

Figure 5. shows relative mean fluorescence index (MFI) values for an EBOV +ive control sera across serial dilutions. While there is cross reactivity, the EBOV MFI values are consistently greater than the other viral GPs and at higher dilutions the separation becomes significant.

3. Database access will be secure and limited to key personnel (see data management plan). Raw MFI values from the MAGPIX will be used to calculate reactivity to each viral antigen and based on relative strength of reactivity (Fig 5) and determinations of negative cutoffs based on

reference sera, we will calculate prevalence rates for each time point and compare rates between the two timepoints. Serological profiling can be used to detect reactive antibodies against all specific filoviruses and henipaviruses in a samples and compare strength of reactivity and cross-reactivity against multiple antigens using a single sample⁴¹. We will compare the antibodies across all specific viral antigens to assess which virus or groups of viruses are responsible for the immunological response⁴²⁻⁴⁴. We will assess exposure to non-Zaire ebolavirus species, which may indicate spillover of filoviruses has occurred separate to the Ebola outbreak of 2013. We will also look at evidence for exposure to Nipah-like henipaviruses and compare exposure rates to both viral groups within and between our two sample collection time points.

C.2.4. Expected outcomes. We anticipate obtaining serological profiles of exposure to filoviruses and henipaviruses from each individual in our cohort. In previous studies we found antibodies against both Ebola and Marburg virus. While the Ebola antibodies are attributable to the epidemic, Marburg antibodies, in

Commented [MK7]: I get the purpose of this structure, but the variety in how new sections start (left justify with a paragraph break or tabbed without a paragraph break) despite equivalent nestedness (e.g., C.2.3. vs C.2.4) is moderately noticeable to me

patients EBOV IgG negative, suggest possible exposure from an animal (e.g., bat) reservoir. We also anticipate seeing reactivity to Bombali virus (BOMV), given the presence of the reservoir species in Liberia (*Mops condylurus*) and reactivity to the African henipaviruses (GhV and AngV), although this may represent reactivity to an antigenically related virus. Serological results from this and the bat study will inform our strategy for prioritizing which bat samples we test by PCR.

C.2.5. Potential problems and solutions. -While our preliminary data suggest there will be detection of immune responses to filoviruses including EBOV-Zaire and, significantly, MARV, it is possible that evidence of exposure to other pathogens, including henipaviruses will not be detected. This would be an important finding in this large cohort, especially if these viruses are detected in local bat species, that would warrant further investigation. It is also possible that there will be few or no seroconversion events among the cohort during the 24-month period of follow-up. This too would be reassuring but would suggest a need for longer follow-up

of this cohort. To address the possibility that reactivity to EBOV-Zaire virus may be explained by infection during the 2013 Ebola epidemic, we will create a polyclonal sera reference standard utilizing convalescent sera collected from human survivors of EVD. This internal reference standard will be calibrated to the WHO EBOV human serology standard (Fig 6A) permitting direct interpolation of anti-EBOV IgG as an MFI to a standard antibody concentration (binding antibody units/mL). The internal reference standard will then be included in our human serology testing strategy allowing semi- or quantitative measurement of anti-EBOV IgG. These EBOV human serology standards will permit us to establish positive and negative predictive performance values for the multiplex assay, furthermore, we will be able to

Commented [MK8]: A and B were hidden

Formatted: Font: Bold

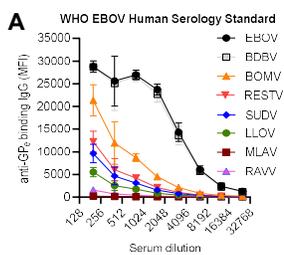

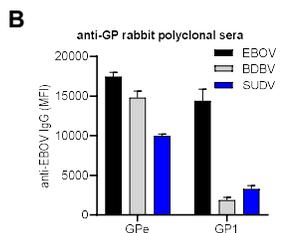

Figure 6A & B. A) The WHO EBOV human serology standard was testing for immunoreactivity in a filovirid GP-trimer based multiplex assay. Filovirids are indicated along with sera dilution factors; data is the mean of three independent experiments. **B)** Antisera from EBOV GP-trimer immunized rabbits were tested in multiplex panels comprised of GP-trimer and GP1 subunit proteins. Anti-EBOV polyclonal IgG was less reactive with GP1 from BDBV and SUDV.

investigate immunoreactivity of EVD survivors against heterotypic ebolaviruses. Our preliminary data indicates that EBOV+ sera IgG is highly cross-reactive with soluble native-like trimeric envelope glycoprotein (GP) antigens from both EBOV and BDBV (Figure 6A). EBOV GP, matrix protein (VP40), and nucleocapsid protein (NP) antigens have all been used in a variety of serological tests, however, the frequency of seroconversion against each antigen has not been fully described. In a longitudinal study of EVD survivors, high seroconversion against GP and VP40 was observed, with affinity maturation occurring overtime against GP⁴⁵. Antigens based on the GP are likely to provide an optimal intrinsic balance of sensitivity and specificity. To limit the degree of heterotypic ebolavirus cross reactions we will test any anti-ebolavirus GP trimer antigen-seropositive samples with a pan-ebolavirus GP1 antigen-based panel. In preliminary studies, GP1 antigens improve specificity and differentiation of antibodies reactive with homotypic ebolaviruses in polyclonal antisera from rabbits immunized with GP trimer immunogens (Figure 6B).

C.3. Aim 2. To identify reservoirs and characterize the infection dynamics of filoviruses and henipaviruses in key bat species in Liberia.

C.3.1 Rationale and preliminary data. Bats have been established as important hosts for filoviruses and henipaviruses in Africa and Asia, with combinations of viral isolation, molecular detection or serology providing substantial evidence^{30,46-49}. MARV was isolated from Egyptian rousette bats in Uganda, and RNA has since been detected in these bats in Sierra Leone, which borders Liberia⁵⁰. To date, EBOV has never been isolated from bats, although molecular and serological evidence suggest that multiple frugivorous bats may carry EBOV in Central Africa^{50,51}. Prior to the 2014 epidemic, Zaire ebolavirus had not been reported in West Africa, and the animal reservoir remains unknown³². From 2016-2019, our group (PI Epstein & KP Desmond) implemented a large-scale project to identify reservoirs for EBOV in West Africa, under the USAID PREDICT Project⁵². This effort led to the discovery of a new species of Ebola (Bombali virus)⁵³, the detection of MARV in ERBs in Sierra Leone³³, and in 2018, we detected, for the first time in West Africa, EBOV RNA and anti-EBOV IgG antibodies in bats (Figure 7A-D).

Formatted: Font: Bold

While this finding generated the first evidence of which bats

may be reservoirs for Zaire ebolavirus, longitudinal studies are required to more completely understand the role these species play in EBOV circulation— either as reservoirs that maintain the virus within a local population, or as incidental hosts, infected by an unknown bat species. One-off, cross-sectional studies have a low probability of detecting any specific filovirus or henipavirus given their low prevalence and short viremic periods^{34,54}, and thus provide a poor characterization of viral diversity. The lack of understanding of **filovirus and henipavirus diversity and their natural reservoirs in West Africa significantly impedes risk-based public health interventions to prevent human outbreaks**. Longitudinal sampling is also needed to separate reservoir hosts from spillover hosts. For example, MARV has been isolated repeatedly from *R. aegyptiacus* in Uganda, which, when paired with experimental infection studies showing infection and shedding of MARV by *R. aegyptiacus*, strongly suggests that *R. aegyptiacus* is indeed a Marburg virus reservoir^{35,55,56}. Similarly, our longitudinal studies of Nipah virus in *Pteropus medius* bats in Bangladesh, which included the same multiplexed serological assay proposed here, confirmed them as a reservoir for NIV and identified important mechanisms driving viral circulation²⁹. **Understanding which species persistently carry filoviruses and henipaviruses will provide important insights into how they are maintained in nature and what species should be targeted for follow-up studies on bat habitat use and human-bat contact patterns.**

C.3.2. Sampling design. We will repeatedly sample three bat species associated with filoviruses or henipaviruses, based on our preliminary data: *M. nimbae* (EBOV), *H. ruber* (EBOV), and *R. aegyptiacus* (MARV & Henipaviruses). We will sample bats at roost sites in Bong county, as close as possible to the human study sites in Aim 1. In Y2-Y4, we will sample 40 individuals of each species every two months for 36 months and collect excreta using plastic tarps placed underneath bat roosts (details below and in C.3.3).

Bat capture and sampling. Briefly, we will use either harp traps or mist nets to capture bats, depending on the capture site. Personnel will wear appropriate personal protective equipment (e.g., Tyvek suits or dedicated long clothing; double nitrile gloves; an N95 respirator and safety glasses or a PAPR)⁵⁷. Traps and nets will be attended continuously during capture periods. Bats will be removed from mist nets immediately upon entanglement to avoid injury. Bats will be removed from harp traps after approximately 1 hour and ~~bats will be~~ placed in individual cloth bags until processed. Body measurements, blood, oropharyngeal swabs, and rectal swabs (or fecal pellets) will be collected from each bat. Swabs will be collected in duplicate; one swab will be placed in a cryovial containing Trizol lysis buffer and the other in viral transport medium (VTM). For bats <50g, blood will be collected in a microhematocrit tube and spun down using a portable centrifuge. A bulb will be used to expel serum from the tube into a cryovial. For larger bats >50g, a tuberculin syringe or 1ml syringe and 27g needle will be used to draw blood from the radial artery or vein⁵⁷. Blood will be placed into a conical vial and centrifuged. Serum will be aliquoted into a cryovial using a pipette. During site visits we will also lay out plastic tarps to collect pooled environmental excreta in Trizol and VTM to improve opportunity to detect viral RNA. All samples will be placed in a vapor phase liquid nitrogen dry shipper or portable battery-powered ultracold freezer, immediately upon collection and then transferred to a -80C freezer at the Phebe lab until testing.

C.3.3. Testing plan, Data analysis, sample size, and power analysis.

Serology: At the end of Y3, we will screen all serum samples collected to date using the **MAGPIX** multiplex assay for IgG against filoviruses and henipaviruses. We will analyze temporal dynamics in seroprevalence using general additive models (GAMs), which are analyses that we have used successfully in many previous studies of similar design²⁹. These methods are well adapted for capturing long-term temporal fluctuations in prevalence and moderately sensitive at capturing short-term changes in seroprevalence which can be used to identify population-level disease outbreaks. For example, we estimated that with 40 bats sampled every two months, we would be able to statistically detect an increase in seroprevalence (at a 95% CI limit) of greater than 25% between consecutive sampling events > 80% of the time, assuming a bat population seroprevalence of at least 10% in advance of a bat colony infection (estimated by, in brief, by simulating a fluctuating true seroprevalence value, simulating samples given this underlying seroprevalence, fitting a GAM to these samples, and then calculating if CI on true prevalence between the two sampling occasions over which the change in seroprevalence occurred were non-overlapping). While this is a large change, it is within a range to

Commented [MK9]: I think Eric made some comment about this phrasing? Maybe I am misremembering the specific context...

Formatted: Indent: First line: 0"

be expected if infection were to sweep through a bat community²⁹. MAGPIX-positive bat sera will be sent to RML for serum neutralization assays using viral isolates or VSV pseudoviruses under BSL4 conditions.

VSV-pseudotype neutralization assays: Serological results will be confirmed using VSV-pseudotype neutralization assays for the following filoviruses EBOV, SUDV, BDBV, RETV, BOMV, MARV and RAVN. If novel henipavirus sequences are detected, additional assays will be developed to test positive sera. Serum samples will be inactivated using γ -irradiation (4 MRad). Neutralization of irradiated and heat-inactivated serum samples will be assessed in Vero 352 E6 cells. Briefly, cells were seeded in 96-well round-bottom plates for 24 hours, serial dilutions of heat-inactivated serum samples will be performed in DMEM supplemented with 2% FBS, penicillin/streptomycin, and L-glutamine. Each plate will contain negative serum control, cell-only control, and virus-only control. VSV EBOV-GFP will be added to each well of the serum dilution plate and the serum-virus mix 357 was incubated at 37°C for 1-hour. The mix was added to the cells and incubated at 37°C for 24 hours. The cells will then fixed with 4% paraformaldehyde at room temperature 359 for 15-minutes and centrifuged at 600 x g for 5-minutes at room temperature. The supernatant will be discarded and FACS+EDTA buffer was added. Samples will be run on the FACSymphony A5 Cell Analyzer (BD Biosciences, Mississauga, ON, Canada) and FITC MFI 362 was measured. Data will be analyzed using FlowJo.

Formatted: Font: No underline, Font color: Black

Molecular testing: We will use specific filovirus taqman real-time PCR assays to screen oropharyngeal, fecal and environmental samples from bats for EBOV and MARV RNA at the UNC-Phebe lab^{55,58}. Testing bat samples by PCR may allow us to detect viral RNA during active infection, providing important information about the prevalence and timing of infection within target species. **Because we expect viral prevalence to be significantly lower than seroprevalence, estimated at <5%^{25,27,49}**, we developed a sampling scheme focused on maximizing our probability of detecting viral RNA with qPCR. To compare power under alternative sampling designs, we built simulation-based power analyses that estimated power to detect: 1) viral EBOV or MARV RNA in at least one bat; and 2) the expected number of positive cases, in each bat species. In brief, we estimated power for total sample sizes between 1500-3000 (between 500 and 1000 bats sampled per species) spread across a variable number of visits per year (2-6), while allowing for uncertainty in true infection dynamics in the bat populations, specifically: 1) prevalence during one three-week period (with unknown timing) per year of high prevalence ranging from 1-5%); and 2) an otherwise low background prevalence (0-1%). Given these estimates of yearly infection dynamics, these analyses showed that with 672 samples per species (minimum 32 individual bats per sampling event), spread across 6 sampling occasions per year, we would obtain a per-species probability of acquiring 0 positive samples of <4% (<1% at 40 bats per event – our target number) and an expectation of ~3-6 RNA positive results (~5-10 positives at 40 bats per event). Because henipaviruses have not been previously described in Liberia, we will focus our resources on filovirus testing by PCR. –However, if henipavirus serology suggests active circulation, we may send a set of samples to RML for pathogen discovery (see RML letter of support).

Commented [MK10]: Just trying to get a bit more consistency among equivalently nested sections

Formatted: Underline

Viral isolation: PCR-positive cDNA samples and their aliquot in VTM will be sent to RML for further sequencing and attempts at viral isolation under BSL4 conditions. If attempts to culture do not work, we will use next generation sequencing techniques to get whole genome sequence and further characterize the virus at RML. Novel viruses will be characterized and rescued (reverse engineered using a minigenome system to synthetically create infectious viral particles⁵⁹) at RML under secure, biosafety level 4 conditions, then used for serum neutralization assays in bat and human sera to determine more precise exposure rates. –Sequences from the glycoproteins of any novel viruses discovered will be used by USU (Co-I Laing) to generate purified proteins and added to the Luminex assay, which will improve its specificity.

Commented [MK11]: Same comment about consistency (compared to above section on "serology"). Maybe this bothers others much less :)

VirCapSeq-VERT and myBaits probe-based enrichment for recovery of full-length genome sequences of filoviruses: Although shotgun sequencing provides opportunities to analyze all host and virus genetic material, the larger average genome size of bacteria and hosts compared to viral genomes complicates a detailed analysis of the virome, particularly vertebrate viruses. We have established a positive selection probe capture-

Formatted: Indent: First line: 0.5"

based system to enrich for viral sequences. Here, we will take advantage of these probe capture-based methods (VirCapSeq-VERT and myBaits probe library) to enrich for vertebrate viral sequences of interest. Sample libraries will be normalized and combined in 4- to 12-plex reactions for solution capture hybridization using either the HyperExplore custom bait library version of VirCapSeq-VERT probe set or our custom myBaits probe library. For HyperExplore custom bait library probe set, libraries will be enriched for virus following the SeqCap EZ HyperCap Workflow User's Guide, version 2.3, while for custom myBaits probe library, the myBaits Hybridization Capture for Targeted NGS protocol, Version 4.01 will be used. Sequencing libraries will be normalized and sequenced as 2 X 150 bp fragments on Illumina's MiSeq or NextSeq sequencing platforms, following Illumina's standard procedure (Illumina, San Diego, CA). NGS data will be analyzed using metavirs (<https://openomics.github.io/metavirs/>), a comprehensive viral metagenomics pipeline to assemble, annotate, and classify viruses. It relies on technologies like Singularity1 to maintain the highest-level of reproducibility. The pipeline consists of a series of data processing and quality-control steps orchestrated by Snakemake2, a flexible and scalable workflow management system, to submit jobs to a cluster. The pipeline is compatible with data generated from Illumina short-read sequencing technologies. As input, it accepts a set of FastQ files and will be run on-premises using the NIAID RML Big Sky supercomputing cluster.

C.3.5. Expected outcomes. -Based on our prior work, our multifaceted analysis approach, and calculated power given our proposed temporal sampling strategy, we expect to be able to use temporal serological data to describe filovirus and henipavirus viral dynamics over time. Our molecular screening will primarily focus on filoviruses because we have known targets, and we expect to detect EBOV or MARV RNA, despite low prevalence and short-lived infections. Sequence data from positive samples will 1) provide substantial evidence for the identification of EBOV reservoirs and help explain which virus is responsible for the observed IgG response in bats (and possibly people); and 2) provide valuable information about viral diversity, about which little is known. Henipavirus serology, in the absence of sequence data, will allow us to identify potential bat reservoirs, analyze temporal trends, and generate hypotheses for future targeted studies.

C.3.6. Potential problems and solutions.

Serological tests are greatly hindered by the inherent antibody cross-reactivity between antigens from known ebolaviruses, challenging data interpretations that antibodies are EBOV-specific or EBOV, BDBV, and SUDV cross-reactive⁴⁰. This is also true for the henipaviruses in the panel. The advantage of the multiplexed platform is that we can simultaneously see relative MFI values for all the filoviruses and henipaviruses.

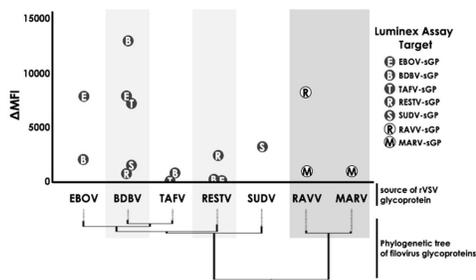

Figure 8. Captive-bred ERBs were experimentally challenged with VSV-filoGPs, the GP source is indicated on the x-axis. In a GP-trimer multiplex test the homotypic ebolavirus bat antisera were most reactive with the homotypic ebolavirus GP-trimer antigen.

from the homologous virus should cause the most intense reaction, particularly at higher dilutions. Co-Is Laing and Munster have demonstrated that homotypic and heterotypic ebolavirus-antibody reactions can be simultaneously measured and accounted for in ERBs challenged with replication-competent VSV-filoGP (**Figure 8**). Still, there is some cross reactivity, and we will use additional tools such as viral neutralization assays as a secondary test, and our statistical approach can correct for a portion of cross reactivity. Past studies have relied on individual ELISAs which had varying degrees of specificity depending on which test was used, but often couldn't rule out cross-reactivity. The Luminex filovirus multiplex assay has predictable patterns of cross-reactivity, but we will still be able to discern to which virus the serum is most reactive.

C4. Aim 3: To characterize behaviors associated with exposure to filoviruses and henipaviruses.

C.4.1 Background and rationale. As described above, there is substantial interaction between wildlife, domestic animals, and people living in rural Liberia. -Our group collected questionnaire data from 585 people across Liberia as part of the USAID-funded Ebola Host Project between 2016 and 2019. -When asked about animal exposures during the 2013-2016 Ebola outbreak, participants frequently reported contact with both domestic and wild animals. Common types of animal contact included animals coming inside the dwelling (58%), cooking or handling animal meat (44%), and eating raw or undercooked meat (31%). Additionally, 26% reported slaughtering and 12% reported hunting or trapping an animal. In the ENABLE Study of 5,005 residents of Bong County, survey questions mainly focused on rodent exposures relevant to Lassa fever, but 12% of participants reported hunting or preparing wild animal meat. Little is known about the prevalence and type of other potential bat exposures in this region of Liberia. Elsewhere in West Africa, EcoHealth Alliance participated in the response to Ghana's 2022 cluster of MARV cases, working with local partners to administer a behavioral risk questionnaire characterizing bat exposures in three affected communities¹⁶. Many participants lived in close proximity to bats, with one fifth reported exposure to bats inside a dwelling or other building in the previous four months. When asked about exposures more relevant to Egyptian Rousette bats, a known MARV reservoir and a target species in this proposed study, participants commonly reported bats feeding on fruit trees on their home compound, eating fruit bearing bite marks, and exposure to bats inside a cave or mine.

C.4.2. Research design. As described in Aim 1, serum collected at baseline (in 2021) and at month 24 (in 2023) during the ENABLE Study will be screened for filoviruses and henipaviruses, enabling us to calculate seroprevalence at baseline and seroconversion over a two-year period. In addition to providing blood specimens, the 1,024 participants who initially enrolled responded to baseline questionnaires on demographics, healthcare-seeking behaviors, health status, and animal exposures. At month 24, the 921 participants still actively enrolled are administered repeat questionnaires. This final survey includes additional items based on the Ghanaian questionnaire and asks specifically about bats including the respondents' activities in their habitats (entering forests, caves, and mines), direct contact (hunting, eating handling), indirect contact (presence in home or other used structure), and observed characteristics of bats encountered (fruit tree dwelling). By pairing this existing survey data with the new serology results generated from archived samples under Aim 1, as well as new data on nearby bat infection from Aim 2, we will be able to develop comprehensive risk profiles for exposure to filoviruses and henipaviruses in this community.

C.4.3. Data analysis. The primary outcome for this analysis will be testing positive for IgG antibodies against any known filoviruses or henipaviruses. For both families of viruses, and for each species of virus within those families, we will use the serology results generated under Aim 1 to examine risk factors for seropositivity at baseline and seroconversion between baseline and month 24. We plan to conduct a multivariate logistic regression, with appropriate weights applied to account for the single-stage cluster sampling design of the ENABLE Study, in which members of randomly selected households were surveyed and tested. We will use data from both the baseline and month 24 questionnaires to examine the effects of sampling site, participant demographics (e.g., age, gender, occupation), environmental exposures (e.g., animals present in and around the dwelling), and behavioral risks (e.g., direct contact with bats through hunting, preparing, or eating them, entering caves or mines where bats live).

Power analysis: To assess our power to identify risk metrics for seroconversion (or overall seropositivity), we built simulation-based power analyses that consisted of, in brief: 1) simulating survey responses for N (400-1000) individuals, while allowing for moderate unevenness in representation across five binary categories (as **largegreat** as 80%-20,% for **eachexample**); 2) examining a range of effect sizes (odds ratios ranging from 1-2.5) for these five binary categorical predictors (e.g., sex, encountered a bat, handled a bat, etc.). Summarizing across 1,200 simulations of surveys of 400-1000 individuals given joint uncertainty in the representation within these surveys and effect sizes, we estimated that we would have at least 80% power

Formatted: Indent: First line: 0.5"

to detect significant effects for each predictor given an odds ratio of 1.65 or greater with 1,000 survey responses or ~1.80 (for example, with a rate just under 5% for Group1 = 0, just over 8% for Group1 = 1) -with 750 responses.

C.4.4. Expected outcomes. By combining serology results with detailed questionnaire data on participant demographics and animal exposures, we will be able to use odds ratios to identify behaviors significantly associated with seropositivity (e.g., exposure to filoviruses or henipaviruses). We expect to be able to also identify age and gender-based risk factors given our sample size. Based on previous experience conducting behavioral risk surveys, including a recent study in Ghana following a Marburg outbreak, we expect to be able to develop risk mitigation messaging that uses evidence from Aims 1 and 2 as well as results from this aim.

C.4.5. Potential problems and solutions. We anticipate that most IgG positive individuals for either set of viruses will be adults, with the likelihood of exposure and having antibodies increasing with age. Because we don't know how long IgG antibodies persist at detectable levels, it will not be possible to accurately determine when exposure occurred, with the exception being EBOV antibodies that most likely occurred as a result of contact with another infected person during the 2014-2016 outbreak. We will address this in two ways: by looking at respondents 1-6 yrs old, we will know that any filovirus antibodies they have are most likely not due to the epidemic, and we will be able to determine whether there are any significant associations with particular behavior that promotes direct animal contact, consumption of contaminated fruit, or exposure to bat habitats (e.g. caves or mines). For adult respondents, we will focus on exposures (based on relative MFI values) specific to non-EBOV filoviruses and henipaviruses and see whether there are associations with specific behaviors.

D. Summary and Conclusions.

West Africa is a hotspot for emerging zoonotic viruses such as Ebola, Marburg and potentially Nipah-related henipaviruses – groups that have been identified by WHO as among the most significant pathogens that threaten global health. Liberia is also a biodiversity hotspot, with some of the largest tracts of primary forest remaining in the region, and its population relies on wildlife as a primary source of protein, creating continued risk of spillover of high consequence zoonotic pathogens. This project has the potential to determine the origins of Zaire ebolavirus in West Africa, characterize the circulation of Ebola and other filoviruses and henipaviruses in common bat species, identify background rates of spillover in rural human populations, and identify high-risk behaviors associated with exposure to these bat-borne zoonoses. Our group comprises an unparalleled multidisciplinary group of leading experts in epidemiology, clinical medicine, virology, serology, and disease ecology all with deep experience working in Liberia and implementing zoonotic virus research, giving this project a high chance of success in generating impactful results that will help prevent future epidemics in West Africa.

Jon,

Minor edits and tidying throughout + a few comments. Happy to go through v8 tomorrow morning (if you would like me to) to conduct any needed cleanup that slips through (you will see the sort of thing I am talking about when you open the document).

Subject: Complete draft 7 for rapid review

Hi all,

I've compiled a near final draft, incorporating the text you each provided and then cutting it down to fit within the 13 page (1 page specific aims and 12 page research strategy) limit. Thank you all for excellent contributions to this. I'm sure it's not perfect, but I think it's solid.

If you're able to go through it today and check it for overall readability and accuracy where you have preliminary data, that would be fantastic. Please do use track changes and change the file name to add your initials when you edit, and please do not add too much text, as there's not much space at the end.

I do think Aim 3 might be a little thin, so if Shannon, Dave and Billy could look through

that and see if you think it's missing anything, there's space for a few extra lines there.

Please return your edits to me by 7pm, if possible, so I can finalize the draft. Our plan is to submit at noon tomorrow and deal with any errors that may pop up.

While you're reviewing this, I'll work on the summary and narrative, and other peripheral pieces.

Thanks again. We're in the home stretch!

Cheers,
Jon

A. Personal Statement

The spillover of zoonotic viruses into human populations remains an ever-prevalent threat to public and global health. Continual outbreaks of known and unknown zoonotic viruses highlights the paucity of our understanding of the viral diversity, geographic distribution, wildlife hosts, and human populations at-risk for spillover. I am a recently appointed assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses. I have completed virological training and spent my time as a post-doctoral fellow applying *in vitro* techniques to characterize the replication and mammalian ephrin receptors that mediate cellular entry of emergent henipaviruses. Since the start of the COVID-19 pandemic, I pivoted the focus of my research team to serological analysis of SARS-CoV-2 infection, and then to COVID-19 vaccine-induced antibody durability. In my ongoing research, I develop serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Since my position as a postdoctoral fellow I have worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs. Across all of these international collaborations, we have aimed to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence. Throughout these research projects, we have detected unexpected serological profiles in communities of bats and humans that have not fit our prior understanding of the viral diversity established or detected by genetic techniques. This proposal aims to better understand these serological profiles of wildlife and humans with a targeted focus on henipaviruses and filoviruses. Ongoing projects that I would like to highlight include:

B. Positions, Scientific Appointments and Honors

Positions

- 2021-pres. Assistant Professor, Department of Microbiology and Immunology, School of Medicine, Uniformed Services University, Bethesda, MD.
- 2021-pres. Joint Appointment, Emerging Infectious Diseases Graduate Program, School of Medicine, Uniformed Services University, Bethesda, MD.

- 2019-21 Research Assistant Professor, Department of Microbiology and Immunology, Uniformed Services University, Bethesda, MD.
- 2016-19 Postdoctoral fellow, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD.
- 2010-16 Graduate research student, Department of Microbiology, Uniformed Services University, Bethesda, MD.

Other Experiences and Professional Memberships

- 2022-pres. Executive committee member, Emerging Infectious Diseases Graduate Program, USUHS
- 2021-pres. Research center representative, Laboratory Assays Oversight and Quality Working Group, Emerging Infectious Diseases: Southeast Asia Research Collaboration Hub (EID-SEARCH), Centers for Research in Emerging Infectious Diseases (CREID), NIAID, DMID, NIH
- 2021-pres. Review editor, *Frontiers in Virology - Emerging and Reemerging Viruses*
- 2021-pres. Ad hoc reviewer, *Frontiers in Immunology*, *Journal of Clinical Immunology*
- 2021-pres. Steering committee member, JPI/Military Infectious Diseases Research Program, Emerging Infectious Diseases
- 2019 Ad hoc reviewer, EcoHealthNet 2.0 Program, EcoHealth Alliance
- 2018 Ad hoc reviewer, Pakistan One-Health Fellowship Program, National Academy of Sciences & Pakistan Academy of Sciences
- 2014-2019 Member, American Society of Tropical Medicine and Hygiene
- 2014-2019 Member, American Society of Microbiology
- 2014-2019 Volunteer, AAAS STEM K-12 Volunteer Program

Mentoring

- Postdoctoral fellows* Si'Ana A. Coggins, PhD, 2020 - 2022
- Graduate students* Marana S. Tso, BS, 2021 -
McKenna Roe, BS, 2022 -
- Committee member* Celeste Huaman, BS, 2021 -
2LT Connor Perry, BS, 2021 -

Honors

- 2021-2022 Impact Award, USUHS School of Medicine
- 2021 Outstanding Research Accomplishment/Team/SARS-CoV-2, The EPICC COVID-19 Cohort Team, Military Health System Research Symposium
- 2020-2021 Impact Award, USUHS School of Medicine
- 2015-2016 Val G. Hemming Fellowship, Henry M. Jackson Foundation
- 2015 East Asia and Pacific Summer Institutes Fellowship, National Science Foundation

C. Contributions to Science

1. Lyssaviruses and the prototype, rabies virus, remain a public health concern. Beginning with my PhD thesis work, I've researched the virus host-interactions between a rabies-related lyssavirus, Australian bat lyssavirus (ABLV), and its bat host (*Pteropus alecto*). Research has focused on ABLV cellular entry mechanisms, the development of an animal model and ABLV reporters and exploration of novel monoclonal antibodies that neutralize ABLV and other phylogroup I lyssaviruses. Furthermore, comparative bat immunology research was conducted using black flying fox cell lines and ABLV as a model virus/host interaction. Physiological adaptations that accompanied the evolution of flight in bats have been proposed to contribute to the frequent role of bats as asymptomatic hosts of highly pathogenic zoonotic viruses. Comparatively studying the autophagy pathway in bat cell lines revealed that bat cells had elevated levels of basal autophagy and experienced significantly less cell death when challenged with high virus doses.

PMID: 33804519; PMCID: PMC8001737.

2. My research experience as a postdoctoral fellow furthered my training in molecular virology techniques. I constructed a recombinant Cedar virus cDNA plasmid and optimized a reverse genetics approach to rescue a recombinant Cedar virus reporter virus, a non-pathogenic *Henipavirus* species. A molecular biology methods chapter detailing recombinant Cedar virus reverse genetics has been submitted and in press. Using this recombinant Cedar virus, we determined that Cedar virus can utilize several non-canonical henipavirus ephrin receptors for cellular entry and explored the structure of the receptor-binding pocket to understand the receptor promiscuity. The non-pathogenic phenotype of CedV creates a potential for CedV to act as a model henipavirus to explore host-pathogen interactions, cellular tropism and factors that determine henipaviral disease pathogenesis. Additionally, I have collaborated on projects detailing henipavirus infection and replication in bat hosts with colleagues at the Rocky Mountain Labs, studying whether specific species of bats are more competent hosts and whether virus-host restriction exists.

3. Bats are increasingly identified as animal reservoirs of emerging zoonotic viruses (e.g. Nipah virus, Ebola virus and SARS-coronavirus). I lead collaborative biosurveillance and research preparedness training including data analysis and interpretations at international partner institutes with lab technicians, field and lab scientists, and masters, doctoral and postdoctoral trainees. Collaborative biosurveillance is presently underway in Thailand (Chulalongkorn University, Bangkok) Malaysia (National Wildlife and Forensic Lab, Universti Putra Malaysi, National Public Health Lab) via NIH Centers for Research in Emerging Infectious Diseases, EID-Southeast Asia Research Collaborative Hub. As a collaborator within the DARPA PREEMPT network I supported surveillance for coronaviruses and other priority emerging zoonotic viruses, henipaviruses and filoviruses, in Ghana (Zoological Society of London), Australia (Black Mountain Labs) and Bangladesh (icddr,b). We aim to characterize the geographic distribution of zoonotic filoviruses/henipaviruses/coronaviruses, transmission dynamics in wildlife hosts and generate risk-models for Ebola virus, Nipah virus and SARS-related CoV outbreaks. Results discovered so far suggest a wider

geographical footprint of Asiatic filoviruses and have identified several fruit bat species that act as natural reservoirs for these viruses.

4. Responding to the emergence of SARS-CoV-2, our lab developed multiplex serology strategies to identify SARS-CoV-2 antibodies and address research questions related to whether pre-existing antibody memory induced by prior infection with seasonal human coronaviruses affects COVID-19 severity. Our lab's serology efforts supported NIH and DHA collaboratively funded protocols including prospective, longitudinal serological analysis of hospital and community subjects, and health-care workers; and cross-sectional analyses of SARS-CoV-2 infection among deployed military health-care workers.

5. In addition to providing serologic assessment of SARS-CoV-2 infection, my research team is actively engaged in examining the durability of COVID-19 vaccine induced humoral immunity. Antibody responses, particularly neutralizing antibodies, are frequently cited as a predictive correlate of protection. With the emergence of variants of concern and waning circulating antibodies, the timing of booster shots remains an important measure for controlling the pandemic. In my lab we evaluate the duration of neutralizing antibodies, durability and breadth of antibody responses against emerging variants of concern, hybrid immune responses, and post-vaccination infections.

BUDGET JUSTIFICATION

The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (HJF) in partnership with the Uniformed Services University of the Health Sciences (USUHS) will manage this proposal, if awarded.

Personnel

Key Personnel:

Eric Laing, Ph.D., Multi-Principal Investigator (.96 calendar month; 8% effort). Dr. Laing will be responsible for the overall coordination of this project. Dr. Laing will oversee the lab activities pertaining to the production of recombinant virus protein antigens and the establishment of serological profile standards. Dr. Laing will provide mentorship to graduate students and assist with data analysis. He will provide the necessary concepts and practice of viral glycoprotein antigen preparation for serological application to co-investigators and collaborators. Dr. Laing will also provide the virological and immunological expertise necessary to understand the serological profiles of control animal and wildlife antisera. Dr. Laing will be a government employee and no salary support is requested.

Other Personnel:

Dr. Si'Ana Coggins, PhD, Scientist (6 calendar months; 50% effort, YR1-5). Dr. Coggins will assist with the supervision of all lab activities at USU. As trained biochemist Dr. Coggins will oversee all protein expression and maintain the quality and rigor of the research. Dr. Coggins will work closely with the research assistant, Mr. Lucas, and graduate student, Ms. Roe, to execute the lab experiments described in the grant application. Dr. Coggins is an employee of the Henry M. Jackson Foundation and salary support is requested for year 1-5.

Ms. Marana Tso, BS, Doctoral Candidate (1.8 calendar months; 15% effort, YR1-2). Ms. Tso will assist statistical serological analysis and the development of multidimensional spatial models. Ms. Tso will be an employee of the Henry M. Jackson Foundation and salary support is requested for year 1-2.

Ms. McKenna Roe, BS, Doctoral Student (3 calendar months; 25% effort, YR2-3). Ms. Roe will conduct the *in vitro* experiments outlined in aim 1 of the grant application. Ms. Roe participate in serology statistical analysis and contribute to the development of the *in silico* tools for analysis in aims 2 and 3. Ms. Roe will be an employee of the Henry M. Jackson Foundation and salary support is requested for year 2-3.

Mr. Brendan Lucas, BS, Res Asst I (6 calendar months; 50% effort, YR1-2; 12 calendar months; 100% effort YR3-4). Mr. Lucas will assist Dr. Coggins in the production of soluble glycoproteins and be responsible for microsphere coupling in YR1-5. Mr. Lucas will participate in serological testing rabbit immunization antisera, and assist Ms. McKenna Roe in antigenic cartography and testing of hammer-headed fruit bat and Madagascan rousette sera in YR1-3. He will also prepare shipments of materials to the regional partner lab, at Chulalongkorn University and University of Pretoria in YR4-5. Mr. Lucas is an employee of the Henry M. Jackson Foundation and salary support is requested for year 1-4.

Mr. Spencer Sterling, Mph, Res Assoc II (3 calendar month; 25% effort, YR3-4; 6 calendar months; 50% effort, YR5) Mr. Sterling will assist with the project in YR3-4 when testing and analysis begin at Chulalongkorn University. Mr. Sterling will participate in serological data analysis in YR5. Mr. Sterling is an employee of the Henry M. Jackson Foundation and salary support is requested for year 3-5.

Domestic Travel: \$16,900 YR1-5

Based on FY23 government per diem rates and historical travel to New York City (NYC), we estimate \$3,400 should cover the travel costs of Dr. Laing, Dr. Coggins, Ms. Tso, and Mr. Lucas to travel to NYC in YR1 to meet with the other PI and initiate the *in silico* analysis. In YR2-3 we anticipate traveling twice to NYC to continue statistical analysis with our partner and have budget \$5,500 and \$5,000, respectively, in travel for each year. In YR4-5, travel will be reduced to Dr. Laing and Dr. Coggins and projection that one trip per year (\$1,500) for coordination and analysis will be required.

Equipment:- \$32,000 YR1

Year 1 - \$32,000

To perform the multiplex serologies outline in the research application we will require a Luminex MAGPIX multiplexing system. These systems remain the only field deployable multiplexing system, are cost-effective,

and remain widely used by several of our research collaborators in resource-limited settings.

Supplies: \$371,325 YR1-5

Based on current prices, the following equipment and supplies will be needed to support this project: MAGPIX multiplexing system, recombinant production of 38 protein antigens, rabbit immunizations, magnetic beads, plastic consumables, cell culture materials, affinity matrices and control antibody materials.

Year 1 - \$114,475

MAGPIX multiplexing system
Recombinant protein production
Multiplex serologies and consumables
Rabbit immunizations

Year 2 - \$81,424

Recombinant protein production
Multiplex serologies and consumables
Rabbit immunizations

Year 3-5 - \$58,475

Recombinant protein production (*de novo*)
Multiplex serologies and consumables

**Note* Dr. Laing is seeking a commercial vendor for assistance with custom protein production. If this materializes, supply budget reserved for recombinant protein production will be reallocated to pay for the invoices.*

HJF 2023 INDIRECT COSTS AND FRINGE BENEFIT RATES:

FY23 Henry M. Jackson Foundation (HJF) Fringe Benefits and Indirect Costs:

Henry M. Jackson Foundation (HJF) Fringe Benefits and Indirect Costs: The Henry M. Jackson for the Advancement of Military Medicine, Inc. (HJF) indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The IDC applied is 36.74% (USU On-site Overhead) for all allowable direct costs, less subawards. Additionally, a 16.7% (Companywide G&A) rate is applied on the total direct costs less subawards plus the USU On-site Overhead rate. For proposals including subawards, 1.93% is applied to the total subaward cost. The fringe rate is 29.42% for Tier 1 HJF employees, and 7.29% for Tier 2 HJF employees. The provisional rate agreement for FY 2023 covering the fringe benefits and indirect cost rates was approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

EQUIPMENT (LAING - USU/HJF)

Laing Laboratory

BioRad BioPlex 200 HTF multiplexing system (3)
centrifuges: Eppendorf 5425 microfuges (2)
inverted microscopes for tissue culture (1)
gel electrophoresis equipment for protein (2) and DNA (2) gels
semi-dry protein transfer apparatus (2)
refrigerator
freezers (-20 C, -80 C)
platform orbital shakers (5)
sonicator with cup horn and microtip
heating blocks (2)
waterbaths (1)
biosafety cabinets (2)
CO₂-tissue culture incubators (2)
GE-ATKA low pressure chromatography systems, including UV detectors and fraction collectors (2)

Departmental

Fuji LAS-4010 chemiluminescence/fluorescence CCD camera imaging system
Epifluorescence microscopy system (Fully-automated Zeiss AxioObserver epifluorescence microscope)
IVIS in vivo imaging system (equipped to detect luminescence and fluorescence)
2D gel electrophoresis system (protein)
Alpha-Innotech gel documentation system (EtBr-stained gels)
MilliQ ultra-pure water system
Nanodrop spectrophotometer
Luminometer
Fluorescence plate readers (2)
bacterial shakers (6)
Perkin-Elmer and Eppendorf thermal cyclers (5)
ELISA plate readers (2)
balances (6)
pH meter (2)
Lonza Nucleofector 4D Shuttle – core unit and X-unit
Coulter Z1-Dual cell counter
Beckman Allegra 25R; Thermo-Fisher Jouan GR4i; various rotors
BioRad iQ5 real-time PCR system
Luminex MagPIX multiplexing system

Core facilities (USU BIC – fee for service or free)

Translational Imaging Facility

Siemens Inveon SPECT/PET/CT Scanner
Bruker In-Vivo Xtreme II: supports bioluminescence, X-ray, and direct radioisotopic imaging
Bruker Biospec 70/20 USR MRI
Image Guided Therapy 7T MR guided Focused Ultrasound System for neurological applications

Flow Cytometry

Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers (2)
15-parameter FACSAria II FACS sorter, including a 541nm laser upgrade for sorting of RFP-expressing cells
Amnis Image Stream X Mark II imaging flow cytometer with IDEAS statistical image analysis software
Bio-Rad Bio-Plex 200 multi-analyte bioassay detection system
Offline data analysis stations (3) with software packages including: FlowJo, WinList, and ModFit

Microscopy

Zeiss 710NLO confocal system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm
Zeiss 700 confocal system with 405/458/488/514/561/633 laser lines

Zeiss Elyra PS.1 Superresolution microscope for superresolution structured illumination microscopy (SR-SIM), photoactivated localization microscopy (PALM), and direct stochastic optical reconstruction microscopy (dSTORM). System is fully equipped, including the 3D-PALM/dSTORM option.

Becker-Hickl 2-detector FLIM system (for FRET – attached to Zeiss 710NLO)

Zeiss AxioExaminer.Z1 upright confocal system with Coherent Chameleon multiphoton laser for in vivo imaging and electrophysiology

Zeiss AxioImager.M2 upright microscope and MicroBrightField Stereo Investigator software (stereology analysis).

Leica AF6000 system, including an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control

Wide-field fluorescence microscopes (3)

Transmission electron microscope (Philips CM100 transmission EM)

Ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment)

Offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph.

Genomics

Fuji FLA-5000/LAS-3000 chemiluminescence/fluorescence CCD/laser scanning imaging systems

ABI 9800 Fast Thermal Cycler

ABI 7500 Real Time PCR System

ABI 3500xl Genetic Analyzer

ABI 394 DNA/RNA Synthesizer (2)

ABI 3900 DNA Synthesizer

Eppendorf epMotion 5075 VAC Liquid handling robot

Thermo Scientific Evolution 300 UV/Vis Spectrophotometer

Systec MediaPrep & Plate Pourer

Proteomics

Agilent 1100 HPLC (2)

AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer

AB SCIEX Q-TOF tandem mass spectrometer

Genetix QArray2 Micro array printer

Histopathology

Fee-for-service histology and immunohistochemistry

Nanozoomer digital slide scanner

Structural Biology

X-ray crystallography facility with a Rigaku HighFlux HomeLab X-ray diffraction system, including:

- MicroMax-007 HF, a microfocus rotating anode generator
- R-Axis Imaging Plate detector
- X-stream 2000 cryogenic system
- AB Sciex 4000 QTRAP LC/MS/MS System

Facilities and Other Resources

Uniformed Services University of the Health Sciences Dr. Eric Laing (Principal-Investigator)

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Laing is an Assistant Professor in the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators. Dr. Laing is currently involved in active collaborations within the University, in areas of viral immunology and vaccine and antiviral therapeutics and animal model development. USU is also physically located directly across from the main NIH campus in Bethesda. The overall broad scientific environment at both USU and the NIH is highly conducive to productive collaborations. The PI often uses these resources to his advantage, both for his research objectives and interests and in assisting in adjunct faculty appointments within the Emerging Infectious Diseases graduate program for both on and off-campus scientists interested in participating in graduate education and graduate student training. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional. In addition, multi-lab Immunology journal club, Immunology data club, Virology journal club, and Virology data club exist. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club.

Dr. Laing has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., Bruker In Vivo Xtreme II; Siemens Inveon SPECT/PET/CT Scanner) are not overbooked and therefore readily available to the laboratory personnel. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase advanced and very expensive equipment, including the Zeiss 710NLO system and the FACSAria 15-parameter cell sorter. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by the most recent USU purchase of cutting-edge equipment: the Zeiss Elyra PS.1 super-resolution microscope.

Laboratory: Dr. Laing's laboratory is 453 sq. ft. and is currently supported by two graduate students, two research assistants, two research associates, and one scientist. Dr. Laing also has access to 3 rooms within the department totaling 1,440 sq. ft. where BSL-2 virus rescues are performed and blood specimen samples are handled. Dr. Laing has access to or possesses routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, waterbaths, free-standing biosafety cabinets, and CO₂-tissue culture incubators. Additionally, Dr. Laing has access to three BioPlex 200 HTF multiplexing systems, one MAGPIX multiplexing system, an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope, upgraded in 2015), and two complete GE-ATKA low pressure chromatography systems, with integrated UV detectors, fraction collectors, and pump systems, and gradient fractionator apparatus.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. The USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. It, and the University's animal care and use program, is managed by the Center for Laboratory Animal Medicine, which is directed by a veterinarian who is an ACLAM Diplomate and staffed with three other veterinarians, a graduate animal husbandryman, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates to lower vertebrates, to higher vertebrates including non-human primates and domestic livestock, as well as the more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers (Intel i5/i7 or similar processors and ≥ 2 GB of RAM) are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories of both investigators. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro.

Office: Dr. Laing has an office separate from but proximal to the laboratories. Trainees and technicians have desks in the laboratory or in a separate office area proximal to the laboratory. The department employees one senior program manager, administrative officer, administrative specialist and a microbiologist.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely consult with Cara Olsen, Research Assistant Professor (the full-time Biostatistics Consultant of the BCC), regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data. The USU Translational Imaging Facility (TIF) houses state-of-the art equipment for live animal imaging, including a Siemens Inveon SPECT/PET/CT Scanner, a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system, and a Bruker In-Vivo Xtreme II bioluminescence and X-ray imaging system.

The USU Biomedical Instrumentation Center (BIC) houses core equipment for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). The BIC Flow Cytometry Core includes two Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers, one 15-parameter FACSAria FACS sorter, and one Amnis Image Stream X Mark II imaging flow cytometer, as well as off-line analysis workstations.

The BIC Imaging Core houses three confocal microscopes, including a Zeiss 700 inverted system with 405/458/488/514/561/633 laser excitation; a Zeiss 710NLO inverted system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm; and a Zeiss AxioExaminer-Z1 upright microscope equipped with a direct-coupled Coherent Chameleon tunable infrared laser for ex vivo and in vivo multiphoton imaging projects. A Becker-Hickl two-detector FLIM system (for FRET analyses) is connected to the inverted Zeiss 710NLO system. Recently, the BIC has also acquired a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. The BIC also houses a Leica AF6000 system, consisting of an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control, allowing extended term (days) live cell analyses. Additionally, there is a stereology system consisting of a Zeiss AxioImager.M2 upright microscope connected to MicroBrightField's Stereo Investigator software package. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph Basic. The Imaging Core also includes a transmission electron microscope (Philips CM100 transmission EM) and an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment).

The BIC Genomics core includes an ABI 3900 DNA synthesizer, an ABI3500xl Genetic Analyzer (for sequencing), a Roche LightCycler 480 for real-time PCR, and Systec Mediaprep and Plate Pourer instrument. There is also an integrated Fuji FLA-5000/LAS-3000 imaging system for many applications that involve fluorescence and chemiluminescence imaging of gels and blots. The BIC Proteomics Core includes two Agilent 1100 HPLCs, an AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer, and an AB SCIEX Q-TOF tandem mass spectrometer.

The BIC Structural Biology Core includes a Rigaku HighFlux HomeLab X-ray diffraction system, with a MicroMax-007 HF microfocus rotating anode generator, an R-AXIS Imaging Plate detector, and an X-stream 2000 cryogenic system. Other available BIC instruments and services include histopathology and PET/CT instrumentation for small animal research.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available in print and via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology and is maintained through extramural grant support.

Authentication of Key Resources and Scientific Rigor

Laboratory (USUHS)

Our project aims to optimize multiplex serology protein antigen panels and serological profile standards for henipavirus (e.g. Nipah virus) and ebolaviruses (e.g. Ebola virus). To achieve the aims outlined in the technical proposal, we propose to utilize established stable cell lines to express native-like soluble ectodomain tetramers of all presently described henipaviruses and filoviruses, and purify native-like proteins via size-exclusion and affinity chromatography. Purified envelope glycoproteins will be used to immunize rabbits as animal models to investigate the how antibody response to these protein antigens is shaped after three sequential immunizations. Protein antigens will be coupled to microspheres for multiplex serology applications utilizing Luminex xMAP-based technologies, and testing will be conducted to look at the magnitude and breadth of antigen-specific and cross-reactive antibody responses. These data will be utilized to develop a comprehensive antigen cartographic map, defining the serogroups of henipaviruses and filoviruses based on two envelope protein antigen per virus. Our custom multiplex serology assay will be optimized, qualified, and verified for non-clinical research application in our USUHS lab. Then materials and knowledge will be transferred to the regional partners at Chulalongkorn University and the University of Pretoria where testing of field collected samples will occur. Our goals are to develop *in vitro* and *in silico* models to identify and characterize known and unknown henipaviruses and filoviruses leveraging sera banks collected by collaborators, and co-investigators participating in active field surveillance.

USU will actively engage with EcoHealth Alliance (PI: Ross, N) to ensure that the highest quality science, public accountability, and social responsibility in the conduct of science are maintained throughout. The overall goal is to ensure that the underlying scientific foundation of the project from conception to completion is scientifically sound.

The Laing laboratory at USUHS employs quality systems to insure rigor, reproducibility, and robust and unbiased results in all experiments.

The reagents that are used in our lab are routinely authenticated as follows:

Expression constructs: All new expression constructs are verified by (1) restriction digest and electrophoretic separation of fragments to ensure fragments of the predicted size are generated and (2) sequencing to ensure the correct sequence is present with no spurious mutations.

Cell lines: Cell lines will be routinely validated using either flow cytometry and/or functional tests. SOPs, as detailed documents, for work with cell lines been established in the Laing laboratory and all laboratory staff are required to be familiar with this documentation.

Commercial chemical reagents: Such reagents are validated by one or both of the following: (1) performance comparison to previous lots of the same reagent; (2) use in an established assay that incorporates one or more validated performance controls.

Rigor and Reproducibility (all investigators)

The premise of our investigation is based on both basic science discoveries and non-clinical data. Our *in vitro* mechanistic studies are invariably correlated with *in vivo* cell-based assays so as to establish biological relevance. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility.

USU Investigator: Eric D. Laing, Ph.D. (PI), Assistant Professor, Department of Microbiology and Immunology

Prime Investigator: Noam Ross, Ph.D. (PI), Principal Scientist for Computational Research, EcoHealth Alliance

Grant Type: NIH R01; Multi-PI, Early Stage Investigators

Title: Characterizing unknown emerging viruses through targeted serological profiling

Statement of Work (USU-Laing) - Period of Performance 01/01/2024 - 12/31/2028

Major Milestones, Tasks and Timeline.

The spillover of zoonotic viruses into human populations remains an ever-prevalent threat to public and global health. Among the WHO list of priority pathogens that are threats to global health and security, Nipah virus (NiV), Ebola virus (EBOV), Marburg virus (MARV) are in the top ten. NiV, EBOV, and MARV, are prototypical viruses of their respective genera, *Henipavirus*, *Ebolavirus*, *Marburgvirus*, and the *Henipavirus* and *Ebolavirus* genera include other species of viruses and isolates that range in their confirmed, e.g. NiV, Langya virus, EBOV, MARV; or inconclusive pathogenic potential, e.g. Bombali virus, Ghana virus. In recent years, we have witnessed spillover of henipaviruses, ebolaviruses, and marburgviruses in regions not previously associated with outbreaks. For example, the 2014 outbreak of Ebola virus disease in western Africa was the largest recorded and highlighted the need for a global health security agenda. In 2022, MARV caused fatal disease in Ghana, a region with no historical outbreaks; and SUDV re-emerged in Uganda. In 2021, a never before described henipavirus, Langya virus, was isolated from patients with acute febrile illness in southern China and then detected in shrews; and since 2019 annual spillovers of NiV in Kerala, India have occurred, well outside the recognized hot-spots in Bangladesh. These outbreaks of known and unknown zoonotic viruses demonstrates our paucity of understanding the geographic distribution, wildlife hosts, at-risk human populations, and viral diversity in these three genera.

We have laid-out a series of aims and hypotheses that will contribute significant insight into identifying and characterizing known and importantly unknown viruses through targeted serological profiling and multidimensional spatial statistical modeling. Serological profiling of wildlife hosts and at-risk human communities can provide a wealth of data about the virus infectome, however, the interpretation of this data requires stringent *in vitro* and *in silico* tools. In this grant application we aim to develop and apply lab and computational tools necessary to identify and characterize known and unknown henipaviruses and filovirids that have been detected in bat and humans hosts. The major Milestones and associated tasks to be conducted by Uniformed Services University, along with a timeline of this proposal's goals are shown below.

Major Milestones (Format: Year #. Task #. Sub-task#)

Milestone 1: Develop ebolavirus, marburgvirus, and henipavirus envelope glycoprotein serologic standards. YR1-2. We will create comprehensive serological profiles for filoviruses and henipaviruses to characterize the spatial antigenic relationships between specific virus protein antigens and across related viruses. In doing so we will establish critical priors that will be used to test and develop statistical models focused on exploring virus antigenic and phylogenetic relationship. The individual subtasks linked to this specific **Milestone 1** are:

- 1.1.1 Purification of filovirid and henipavirus envelope glycoprotein antigens as native-like ectodomain
- 1.1.2 Purified native-like filovirid GP protein antigen immunizations of rabbits
- 1.1.3 Establish antigen cartographic relationships among filovirids based of the envelope glycoprotein antigens, GP (trimer) and GP1 subunit protein
- 2.1.1 Purified native-like henipavirus G+F protein antigen immunizations of rabbits

USU Investigator: Eric D. Laing, Ph.D. (PI), Assistant Professor, Department of Microbiology and Immunology

Prime Investigator: Noam Ross, Ph.D. (PI), Principal Scientist for Computational Research, EcoHealth Alliance

Grant Type: NIH R01; Multi-PI, Early Stage Investigators

Title: Characterizing unknown emerging viruses through targeted serological profiling

- 2.1.2 Establish antigen cartographic relationships among henipaviruses based of the envelope glycoprotein antigens, G/RBP (tetramer) and F (trimer)
- 2.1.3 Leave-one-out, filovirid/henipavirus sequential immunizations

Milestone 2. Perform multiplex serologic testing of fruit bat sera collected in the Republic of Congo and Madagascar. YR2-3. A wildlife host for Bundibugyo virus (BDBV) has not yet been identified, yet we have detected BDBV reactive sera in populations of hammerhead fruit bats collected in the Republic of Congo and Madagascan rousettes collected in Madagascar with collaborators, Drs. Vincent Munster (RML) and Cara Book (U. Chicago), respectively. We aim to refine the serological profiles of these bat populations, which will permit us to characterize the antigenic and phylogenetic relatedness of these BDBV-like viruses. The individual subtasks linked to this specific *Milestone 2* are:

- 2.2.1 Identify sera samples of hammerheaded fruit bats and Madagascan rousettes that were immunoreactive with Bundibugyo virus glycoprotein antigens
- 2.2.2 Test individual bat serum samples with an optimized panel of virus envelope glycoprotein antigens
- 3.2.3 Create multidimensional spatial models of filovirus serological profiles in hammerheaded fruit bat and Madagascan rousettes

Milestone 3. Examine the targeted serological profiles of guano farmers and Egyptian fruit bats. YR4-5. Through present work within the Emerging Infectious Diseases-Southeast Asia Research Collaborative Hub (EID-SEARCH) and South African Bat Research Network (SABRENET) we have detected unique serological profiles to henipaviruses in humans and filovirids in Egyptian fruit bats. In this proposal we aim to develop new *in vitro* and *in silico* serological profiling techniques to improve our understanding of these henipavirus and filovirus viral shadows. The individual subtasks linked to this specific *Milestone 3* are:

- 4.3.1 Transfer of optimized antigen panel to co-investigator, Dr. Wanda Markotter, lab at the University of Pretoria (SABRENET)
- 4.3.2 Transfer of optimized antigen panel to co-investigator, Dr. Supaporn Wacharapluesadee, at the Chulalongkorn University (EID-SEARCH)
- 4.3.3-5.3.3 Testing and analysis of EID-SEARCH collected human guano farmer sera to improve our understanding of the Mojiang virus-like serological profile
- 4.3.3-5.3.4 Testing and analysis of SABRENET collected Egyptian fruit bat sera with Ebola virus and Bombali virus serologic profiles to discover the intermediate ebolavirus this bat community hosts.

Milestone 4. Disseminate reports to relevant stakeholders. YR1-5. The individual subtasks linked to this specific *Milestone 4* are:

- 1.4.1-5.4.1 Submit progress reports to NIH
- 1.4.2-5.4.2 Conduct presentations/meetings at times and places specified in the grant schedule
- 2.4.3-5.4.3 Upload immunological and serological data and multiplex standard-operating-procedures to ImmPort
- 2.4.4-5.4.4 Prepare publications

LETTER OF INTENT TO COLLABORATE

February 1, 2023

Noam Ross, PhD
Principal Scientist, Computational Research
EcoHealth Alliance
520 Eighth Avenue, Suite 1200
New York, NY 10018

Dear Dr. Ross:

This letter confirms The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc.'s (HJF) intent to collaborate with EcoHealth Alliance in response to the NIH PA-20-185, and is offered on the condition EcoHealth Alliance agrees that if it receives an award for the subject project, it will issue a subaward to HJF for the work hereby proposed.

Confidentiality Notice: This letter of Intent, including all proposal documents attached hereto, contains HJF confidential and proprietary information and is provided for use solely in connection with HJF's and the (Prime Institution) joint pursuit of the project listed below. Any unauthorized use, disclosure or distribution is prohibited.

Prime Institution:	EcoHealth Alliance
Prime Principal Investigator:	Noam Ross, PhD
Project Title:	Characterizing unknown emerging viruses through targeted serological profiling
Proposed Principal Investigator:	Eric Laing, PhD; USU-MIC
Proposed Project Period:	01/01/2024 – 12/31/2028
Proposed Budget Amount:	\$1,041,889 Direct Costs
	\$ 620,712 Indirect Costs
	\$1,662,601 Total Cost

HJF confirms that it has in place a written and enforced financial conflict of interest policy that applies to all HJF investigators and any other HJF employees responsible for the design, conduct or reporting of the budgeted activities. U.S. Government Principal Investigator(s) (if any) are subject to federal regulations governing conflicts of interest.

Your submission of a prime proposal that includes the subaward activities hereby proposed by HJF will constitute your acknowledgment of, and agreement to, the terms set forth in this letter.

Sincerely,

(b) (6)

Lisa Straker
Deputy Director
Investigator Initiatives-Business Development

cc: Eric Laing, PhD

Hello Dr. Ross,

On behalf of the Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., attached are the documents for Dr. Eric Laing, Uniformed Services University of the Health Sciences to collaborate with EcoHealth Alliance in response to PA-20-185 Funding Opportunity. Please let me know if you need additional information and/or you have any questions. Also, please reply to this email to confirm receipt of this proposal submission.

Yours in good health,

Jacquelyne M. Ford

Sr. Proposal Specialist, Domestic Portfolio

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Vincent J. Munster

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Chief, Virus Ecology Unit

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Utrecht University	MSc	1999 - 2001	Molecular Microbiology
Erasmus University	PhD	2002 - 2006	Molecular Virology
Erasmus Medical Center	Postdoctoral	2006 - 2009	Influenza transmission
Rocky Mountain Laboratories, NIH/NIAID	Postdoctoral	2009 - 2012	Virus Ecology

A. Personal statement

Past outbreaks of bat-borne zoonotic viruses such as coronaviruses, henipaviruses and filoviruses, have had an enormous impact on human and wildlife health. The unpredictability of the zoonotic introductions of these bat-borne limits the potential for effective intervention strategies. One of the main reasons for the absence of successful pre-emptive strategies is our lack of understanding of the ecology, evolution and interaction with the immune system of these pathogens in their respective natural reservoirs. I have gained extensive laboratory and field experience. I have expanded my expertise over the last year towards the field of bat-borne zoonotic diseases (Ebola, Marburg, Nipah and MERS-CoV), conducting field studies in the Republic of Congo and Mali and experimental studies at the Rocky Mountain Laboratories high and maximum containment facility (BSL3 and BSL4). Within the NIAID Virus Ecology unit (http://www.niaid.nih.gov/labsandresources/labs/aboutlabs/lv/virusecology/Pages/default.aspx#niaid_inlineNav_Anchor) my work focuses on natural reservoirs of emerging viruses and elucidation of the underlying biotic and abiotic drivers of zoonotic and cross-species transmission events. Over two decades, I have a demonstrated record of accomplished and productive research resulting in over 190 peer-reviewed publications.

B. Positions and Honors**Positions**

2013 – Present Chief, Virus Ecology Unit, Laboratory of Virology, Rocky Mountain Laboratories, NIAID/NIH
2009 – 2012 Post-doctoral fellow, Disease Modelling and Transmission Section, NIAID/NIH.
2006 – 2009 Postdoctoral research fellow at the Department of Virology, Erasmus Medical Center.

Other Experiences and Professional Memberships

2021 Member WHO virus evolution working group
2020 Member WHO animal working group
2020 Member Operation Warp Speed / CAG
2020 NIAID coronavirus response
2018 DRC Ebola Outbreak: NIAID Internal Coordination Working Group
2018 NIAID Viral Pathogen Preparedness Working Group
2018 Scientific Advisory Board, DTRA Western Asia bat research project
2017 FAO-OIE-WHO global technical meeting on MERS-CoV, Geneva
2017 WHO Global Outbreak and Alert Network workshop meeting, Hong Kong
2017 WHO Environmental Contamination of MERS-CoV meeting, Hong Kong
2016 Graduate faculty appointment, Marshall University, Joan C. Edwards School of Medicine

2016 PhD thesis examiner, University of Melbourne, Australia
 2015-2016 Member the Scientific Advisory Group of the NIAID workshop on MERS animal models
 2015 Member the Scientific Advisory Group organizing the NIAID workshop on MERS animal models.
 2015 Member of the ASPR SPIRiT Ebola environmental working group.
 2015 Member of the ASPR Science Disaster Preparedness working group.
 2014-2015 Team lead of the combined WHO - CDC/NIH diagnostic laboratory during the Ebola virus outbreak, Monrovia, Liberia.
 2014 American Society for Virology, Program Planning Committee.
 2014 Moderator, IOM/NRC Workshop on Research Priorities to Inform Public Health and Medical Practice for Domestic Ebola Virus Disease, Institute of Medicine of the National academy of Sciences.
 2014 Organizer of the fifth ESWI Influenza Conference in Riga, Latvia.
 2014 Scientific organizing committee of the Endemic and Emerging Viral Diseases of Priority in the Middle East and North Africa.
 2013 WHO-ISARIC joint MERS-CoV Outbreak Readiness Workshop.
 2013 Member Coronavirus Therapeutics Interagency Working Group (NIH, CDC, BARDA and DoD).
 2013 Moderator, NIAID MERS-CoV Research: Current Status and Future Priorities Meeting.
 2013 Editor for PLoS One, One Health and Frontiers in Cellular and Infection Microbiology
 2011-2014 Board member of the European Scientific Working group on Influenza.
 2008 Member of the OIE ad hoc Group on Wildlife Disease Surveillance.
 2005-present Reviewer for journals including: Lancet Infectious Diseases, Nature, Nature Medicine, PNAS and Science.

Grant application reviewer

2019 AAAS for the Saudi Arabia's Ministry of Education Research
 2018 BBSRC, UK
 2018 Italian Ministry of Health
 2017 BBSRC (Biotechnology and Biological Sciences Research Council), UK
 2016 USAID Combating Zika and Future Threats Grand Challenge
 2016 FINOVI Foundation, France
 2015 Italian Ministry of Health
 2015 Referee Panel for Health and Medical research Fund, HKSAR
 2015 Human Frontier Science Program
 2012 Referee Panel for Health and Medical research Fund, HKSAR
 2008-2009 National Medical Research Council, Singapore
 2008 Minnesota Center of Excellence for Influenza Research and Surveillance, USA
 2007 Department for Environment, Food and Rural Affairs, UK

Miscellaneous

2014-2015 Team lead of the combined CDC/NIH diagnostic laboratory under GOARN/WHO during the Ebola virus outbreak, Monrovia, Liberia, providing diagnostic services to several Ebola treatment units in the Monrovia area
 2015-2018 Thompson Reuters / Clarivate highly cited researcher 2015, 2016, 2017 and 2018

Honors

2020 AAAS Golden Goose award, COVID-19 response
 2016 European Society for Virology young investigator award
 2015 NIH Director's award, in recognition of the establishment and running of diagnostic field laboratory during the Ebola virus outbreak in West Africa.
 2014 NIAID merit award for the development of a nonhuman primate disease model and a treatment strategy for MERS-CoV
 2014 ASM IAAC young investigator award
 2014 NIH Director's award, in recognition of the exceptional and rapid response to the emergence of MERS-coronavirus.
 2011 European Scientific Working group on Influenza, Best Body of Work award for Young Scientists.

C. Contributions to Science

1 During my PhD working on avian influenza at Erasmus Medical Center, it became clear to me that there was a lack of integration between bench virology and fieldwork. Being trained as a "classical" molecular virologist I could very well answer questions on what mutations would make a virus more pathogenic, but the translation of this knowledge to real world situations remained elusive. Integrating various disciplines helped me to understand the ecology and drivers of avian influenza and pandemic influenza outbreaks.

2 My research group at the Rocky Mountain Laboratories of the NAID/NIH is built around the concept of complete integration of fieldwork, experimental work and computational modeling to allow study of emerging viruses in their natural, intermediate and human hosts. It is clear that past outbreaks of zoonotic viruses have had an enormous impact on human and wildlife health and that the unpredictability of cross-species transmission events limits the potential for effective intervention strategies. My lab aims to identify the underlying changes in virus-host ecology that allow these viral pathogens to cross the species barrier. Recognizing the strengths and weaknesses of a unilateral focus on field research on one hand and experimental research on the other, we have combined both approaches in one research program. This integrated approach has contributed greatly to the rapid advancements in our knowledge on the emergence of MERS-CoV. Using a combination of fundamental concepts of host species restriction of MERS-CoV and protein-protein binding interaction modeling we predicted potential MERS-CoV host species, which were tested in experimental infections. Our field studies in the Middle East confirmed camels as the primary reservoir for MERS-CoV.

3 My research group was directly involved in the response to several outbreaks including the Ebola virus outbreak in West Africa by providing diagnostic support at the request of the WHO for several Ebola treatment units in Monrovia, Liberia and SARS-CoV-2. The emergence of Ebola virus in West Africa highlighted significant gaps in our knowledge, including fundamental ecological questions surrounding zoonotic and human-to-human transmission. In order to understand the drivers of transmission, we examined the stability of the virus within tissues and on body surfaces and determined the potential for transmission. The results from this study directly aided the interpretation of epidemiologic data collected from human corpses and are also applicable to interpreting samples collected from remains of wildlife infected with Ebola virus, especially nonhuman primates, and helped to assess the risk of zoonotic transmission. With the current COVID19 pandemic we are actively involved in the development of medical countermeasures and providing critical experimental data supporting direct public health decisions and interventions.

Hi Vincent,

Sorry for the late reply to this email and follow-up for R01 Letter of Support. Noam and I are hoping to submit by this Friday. I've drafted a LOS (attached), can you make any edits, add your letterhead, sign and send back to us? You sent Jon a biosketch for the Liberia-focused R01, I can grab that from the email thread if that works for you.

Also, there's a good chance my research group will be participating in surveillance in Jordan, Oman, and Republic of Georgia so I'll probably need to increase the breadth of MERS-like CoVs in the multiplex. We're still finalizing the IAA with NCI FNL but I'll prob loop back to you for aliquots of bat sera from Jordan to cross-verify antigen performance.

Hi Vincent,

Really appreciate your support.

One of my ideas was to write that we could leverage the R24 Bat ID model to verify/validate rabbit-immunizations. So it's awesome to hear that you are already on the same page. Wanda Markotter even brought this up during a meeting this morning and I think it's an obvious limitation that a reviewer might pick at, if we only propose antigen immunization in rabbits. Wanda has also offered to do some bat-infection experiments so I'll write that in and make sure there is money in a budget for her lab to do that as well.

RE: CoVs

Chris/my lab pulled back from expressing CoV antigens in-house and have been working with Dominic Esposito's Protein Expression lab at NCI FNLCR. We're in the process of re-establishing an IAA with his group and he's interested in de novo expression of bat CoV antigens. Do you have particular RBD, S1, or spike (S-2P) antigens that you would want for a custom panel? We're going to build out something related to Wanda's work, and work with Supaporn and Gavin Smith in southeast Asia.

Sounds great,

Looping in my postdoc Dr. Sarah van Tol as well, as she will be doing some bat infection studies soon here at RML and we could share some sera (Artibeus) from these experiments as well.

We could also in the future (my colony is still at CSU, but will be moving to RML) do some bat protein immunizations and use those as controls to validate your rabbit antisera.

Speaking of which, I have a nice serum set of bats from Jordan (Rhinolophus and Rousettus) for which we detected a variety of corona's in (the darker ones), would like to run these through the corona luminex and see what their serum cross reactivity looks like. I could do it here on the magpix, but could share an aliquot of the sere with you as well.

Vincent Munster, PhD
 Chief Virus Ecology Section
 Rocky Mountain Laboratories
 NIAID/NIH

From: Laing, Eric <eric.laing@usubs.edu>

 To: Munster, Vincent (NIH/NIAID) [E] <vincent.munster@nih.gov>; Noam Ross <ross@ecohealthalliance.org>
 Subject: [EXTERNAL] R01_Applied serology methods and statistics

Hi Vincent,

Noam and I are putting together a "methods" focused R01 that leverages ongoing work via a NIH center and DTRA BTRP project with Wanda Markotter. My lab is going to further optimize a 28plex panel of antigens (henipa/filo-focused) that balances two goals: a) discovery of new viruses through serology and b) specific detection of homotypic viruses. We are going to include a ton of protein-immunizations of rabbits to establish cross-reaction matrices for each virus and standard antigenic cartography. Noam is working on novel multidimensional spatial analyzes for Aim 2. In Aim 3 we are proposing to re-test/re-analyze data with the in vitro and in silico tools developed through Aims 1 and 2.

I was wondering whether you would be willing to share with my lab some of the sera collected from bats in the Republic of Congo that has interesting sero-positives for the research being outlined in Aim 1 and 3, and be listed as a collaborator on the project? If so, I would include the retesting of those sera with the optimized panel and downstream analysis in the proposal, and I could provide a draft LOS. The Specific Aims are below:

Specific Aims

1. Create multiplex serological panels optimized for viral discovery
2. Develop novel statistical approaches for identifying and characterize novel virus signals from multiplex data
3. Determine epidemiological patterns of novel virus exposure in human and bat populations.

Kind regards,
 Eric

Kingston University, UK	PhD	2017	Disease Ecology

A. Personal Statement.

The goal of this research is to create and validate novel laboratory and statistical methods for detecting, identifying, and characterizing zoonotic viruses via serological techniques, and apply these methods to better understand reservoirs and spillover processes of viruses at the human-wildlife interface. The work will include re-analysis of longitudinal data of Nipah Virus circulation in Bangladesh. I am well positioned to contribute and provide expertise to this work, as this data emerges from research I led over nearly 20 years involving epidemiological studies of bat-origin viruses in Bangladesh, including as current PI of an NIH NIAID-funded U01 studying Nipah virus spillover. This is part of over 20 years of experience conducting epidemiological and immunological studies of bat-origin viruses and the last 15 years managing large-scale multidisciplinary surveillance in wildlife and humans in Liberia, South Africa, Malaysia, India, as well, under various US federal agency-funded projects. I have trained multidisciplinary teams to conduct fieldwork in Malaysia, India, Bangladesh, Saudi Arabia, Cambodia, The Philippines, and Liberia and conducted ecological and epidemiological studies of zoonotic viruses in bats, including henipaviruses, filoviruses, and coronaviruses. My work has led to the discovery of bats as the reservoir for SARS-CoV, the identification of MERS-CoV in bats and camels in Saudi Arabia, the identification of Reston ebolavirus in bats in The Philippines and the detection of Zaire ebolavirus for the first time in bats in West Africa (Liberia). I have also conducted and coordinated data analyses from field and lab activities including identifying novel viral agents (the first bat pegivirus) and confirming that *Pteropus* fruit bats are reservoirs for henipaviruses. I spent five years working as a visiting research fellow at Columbia University's Center for Infection and Immunity conducting Nipah virus and pathogen discovery research, using molecular and serological techniques, bioinformatics, and phylogenetic analysis, all of which has given me a strong understanding of the links between immunology and epidemiology in wildlife and humans and the challenges and constraints of serological diagnostics and quantitative analysis in these systems. I have extensively collaborated with PIs

Ross and Laing as well as Co-Investigators Markotter and Wacharapluesadee over the last 10 years and have active projects with each. Collectively, we bring unprecedented data, resources and comprehensive expertise to this project to transform how serology is used in zoonotic disease surveillance.

B. Positions and Honors

Positions and Employment

- 2002 Extern, Division of Viral and Rickettsial Diseases, CDC, Atlanta, GA
- 2003-09 Senior Research Scientist, EcoHealth Alliance, New York, NY.
- 2003 - Adjunct Clinical Associate, Tufts University Cummings School of Vet. Med., MA.
- 2006-10 Research Fellow, Center for Infection and Immunity, Columbia University, NY,
- 2008- Adjunct Assoc. Prof. Mt Sinai School of Medicine, Infectious Dis. Dept. NY
- 2009-16 Associate Vice President, Conservation Medicine Program EcoHealth Alliance, NY
Executive Director, Consortium for Conservation Medicine, EcoHealth Alliance, NY
- 2016- Adjunct Associate Professor, Columbia University Mailman School of Public Health, NY
- 2016 - Vice President for Science and Outreach, EcoHealth Alliance
- 2020 - Adjunct Professor, University of Pretoria School of Medicine, Dept. Medical Virology, RSA

Other Experience and Professional Memberships

- 2003 - Member, IUCN Veterinary / Wildlife Health Specialist Group
- 2004 Invited speaker, *WHO, Emerging Zoonotic Diseases Working Group* meeting
- 2006 Member, Delta Omega Public Health Honors Society
- 2010- Invited speaker, Institute of Medicine Forum on Microbial Threats, National Academies of Science
- 2011- Admissions Committee, Tufts University Masters in Conservation Medicine degree program
- 2012- Scientific Advisory Board, Lubee Bat Conservancy
- 2013- Science Advisor: Center for Health and the Global Environment, Harvard University
- 2015 - Editorial Board, *One Health* journal;
- 2016 Subject Matter Expert for USDA APHIS National Wildlife Research Center personnel review
- 2017 - Chief Science Advisor to Smithsonian National Museum of Natural History “Outbreak” exhibit (through 2022);
Board of Advisors, Tufts University Cummings School of Veterinary Medicine (2017-)
- 2018 - WHO Blueprint R&D Nipah virus SME; Scientific review committee for IMED 2018
- 2019 - Global Health SME for Aspen Institute Congressional Delegation: Rwanda;
Technical lead, WHO SEARO Nipah virus prevention strategy development for South Asia (2019-2023)
- 2020- Expert witness, US Senate Committee on Environment and Public Works (wildlife trade & epidemics)
- 2020-21 Founder, Jackson Heights Science Communication Initiative (@jhscicomms) – community outreach group communicating COVID-19 science to local public in NYC
- 2022-23 Guest Editor – *Viruses* journal special issue

Honors

- 2002 Certificate of International Veterinary Medicine, Tufts University Sch. Vet. Med. (1st recipient)
- 2002 Hills award for excellence in veterinary clinical nutrition
- 2002 Sylvia Mainzer Award for Outstanding Achievement in Public Health
- 2006 Inductee & Keynote speaker, Delta Omega Honor Society for Public Health (Alpha Rho Chapter)
- 2007 Outstanding Alumnus award, Tufts Cummings School of Veterinary Medicine
- 2012 Young Alumni Achievement Award, Tufts University
- 2013 Named one of the ten “Distinguished Alumni” by Tufts University School of Medicine
- 2014 Commencement speaker, Tufts University Medical School Graduate Programs in Public Health

2021 Pensinger Lecture in Comparative Medicine at the University of Illinois College of Veterinary Medicine; Griffin Circle Award; Garden School, NYC; for technical guidance and assistance developing COVID-19 safety protocols and policies

C. Contributions to Science

1. Research on the epidemiology of emerging zoonotic viruses, including SARS-CoV, Nipah virus and Reston ebolavirus. A range high impact emerging viruses appear to have bat origins (e.g. SARS-CoV, Ebola viruses, NiV, HeV, MERS-CoV). My research has focused on identifying bat reservoirs and the epidemiology of Nipah and Hendra virus, Reston ebolavirus, SARS-CoV, and MERS-CoV. I have developed and led field teams in Asia and Africa that conduct surveillance for zoonotic viruses in bats and other wildlife, as well as humans and livestock. In Malaysia, my work helped identify the agricultural drivers of NiV emergence. In Bangladesh and South Africa, I helped characterize henipavirus infection dynamics and the ecology of its bat reservoir including patterns of habitat use as they relate to spillover to humans and livestock. In China, I led initial fieldwork that identified Horseshoe bats as the natural reservoir for SARS-like CoVs and collaborated on the identification of SL-CoVs in bats that use the same receptor as SARS-CoV. Under the USAID-funded Emerging Pandemic Threats: PREDICT program, **I managed field and laboratory teams in Liberia, Malaysia, India, and Bangladesh that conducted human and wildlife surveillance for novel viruses as well as important viral zoonoses such as Ebola, Nipah virus, MERS-CoV, and HPAI. We recently identified Zaire ebolavirus in a bat in Liberia, the first detection of Ebola in a bat in the region.** This work has been instrumental in advancing our understanding of viral dynamics and diversity in wildlife reservoirs and how environmental change and human behavioral factors drive zoonotic virus emergence.

2. Experimental studies of bat ecology and immunology to understand emerging zoonoses. In an effort to approach epidemiological studies more comprehensively, we have integrated field and laboratory experimental studies, including experimental infections, into larger field epidemiological studies. I have helped pioneer the use of satellite telemetry and mark-recapture studies on bat Nipah virus reservoirs to help define geographic range of these viruses. My work has helped show that in Malaysia, Nipah virus bat reservoirs have long-range, international migratory movements that explain viral maintenance at low incidence and observed patterns of viral genetic diversity. I have used experimental NiV infections (BSL 4) and immunological experiments in bats to generate actual data about viral shedding, pathogenesis, and antibody persistence in

bats, which has informed empirical field data and mechanistic models of viral dynamics. This work has enhanced our ability to understand how Nipah and other viruses circulate in bat populations and how specific age groups contribute to viral outbreaks within bats.

3. Identification of novel pathogens in bats and other wildlife with zoonotic potential. My work on the ecology of viruses in bats led to my discovery of a novel flavivirus (GB virus) in the Bangladesh fruit bat *Pteropus medius*, related to the hepatitis C virus, and now classified as a *Pegivirus*, as well as a novel morbillivirus in Brazilian bats. An additional 55 novel viruses, some related to Nipah, and serological evidence of filoviruses have been identified in these samples, demonstrating the importance of livestock surveillance in rural South Asia to discover potential zoonoses. Under the USAID PREDICT project, I led work in Liberia, Bangladesh, India, and Malaysia. As a collaborative group, we discovered more than 1200 novel viruses in 25 countries. I served as a technical lead throughout the 10-year project, designing SOPs for wildlife surveillance, and training dozens of scientists and government officials from wildlife and agricultural ministries in more than 25 countries. In South Africa, we are working to understand the diversity of henipaviruses, filoviruses and coronaviruses in Egyptian rousette bats and use serology to determine rates of spillover of these groups of viruses into livestock and human populations.

A. Personal Statement

The goal of this research is to create and validate novel laboratory and statistical methods for detecting, identifying, and characterizing zoonotic viruses via serological techniques, and apply these methods to better understand reservoirs and spillover processes of viruses at the human-wildlife interface. I am uniquely suited to lead this work as a mathematical and statistical disease ecologist with extensive experience collaborating with field epidemiologists and virologists in zoonotic disease surveillance. As a Principal Scientist for Computational Research at EcoHealth Alliance, I lead work in ecological and epidemiological modeling, statistical design and interpretation, and data management for our work across multiple USAID, NIH, NSF, and DTRA-supported disease surveillance projects in South and Southeast Asia, Sub-Saharan and Western Africa. This includes disease systems such as Nipah virus, Rift Valley Fever, and emerging filoviruses and sarbecoviruses. Central to this work is modeling and collaborative interpretation of serological and molecular data to infer underlying infections and disease dynamics and evolution. This experience has given me a strong understanding of the ecological, biological, and laboratory processes that serological data. My expertise in dynamic epidemiological processes and linking mechanistic and statistical models allows me represent the underlying biology in tractable, interpretable ways. Through my work with rOpenSci, I lead peer-review of statistical software tools, overseeing the publication of over 300 software packages and the leading standards for the correctness, accessibility, and documentation of research software, which will enable me to ensure that output of this project will be useful and accessible tools for research and surveillance. I am also PI for multiple projects that focuses on machine learning to forecast the emergence and movement veterinary disease outbreaks. I have collaborated with PI Laing and Co-Investigators Epstein, Markotter, Wacharapluesadee extensively and we bring complementary and collectively unique expertise to allow us to execute this project.

Current supported projects that highlight my work and collaborations includes:

As Principal Investigator:

- **Predicting biothreat impacts from early-stage data via transfer learning** (DTRA, 08/2021 – 07/2023)
- **An open source framework for Rift Valley Fever forecasting** (Wellcome Trust, 08/2021 – 07/2023)
- **Expanding statistical software peer review** (Sloan Foundation, 08/2019-06/2024)

As Collaborator:

- **Study of Nipah virus dynamics and genetics in its bat reservoir and of human exposure to NiV across Bangladesh to understand patterns of human outbreaks** (NIH, 09/2020 – 06/2025)
 - Role: Co-I, with PI Jonathan Epstein and Senior Personnel Eric Laing

- **Biosurveillance for viral zoonoses around bat-livestock-human interfaces in South Africa** (DTRA, 07/2020 – 07/2025)
 - Role: Co-I, with PI Wanda Morkotter, Co-I Jonathan Epstein, and Co-I Laing
- **Biosurveillance for spillover of henipaviruses and filoviruses in rural communities in India**
 - Role: Project Scientist, with PI Jonathan Epstein

B. Positions, Scientific Appointments, and Honors

2020 - Present	Principal Scientist, Computational Research, EcoHealth Alliance
2016 – 2019	Senior Research Scientist Ecologist, EcoHealth Alliance
2015 – 2016	Disease Ecologist, EcoHealth Alliance
2010 – 2015	Graduate Researcher, University of California-Davis
2007 – 2009	Senior Analyst, Environmental Strategy and Markets, GreenOrder
2006 – 2007	Analyst, Environmental Strategy and Markets, GreenOrder
2006	Contract Researcher: Energy Efficient Products Initiative, Wal-Mart

C. Contributions to Science

1. **Detecting emerging diseases and the drivers of their dynamics:** A heavy component of my research is collaborating with field surveillance teams to identify spillovers of novel emerging diseases by devising sampling designs, interpreting molecular and serological data, and using mechanistic and nonparametric models to best detect disease emergence events and elucidate predictive factors. Importantly this has included developing statistical approaches to deal with rare events and sparse predictors. This work has helped identify novel spillover events and actionable behavioral risk factors.

2. **Modeling dynamics of Heterogeneity:** I have worked on both theoretical and applied approaches of dealing with individual-and system-level heterogeneity ecological-epidemiological dynamics. This work includes complex size structure of populations modeled with integral projection models, and heterogenous disease states in multi-infection fungal systems, and is directly applicable to this proposal's aims of capturing the complexity of multidimensional immune states to identify viruses. My work showed how and where these models diverged from other, traditional models in their properties, and identified statistical patterns that could be used to identify processes of disease amplification in hosts. I developed numerical tools for modeling and simulation of controls and intervention, making it tractable to use such statistical and simulation models in ecology, and this work has been used in applied disease management.

Ross N (2015). *Disease with Multiple Infections: Population Structure, Dynamics, and Control*. University of California, Davis. Dissertation.

3. **The macroecology of disease emergence:** I have worked in understanding global patterns and drivers of disease distributions, host-sharing and spillover. This work involved integrating models of macroecological processes, host and disease phylogenies, climate as well and human travel and behavior. This also includes using modern data science tools to extract information about disease events from unstructured and textual sources to assemble sufficient data to produce such analyses.

Many thanks, Wanda!

The NIH biosketch section (C) is a little more expansive and narrative than just the list of four papers, unfortunately. They ask for descriptions of major contributions, each with up to four references as examples. I'm attaching Jon's and mine for reference. (Sorry! I am always embarrassed for how much of a to-do NIH and NSF make these.)

Would you be able to expand on this? If you just take a few minutes to put in some bullets or pasted text and references to additional papers/topics, we're happy to with stitching it together and formatting!

Noam

Afternoon Noam

See the attached documents requested. Let me know if you need anything else.

Wanda

On Sat, 28 Jan 2023 at 00:28, Noam Ross <ross@ecohealthalliance.org> wrote:
Dear Wanda,

Find attached two documents for your review: A letter of support and a budget justification.

- The LoS requires only your review or edits, signature and to be on UP letterhead.
- The budget justification just requires your review. I do note that it describes a 35% fringe benefits rate, as the budget did, but this should be based on the institutional rate. If this should be different, described differently, and/or we should modify the budget to incorporate this into base salary or time, please let me know. Thank you!

On Thu, Jan 26, 2023 at 1:50 PM Noam Ross <ross@ecohealthalliance.org> wrote:
Great, Wanda. I've moved your salary to two lines for the postdoc and lab technician.
We will still list you as committing 2 weeks/yr as the institutional lead at no salary.

If we could have the BioSketch and Facilities description by the end of your Tuesday, that would be great.

I'm doing a last pass over all the paperwork requirements to make sure there isn't other info I'll need from any partners. There will be a Letter of Support and Budget Justification, both of which I'll draft before next week for you to review.

Afternoon Noam

Thanks for this. Overall it looks fine. I usually do not claim direct salary, but it can be directed to a postdoc salary, so you can keep it as is or split a technician and a postdoc and have both. I think both will be needed.

The sample costs are fine.

I still owe you a bio sketch and equipment description. When do you need that at the latest?

W

On Thu, 26 Jan 2023 at 02:10, Noam Ross <ross@ecohealthalliance.org> wrote:

Dear Wanda,

Find attached a rough proposed budget for your participation in our serology methods proposal, based on the per-plate costs you provided. My apologies for getting this to you late. We've estimated that we want to re-test up to 6,000 samples from SABRENET and related projects. This is based on current positive hit rates, and including matched negative samples. We propose to do this across years 3 and 4 of the project, after the bulk of our panel modifications and statistical testing take place in years 1 and 2. We include budget for personnel time extending into year 5 of the grant for you and a postdoc/tech to continue to participate in analysis and interpretation.

I have made some very rough guesses in the attached to understand the order of magnitude. For instance, I'm unsure if you need to take direct salary and don't know at rate that would be (other PI partners doing testing/re-analysis are taking 2 weeks/yr). Please let us know how this looks and adjust as appropriate.

Best,
Noam

Afternoon

Thank you for the discussion. It will be an interesting project

Attached are some costs for consideration

To run one plate (about 80 sample, considering controls also) costs us about 265 USD labour included. So the total costs will depend on how many samples you want to include and repeats. These costs also assume we are getting coupled beads with antigen from USU, so no costs on that was considered.

I also mention the costs for collecting the samples and costs of a research scientists for consideration.

Let me know if you have questions. Marinda will send you the breakdown of the samples.

Will send the bio and equipment list by the end of this week.

Wanda

Dear Wanda, Marinda, and Marike,

Good to speak with you today. I'm writing with the materials for the biosketch and facilities document for the application. Find attached a template and example NIH format biosketch that we'll need for Wanda. ([Further instructions here if needed](#)).

We'll also need a Facilities & Equipment document that summarizes resources available at your institution and lab, with a focus on what is needed to run Luminex and associated we will need (this is actually Supaporn's for a different NIH project), ([Instructions](#))

It would be great if we could get these by **Wednesday, Jan 25th**.

If we get some preliminary figures on samples by species and costs, we'll get budget info to you ASAP next.

Best,
Noam

Facilities and Other Resources

Uniformed Services University of the Health Sciences Dr. Eric Laing (Co-Investigator)

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Laing is an Assistant Professor in the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators. Dr. Laing is currently involved in active collaborations within the University, in areas of viral immunology and vaccine and antiviral therapeutics and animal model development. USU is also physically located directly across from the main NIH campus in Bethesda. The overall broad scientific environment at both USU and the NIH is highly conducive to productive collaborations. The PI often uses these resources to his advantage, both for his research objectives and interests and in assisting in adjunct faculty appointments within the Emerging Infectious Diseases graduate program for both on and off-campus scientists interested in participating in graduate education and graduate student training. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional. In addition, multi-lab Immunology journal club, Immunology data club, Virology journal club, and Virology data club exist. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club.

Dr. Laing has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., Bruker In Vivo Xtreme II; Siemens Inveon SPECT/PET/CT Scanner) are not overbooked and therefore readily available to the laboratory personnel. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase advanced and very expensive equipment, including the Zeiss 710NLO system and the FACSAria 15-parameter cell sorter. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by the most recent USU purchase of cutting-edge equipment: the Zeiss Elyra PS.1 super-resolution microscope.

Laboratory: Dr. Laing's laboratory is 453 sq. ft. and is currently supported by two graduate students, two research assistants, two research associates, and one scientist. Dr. Laing also has access to 3 rooms within the department totaling 1,440 sq. ft. where BSL-2 virus rescues are performed and blood specimen samples are handled. Dr. Laing has access to or possesses routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, waterbaths, free-standing biosafety cabinets, and CO₂-tissue culture incubators. Additionally, Dr. Laing has access to three BioPlex 200 HTF multiplexing systems, one MAGPIX multiplexing system, an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope, upgraded in 2015), and two complete GE-ATKA low pressure chromatography systems, with integrated UV detectors, fraction collectors, and pump systems, and gradient fractionator apparatus.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. The USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. It, and the University's animal care and use program, is managed by the Center for Laboratory Animal Medicine, which is directed by a veterinarian who is an ACLAM Diplomate and staffed with three other veterinarians, a graduate animal husbandryman, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates to lower vertebrates, to higher vertebrates including non-human primates and domestic livestock, as well as the more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers (Intel i5/i7 or similar processors and ≥ 2 GB of RAM) are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories of both investigators. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro.

Office: Dr. Laing has an office separate from but proximal to the laboratories. Trainees and technicians have desks in the laboratory or in a separate office area proximal to the laboratory. The department employees one senior program manager, administrative officer, administrative specialist and a microbiologist.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely consult with Cara Olsen, Research Assistant Professor (the full-time Biostatistics Consultant of the BCC), regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data. The USU Translational Imaging Facility (TIF) houses state-of-the art equipment for live animal imaging, including a Siemens Inveon SPECT/PET/CT Scanner, a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system, and a Bruker In-Vivo Xtreme II bioluminescence and X-ray imaging system.

The USU Biomedical Instrumentation Center (BIC) houses core equipment for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). The BIC Flow Cytometry Core includes two Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers, one 15-parameter FACSAria FACS sorter, and one Amnis Image Stream X Mark II imaging flow cytometer, as well as off-line analysis workstations.

The BIC Imaging Core houses three confocal microscopes, including a Zeiss 700 inverted system with 405/458/488/514/561/633 laser excitation; a Zeiss 710NLO inverted system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm; and a Zeiss AxioExaminer-Z1 upright microscope equipped with a direct-coupled Coherent Chameleon tunable infrared laser for ex vivo and in vivo multiphoton imaging projects. A Becker-Hickl two-detector FLIM system (for FRET analyses) is connected to the inverted Zeiss 710NLO system. Recently, the BIC has also acquired a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. The BIC also houses a Leica AF6000 system, consisting of an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control, allowing extended term (days) live cell analyses. Additionally, there is a stereology system consisting of a Zeiss AxioImager.M2 upright microscope connected to MicroBrightField's Stereo Investigator software package. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph Basic. The Imaging Core also includes a transmission electron microscope (Philips CM100 transmission EM) and an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment).

The BIC Genomics core includes an ABI 3900 DNA synthesizer, an ABI3500xl Genetic Analyzer (for sequencing), a RocheLightCycler 480 for real-time PCR, and Systec Mediaprep and Plate Pourer instrument. There is also an integrated Fuji FLA-5000/LAS-3000 imaging system for many applications that involve fluorescence and chemiluminescence imaging of gels and blots. The BIC Proteomics Core includes two Agilent 1100 HPLCs, an AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer, and an AB SCIEX Q-TOF tandem mass spectrometer.

The BIC Structural Biology Core includes a Rigaku HighFlux HomeLab X-ray diffraction system, with a MicroMax-007 HF microfocussing rotating anode generator, an R-Axis Imaging Plate detector, and an X-stream 2000 cryogenic system. Other available BIC instruments and services include histopathology and PET/CT instrumentation for small animal research.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available in print and via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology and is maintained through extramural grant support.

A. Personal Statement

The spillover of zoonotic viruses into human populations remains an ever-prevalent threat to public and global health. Continual outbreaks of known and unknown zoonotic viruses highlights the paucity of our understanding of the viral diversity, geographic distribution, wildlife hosts, and human populations at-risk for spillover. I am a recently appointed assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses. I have completed virological training and spent my time as a post-doctoral fellow applying *in vitro* techniques to characterize the replication and mammalian ephrin receptors that mediate cellular entry of emergent henipaviruses. Since the start of the COVID-19 pandemic, I pivoted the focus of my research team to serological analysis of SARS-CoV-2 infection, and then to COVID-19 vaccine-induced antibody durability. In my ongoing research, I develop serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Since my position as a postdoctoral fellow I have worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs. Across all of these international collaborations, we have aimed to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence. Throughout these research projects, we have detected unexpected serological profiles in communities of bats and humans that have not fit our prior understanding of the viral diversity established or detected by genetic techniques. This proposal aims to better understand these serological profiles of wildlife and humans with a targeted focus on henipaviruses and filoviruses. Ongoing projects that I would like to highlight include:

B. Positions, Scientific Appointments and Honors

Positions

- 2021-pres. Assistant Professor, Department of Microbiology and Immunology, School of Medicine, Uniformed Services University, Bethesda, MD.
- 2021-pres. Joint Appointment, Emerging Infectious Diseases Graduate Program, School of Medicine, Uniformed Services University, Bethesda, MD.

- 2019-21 Research Assistant Professor, Department of Microbiology and Immunology, Uniformed Services University, Bethesda, MD.
- 2016-19 Postdoctoral fellow, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD.
- 2010-16 Graduate research student, Department of Microbiology, Uniformed Services University, Bethesda, MD.

Other Experiences and Professional Memberships

- 2022-pres. Executive committee member, Emerging Infectious Diseases Graduate Program, USUHS
- 2021-pres. Research center representative, Laboratory Assays Oversight and Quality Working Group, Emerging Infectious Diseases: Southeast Asia Research Collaboration Hub (EID-SEARCH), Centers for Research in Emerging Infectious Diseases (CREID), NIAID, DMID, NIH
- 2021-pres. Review editor, Frontiers in Virology - Emerging and Reemerging Viruses
- 2021-pres. Ad hoc reviewer, Frontiers in Immunology, Journal of Clinical Immunology
- 2021-pres. Steering committee member, JPI/Military Infectious Diseases Research Program, Emerging Infectious Diseases
- 2019 Ad hoc reviewer, EcoHealthNet 2.0 Program, EcoHealth Alliance
- 2018 Ad hoc reviewer, Pakistan One-Health Fellowship Program, National Academy of Sciences & Pakistan Academy of Sciences
- 2014-2019 Member, American Society of Tropical Medicine and Hygiene
- 2014-2019 Member, American Society of Microbiology
- 2014-2019 Volunteer, AAAS STEM K-12 Volunteer Program

Mentoring

- Postdoctoral fellows* Si'Ana A. Coggins, PhD, 2020 - 2022
- Graduate students* Marana S. Tso, BS, 2021 -
McKenna Roe, BS, 2022 -
- Committee member* Celeste Huaman, BS, 2021 -
2LT Connor Perry, BS, 2021 -

Honors

- 2021-2022 Impact Award, USUHS School of Medicine
- 2021 Outstanding Research Accomplishment/Team/SARS-CoV-2, The EPICC COVID-19 Cohort Team, Military Health System Research Symposium
- 2020-2021 Impact Award, USUHS School of Medicine
- 2015-2016 Val G. Hemming Fellowship, Henry M. Jackson Foundation
- 2015 East Asia and Pacific Summer Institutes Fellowship, National Science Foundation

C. Contributions to Science

1. Lyssaviruses and the prototype, rabies virus, remain a public health concern. Beginning with my PhD thesis work, I've researched the virus host-interactions between a rabies-related lyssavirus, Australian bat lyssavirus (ABLV), and its bat host (*Pteropus alecto*). Research has focused on ABLV cellular entry mechanisms, the development of an animal model and ABLV reporters and exploration of novel monoclonal antibodies that neutralize ABLV and other phylogroup I lyssaviruses. Furthermore, comparative bat immunology research was conducted using black flying fox cell lines and ABLV as a model virus/host interaction. Physiological adaptations that accompanied the evolution of flight in bats have been proposed to contribute to the frequent role of bats as asymptomatic hosts of highly pathogenic zoonotic viruses. Comparatively studying the autophagy pathway in bat cell lines revealed that bat cells had elevated levels of basal autophagy and experienced significantly less cell death when challenged with high virus doses.

PMID: 33804519; PMCID: PMC8001737.

2. My research experience as a postdoctoral fellow furthered my training in molecular virology techniques. I constructed a recombinant Cedar virus cDNA plasmid and optimized a reverse genetics approach to rescue a recombinant Cedar virus reporter virus, a non-pathogenic *Henipavirus* species. A molecular biology methods chapter detailing recombinant Cedar virus reverse genetics has been submitted and in press. Using this recombinant Cedar virus, we determined that Cedar virus can utilize several non-canonical henipavirus ephrin receptors for cellular entry and explored the structure of the receptor-binding pocket to understand the receptor promiscuity. The non-pathogenic phenotype of CedV creates a potential for CedV to act as a model henipavirus to explore host-pathogen interactions, cellular tropism and factors that determine henipaviral disease pathogenesis. Additionally, I have collaborated on projects detailing henipavirus infection and replication in bat hosts with colleagues at the Rocky Mountain Labs, studying whether specific species of bats are more competent hosts and whether virus-host restriction exists.

3. Bats are increasingly identified as animal reservoirs of emerging zoonotic viruses (e.g. Nipah virus, Ebola virus and SARS-coronavirus). I lead collaborative biosurveillance and research preparedness training including data analysis and interpretations at international partner institutes with lab technicians, field and lab scientists, and masters, doctoral and postdoctoral trainees. Collaborative biosurveillance is presently underway in Thailand (Chulalongkorn University, Bangkok) Malaysia (National Wildlife and Forensic Lab, Universti Putra Malaysi, National Public Health Lab) via NIH Centers for Research in Emerging Infectious Diseases, EID-Southeast Asia Research Collaborative Hub. As a collaborator within the DARPA PREEMPT network I supported surveillance for coronaviruses and other priority emerging zoonotic viruses, henipaviruses and filoviruses, in Ghana (Zoological Society of London), Australia (Black Mountain Labs) and Bangladesh (icddr,b). We aim to characterize the geographic distribution of zoonotic filoviruses/henipaviruses/coronaviruses, transmission dynamics in wildlife hosts and generate risk-models for Ebola virus, Nipah virus and SARS-related CoV outbreaks. Results discovered so far suggest a wider

geographical footprint of Asiatic filoviruses and have identified several fruit bat species that act as natural reservoirs for these viruses.

4. Responding to the emergence of SARS-CoV-2, our lab developed multiplex serology strategies to identify SARS-CoV-2 antibodies and address research questions related to whether pre-existing antibody memory induced by prior infection with seasonal human coronaviruses affects COVID-19 severity. Our lab's serology efforts supported NIH and DHA collaboratively funded protocols including prospective, longitudinal serological analysis of hospital and community subjects, and health-care workers; and cross-sectional analyses of SARS-CoV-2 infection among deployed military health-care workers.

SARS-CoV-2 Infections and Serologic Responses Among Military Personnel Deployed on the USNS COMFORT to New York City During the COVID-19 Pandemic. *Open*

5. In addition to providing serologic assessment of SARS-CoV-2 infection, my research team is actively engaged in examining the durability of COVID-19 vaccine induced humoral immunity. Antibody responses, particularly neutralizing antibodies, are frequently cited as a predictive correlate of protection. With the emergence of variants of concern and waning circulating antibodies, the timing of booster shots remains an important measure for controlling the pandemic. In my lab we evaluate the duration of neutralizing antibodies, durability and breadth of antibody responses against emerging variants of concern, hybrid immune responses, and post-vaccination infections.

BUDGET JUSTIFICATION

The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (HJF) in partnership with the Uniformed Services University of the Health Sciences (USUHS) will manage this proposal, if awarded.

Personnel

Key Personnel:

Eric Laing, Ph.D., Co-Investigator (0.8 calendar month). Dr. Laing will be responsible for the coordination of the project activities with the principal investigator and other co-investigators. Dr. Laing will oversee the lab activities pertaining to the production of recombinant virus protein antigens and the establishment of the multiplex serology test. Dr. Laing will provide mentorship to the postdoctoral student and assist with data analysis. Dr. Laing will oversee serological training activities at the partner lab in Bong, Liberia and assist with in-country testing and data interpretation. He will provide the necessary concepts and practice of viral glycoprotein antigen preparation for serological application to co-investigators and collaborators. Dr. Laing will also provide the virological and immunological expertise necessary to understand the serological profiles of humans and wildlife antisera. Dr. Laing will be a government employee and no salary support is requested.

Other Personnel:

Dr. Si'Ana Coggins, PhD, Associate Scientist (6 calendar months, YR1-3; 3 calendar months, YR4-5). Dr. Coggins will assist with the supervision of all lab activities at USU and interface with the project management teams. As a trained biochemist Dr. Coggins will oversee all protein expression and maintain the quality and rigor of the research. Dr. Coggins will work closely with the research assistant, Mr. Lucas in year 1 to prepare protein antigens, verification of material quality, coordinate the transfer for materials to the partner institute in Bong, Liberia, and assist in the project activities. Dr. Coggins is an employee of the Henry M. Jackson Foundation and salary support is requested for years 1-5.

Mr. Brendan Lucas, BS, Res Asst I (6 calendar months, YR1). Mr. Lucas will assist Dr. Coggins in the production of soluble glycoproteins and be responsible for microsphere coupling in YR1. Mr. Lucas will participate in serological testing and quality verification of the material. He will also prepare shipments of materials to the regional partner lab. Mr. Lucas is an employee of the Henry M. Jackson Foundation and salary support is requested for year 1.

TBD, Postdoctoral Fellow (12 calendar month, YR2-5). A postdoctoral fellow will be hired to participate in the scientific activities described in this grant application. The postdoctoral fellow will assist with the preparation of materials for testing of human and wildlife samples, and be the statistical analysis of the serological data. The postdoctoral fellow will develop statistical models to analyze serologic, host, and ecological data. The postdoctoral fellow will work closely with epidemiologists at the prime institute to generate data for yearly reports. The postdoctoral fellow will be an employee of the Henry M. Jackson Foundation and salary support is requested for year 2-5.

International Travel:

Based on FY23 Department of State per diem rates and historical travel to Liberia (outside of Monrovia), we estimate \$3,640 should cover the travel costs of two lab members to travel to initiate and maintain project activities in the partner lab over one week in all years.

Domestic Travel:

Based on FY23 GSA per diem rates, we request \$1500 for multiple trips to the Principal Investigator home office in New York City for collaboration and meetings for years 4-5.

Supplies:

Based on current prices, the following equipment and supplies will be needed to support this project: Recombinant production of 34 protein antigens, magnetic beads, plastic consumables, cell culture materials, affinity matrices and control antibody materials.

Year 1 - \$66,957

Recombinant protein production

Multiplex serologies and consumables

Year 2-3 - \$20,683

Recombinant protein production (reduced)
Multiplex serologies and consumables

Year 4-5 - \$11,673

Multiplex serologies and consumables

Indirect Costs:

HJF indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The fringe rate used is 29.42 % for Tier 1 employees and 7.29% for Tier 2 employees (all employees in this proposal are Tier 1).

The HJF indirect cost is calculated based on the value-added cost base overhead rates. The IDC rate is 36.74% USU Onsite Overhead. Additionally, 16.70% Companywide G&A and applied on the total direct cost less subaward plus the USU Onsite Overhead. For proposals including subawards, an additional 1.93% is applied on total external subaward costs.

The above fringe benefits and indirect cost rates for FY2023 were approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

Hi, all,

Please send me your itemized budgets & justifications ASAP. I am looking for updated budgets to meet the new (reduced) yearly totals for USU, UNC, and NPHIL.

I need to have enough time to get them approved by EHA and input into NIH ASSIST, so please have them to me by Wednesday morning at the latest.

Please let me know if I can answer questions about yearly budget targets or anything else.

Best,
Madeline

Project Abstract (250 words)
<p>Prototypical henipaviruses (Hendra and Nipah virus) are bat-borne zoonotic viruses and cause high mortality. The recent detection of closely related Mojiang and Langya viruses in rats and shrews, and isolation of Langya virus from individuals with acute febrile illness, challenges the dogma that fruit bats are the sole henipavirus reservoirs. The recently expanded <i>Henipavirus</i> genus includes two other shrew-borne viruses (Gamak and Daeryong viruses), and the Madagascan fruit bat-borne Angovkeely virus. As part of EID-SEARCH activities, we found serological evidence of infection by a Mojiang-related virus in a community of Thai bat guano collectors who have occupational exposure to microbats and rodents. Identifying the wildlife reservoir of this likely novel virus will assist intervention strategies to reduce spillover risk. However, PCR detection or virus isolation in wildlife is challenging, and new serological approaches may be more successful in identifying reservoir hosts. This project aims to identify novel viruses and zoonotic reservoirs through serologic and cellular immune discovery. We will conduct follow-up human and wildlife (shrews and rodents) surveillance in the province where the seropositive humans were identified and apply an expanded serological test and genomic sequencing to detect this novel MojV-like henipavirus. Further, we</p>

Study Personnel

Krongkan Srimuang, Ph.D., is a researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital and supports the Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of Southeast Asia (EID-SEARCH) research. Dr. Srimuang is also a medical technologist working to identify, detect and characterize the spill-over risk of high zoonotic potential viruses from wildlife and humans using serology techniques, Next-generation sequencing, and PCR assays to identify novel viruses. Dr. Srimuang also performs the project Smart Sentinel Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) to identify, detect and characterize the novel/known Respiratory Viruses in our country, Thailand by using multiplex real-time PCR, family PCR and Next-generation sequencing of novel viral pathogens. Dr. Srimuang graduated with Ph.D. in Tropical Medicine from the department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University.

Spencer Sterling, MPH, is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Mr. Sterling will planning, sample processing, data analysis, and report preparation for this project.

Dr. Eric Laing will act as mentor for Dr. Srimuang and Mr. Sterling under the Centers for Research in Emerging Infectious Diseases (CREID) Pilot Research Program. Dr. Laing is an assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses at Uniformed Services University, Bethesda, MD. Part of Dr. Laing's research focus in on the development of serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Dr. Laing has worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Through these collaborations, Dr. Laing's research group aims to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence.

Dr. Supaporn Wacharapluesadee, Ph.D. is the head laboratory at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, a WHO Collaborating Centre for Research and Training on Viral Zoonoses. Dr. Wacharapluesadee research interests include emerging infectious diseases in bats (including Nipah, Rabies, Coronavirus, and novel pathogens) as well as molecular diagnoses and sequencing of viruses. During the past 10 years, Dr. Wacharapluesadee got funding from USAID PREDICT to conduct the surveillance for novel virus in wildlife and human, and from Biological Threat Reduction Program US DTRA to conduct the EID surveillance in bat using the molecular technology and multiplex serology panel (Luminex technology). TRC-EIDCC is responsible for molecular diagnoses services to the hospital, and is the reference laboratory for rabies virus, MERS-CoV, Ebola, Zika, and other infectious diseases diagnoses for Ministry of Public Health, Thailand and laboratory training center on national and regional level. Dr. Wacharapluesadee has served and consulted on several WHO and Thai government committees.

Specific Aims

The recent discovery of novel shrew and rodent-borne henipaviruses in East and Southeast Asia has highlighted gaps in our understanding of henipavirus transmission and underscores the importance of surveillance activities in the region. In particular the isolation of Langya virus from acutely ill humans and shrews demonstrated the need to further surveillance and therapeutic development against emergent henipaviruses. Therefore, this project aims to expand the study of known reservoirs of zoonotic pathogen origin by using genetic and serologic techniques, and to use cellular immune discovery in seropositive humans as a tool to determine henipaviral antigenic relatedness to assist with the functional assessment of current therapeutics as and their effect on these novel viruses.

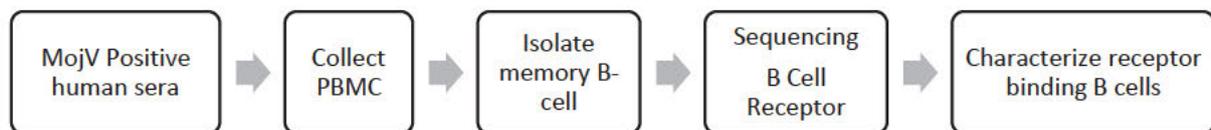

In our study, we detected that a high seroprevalence against MojV in human participants near the Khao Chong Phran Non-hunting Area in Ratchaburi province who we identified as representing a high risk population for zoonotic spillover. Yet, no virus sequences were detected. We hypothesize that (i) there is a novel henipavirus present in the local wildlife population that has spilled over into the human population at least once, and (ii) the antibodies from these seropositive people will react with the novel shrew-borne henipaviruses in a way that can inform us on therapeutic approaches for future outbreaks. We will follow-up with persons who had high anti-MojV IgG levels, sample new participants within this community who interact with the local wildlife, and sample shrews and rodents to identify the wildlife source of the MojV-like henipavirus. Additionally, in collaboration with NIH VRC PREMISE, MojV receptor binding protein (RBP) and fusion protein-reactive B cell will be isolated from previously-identified seropositive human participants. MojV-like virus-specific B-cell receptors will be sequenced and monoclonal antibodies specific to the infecting MojV-like virus RBP and F protein will be generated and tested for cross reactivity against presently described rodent associated henipavirus envelope glycoproteins, and cross neutralization against Langya virus.

The proposed project has two Aims:

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

The proposed project has two Objectives:

Objective 1. To use metagenomic and targeted sequencing approaches in human and wildlife populations to detect the Thai MojV-like virus.

Objective 2. To isolate and sequence memory B-cells from humans positive for Mojiang virus in Ratchaburi province, Thailand for antibody discovery.

Study Rationale

Nipah virus (NiV) and henipaviral diseases are among the most virulent of zoonotic diseases. The genus *Henipavirus* is currently composed of nine viruses including the prototypes, NiV and Hendra virus (HeV), and Cedar virus (CedV), Ghana virus (GhV), Mojiang virus (MojV) (McLinton et al., 2017), Langya virus (LayV) (Zhang X et al., 2022), Gamak virus (GAKV), Daeryong virus (DARV) (Lee et al., 2021), and Angavokely virus (AngV) (Madera et al., 2022) (Table 1). HeV was first identified in Australia in 1994 as a cause of respiratory illness and fatal encephalitis in humans and horses. Closely following the discovery of HeV, NiV was identified in 1999 in Malaysia after outbreaks of fatal encephalitis in humans, with swine determined to be the intermediate host. Annual outbreaks of NiV have occurred in Bangladesh and are associated with the consumption of raw date palm sap, and since 19 May 2018 annual outbreaks of NiV associated encephalitis of been recorded in Kerala, India (Uwishema et al., 2022). Both HeV and NiV have a broad host range capable of infecting several mammalian orders, and can enter and infect endothelial cells, vasculature, and the central nervous system leading to severe multisystem organ diseases and high mortality. The broad host and tissue tropism of these viruses has been attributed to the use of the ephrinB2 and ephrinB3 ligands, highly conserved proteins with critical functions in evolutionary development, as virus receptors (Bossart et al., 2008). There are currently no vaccines or therapeutics and NiV and henipaviral diseases remain WHO Blueprint list priority pathogens (Middleton and Weingartl, 2012).

A close relative of HeV, CedV was isolated from Australian bats in 2012 and found to be non-pathogenic, failing to cause any clinical symptoms in ferrets and guinea pig animal models (Marsh GA et al., 2012). The natural reservoirs of HeV, NiV, and CedV are flying foxes (*Pteropus sp.*) (Middleton and Weingartl, 2012). GhV was detected in Ghana in straw-colored fruit bats (*Eidolon helvum*) during routine surveillance in 2015 and was the first henipavirus found outside of the Indo-Pacific region. GhV showed a close phylogenetic relationship with HeV and NiV, and like HeV, NiV, and CedV the GhV RBP can mediate binding to ephrinB2 ligand and mediate cellular fusion (Drexler, J. F., 2009). Recent investigations into Madagascan fruit bats (*Eidolon duprenum*) detected a second African henipavirus, AngV. As neither GhV nor AngV have been isolated or rescued, the pathogenic and zoonotic potential of these African fruit bat associated henipaviruses remains unknown.

Multiple genera of small mammals were tested for viral RNA, and MojV was detected in yellow-breasted rats (*R. flavipectus*) (Wu Z et al., 2014). The discovery of the MojV genome occurred during follow-up investigations into lethal pneumonia from three miners in 2012 in China, however the pathogenic nature of this virus has only been suggested and no isolates have been discovered or tested in an animal model. Additionally, the novel shrew-borne henipaviruses, GAKV and DARV were found in the Republic of Korea in 2017-2018. (Lee et al., 2021). Most recently, a close relative of MojV, Langya henipavirus (LayV) was recently isolated from febrile patients in eastern China. Subsequently, LayV was identified in shrews (Zhang et al., 2022), increasing the number of Asiatic rodent-associated henipaviruses to four. These recent discoveries are challenging the paradigms surrounding henipaviruses and their associations with bats and may suggest a novel rodent sub-genus of henipaviruses.

The henipaviral genome consists of six structural proteins including nucleocapsid (N), phosphoprotein (P), matrix protein (M), fusion protein (F), receptor-binding protein (RBP), and large (L) protein (approximately length of 18,000 nucleotides) (Luby, S. P., & Gurley, E. S., 2012). In HeV and NiV, slippage sites within the P protein lead to the expression of the V, W, and C proteins. These proteins are virulence factors and are absent in CedV.

Table 1 Summary viruses in Henipavirus

Henipavirus	Origin (Year)	Reservoir	Genome (nucleotides)	Symptom for human	Reference
Hendra virus (HeV)	Australia (1994)	Fruit bats	18,234	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Nipah virus (NiV)	Malaysia (1999)	Fruit bat	18,246	Encephalitis	Luby, S. P., & Gurley, E. S., 2012
Ghana virus (GhV)	Africa (2009)	Fruit bat (<i>Eidolon helvum</i>)	18,530	No data	Drexler, J. F., 2009
Cedar virus (CedV)	Australia (2012)	Fruit bat	18,162	Non-pathogenic	Marsh, G. A et al., 2012
Mojiang virus (MojV)	China (2012)	Rodent	18,404	Febrile	Wu Z et al., 2014
Gamak virus (GAKV)	Korea (2017-2018)	Shrew	18,460	No data	Lee et al., 2021
Daeryong virus (DARV)	Korea (2017-2018)	Shrew	19,471	No data	Lee et al., 2021
Langya virus (LayV)	China (2019)	Shrew	18,402	Acute febrile	Zhang et al., 2022
Angavokely virus	Madagascar (2019)	Fruit bat	16,740	No data	Madera et al., 2022

Viruses in the genus *Henipavirus* have a broad reservoir and may cause high case fatality rates following human infection. The discovery and characterization of the novel Henipavirus is a high public health priority.

Khao Chong Phran, a cave in Ratchaburi Province, has possibly the largest colony of bats in Thailand. There are estimated to be around 2 million bats in the cave and 95% are insect-eating bats (Department of National Parks, Wildlife and Plant Conservation, Thailand). Moreover, Khao Chong Phran has many community sites, such as cave entrances near communities, guano collection, and tourism sites, which risk zoonotic spillover. Bats are widely considered the animal hosts of zoonotic pathogens such as rhabdoviruses, coronaviruses, paramyxoviruses, and filoviruses, and many of the host species can be found in Thailand.

MojV was associated with a severe pneumonia-like illness killing three of six miners in 2012 in a mineshaft Yunnan, China. Interestingly, this mineshaft was also site where RaTG13, a beta-coronavirus most closely related with SARS-CoV-2, was detected in *Rhinolophid* bats (Rahalkar and Bahulikar, 2020). Identifying the wildlife reservoir of this novel virus will assist intervention strategies to reduce spillover risk.

Research Gaps

As a part of Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH), serological investigations using a multiplex microsphere-based immunoassay (MMIA) have detected 19% (54/284) seroprevalence for MojV in a high-risk cohort, including one person with a high magnitude and durability of anti-MojV IgG across longitudinal samples. Despite this, genomic surveillance has not detected MojV or any novel MojV-like viruses. For this result, we would

like to identify and characterize the origin of the Mojiang virus-reactive serum and to explore the novel MojV-like virus in Thailand.

Serological and cellular immunity is an important resource for virus discovery detection by using the specificities and characteristics of memory B cells from peripheral blood mononuclear cells (PBMC). The immune response will recognize and induce antibodies specific to the infecting pathogen. Characterizing the memory B cell response to an unknown pathogen in humans could in the detection of the exposure pathogen in humans. Molecular techniques such as PCR can detect only the genomic material in the body, but memory B cells are long-lived and thus have a much larger window of detection.

Memory B-cell differentiation is characterized by somatic hypermutation in antibody variable region genes (V) and selection of B cells expressing high-affinity variants of this antigen receptor and high sequence similarity in individuals exposed to the same antigen reflect antigen-driven clonal selection and form shared immunological memory between individuals (Yang et al., 2021). Memory B cells are highly abundant in the human spleen, and can proliferate 45% of the total B cell population in this organ (Hauser et al., 2015). Memory B cells can be detected in the Ig variable (IgV) genes in a fraction of IgM+ B cells. In humans, B cells expressing the memory marker CD27+ can be found in the marginal zone of spleen and circulate in the blood. After re-exposure to antigen, memory B cells can quickly proliferate and differentiate into plasma cells. Many studies the antibody diversity and specificity of the naturally paired immunoglobulin heavy and light chains for affinity maturation of B cell receptor (BCR) after virus infection such as SARS-CoV-2 infection (Yang et al., 2021), influenza (Dougan, S et al., 2013), HIV (Moir, S., & Fauci, A. S.,2017), etc. The characterization of memory B cells can be used to develop monoclonal antibodies and produce an effective therapeutic.

Significance and Approach

East and Southeast Asia is one of the world's highest-risk emerging infectious diseases hotspots. From this region emerged both SARS-CoV-1 and SARS-CoV-2, recurrent outbreaks of novel influenza strains, and the spillover of dangerous viral pathogens such as Nipah virus. The diversity of coronaviruses, henipaviruses, and filoviruses are found in wildlife reservoirs in Southeast Asia and likely due to the high diversity of wildlife, and the demography of the human population brings humans and wildlife into close contact. The spillover of viruses from animals to humans is often misdiagnosed and the clinical symptoms from patients is underestimated during the pandemic. This study provides a surveillance strategy in human and wildlife populations to better understand immunity to novel pathogens and identify the origin of these pathogens to serve as an early warning system to prevent outbreaks of emerging viruses.

This study uses immunology (serologic and cellular) to identify a novel virus that can aide in effective vaccine discovery and development, monoclonal antibody production for prevention and therapy, and generate data resources for early detection and diagnostic assays. Whereas PCR detection or virus isolation in wildlife is challenging, this new serological approach may be more successful in identifying reservoir hosts.

The Indo-Pacific region has a high risk of novel viral emergence. This study provides an opportunity for in-country research capacity building by linking local infectious disease scientists with an international collaborative network that has proven capacity to conduct this work and produce significant findings. Moreover, a global sero-surveillance network for surveillance technology extends virologic and immunologic screening to product discovery. This study will benefit and expand the CREID, EID-SEARCH networks, and the global sero-surveillance network to improve our understanding of immunology to identify novel pathogens and their origin to prevent future pandemics.

Research Methods

Aim 1. Longitudinal sampling of humans with MojV RBP-reactive serum, syndromic surveillance and investigations into the shrew and rodent population

Serological profiling provides an indirect measurement of the infecting virus. Despite 19% (54/284) seroprevalence in humans, we have not detected nucleic acid sequences of MojV or MojV-like henipaviruses in this human cohort. Additionally, we intend on expanding our understanding of henipavirus prevalence in this population with longitudinal sampling of the wildlife and human populations in this region.

Animal samples collection

200 shrews or rodents in and around the Khao Chong Phran cave in Ratchaburi Province (Figure 1) will be collected for surveillance targeting the Mojiang-like virus. We plan two sampling trips to collect target shrews and rodents. Due to limited knowledge of the local shrew population, we are unsure as to whether we can collect up to 200 samples and will supplement the collection with rodents, as needed. Samples will be collected based on the following enrollment criteria: random age, random weight, random sex. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored. Oral swab and rectal swab will also collect in 200 shrews or rodents. Blood from animals will be collected using a needle to collect venous blood, and collected blood will be centrifuged and the serum will be removed and stored.

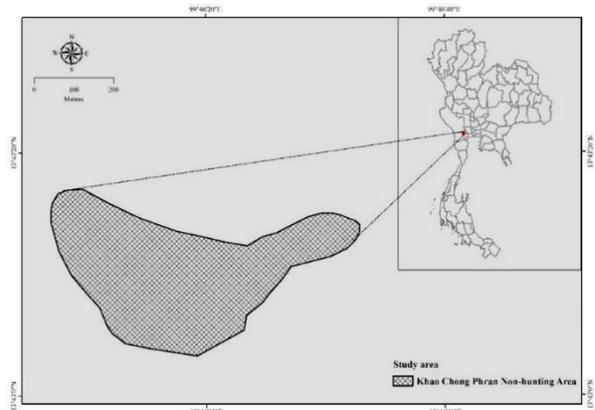

Figure 1: Map of Khao Chong Phran Non-hunting Area, Ratchaburi Province, Thailand (Boonpha N et al., 2019)

Human surveillance

Four of the samples from prior investigations have shown high MojV RBP-reactive antibody titers and will be selected for follow-up sampling. Additionally, 100 human serum samples, nasopharyngeal swabs, throat swabs and questionnaires will be collected from persons deemed to be in close contact with wildlife, and people who present with or have recent history of undiagnosed acute febrile illness using the following enrollment criteria;

- Adults (≥ 18 years of age) who sign in the informed consent
- Who present with or have recent history of illness without diagnosis, such as severe/acute respiratory illness (SARI/ARI), Influenza-like illness (ILI), fever of unknown origin (FUO), or respiratory tract infection
- Who is the bat guano collector in the cave
- Who lives or works around wildlife habitats
- Who is involved with livestock or wildlife farming
- Who hunts or works with wildlife
- Who has not been previously sampled as part of the EID-SEARCH and PREICT projects

Sample size justification

Human population

$$n = \frac{N}{1 + Ne^2}$$

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

n = sample size of the study

N = population size for finite populations: 8,150 (data from 2018)

e = error: 10%

$$n = \frac{8,150}{1 + (8,150 \times 0.1^2)}$$

n = 98.79 (round up to 100 samples)

Wildlife population

We will target a total of 200 individuals of shrews and/or rodents across two trips for this project. This sample size is estimated based on a realistic detection rate and required sampling efforts from previous wildlife surveillance work, given the rodent/shrew population at the study site. Previous publications regarding Henipavirus discovery in small mammals had an average PCR detection prevalence between 20 and 33% (Wu et al., 2014, Lee et al., 2021, and Zhang et al., 2022). We acknowledge the challenge of identifying positive results, and very limited serology research has been done to provide guidance. However, we will make the best use of previous data and experience to conduct sampling at the selected site where human positives have been. We are confident that this targeted sampling and testing strategy offers the best chance to identify positive results and potentially novel henipaviruses.

Targeted viral sequencing and serologic testing

Targeted sequencing

For samples from shrews, rodents, and acute individuals, we will use targeted sequencing and metagenomic approaches in an attempt to detect the Thai MojV-like virus. The nucleic acid from oral swab and rectal swab will do target sequencing in henipavirus Family PCR and Sanger sequencing.

Serological testing

Serum samples will be tested for RBP and envelope fusion protein (F) binding to the known henipavirus species, including the Nipah, Hendra, Cedar, Mojiang, Ghana, Langya, Gamak, and Daerong viruses to further investigate the seroprevalence in this region. Additionally, prior positive samples will be re-tested with the expanded panel to enhance our understanding of the antigenic relationships between the novel shrew-borne henipavirus and the Thai virus.

Data analysis

Sequencing will be analyzed assembling reads in MEGA11. The consensus sequences will compare to the references strains available in the GenBank data-base using the Basic Local Alignment Software Tool (BLAST) (National Center for Bio-technology Information). Serological data will be analyzed using cluster analysis in RStudio.

Aim 2. Characterization of monoclonal antibodies from humans with serological profiles consistent with MojV infection.

In collaboration with NIH VRC PREMISE, MojV RBP and F-reactive B cells will be captured, and the B cell receptor will be sequenced from previously-identified seropositive human participants. MojV-like virus-specific mAbs will be generated from the corresponding sequences and will be assessed for binding potential to LayV RBP and F, as well as their neutralization potential.

Importance: The isolation of these mAbs represents a potential therapeutic for MojV, MojV-like henipas, and LayV, depending on how well these cross react.

Target human population

Human positive serum for MojV was found close to Khao Chong Phran Non-hunting Area in Ratchaburi Province (Figure 2).

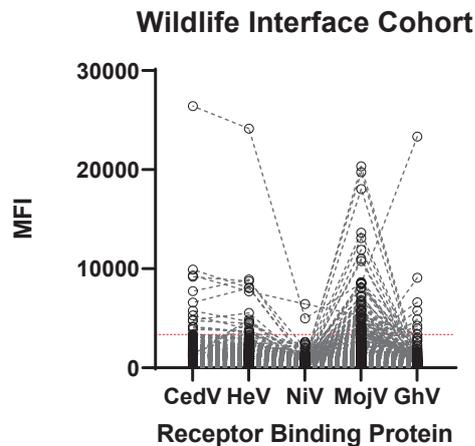

Figure 2: Seroprevalence of henipavirus proteins from a community with a large wildlife interface during 2017-2018. MFI is the median fluorescence intensity for IgG reactivity to each protein. Red-dashed line is at 3,357 MFI, a threshold for seropositivity.

PBMC sorting and B cell isolation

Whole blood from MojV-positive people will be collected in individual heparin tubes and processed for PBMC isolation using Density Gradient Centrifugation (SepMate™ PBMC Isolation Tubes). Human PBMCs will be stained with antibodies for positive markers of IgG memory B cells, and antibodies to negatively select and avoid contamination with dead cells, T cells, NK cells or monocytes (live, CD3, CD14, CD56, IgM, IgA, CD19+, CD20+, CD27+). Avi-tag for biotinylation and 6xHIS tag for Nickel purification using the HisPur™ Ni-NTA Spin Purification Kit (Thermo Fisher Scientific, Waltham, MA). Single Memory B Cells will be sorted, cells will proliferate, cDNA will be synthesized, then Heavy and light chain variable domains will be amplified (Waltari E et al., 2019).

B cell receptor amplicon preparation and recombinant antibody sorting

Total RNA yields from the PBMC will be determined by absorbance at 260 nm on the NanoDrop™ One (Thermo Fisher Scientific). Total RNA will be used for first strand cDNA synthesis with gene-specific reverse transcription (RT) primers directed to the constant regions. The RT primers for IgG, IgM, IgA, lambda, and kappa will be included. Light chain and heavy chains will be amplified into amplicon. Double-stranded cDNA will be sequenced. After completion of MiSeq sequencing, antibody repertoires will analyze using methods based on the pipeline. Heavy and light-chain sequences will be assembled into an expression vector and transfected into cells for monoclonal antibody expression. Recombinant antibody will be isolated and purified for downstream applications.

Functional assessment

We will first determine the extent to which isolated mAbs can bind to native-like MojV RBP and F proteins. We will also characterize the cross-reaction potential of these mAbs will be assessed against GamV, DarV, and LayV RBP and F. Neutralization of viruses remains a critical correlate of protection for most vaccine strategies. However, MojV has not been isolated or rescued, and the virus receptor for MojV has not yet been discovered (Rissanen et al., 2017; Cheliout et al., 2021). Thus, a functional assessment of MojV neutralizing potential is not possible. Though, we will test the cross-neutralization potential of these anti-MojV RBP and F mAbs to neutralize LayV utilizing a plaque reduction neutralization test with EID-SEARCH co-investigators at Duke-NUS. As LayV causes acute illness in human, cross neutralization functionality of these mAbs has therapeutic potential.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Research Performance Sites

This proposed study will be implemented at the King Chulalongkorn Memorial Hospital (KCMH) collaborating with the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC). KCMH is a 1,000-bed, university hospital in close coordination with the Faculty of Medicine, Chulalongkorn University. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. It's one of the center hospitals for Emerging Infectious Diseases in Thailand, especially for domestic and international patients.

TRC-EIDCC was established by the Committee of the Emerging Infectious Disease Center, which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. Our clinical center provides standard medical care to patients with emerging and recurrent diseases and disease transmission. Moreover, the center plans preparedness activities, trains medical and government staff on interventions, hosts conferences for medical and public health professionals, creates networks of medical care for patients with emerging and recurrent diseases, and leads research and development projects for medical care and disease control. Apart from medical innovation in emerging and recurrent diseases, the clinical center strives to be the model of infectious diseases clinical services and pandemic control through research activities surrounding infectious diseases and effective disease control measures.

We also collaborate with the Department of National Parks, Wildlife and Plant Conservation for detecting novel pathogens from animals such as bats, rodents, and shrews in our country. We also collaborate with the Department of Disease Control of Thailand (Thai-DDC) to support the Thai government and national policy makers through molecular diagnosis, including the identification of the first case of SARS-CoV-2 infection in Thailand. TRC-EIDCC prides itself on its high performance in research laboratory services and is a part of the national reference laboratory for COVID-19 and other emerging infectious diseases confirmation in Thailand.

CREID Research Center Collaboration

The goals and objectives of the proposed research project, “Immune memory bait & capture to identify emerging henipavirus origins”, are fully consistent with the specific aims of EID-SEARCH. EID-SEARCH takes a One Health approach to understanding zoonotic disease emergence, with a focus on viral diversity in wildlife at high-risk human animal interfaces. EID-SEARCH aims to understand the frequency and causes of virus spillover in high-risk communities across Southeast Asia and identify strategies and tools to reduce this risk. As the proposed research focuses on the links between farming practices, wildlife diversity, virus diversity, and cross-species transmission in Thailand, we expect the results of the project to make a significant contribution towards the overall goals of EID-SEARCH.

The proposed project is well-designed, leverages cutting-edge technology, and includes a robust ecological component that corresponds to the overall research strategy of EID-SEARCH. The EID-SEARCH team is highly motivated to support the application of metagenomics to ecological questions and assist in the analysis of the unique dataset that will be generated from this research. With the heightened focus on identifying and limiting risks associated with the complex interactions between humans, wildlife, and domestic mammals that has resulted from the emergence of SARS-CoV-2 from a wet market in China, the proposed research is both timely and likely to yield highly-cited, impactful publications for EID-SEARCH and Thailand partners.

The EID-SEARCH team includes a number of experts in study design, laboratory-based diagnostics, genetic and genomic analyses, and ecological modelling who will contribute to project implementation, data analysis, and manuscript preparation as required. Communication and coordination mechanisms will be set up between the Thailand research team and scientists at the EID-SEARCH research sites for resource sharing, training, knowledge exchange, and mentorship. In particular, EID-SEARCH will facilitate and encourage relationships between our partners in Southeast Asia (based in Malaysia, Singapore, and Thailand) that will facilitate Thailand team professional development and strengthen research capacity in the region. Dr. Eric Laing, the project Mentor, has an established relationship with both Dr. Krongkan and Spencer Sterling, and will act as the liaison between EID-SEARCH and the TRC-EIDCC research team. Further, Dr. Doeuk who is the director of the VRC PREMISE program is enthusiastic about the opportunity to collaborate and apply their rapid assembly, transfection and production of immunoglobulin (RATP-Ig) workflow as a serologic/immunologic based approach for therapeutic and virus discovery (see Letter of Support). An expected outcome of this research project will be pilot data to support a joint funding application in the future.

Mentoring Plan

Goals for Pilot study and Career

Krongan Srimuang: My career goal is to be an expert scientist in either an academic research laboratory or a lecturer in medical science. My long-term research interests include the understanding of priority emerging infectious diseases, genetics, and epigenetics using molecular and serologic techniques. Detection of novel pathogens in their wildlife vectors can help characterize the pathogenicity, virulence, and evolution of these and other closely related pathogens. I believe that this pilot study can provide training in new techniques for the detection, identification, and characterization of novel pathogens that are currently unavailable in Thailand. My goal for the Pilot study is to gain more knowledge and skills for a lifelong career in public health-related research. I wish to expand my skills in novel virus detection using next-generation serologic techniques such as PBMC studies and memory B-cell isolation and sequencing that can contribute to improved surveillance and research capacity at human-animal interfaces. My mentors Dr. Laing and Dr. Wacharapluesadee can provide me with opportunities to develop and apply project skills and improve my scientific writing.

My education has provided me with a strong foundation to expand for this study. I received my undergraduate degree in Medical Technology from Chulalongkorn University which included training in molecular biology, serology, immunology, chemistry, virology, bacteriology, mycology, parasitology, hematology, clinical microscopy, transfusion medicine, and forensic medicine. My interest in molecular technology led me to pursue a Ph.D. at the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, which provided me with training in several molecular techniques including conventional PCR, real-time PCR, Next Generation Sequencing (NGS), etc. The emergence of COVID-19 motivated me to focus on emerging infectious diseases. I am currently completing my post-doctoral fellowship at the Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital with Dr. Wacharapluesadee. Throughout this fellowship, I have continued learning advanced and innovative techniques to detect, identify, and characterize the novel pathogens. Through this pilot project, I will learn about the Peripheral Blood Mononuclear Cells (PBMC) which are a critical part of many subdivisions of medical research including Infectious diseases, Vaccine development, and Immunology. This project aims to study zoonotic reservoirs for by using serologic and cellular immune discovery in humans, and applying this immune knowledge in wildlife for early detection and identification of novel pathogens. This proposed study will expose me to various techniques and immunology topics that I useful in designing and testing new pipelines as technological advances continue to develop. This study will also allow me to develop, manage, and communicate my research.

Spencer Sterling: My overall career goal is to understand the factors that lead to viral zoonosis and to build epidemiological capacity in regions with the highest risk for zoonotic spillover. Through my training and educational experiences, I have learned laboratory and epidemiological techniques that can assist in the understanding of zoonosis. I wish to continue my education by expanding my repertoire of molecular techniques to include studies of the immune system's response to zoonotic disease in humans and animals, as well as to learn next-generation sequencing techniques. Additionally, I would like to use my experience in epidemiological techniques to train scientists in the Southeast Asian region in order to build local capacity in infectious disease research. Dr. Laing has been a mentor for me throughout my career, and this project would allow for this relationship to expand into new molecular areas, as well as grant writing and project management skills. My professional relationship Dr. Wacharapluesadee with began in 2018 when I participated in a DTRA BTRP funding project that focused on transferring antigen-based multiplex serological technology to her lab group. Currently, I am a Visiting Scientist at TRCEIDCC and I work closely with Dr. Srimuang, and other members of Dr. Wacharapluesadee's research group on EID-SEARCH activities. Additionally,

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Dr. Wacharapluesadee has decades of experience in infectious disease research in the region and has mentored scientists that have gone on to careers at the Thai Ministry of Public Health, Department of Disease Control, Department of Parks and Wildlife, academia, and the private sector. Both mentors have encouraged Dr. Srimuang and I to apply for this pilot study as well as pursue other funding mechanisms for our research interests. Both mentors will provide for me the ability to independently pursue my research interests in the zoonotic epidemiology and train me on the best practices of scientific communication.

Vertebrate Animals Section Requirements

Animal samples will be collected in Ratchaburi Province for this project under Aim 1 to understand the antigenic relationships among known and unknown henipaviruses. Protocol to perform animal sample collection has been reviewed and approved by the Institutional Animal Care and Use Committee at Tuft University under the EID-SEARCH project (No. G2020-42) and the Institutional Animal Care and Use Committee at Chulalongkorn University (No. 019/2563)

1. Description of Procedures

Rodents (order: *Rodentia*) and Shrew (order: *Scandentia* and *Eulipotyphla*)

- Species: Free-ranging rodents (family *Hystricidae*, *Muridae*, *Sciuridae*, *Spalacidae*) and shrew (tree shrews, shrews, moles) that present at the sites.
- Age & sex: Adults and juveniles, males and females. Neonates will not be sampled.
- Target Number: 200 individuals
- Capture and Restraint: Free-ranging wild mammal species will be captured with metal box traps (Sherman/Tomahawk traps). Traps will be prepared with food, water, padding and shelter, and be checked at least every 12 hours, in the morning and in the afternoon. If adverse weather (extreme heat, rain) is expected or researchers are working in areas where predation is common, traps will be checked more frequently and closed during adverse weather. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. Depending on the species, individual size, captive or free-ranging status of the individual, manual or chemical restraint and anesthesia (gas or injectable anesthesia) will be applied. Animals will be manually restrained during sampling utilizing insulated bite gloves to prevent injury to the handler and animal. Based upon past field experience (>20 years of animal capture and release in Southeast Asia), we do not expect to trap sick, debilitated, or young animals that would be too young to cope with capture. Sick and debilitated animals tend not to roam widely, reducing their opportunity to enter traps. Additionally, should sick, debilitated, or young animals enter traps, we anticipate that they will not suffer adverse conditions because the traps contain food (the bait) and liquid (water or fruit as a source of water). These individuals would be examined by a veterinarian, rehydrated and if presenting clinical signs treated by a veterinarian, prior to release or sampling then release.
- Sample Collection: Once anesthetized or safely restrained, whole blood will be collected through the appropriate venipuncture site, no more than 1 ml of blood per 100 g (= 10 ml/kg or 1%) of body weight will be collected at any one time. Anesthetized animals will be monitored regularly during recovery until they can no longer be safely handled, at which point they will be confined in a trap or cage. Swabs will be taken from the oropharynx, urogenital tract, and rectum. No destructive sampling is planned, but any individuals that die during capture or sampling will have a necropsy performed with organ samples collected.
- Release: Wild mammals are held for a maximum of thirteen hours depending on trap timing, but typically less than three hours. Captive animals are held for a maximum of two hours but typically less than one hour. At the completion of sampling, animals may be provided with rehydrating fluids (either subcutaneously if anesthetized or orally if manually handled and accepted). Wild mammals will be released at the site of capture in a location that allows for further recovery or safe escape (e.g., bodies of water, known predatory areas, and human settlements will be avoided). Captive mammals will be released back into their captive setting as is appropriate for the species, either isolated or in social group if it is deemed safe from aggression from enclosure mates while the post-recovery period continues.

2. Justifications

The purpose of this study is to identify zoonotic pathogens through serologic and cellular immune discovery, including developing methods and standards for direct antibody-mediated virus capture in people and wildlife, focusing on rodent/shrew-borne Henipaviruses (HNVs). This will require hands-on fieldwork to collect whole blood and serum samples from rodents and shrews for lab analysis. One technique that avoids the direct capture and sampling of animals is to collect fresh feces or urine, but this will not be able to provide the appropriate samples for serologic analysis, and the research objectives cannot be achieved using an alternative methods (e.g., computational, human, invertebrate, in vitro). Therefore, we believe there are no viable alternatives than the use of live animals.

3. Minimization of Pain and Distress

In every situation, sampling of wildlife will be conducted in the most humane manner while minimizing the impacts on individual animals and their wild populations. In all instances, the fewest number of animals will be sampled that will provide valid information and statistical inference for the pathogen and disease of interest and every effort will be made to minimize stress and discomfort for the animal.

Small mammals may be held for up to 13 hours depending on trap capture timing. Field animal sampling team with zoologists and veterinarians have been well trained and have extensive experience in capture, anesthesia, and sampling of wildlife. In our team's experience, the target species tolerate the described procedure well. Mist nets will be attended continuously during capture periods. This will minimize stress and injury from entanglement.

For rodents and shrews, food, water, padding and shelter will be provided at traps, which will be checked at least every 12 hours. Traps will be checked more frequently or closed if adverse weather (extreme heat, rain) is expected, or researchers are working in areas where predation is common. Veterinary staff will be prepared to deal with a variety of trap injuries, including lacerations, broken teeth, and crush injuries. All animal individuals will be monitored by a veterinarian or experienced field team member during all stages of capture, processing, anesthesia and release. Animals will be kept in a cool place, free from adverse weather conditions and access by non-field team members or other animals while in the pillowcases, trap, or cage for recovery. All recovering individuals will be observed until they are able to effectively ambulate and orient to their surroundings. Animals that are injured during the capture or sampling process will be assessed by an experienced team leader or attending veterinarian, and if the animal is determined to be unlikely to survive if released, it shall be euthanized humanely (see euthanasia section).

4. Method of Euthanasia

In the event that an animal has been injured or is moribund, a determination will be made as to whether it may be treated and released on site by veterinarians or transferred to facility that may treat and rehabilitate the animal, or if, as a last resort, the animal will require euthanasia. Euthanasia methods will vary depending on species; however methods to be used will not deviate from the AVMA "Guidelines for the Euthanasia of Animals" (2020 edition). Any animal that is euthanized using a chemical agent will be disposed of such that it will not be permitted to enter the food supply either through markets or hunting.

Human Subjects Research

1. Risks to the subjects

In this project, we will target populations in one community site who with frequent exposure to bats and other wildlife based on our previous behavioral survey. Subjects will be enrolled voluntarily, and informed consent will be obtained from all participants. Enrolled participants will provide biological samples. Survey data and biological samples will be collected from enrolled participants, and follow-up data collection will be performed among participants whose samples were tested positive.

Biological samples and questionnaire data will be collected from individuals who meet recruitment and inclusion criteria and complete the informed consent process. During data collection, a standardized questionnaire will be administered to all participants. This questionnaire will collect information of demographic background, wildlife contact, travel and daily movement, and unusual SARI/ILI symptoms, and biological specimens will be collected from participants. Both questionnaire and biological data will be analyzed to assess the exposure to coronaviruses and the spread risk among humans. From all participants, a one-time whole blood sample (Max. 15 mL) will be collected during the study period. This sample will allow us to test for historical exposure to bat or rodent-born henipaviruses and collect Peripheral Blood Mononuclear Cells (PBMCs) for those study participants whose serum tests are positive.

The potential risks to study participants as a result of study participation are minimal. The biological specimen will be collected by locally certified healthcare professionals who are proficient in phlebotomy techniques, the volume of blood being collected is within normal safety limits and the swab sample is not overly invasive. The questionnaire will be designed to assess exposure risk and may ask personal questions; however, the administration will be conducted privately and confidentially to protect individuals' health and exposure information. There may be some stress or discomfort for participants who are informed that they have been exposed to a zoonotic virus, to reduce this counseling will be available and options for future medical care will be included in the discussion with the health official or physician reporting results back to individuals.

2. Adequacy of protection against these risks

2.1 Informed consent and assent

Only consented participants will be enrolled in the study. No research procedures will be undertaken before the participant fully understands the research, agrees to the study procedures, and completes the consent process will be enrolled in the study. Informed consent statements and forms, and project protocols will be translated into the local language of each study site. Research team members involved in this consent process will be required to be fluent in the local language to ensure that the subjects understand the study and all involved procedures.

If participants meet the criteria for enrollment, they will be invited to discuss the details of the study with the research staff. Study staff will review an information sheet and informed consent form with the participant when applicable. Each individual will be provided with a copy of the informed consent form that has been translated into the local language and written with a Flesch–Kincaid readability score equivalent to a 7th-grade reading level or below, to assure that potential participants understand the information being shared. The informed consent form will explain the details of the study, including how and why the individual was selected, the study process and procedures, risks and benefits, financial considerations and the gift of appreciation, confidentiality of data shared, alternatives to participating, and how to obtain more information now or at a later date. The informed consent form will be read in the local language of the site at a location ensuring participant privacy. After which individuals will have as much time as they would like to ask questions and discuss the

study with study staff. The study staff will endeavor to ensure that the participant understands the information provided. The study staff will then ask the participant to consider study participation. Participants will have as much time as required to consider the participation.

Those participants who consent to the study will sign and date two copies of the consent form. These form copies will be countersigned and dated by the study staff. A copy of the signed consent form must be provided to the subject and the other copy will be kept by study staff. Informed consent paperwork will be kept until the end of the project in a locked box at the local country project office.

2.2 Protection against risks

The potential risks to study participants as a result of study participation are minimal. Collection of venous blood samples and nasal or oropharyngeal swab samples pose minimal risk to subjects. Potential complications associated with venipuncture include pain and/or hematoma at the site of collection. Trained medical professionals and/or clinic staff will monitor the blood collection site and treat any complications according to existing health facility protocols. A potential complication of nasal/ oropharyngeal sampling is minor irritation at the time of collection. Employing trained medical and/or clinic staff to collect blood and swab samples will minimize the potential for complications.

Another risk that this study may pose concerns the information to be gained on henipaviruses newly recognized in the community. We will provide participating communities, hospitals, and clinicians with information and background data on target zoonotic viruses to ensure up-to-date communication of risk. Because of the timeline for diagnostic testing and results interpretation, we are not likely to provide results to participating clinics within a time frame that would be clinically relevant to outbreaks of undiagnosed diseases. Therefore, the information provided by this project will not impact patient management or outlook.

If an individual decides to participate in this research, his/her participation and all information provided by the participant will be strictly confidential, and personal identifying information will not be shared with anyone outside of the study staff. Participants will not be identified or named in any reports or publications. Questionnaire information and all biological samples will be identified by an alphanumeric code, not by the participant's name. All records that contain names or other personal identifiers, such as informed consent forms and the confidential participant logbook, will be stored separately from study records. All personal information will be stored securely at the study site in locked files cabinets or password-protected devices in areas with access limited to the research staff of this project. Research databases will be secured with password-protected access systems and controlled distribution web-based certificates and will not contain any identifying characteristics about study participants (e.g., name, address, or telephone number). Access to all data will be limited to the staff involved in this study. The health information disclosed by an individual will not be used by or disclosed (released) to another institution. Any surveillance report that is published or shared with partners will not contain any personally identifying information for individual participants.

3. Potential benefits of the research to the subjects and others

There are no measurable benefits to the individual study participants enrolled in this study. There are benefits to the community and regional healthcare providers to help them understand the risk of zoonotic infections among high-risk populations in the regions they work. At the conclusion of the study, we will deliver an educational workshop reporting aggregate study findings that will be open to both study and non-study participants, describing the health benefits of using personal protection equipment (PPE) and handwashing during animal handling activities throughout the day, as well as to share other prevention/interventions that emerge from the research data.

4. Importance of the knowledge to be gained

There are valuable potential benefits to the public from the knowledge to be gained from this study. One key benefit to the community is sharing information and knowledge to better understand the risk of zoonotic spillover events and related health risks, as well as information sharing with communities on practices that could reduce risks, such as the avoidance of particular animal contacts or the need for PPE and extra care when handling wildlife, that may substantially reduce the risk zoonotic pathogen transmission in the community. This strategy for targeted surveillance and detection of spillover and illness in at-risk human populations can be used as an 'early warning system' to create or implement public health interventions to disrupt disease emergence and/or spread in an area that is beneficial to all. Additionally, there are valuable benefits to the general public from the knowledge to be gained from this study. Knowledge gained will increase understanding of the conditions and human activities associated with the introduction of zoonotic infections into human populations, which may have implications for disease control more broadly.

5. Country- / institution-specific ethics / IRB regulations addressed

Main research protocol and materials to conduct human subject research in this project have been reviewed and approved by the Health Medical Lab Institutional Review Board, US (No. 894ECOH21b) and the Institute Review Board of the Faculty of Medicine, Chulalongkorn University, Thailand (No. 211/64). Amendment for PBMCs collection will be made and approved before the start of this project.

Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Srimuang, Krongkan

eRA COMMONS USER NAME (credential, e.g., agency login):

POSITION TITLE: Research Scientist

EDUCATION/TRAINING (*Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.*)

INSTITUTION AND LOCATION	DEGREE (if applicable)	Completion Date MM/YYYY	FIELD OF STUDY
Chulalongkorn University, Bangkok, Thailand	B.Sc.	03/2012	Medical Technology
Mahidol University, Bangkok, Thailand	Ph.D.	04/2017	Molecular Tropical Medicine and Genetics

A. Personal Statement

I am a medical technologist. My undergraduate training has provided me with a background in multiple biological disciplines including molecular biology, microbiology, and genetics. During my Ph.D., I conducted research with Dr. Mallika Imwong focused on Malaria. My thesis was entitled "Exploring the molecular mechanism of mefloquine resistance in *Plasmodium falciparum*". I conducted research on drug resistance to malaria in Southeast Asia. Specifically, my focus was on molecular techniques in identifying the genetic mutations involved with drug resistance. Moreover, I got experience in *Plasmodium falciparum* malaria culture. After my Ph.D., I worked at the genetics laboratory at Jetanin Institute of Assisted Conception. My responsibilities included Preimplantation Genetic Testing (PGT) is screen embryos for genetic abnormalities such as chromosome copy number gains or losses (PGT-A, aneuploidy screening), single gene disorders (PGT-M, monogenic or single-gene disease), or structural rearrangement (PGT-SR, structural rearrangement to identify embryos with chromosome imbalanced) by using Next Generation Sequencing. Additionally, I conducted genetic screening in couples for detecting carrier diseases such as glucose-6-phosphate dehydrogenase (G6PD), Alpha thalassemia, Beta thalassemia, and Spinal muscular atrophy (SMA) by using molecular genetics techniques. Currently, I am a Research Scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC EIDCC), King Chulalongkorn Memorial Hospital where I investigate emerging infectious diseases under the guidance of Dr. Supaporn Wacharapluesadee. The research focuses on detecting, identifying, and characterizing pathogens and human genome segments using molecular and serology techniques, including Next Generation Sequencing and Multiplex serology assays as a part of EID-SEARCH project. Additionally, I am the laboratory sequencing lead on the Surveillance System: Emerging Viral Pneumonia and Respiratory tract infections (RTIs) project from patients in Thailand as part of a collaboration with the Department of Disease Control.

B. Positions, Scientific Appointments, and Honors

Positions and Scientific Appointments:

02/2022 – Present	Medical research scientist, Emerging Infectious Diseases Clinical Center (EIDCC), King Chulalongkorn Memorial Hospital
05/2017 - 01/2022	Scientist, Genetics Laboratory, Jetanin Institute for Assisted Reproduction
10/2015 - 03/2016	Fellowship at Laboratory of Molecular and Cellular Parasitology, Department of Microbiology and Immunology, National University of Singapore, Singapore.
11/2011 – 02/2012	Training Medical Technology Programs at Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Honors:

2012 -2017	Scholarship for Ph.D. from the Royal Golden Jubilee, Ph.D. Grant (14th Batch).
------------	--------------------------------------------------------------------------------

C. Contributions to Science

Undergraduate Research: I participated in research activities under Dr. Attakorn Palasuwan to study in human genetic variants in proteins, such as G6PD, as they relate to the effect of exercise on the reduction of free radicals in the body. We conducted the multiplex PCR to identify the G6PD variants and found 8 variants including Vanua Lava, Mahidol, Mediterranean, Coimbra, Viangchan, Union, Canton, and Kaiping.

Graduate Research: I continued to studies under Dr. Mallika Imwong in the Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University. My thesis, “Exploring the molecular mechanism of mefloquine resistance in *Plasmodium falciparum*”, focused on the evolution of resistance to mefloquine, which is commonly used in Southeast Asia in Malaria treatment. The mechanism of mefloquine resistance remains unknown, but I focused on the *Pfmdr1* gene which is involved in the drug resistance mechanism in *Plasmodium falciparum*. I found mutations and polymorphisms in *Pfmdr1* gene.

1. **Srimuang K**, Miotto O, Lim P, Fairhurst RM, Kwiatkowski DP, Woodrow CJ, Imwong M; Tracking Resistance to Artemisinin Collaboration. “Analysis of anti-malarial resistance markers in *pfmdr1* and *pfcr1* across Southeast Asia in the Tracking Resistance to Artemisinin Collaboration” Malar J. 2016 Nov 8;15(1):541.

Post-graduate Research: I was a scientist in genetics lab at Jetanin, a holistic center for infertility, offering counseling and treatment with Assisted Reproductive Technologies such as IVF, ICSI, and Preimplantation Genetic Testing (PGT). My work included the development of standard operating procedures for the lab, including Next Generation Sequencing, for detecting and identifying chromosomes in blastocyst growth to an embryo. Additionally, we assisted couples who had a family history of genetic diseases for screening before pregnancy. The carrier screening focused on highly prevalent diseases in Thailand such as alpha thalassemia, beta thalassemia, G6PD, and SMA. Currently, I am a Research Scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital. I am currently tasked with using molecular and serological techniques in the surveillance of novel, exotic, and known pathogens in wildlife and humans.

1. **Srimuang K**, Udompat P, Thippamom N, Petchrat S, Doung-Ngern P, Kripattanapong S, Supataragul S, Sterling SL, Wacharapluesadee S, Puthachoen O. “Genetic characterization of Norovirus strains from an unusual diarrheal outbreak in the community in Eastern Thailand” (Submitted, January 2023)

A. Personal Statement

As a current employee with Dr. Eric Laing under his emerging infectious diseases research program. My academic training and research experience have provided me with a background in molecular biology, virology, and epidemiological techniques for zoonosis investigations. As part of my original post-baccalaureate work, I worked in a small team lead by Dr. Chris Border tasked with developing a serological binding assay for Coronaviruses, Filoviruses, and Henipaviruses. During this process, I worked closely with Dr. Laing and scientists from multiple Asian countries in developing and applying the multiplex techniques for rapid, high-throughput serological assays. Throughout this time, I have led technical and data analysis trainings in Cambodia, Bangladesh, and Thailand, and have assisted collaborators in Singapore, Malaysia, Australia, India, South Africa, and the United Kingdom in implementing these novel techniques. Currently, I am a visiting scientist with Dr. Supaporn Wacharapluesadee in the Emerging Infectious Diseases Clinical Center at King Chulalongkorn Medical Hospital as part of the CREID-EID SEARCH program.

B. Positions, Scientific Appointments, and Honors

05/22-present Visiting Scientist, King Chulalongkorn Medical Hospital, Bangkok, Thailand. Advisors: Dr. Supaporn Wacharapluesadee, Dr. Opass Putchaeron, and Dr. Eric D. Laing.

02/22-present Scientific Project Coordinator, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisors: Dr. Christopher C. Broder and Dr. Eric D. Laing

- 08/20-02/22 Research Associate 2, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 08/19-08/20 Senior Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 06/15 – 08/19 Research Assistant, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder
- 01/14-08/14 Laboratory research internship, Department of Microbiology, Uniformed Services University, Bethesda, MD. Advisor: Dr. Christopher C. Broder

C. Contributions to Science

1. **Post-Baccalaureate:** My post-baccalaureate research works primarily targeted understanding the adaptive immune response to emerging zoonotic viruses as a tool for virus discovery. As part of the assay development team, I designed and expressed soluble, native-like filovirus and henipavirus attachment glycoproteins and developed the monoclonal antibodies and antisera used as standards in the assay. I have led technical training for international projects and assisted in data analysis
 - a. Laing ED, Mendenhall IH, Linster M, Low DHW, Chen Y, Yan L, **Sterling SL**, et al. “Serologic evidence of fruit bat exposure to filoviruses, Singapore, 2011–2016”. (2018). *Emerg Infect Dis.* 24(1):114-117. doi: 10.3201/eid2401.170401. PMID: 29260678.

2. **Professional Studies:** While employed, I continued my studies by pursuing a Master’s in Public Health with a focus on Epidemiology. Immediately preceding my thesis work, COVID-19 was declared a pandemic, and I worked along side Dr. Eric Laing to develop and standardize a human coronavirus serological panel to track the serological response to SARS-CoV-2 infections and vaccinations among a military cohort. For my thesis, I evaluated the humoral immune response to SARS-CoV-2 patients as it related to the severity of the disease, where we observed significantly more robust antibody responses in people with more severe disease.

A. Personal Statement

The spillover of zoonotic viruses into human populations remains an ever-prevalent threat to public and global health. Continual outbreaks of known and unknown zoonotic viruses highlights the paucity of our understanding of the viral diversity, geographic distribution, wildlife hosts, and human populations at-risk for spillover. I am a recently appointed assistant professor dedicated to biosurveillance and virological research of emergent zoonotic viruses. I have completed virological training and spent my time as a post-doctoral fellow applying *in vitro* techniques to characterize the replication of, and mammalian ephrin receptors that mediate cellular entry of emergent henipaviruses. Since the start of the COVID-19 pandemic, I pivoted the focus of my research team to serological analysis of SARS-CoV-2 infection, and then to COVID-19 vaccine-induced antibody durability. In my ongoing research, I develop serological-based approaches to identify the infectome of wildlife and human communities for the assessment of virus spillovers. Since my position as a postdoctoral fellow I have worked collaboratively with national and international researchers including institutional partners at Duke-NUS, Chulalongkorn University, University of Pretoria, and Rocky Mountain Labs towards these goals. Across all of these collaborations, we have aimed to identify known and unknown viruses, the wildlife reservoirs of priority pathogens, the high-risk interfaces for spillover and the biotic/abiotic drivers of virus emergence. Throughout these research projects, we have detected unexpected serological profiles in communities of bats and humans that have not fit our prior understanding of the viral diversity established or detected by genetic techniques. This proposal aims to better understand these serological profiles of wildlife and humans with a targeted focus on henipaviruses and filoviruses. Ongoing projects that I would like to highlight include:

- HDTRA12110037. DTRA BRTP, E. Laing (Co-PI). 08/2021-07/2026, “Informing biosurveillance, contribution of pteropodid fruit bats to virus spillover in the Philippines.”

B. Positions, Scientific Appointments and Honors

Positions

- 2021-pres. Assistant Professor, Department of Microbiology and Immunology, School of Medicine, Uniformed Services University, Bethesda, MD.
- 2021-pres. Joint Appointment, Emerging Infectious Diseases Graduate Program, School of Medicine, Uniformed Services University, Bethesda, MD.
- 2019-21 Research Assistant Professor, Department of Microbiology and Immunology, Uniformed Services University, Bethesda, MD.
- 2016-19 Postdoctoral fellow, Henry M. Jackson Foundation, Department of Microbiology, Uniformed Services University, Bethesda, MD.
- 2010-16 Graduate research student, Department of Microbiology, Uniformed Services University, Bethesda, MD.

Other Experiences and Professional Memberships

- 2022-pres. Executive committee member, Emerging Infectious Diseases Graduate Program, USUHS
- 2021-pres. Research center representative, Laboratory Assays Oversight and Quality Working Group, Emerging Infectious Diseases: Southeast Asia Research Collaboration Hub (EID-SEARCH), Centers for Research in Emerging Infectious Diseases (CREID), NIAID, DMID, NIH
- 2021-pres. Review editor, *Frontiers in Virology - Emerging and Reemerging Viruses*
- 2021-pres. Ad hoc reviewer, *Frontiers in Immunology*, *Journal of Clinical Immunology*
- 2021-pres. Steering committee member, JPI/Military Infectious Diseases Research Program, Emerging Infectious Diseases
- 2019 Ad hoc reviewer, EcoHealthNet 2.0 Program, EcoHealth Alliance
- 2018 Ad hoc reviewer, Pakistan One-Health Fellowship Program, National Academy of Sciences & Pakistan Academy of Sciences
- 2014-2019 Member, American Society of Tropical Medicine and Hygiene
- 2014-2019 Member, American Society of Microbiology
- 2014-2019 Volunteer, AAAS STEM K-12 Volunteer Program

Mentoring

- Postdoctoral fellows* Si'Ana A. Coggins, PhD, 2020 - 2022
- Graduate students* Marana S. Tso, BS, 2021 -
McKenna Roe, BS, 2022 -
- Committee member* Celeste Huaman, BS, 2021 -
2LT Connor Perry, BS, 2021 -

Honors

- 2021-2022 Impact Award, USUHS School of Medicine
- 2021 Outstanding Research Accomplishment/Team/SARS-CoV-2, The EPICC COVID-19 Cohort Team, Military Health System Research Symposium
- 2020-2021 Impact Award, USUHS School of Medicine
- 2015-2016 Val G. Hemming Fellowship, Henry M. Jackson Foundation
- 2015 East Asia and Pacific Summer Institutes Fellowship, National Science Foundation

C. Contributions to Science ([†]mentee, *corresponding)

1. Lyssaviruses and the prototype, rabies virus, remain a public health concern. Beginning with my PhD thesis work, I've researched the virus host-interactions between a rabies-related lyssavirus, Australian bat lyssavirus (ABLV), and its bat host (*Pteropus alecto*). Research has focused on ABLV cellular entry mechanisms, the development of an animal model and ABLV reporters and exploration of novel monoclonal antibodies that neutralize ABLV and other phylogroup I lyssaviruses. Furthermore, comparative bat immunology research was conducted using black flying fox cell lines and ABLV as a model virus/host interaction. Physiological adaptations that accompanied the evolution of flight in bats have been proposed to contribute to the frequent role of bats as asymptomatic hosts of highly pathogenic zoonotic viruses.

Comparatively studying the autophagy pathway in bat cell lines revealed that bat cells had elevated levels of basal autophagy and experienced significantly less cell death when challenged with high virus doses.

- a. Weir D. L., **Laing E.D.**, Smith I.L., Wang L.F., and C. C. Broder. Host cell entry mediated by Australian bat lyssavirus G envelope glycoprotein occurs through a clathrin-mediated endocytic pathway that requires actin and Rab5. *Virology*. 2013. 11:40. doi: 10.1186/1743-422X-11-40. 2. My research experience as a postdoctoral fellow furthered my training in molecular virology techniques. I constructed a recombinant Cedar virus cDNA plasmid and optimized a reverse genetics approach to rescue a recombinant Cedar virus reporter virus, a non-pathogenic *Henipavirus* species. A molecular biology methods chapter detailing recombinant Cedar virus reverse genetics has been submitted and in press. Using this recombinant Cedar virus, we determined that Cedar virus can utilize several non-canonical henipavirus ephrin receptors for cellular entry and explored the structure of the receptor-binding pocket to understand the receptor promiscuity. The non-pathogenic phenotype of CedV creates a potential for CedV to act as a model henipavirus to explore host-pathogen interactions, cellular tropism and factors that determine henipaviral disease pathogenesis. Additionally, I have collaborated on projects detailing henipavirus infection and replication in bat hosts with colleagues at the Rocky Mountain Labs, studying whether specific species of bats are more competent hosts and whether virus-host restriction exists.

3. Bats are increasingly identified as animal reservoirs of emerging zoonotic viruses (e.g. Nipah virus, Ebola virus and SARS-coronavirus). I lead collaborative biosurveillance and research preparedness training including data analysis and interpretations at international partner institutes with lab technicians, field and lab scientists, and masters, doctoral and postdoctoral trainees. Collaborative biosurveillance is presently underway in Thailand (Chulalongkorn University, Bangkok) Malaysia (National Wildlife and Forensic Lab, Universti Purtra Malaysi, National Public Health Lab) via NIH Centers for Research in

Emerging Infectious Diseases, EID-Southeast Asia Research Collaborative Hub. As a collaborator within the DARPA PREEMPT network I supported surveillance for coronaviruses and other priority emerging zoonotic viruses, henipaviruses and filoviruses, in Ghana (Zoological Society of London), Australia (Black Mountain Labs) and Bangladesh (icddr,b). We aim to characterize the geographic distribution of zoonotic filoviruses/henipaviruses/coronaviruses, transmission dynamics in wildlife hosts and generate risk-models for Ebola virus, Nipah virus and SARS-related CoV outbreaks. Results discovered so far suggest a wider geographical footprint of Asiatic filoviruses and have identified several fruit bat species that act as natural reservoirs for these viruses.

4. Responding to the emergence of SARS-CoV-2, our lab developed multiplex serology strategies to identify SARS-CoV-2 antibodies and address research questions related to whether pre-existing antibody memory induced by prior infection with seasonal human coronaviruses affects COVID-19 severity. Our lab's serology efforts supported NIH and DHA collaboratively funded protocols including prospective, longitudinal serological analysis of hospital and community subjects, and health-care workers; and cross-sectional analyses of SARS-CoV-2 infection among deployed military health-care workers.

PMID: 33661864; PMCID: PMC7948931.

5. In addition to providing serologic assessment of SARS-CoV-2 infection, my research team is actively engaged in examining the durability of COVID-19 vaccine induced humoral immunity. Antibody responses, particularly neutralizing antibodies, are frequently cited as a predictive correlate of protection. With the emergence of variants of concern and waning circulating antibodies, the timing of booster shots remains an important measure for controlling the pandemic. In my lab we evaluate the duration of neutralizing antibodies, durability and breadth of antibody responses against emerging variants of concern, hybrid immune responses, and post-vaccination infections.

Title: Establishment of a Bat Resource for Infectious Disease Research

Major Goals: The major goals of this proposal is to contribute significant insight into the viral determinants that confer henipaviral pathogenesis. The construction and generation of recombinant henipavirus chimeric viruses will be the primary means for determining how virus receptor usage and the expression of virulence factors act individually or in conjunction to cause limited or severe disease. The recombinant constructs generated from the proposed studies will also be used to determine host determinants of immunity in Jamaican fruit bats and animal models.

OVERLAP

In my role on this project, titled: Immune memory bait & capture to identify emerging henipavirus origins, I will be providing mentorship and my group will be providing recombinant antigenic material for multiplex serologies and our expertise in virology and assay development and interpretation to the PI and Co-PI. These research activities and mentorship overlap with my present role as a co-investigator within the EID-SEARCH center.

I, PD/PI or other senior/key personnel, certify that the statements herein are true, complete and accurate to the best of my knowledge, and accept the obligation to comply with Public Health Services terms and conditions if a grant is awarded as a result of this application. I am aware that any false, fictitious, or fraudulent statements or claims may subject me to criminal, civil, or administrative penalties.

A. Personal Statement

I have 29 years in public health research and 20+ years of experience in emerging viral zoonoses. I have managed many internationally funded research projects that involve working with and managing international and local interdisciplinary teams. Most of my research projects are diagnostics development, pathogen discovery, public health surveillance, field surveillance in wild mammals, human behavioral risk surveys, and clinical research. I conduct workshops on the development of novel diagnostic approaches, appropriate sample collection and handling for different pathogens, and viral characterization *in vitro* and *in vivo*. I am a senior researcher at the Thai Red Cross Emerging Infectious Diseases Clinical Center, which conducts research on emerging zoonoses, clinical research, and public health surveillance research. My research background mainly focuses on understanding the process of zoonotic disease emergence, particularly viral zoonoses. This includes identifying the bat origin of Nipah virus, MERS-CoV, and SARS-CoV-2 and pathogenesis and diagnoses of Rabies. My studies on the emergence of novel betacoronaviruses found in Thai bats and Nipah virus have been published. My laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases, communicable diseases, and wastewater surveillance. I am the DDC instructor on the clinical sampling method and consultant for Ebola, MERS, and COVID-19 diagnosis. I am a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. I led the team to diagnose the first human MERS case in 2015 and the first human COVID-19 case outside China in January 2020. I have been the PI on six multidisciplinary research projects that use epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah, and Hendra viruses, Avian influenza, and novel viruses from bats. I am also the Thailand country coordinator for PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratorians.

B. Positions, Scientific Appointments, and Honors

Positions and Employment

- 1994 -97 Biochemical Technician, Department of Entomology, AFRIMS, Thailand
- 1997 Researcher, Department of Immunology, Chulabhorn Research Institute, Thailand
- 1997 -00 Medical Technologist, The HIV/AIDS Collaboration Thai-US, Thailand
- 2000 -16 Laboratory Chief, Neuroscience Centre for Research and Development & WHO Collaborating Centre for Research and Training on Viral Zoonoses, Faculty of Medicine, Chulalongkorn University Hospital, Thai Red Cross Society, Thailand
- 2016 -21 Deputy Chief of Thai Red Cross Emerging Infectious Diseases Health Science Centre, Faculty of Medicine, Chulalongkorn University Hospital
- 2021 - Senior Researcher, Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital
- Committee member, School of Global Health, Faculty of Medicine, Chulalongkorn University

Other Experience and Professional Membership

- 2010 -14 PREDICT Thailand Country Coordinator
- 2014 - Thai Ministry of Public Health (MOPH) Ebola Diagnostic Committee
- 2015 -19 PREDICT 2 Thailand Country Coordinator
- 2016 - Steering committee, Bat One Health Research Network, BTRP DTRA
- 2021 - WHO Scientific Advisory Group for the Origins on Novel Pathogens (SAGO)

C. Contributions to Science

1. **Research on One Health.** One Health is an integrated, unifying approach that aims to sustainably balance and optimize the health of people, animals, and ecosystems, as the definition by WHO. Our projects are multidisciplinary studies on human surveillance, wildlife surveillance, wastewater surveillance, and human behavior.
 - a. Tangwangvivat R, **Wacharapluesadee S**, Pinyopornpanish P, Petcharat S, Muangnoicharoen H. S, Thippamom N, Phiancharoen C, Hirunpatrawong P, Duangkaewkart P, Chaiden C, Wechsirisana W, Wandee N, Srimuang K, Paitoonpong L, Buathong R, Pawun V, Hinjoy S, Putcharoen O, Iamsirithaworn S. Assessment of SARS-CoV-2 variant wastewater detection strategies in the Bangkok Metropolitan region. **Preprint Research** 2023

Behavioral-biological surveillance of emerging infectious diseases among a dynamic cohort in Thailand. **BMC Infect Dis**. 2022 May 16;22(1):472. doi: 10.1186/s12879-022-07439-7. PMID: 35578171; PMCID: PMC9109443.

2. Research on Public Health Surveillance in Thailand. Effective disease control programs rely on effective surveillance and response systems. Our laboratory collaborates with the Department of Diseases Control for active surveillance on syndromic surveillance and outbreak investigation. Both molecular and serology surveillance systems were conducted to identify the cause of the disease.

- a. Pliapat T, Buathong R, **Wacharapluesadee S**, Siriarayapon P, Pittayawonganon C, Sangsajja C, Kaewpom T, Petcharat S, Ponpinit T, Jumpasri J, Joyjinda Y, Rodpan A, Ghai S, Jittmittraphap A, Khongwichit S, Smith DR, Corman VM, Drosten C, Hemachudha T (2017). PMID: 33552519; PMCID: PMC7841862.

3. Research on diagnostic development. The molecular technique is a gold standard method for pathogen diagnosis and confirmation. The first COVID-19 case outside China in Thailand was primarily detected by family PCR and further confirmed by next-generation sequencing (NGS). The SARS-CoV-2 variants can be identified by the NGS technique or by identifying the mutation markers by MassARRAY technology.

 - d. Siriyasatien P, **Wacharapluesadee S**, Kraivichian K, Suwanbamrung C, Sutthanont N, Cantos-Barreda A, Phumee A. Development and evaluation of a visible reverse transcription-loop-mediated isothermal amplification (RT-LAMP) for the detection of Asian lineage ZIKV in field-caught mosquitoes. **Acta Trop**. 2022 Dec;236:106691. doi: 10.1016/j.actatropica.2022.106691. Epub 2022 Sep 11. PMID: 36103950.
4. **Research on coronavirus prevalence in Thailand.** Numerous high-impact emerging viruses appear to have bat reservoirs. Our surveillance projects study the diversity of coronavirus (CoV) in bats in Thailand. We have isolated and characterized CoVs from many bat species and detected and sequenced CoV in bat guano collectors. Our surveillance studies continue to analyze the drivers of their emergence and risk factors for spillover.
- a. **Wacharapluesadee S**, Duengkae P, Chaiyes A, Kaewpom T, Rodpan A, Yingsakmongkon S, Petcharat S, Phengsakul P, Maneeorn P, Hemachudha T (2019). Longitudinal study of age-specific pattern of coronavirus infection in Lyle's flying fox (*Pteropus lylei*) in Thailand. **Virology** 20;15(1):38.

5. **Research on Nipah virus prevalence in Thai bats.** Nipah virus outbreaks, previously in Thailand's neighboring country, Malaysia, and ongoing in Bangladesh, have high mortality rates. Our surveillance projects study the characterization of Nipah Virus (NiV) in bats in Thailand. In addition, our surveillance studies continue to analyze the drivers of their emergence, understanding their seasonal preferences and risk factors for spillover.

Other Support – Project/Proposal

*Title: Understanding Risk of Zoonotic Virus Emergence in EID Hotspots of South East Asia

*Major Goals: The goals of this project are to identify, characterize and rank spillover risk of high zoonotic potential viruses from wildlife; identify evidence of novel virus spillover and key risk pathways for transmission; and identify and characterize viral etiology of 'cryptic' outbreaks in clinical cohorts.

*Status of Support: Active

Project Number: U01 AI151797

Name of PD/PI: Peter Daszak

*Source of Support: NIH/NIAID

*Primary Place of Performance: EcoHealth Alliance and International Field and Lab Locations

Project/Proposal Start and End Date: (MM/YYYY) (if available): 06/2020 – 05/2025

* Total Award Amount (including Indirect Costs): 7,573,721.35

* Person Months (Calendar/Academic/Summer) per budget period.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Co-PI Plan (only needed if applying as Co-PIs):

What each Co-PI will contribute to the proposed research study?

As stated in the Mentoring Plan, the co-PIs, Krongkan Srimuang and Spencer Sterling have different educational and training backgrounds. This Co-PI plan is proposed to fill the gaps in knowledge of each scientist and supports a collaborative working relationship for project success. Moreover, this plan was developed to maximize the strengths of each PI. Overall, the project is separated into two objectives, the proposal of this project will be equally managed by Dr. Srimuang and Mr. Sterling. Dr. Srimuang will be responsible for PBMC isolation, sorting, and characterization. Mr. Sterling will be responsible for the technical serological aspects of the project. Both will work closely with the Research Center Mentor, Dr. Eric Laing, to develop this project, protocol development, and network connections. Dr. Supaporn Wacharapluesade, the Co-mentor, will support the wildlife sampling, samples collection, and molecular aspects within Thailand.

How the Co-PIs will jointly work with the affiliated Research Center?

Dr. Srimuang is currently employed at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University and supports the molecular biology investigations in the EID-SEARCH project. Mr. Sterling is currently employed by the Henry M. Jackson Foundation for the Advancement of Medical Research (MD, USA), supports research activities for the Laing Lab at the Uniformed Services University, and is a visiting scientist at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University. Mr. Sterling is supporting the serological investigations of the EID-SEARCH project, as well as other projects in the Indo-Pacific region. Both Co-PIs will work closely with Dr. Laing, Dr. Wacharapluesadee, and the staff at EcoHealth Alliance to coordinate field sampling, research activities, data analysis, and manuscript production.

How the Co-PIs will jointly manage the proposed study?

This is a great opportunity for both PIs to undergo training in advanced techniques and develop skills in next-generation serology and molecular sequencing. Dr. Srimuang will learn and practice serologic techniques and data analysis from Mr. Sterling. Mr. Sterling will develop skills in cell isolation and molecular sequencing techniques from Dr. Srimuang. Moreover, Mr. Sterling will coordinate planning, sample processing, data analysis, and report preparation for this project with Dr. Srimuang.

TRC-EIDCC: Thai Red Cross. Emerging Infectious Diseases. Clinical Center

USA: United States

WGS: Whole Genome Sequencing

Facilities and Resources

FACILITIES: Specify the facilities to be used for the conduct of the proposed research.

Laboratory:

The Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC), King Chulalongkorn Memorial Hospital (KCMH) was established by the Committee of the Emerging Infectious Disease Center which recognizes the importance of emerging and recurrent diseases, and emphasizes the importance of pandemic preparedness. The Center was approved to be a part of KCMH by the Thai Red Cross Society, being responsible for medical care in patients with emerging and recurrent diseases. KCMH is a public general and tertiary referral hospital in Bangkok, Thailand. It is one of the largest hospitals in Thailand, and as one of Thailand's leading medical school affiliates is widely considered one of the best public hospitals in the country. TRC-EIDCC laboratory facilities include 3 biosafety cabinets (BSL 2, BSL 2+, BSL2+), 3 automated extraction machines, 2 thermocyclers (Proflex), 2 real-time PCR machines (CFX, Bio-rad), 3 Freezers (-80 °C), 2 refrigerators; 4 °C, 2 autoclaves. Our EIDCC uses the Pathogen Asset Control System (PACS) system for sample tracking. Moreover, our Faculty of Medicine, Chulalongkorn University has a central laboratory, the Chula Medical Research Center (Chula MRC), which provide many instruments for medical, masters, and graduate students, Post-doctoral fellows, and researchers at Chulalongkorn University and KCMH. The Chula MRC laboratory facilities are divided into molecular diagnostics (PCR Thermal Cycler, QStudio6 Flex Real-Time PCR, Droplet Digital PCR, GeneXpert, Film array, Illumina MiSeq), immunology facilities (ELISA testing equipment (reader & washer), Luminex, Flow Cytometry), cell sorting machine and a BSL3 laboratory. Moreover, the facility provides general equipment, such as autoclaves, balances, CO2 incubators, Dual Fluorescence Cell Counter, 4 °C refrigerators, -20°C, and -80°C freezers.

Clinical:

KCMH is a 1,000-bed university hospital, in close coordination with the Faculty of Medicine, Chulalongkorn University. The Thai Red Cross Society provides medical treatment, rehabilitation, health promotion and disease prevention services to the general public and the vulnerable. It also provides biopharmaceutical and sterile medicines that are sufficient to meet the needs of patients and safe in accordance with international standards. It serves as a center for providing eye and organ donation services to patients nationwide in line with international standards. It has specialized doctors and public health personnel and also produces specialized nurses. The TRC-EIDCC in the KCMH provides standard medical care to patients with emerging and recurrent diseases and disease spreading prevention.

Animal:

TRC-EIDCC also collaborates with the Department of National Parks, Wildlife and Plant Conservation for detecting the emerging novel pathogens from animals such as bats, rodents, and pangolins in our country.

Applicant(s) Name (Last, first, middle): Srimuang, Krongkan and Sterling, Spencer, Lee

Computer:

TRC-EIDCC used the service from the Office of Information Technology, Chulalongkorn University that provides the application, network, and software such as Office 365, VPN, WIFI, Microsoft Office, Microsoft Windows, SPSS, Adobe, Zoom Meeting, etc. Moreover, our EIDCC use the Pathogen Asset Control System (PACS) for sample tracking.

Office:

The office and laboratory space are located at the EIDCC at 4th Floor, Jongkolnee Watwong Building and 6th Floor, Aor Por Ror Building, respectively. The applicants will have dedicated desks in both buildings.

Other:

Foreign Site Information

If the Pilot Award will have multiple foreign sites, complete this form for EACH research site

Principal Investigator Name:	Krongkan Srimuang
Project Title:	Immune memory bait & capture to identify emerging henipavirus origins
Institution:	King Chulalongkorn Memorial Hospital
Foreign Research Site:	Rama 4 Road, Pathumwan, Bangkok 10330 Thailand
Point of Contact for Research Site:	Krongkan Srimuang Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital Rama 4 Road, Pathumwan, Bangkok 10330 Thailand krongkan.sr@gmail.com

Introduction (3-4 sentences):

Provide a simple description of the overall goals of the project including the work that will be done at the foreign site. Indicate if any of the NIAID grant funds will be sent to the foreign site.

The goal of this project is to identify the origin of zoonotic pathogens by applying serologic and cellular immune tools in humans and animals for early detection and identification of novel pathogens to prevent the next pandemic.

To achieve this, the project will conduct serological surveillance among humans and rodents/shrews at this site, and perform lab analysis collaborating with NIH PREMISE for antibody-mediated bait & capture of Thai MojV-like virus.

\$149,937 of grant funds will be sent to the site for these research activities.

Foreign component (3-4 sentences):

Describe the specific role of the foreign site (i.e. conduct critical experiments?, conduct data analyses?, provide consultations?, provide samples?, study human and/or animal populations?, conduct observational or interventional clinical trials?, collect samples and/or data to be brought to the US?).

The site will 1) conduct all field work to collect human and animal samples from the study sites; 2) perform laboratory analysis using collected samples; and 3) conduct data analysis as proposed in the project.

Human Subjects (1 word or 1 sentence per bullet):

- **Parent Study IRB approval**
 - **IRB approval number for parent study:** #894ECOH21b (US); #221/64 (Thailand)
 - **IRB approval date:** 12-05-2021 (US); 08-06-2021 (Thailand)
 - **Human Subject Assurance Number: (FWA)#:** #00001102 (external IRB); #00022431 (EcoHealth Alliance); #00000943 (Chulalongkorn University)
- **Does this study require a modification to the IRB approval of a parent study (Yes or No)?**
 - **Yes**
- **Will existing samples from human subjects will be used: (Yes or No)?**
 - **No**
 - **How many subjects provided the existing samples to be used?** N/A
- **Will human subjects be recruited (Yes or No)**
 - **Yes**
 - **Number of human subjects that will be recruited:** 110

- **Population parameters:**
 - **Gender:** 55 males, 55 females
 - **Age Group:** Age >=18 years who provide informed consent.
 -
 - **Race/Ethnicity:** 110 Asian
- **Sample collection will include:**
 - **Blood:** Yes
 - **Urine:** No
 - **Tissues:** No
 - **Other samples (describe):** Nasopharyngeal swab and throat swab
- **Sample collection will be completed in how many visits:** 2 trips
- **Will samples be de-identified (Yes or No)? If No, describe how they will be protected.**
 - Yes
- **Will local IRB approval be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals being sought or state why local IRB approval is not required.**
 - Yes
- **Will informed consent be obtained prior to engaging in any research involving human subjects (Yes or No)? If No, describe alternate approvals/consents being sought or state why informed consent is not required.**
 - Yes
- **Will samples be brought back to the US (Yes or No)?**
 - No
- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

Animal Subjects (1 word or 1 sentence per bullet):

- **Parent study IACUC approval**
 - **IACUC approval number for parent study:** #G2020-42 (US); #019/2563 (Thailand)
 - **IACUC approval date:** 05-05-2020 (US); 03-12-2020 (Thailand)
Animal Welfare Assurance Number: D16-00572 (A4059-01)
- **Does this study require a modification to the IACUC approval of a parent study (Yes or No)?**
 - No
- **Will existing samples from animal subjects will be used: (Yes or No)?**
 - No
 - How many animal subjects provided the existing samples to be used? N/A
- **Will vertebrate animals be collected (Yes or No)?**
 - Yes
- **Species of animals (e.g. rats, mice, rabbits, monkeys):** Rodents, and shrews
- **Animal parameters:**
 - **Total number of animals:** 200 (200 rodents and shrews)
 - **Gender:** 100 males, 100 females
 - **Age range:** 4 - 12 months and elder depending upon species
 - **Lab strain (e.g. Sprague-Dawley rats, Balb/C mice):** None
 - **Wild animals procured in country (e.g. Rhesus monkeys from a reserve):** No
- **What will be done to them or with them and how often?**
 - Free-ranging rodents and shrews will be captured through pit traps and box traps.

- Anesthesia will be conducted for captive rodents and shrews.
 - Once anesthetized blood will be collected.
 - All actions will only be performed one time for each animal individual.
 - All animals will be released after sampling.

- **What are the follow-ups?**
 - No follow-up relevant as per protocol, since all animals will be released after sampling ups

- **What will be their fate at the end of the experiments – will they be euthanized?**
 - All animals will not be held longer than 6 hours (typically less than 3 hours) during the sampling process and released after sampling.

- **Will in-country clearances be obtained prior to engaging in any animal research (Yes or No)? If No, describe alternate approvals or state why in-country clearances are not required.**
 - Yes

- **Will samples be brought back to the US (Yes or No)?**
 - No

- **Will data be brought back to the US (Yes or No)?**
 - Yes, some of the data will be shared with EID-SEARCH partners in the US for relevant analysis.

27th January 2022

Krongkan Srimuang Ph.D.
Research Scientist
Thai Red Cross Emerging Infectious Diseases Clinical Center
King Chulalongkorn Memorial Hospital
Rama 4 Road
Pathumwan, Bangkok 10330
Thailand

Subject: Letter of Support for CREID Network Pilot Research Program

Dear Dr. Srimuang,

I am writing to express my support for your CREID Network Pilot Research Program proposal titled, “Immune memory bait and capture to identify emerging henipavirus origins.” Your preliminary data demonstrating immunoreactivity against Mojiang henipavirus in individuals sampled as part of the Emerging Infectious Diseases Southeast Asia Research Collaborative Hub (EID-SEARCH) center, provides compelling serologic evidence that novel henipaviruses spill over into human populations. Point-of-care diagnostics and nucleic acid-amplification tests rely on our present understanding of medically relevant pathogens. Thus, emergence of novel zoonotic viruses may go undetected. Serological profiling provides us an ability to measure the human infectome through broad-scale peptide arrays or targeted antigen-based detection.

The research activities conducted at the Thai Red Cross Emerging Infectious Diseases Clinical Center are complementary to the focus of the Vaccine Research Center’s PREMISE (Pandemic REsponse REpository through Microbial and Immunological Surveillance and Epidemiology) program. PREMISE works closely with intramural and extramural NIH programs and in partnership with a global network of investigators and collaborators to achieve its objectives through 3 core activities: (1) genetic analysis of zoonotic reservoirs and symptomatic humans for pathogen discovery; (2) development of high throughput, multiplexed serologic and cellular assays; and (3) global blood sampling to identify antigen-specific and cross-reactive immune responses to known and previously unknown viruses of pandemic potential. Biological samples including serum and PBMC are obtained from broad-based population cohorts as well as targeted populations at risk from emerging infections. At the same time, sequence data from known and unknown (through virus discovery) pathogens are analyzed to design and express candidate antigenic proteins of interest. These proteins are then used in high throughput multiplexed assays to screen sera for antibody reactivity. Serum reactivity to candidate antigens is followed by further interrogation of the adaptive immune response at the cellular level using corresponding PBMC samples. Proteins used in the serological arrays are conjugated to fluorophores and used as probes to sort antigen-specific B cells by flow cytometry. In addition, the sequence of such candidate antigens provides the template for the design of overlapping peptide pools to assess T cell responses. Further analysis allows for the identification of

neutralizing antibodies specific for the target antigens as well as specific T cell epitopes which may be tested in animal models. Epitope identification informs and guides immunogen design. At the conclusion of this pipeline of assays and analysis, PREMISE delivers the following:

1. reagent and data resources for early detection and diagnosis
2. monoclonal antibodies with therapeutic potential
3. candidate immunogens for further vaccine development

Thus, PREMISE serves as a translational vehicle to integrate serologic and cellular immune discovery, targeting a broad array of pathogens, into product development, and constitutes an anticipatory reagent repository to accelerate the global response to pandemic threats.

As investigators in the Vaccine Research Center at the National Institute of Allergy and Infectious Diseases (NIAID), we are not eligible to be listed as a “co-investigator” on the application but look forward to participating as collaborators. All materials from us will be provided under an approved material transfer or other collaborative agreement. This collaboration is part of our official duties as employees at the NIAID, and no funds from the grant will be used in intramural research, neither will we accept any form of remuneration, whether in the form of salary, honoraria, or travel expenses. We will provide scientific input and mentoring but will not have any duties associated with programmatic stewardship, which will be performed by NIAID extramural program officials. Further, in keeping with the mission of NIAID to promote and facilitate biomedical research and the dissemination of new knowledge, we would supply requested research materials and technical expertise not only to you, but also to other interested and qualified parties for research purposes.

My group has met with Dr. Eric Laing (USU) one of the two mentors for this pilot research program to discuss ways we can collaborate and support your research application. We are enthusiastic about providing the technological and subject-expertise in immunology and translational therapeutic discovery afforded by the PREMISE program that would enhance your knowledge base and broaden your own scientific training.

Sincerely,

Daniel C. Douek

30 January 2023

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC),

King Chulalongkorn Memorial Hospital

Object: Thai Red Cross Emerging Infectious Diseases Clinical Center support for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

Dear Dr. Srimuang & Mr. Sterling,

Thai Red Cross Emerging Infectious Diseases Clinical Center (TRC-EIDCC) is pleased to support your application to the **CREID Pilot Research Program**, entitled “Immune memory bait & capture to identify emerging henipavirus origins.” We are fully committed to executing the statement of work to study zoonotic reservoirs for pathogen origins by using serologic and cellular immune discovery in humans and wildlife and their application as a tool for early detection and identification of novel pathogens in pandemic prevention.

The work proposed in this project is a great opportunity for collaboration with our team, it serves to enhance the use of serology and immunology for the detection of novel virus pathogens in Thailand using new technology and techniques. Moreover, the building of capacity and capability in our laboratory and Faculty will enhance the regional capacity, and the Chulalongkorn network will be used to ensure the success and completion of this project.

This letter expresses my strong interest in you pursuing this application and I fully support the project. I look forward to collaborating with you on this project and I wish you success in the CREID Pilot Research Program application.

Sincerely,

A black rectangular box containing the red text "(b) (6)", indicating that the signature and name of the sender have been redacted for privacy.

Assistant Professor Opass Putcharoen, MD, Msc

Head of Thai Red Cross Emerging Infectious Diseases Clinical Center

King Chulalongkorn Memorial Hospital

Dr. Krongkan Srimuang, Mr. Spencer Sterling
Thai Red Cross Emerging Infectious Diseases Clinical Center
King Chulalongkorn Memorial Hospital
1873, Rama 4 Road, Pathumwan
Bangkok, Thailand 10330

Dear Krongkan and Spencer,

This letter conveys a strong interest from the Emerging Infectious Disease-Southeast Asia Research Collaboration Hub (EID-SEARCH) at EcoHealth Alliance to collaborate with you at the Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital on the proposed project titled "*Immune memory bait & capture to identify emerging henipavirus origins*" in Thailand.

The question of the origin of emerging Henipaviruses (HPVs) was identified from the EID-SEARCH human surveillance when a Mojiang-related virus was identified in a local population highly exposed to bats in Thailand. Faced with the challenges of PCR detection and viral isolation, this project will establish and validate a new serological approach to develop MojV-like virus-specific MAbs and define the antigenic spatial relationships between all known rodent- and bat-borne HPVs, revealing the serologic signature of all related undiscovered HPVs. This will significantly contribute to the objectives of EID-SEARCH to conduct targeted and strategic surveillance to identify emerging pathogens with zoonotic potential at the high-risk human-animal interfaces. The research population and site for this project – bat guano collection – represents one of the key scenarios where zoonotic spillover is mostly concerned that requires further in-depth investigation to identify the reservoir hosts. In addition to the gained knowledge, established methods from this project will be shared and used as standards in zoonotic HPVs surveillance and prevention strategies in Thailand and regionally through collaborative and coordinative cooperation among multiple stakeholders.

I am very excited to work with you both on this project, given your critical roles in the previous surveillance work to identify the question and develop the research idea. This project will bring valuable insights to advance disease surveillance and early warning systems for endemic and emerging infectious diseases in Thailand. Members of EID-SEARCH are committed to working closely with you to develop the research project and support the efforts necessary for the success of this project. You will be invited to join all training conducted by EID-SEARCH and EcoHealth Alliance regarding emerging infectious disease surveillance, relevant statistical analysis, and grant writing to expand your skill set. You'll also be supported to present the findings from this research at international conferences, the CREID Network meetings, and external partners and produce high-quality publications from this research.

Developing and implementing this project will advance your skills in project management for future research as an independent researcher. Co-Investigators of EID-SEARCH, Dr. Eric Laing from the Uniformed Services University of the Health Sciences and Dr. Supaporn Wacharapluesadee from the Thai Red Cross Emerging Infectious Diseases Clinical Center, have enthusiastically joined the project as your Mentors. Dr. Laing will advise on the study design and provide training on data analysis, and Dr. Wacharapluesadee from your institute will work closely with you to advise on the day-to-day project implementation. Both Mentors will work with you for manuscript writing and provide pertinent and timely career advice to assist in your professional development. They will bring a well-established

EID-SEARCH

Emerging Infectious Diseases
South East Asia Research Collaboration Hub

network of leaders and experts in emerging infectious disease research in Thailand, Southeast Asia, and North America for your network building.

I am confident that this proposed project will bring genuine opportunities for your professional development. And the combined experience in the field and lab and interdisciplinary expertise in serology and public health from the co-PIs will make this a successful and purposeful project to bring public health impacts in a broad region. I look forward to collaborating with you and your team on all phases of this proposed project. I wish you success in the CREID Pilot Research Program application.

Sincerely,

Peter T. Asza

Research Scientist
Thai Red Cross Emerging Infectious Diseases Clinical Center
King Chulalongkorn Memorial Hospital
Rama 4 Road
Pathumwan, Bangkok 10330

Subject: Letter of Support for CREID Network Pilot Research Program

Dear Dr. Srimuang,

I am writing to express my enthusiastic support for your CREID Network Pilot Research Program proposal titled, "Immune memory bait & capture to identify emerging henipavirus origins." In 2018, I led a training and multiplex serology technology transfer to your mentor Dr. Wacharapluesadee's research group via DTRA-funded project Chulalongkorn Luminex Training and Research Preparedness (HDTRA1-17-C-0019), and was excited to leverage those activities into ongoing research within the EID-SEARCH. Since 2015 I have been developing serological-approaches for biosurveillance of zoonotic viruses in wildlife and human populations, and I am excited to serve as a co-mentor for this pilot program application.

I hope to provide you with the research and career developmental support for the activities outlined in the proposal. The serological data on henipavirus exposure in Thai guano farmers provides compelling evidence that Mojiang-like henipaviruses can cross the species barrier and may be widely distributed in Southeast Asia. The research aims detailed in the proposal will facilitate critical follow-up sampling of this human cohort to identify whether acute infection causes clinical disease, estimate the sero-attack rate of this novel henipavirus, and will apply a cutting-edge serologic and immunologic approach for monoclonal antibody development and novel emergent virus immunogenic characterization. If awarded, a collaboration with VRC PREMISE program scientists will facilitate an important opportunity to broaden your knowledge base of cellular immunology and B cell biology. You have an extensive background in next-generation sequencing application, and through this proposal would gain a considerable understanding of how next-generation sequencing is used for BCR-sequencing, IgG characterization and monoclonal antibody discovery.

Your proposal is an excellent extension of the EID-SEARCH activities and significant training opportunity.

Sincerely,

(b) (6)

Eric D. Laing
Assistant Professor
Department of Microbiology and Immunology
Uniformed Services University

30th January, 2022

Dr. Krongkan Srimuang & Mr. Spencer Sterling

Thai Red Cross Emerging Infectious
Diseases Clinical Centre (TRC-EIDCC),
King Chulalongkorn Memorial Hospital

Dear Dr. Srimuang & Mr. Sterling,

I am writing in support as Research Center Mentor for your application to the CREID Pilot Research Program, entitled “Immune memory bait & capture to identify emerging henipavirus origins.”

With my 20 years of experience in conducting surveillance for novel viruses in wildlife, humans, and bats using molecular technology, I will support the growth of the scientists in the CREID Pilot Research Program. The research aims have the potential to significantly enhance our approach to pathogen surveillance at high-risk human-animal interfaces. Given the understanding of pathogen origins by using serologic and cellular immune discovery in humans, and applying these techniques as a tool for early detection and identification of novel pathogens.

As the head laboratory chief at the Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC), King Chulalongkorn Memorial Hospital, Faculty of Medicine, Chulalongkorn University, I believe that this is a great opportunity for our Thailand team to train in the characterization of memory B cells from peripheral blood mononuclear cells (PBMC) and enhanced serological surveillance in novel virus pathogens. Moreover, our laboratory has supported the Department of Disease Control (DDC) in diagnosing emerging infectious diseases and communicable diseases such as Ebola, MERS, and COVID-19. I am also a committee member of the Global Laboratory Leadership Program (GLLP) Thailand, organized by the Department of Medical Sciences. With my experience in diagnosing the first human MERS case in Thailand in 2015 and the first human COVID-19 case outside China in January 2020, I will support multidisciplinary projects involving epidemiology, laboratory, field science, and bioinformatics to diagnose and monitor the emergence of wildlife-origin viral zoonoses, including SARS-CoV, Nipah and Hendra viruses, Avian influenza, and novel viruses from bats. I was also the Thailand country coordinator for the PREDICT project, large contracts from USAID during 2010-2019 involving the successful management of teams of virologists, field biologists, veterinarians, epidemiologists, hospitals, and laboratory staff. I will enthusiastically support the development of a strong knowledge base to build capacity and capability in this project and our team in Thailand.

The CREID Network and the Emerging Infectious Diseases: South East Asia Research Collaboration Hub (EID-SEARCH) will support scientists in regions around the world where emerging and reemerging infectious disease outbreaks. Many Southeast Asian partnerships in EID-SEARCH have strong potential to enhance innovations in this area.

I believe that Dr. Laing, and I will provide scientific skills, expertise, and networks for this project.

Towards that aim, I am committed to supporting your professional development in the following ways:

1. I will maintain regular bi-weekly meetings for the project progresses.
2. I will support the resources in our country and research team in this project.
3. I will create opportunities for scientists network to ensure the success of research project.
4. I will provide and share advice and technical expertise in specific knowledge for this project.

I'm very much looking forward to working closely with you on this 1-year research project and beyond as you continue to develop your surveillance zoonotic disease research program.

Best regards,

(b) (6)

Supaporn Wacharapluesadee, Ph.D.

Head Laboratory,

Thai Red Cross Emerging Infectious Diseases Clinical Centre (TRC-EIDCC),

Pilot Program Application Submission Checklist – Final Application Submission

Title of Application: Immune memory bait & capture to identify emerging henipavirus origins

Submitted by: Krongkan Srimuang and Spencer Sterling

Submission Date: 1/30/2023

Full Application Submission Requirements

- Proposal Cover Sheet
- Title and Table of Contents
- Study Personnel (*1-page limit*)
- Main Application Body Section Requirements (*7-page limit*):
 - Research Aims & Objectives
 - Study Rationale/Research Gap/Impact
 - Significance and Approach
 - Research Methods
- Project Timeline (*1-page limit*)
- Research Performance Sites (*1-page limit*)
- CREID Research Center Collaboration (*1-page limit*)
- Mentoring Plan (*2-page limit*)
- Vertebrate Animals Section Requirements (*3-page limit*):
 - Description of Procedures
 - Justifications
 - Minimization of Pain and Distress
 - Method of Euthanasia (Cover Page Supplement / PHS Fellowship Supplemental Form)
- Human Subjects Research (*3-page limit*):
 - Summary of the parent study and IRB approval information for the study
 - Risks to the subjects
 - Adequacy of protection against these risks
 - Potential benefits of the research to the subjects and others
 - Importance of the knowledge gained or to be gained
 - Country / institution-specific ethics / IRB regulations addressed
- Research, Related Project Information, and Budget/Budget Justification
 - R&R Other Project Information Form
 - Full budget, with total costs of no more than \$150,000
 - Budget justification which describes the labor and other direct costs
 - If your institution does not have adequate funds for a cost-reimbursement award and requires pre-payment of funds during the award year, please note this in your budget justification and outline a payment schedule that will function for your project.

Supporting Documentation

- Biographical Sketch and Other Support. All applications must include:
 - Applicant PI Biographical Sketch (*4-page limit*)
 - Applicant PI Previous/Current/Pending Support (Include funding amounts, *no page limit*)
 - Mentor Biographical Sketch (*4-page limit*)
 - Mentor Current/Pending Support (*no page limit*)
 - Key Personnel Biographical Sketches (*4-page limit each*)
 - Key Personnel Current/Pending Support (*no page limit*)
- Co-PI Plan (only needed if applying as Co-PIs) (*1-page limit*)

Pilot Program Application Submission Checklist – Final Application Submission

Title of Application: Immune memory bait & capture to identify emerging henipavirus origins

Submitted by: Krongkan Srimuang and Spencer Sterling

Submission Date: 1/30/2023

- What each Co-PI will contribute to the proposed research study
- How the Co-PIs will jointly work with the affiliated Research Center
- How the Co-PIs will jointly manage the proposed study
- References Cited (*no page limit*)
- List of Abbreviations, Acronyms, and Symbols
- Facilities, Existing Equipment, and Other Resources (*template provided*)
- NIH Foreign Clearance form (*template provided*)
- Letters of Organizational Support (*2-page limit per letter*)
- Letter of Collaboration from CREID Research Center PI (*2-page limit per letter*)
- Letter from Research Center Mentor (*2-page limit*)
- Letter from Primary Scientific Mentor (if different than Research Center mentor) (*2-page limit*)

RESEARCH & RELATED BUDGET - Budget Period 1

OMB Number: 4040-0001
Expiration Date: 12/31/2022

ORGANIZATIONAL DUNS:

Enter name of Organization:

Budget Type: Project Subaward/Consortium

Budget Period: 1 **Start Date:** **End Date:**

A. Senior/Key Person

Prefix	First	Middle	Last	Suffix	Base Salary (\$)	Months			Requested Salary (\$)	Fringe Benefits (\$)	Funds Requested (\$)
						Cal.	Acad.	Sum.			
Dr.	Krongkan		Srimuang			10.00			24,000.00	0.00	24,000.00

Section J, Fee		
Section K, Total Costs and Fee (I + J)		149,937.00

Name of Individual: Laing, Eric

Commons ID: (b) (6)

Other Support – Project/Proposal

Title: Efficacy testing of a novel human monoclonal antibody therapy for late-stage rabies/lyssavirus infection

Major Goals: The major goals of this project is to test the efficacy of mAb therapy at times beyond day seven post-infection, to more completely define the degree to which mAb therapy can confer protection from death post-onset of clinically evident severe neurological disease.

Status of Support: Active

Project Number: HU00011920118

Name of PD/PI: Schaefer, B.

Source of Support: USUHS/CGHE

Primary Place of Performance: USUHS, Bethesda, MD

Project/Proposal Start and End Date: (MM/YYYY): 09/30/2019 – 09/29/2023

Total Award Amount (including Indirect Costs): \$518,000

Person Months (Calendar/Academic/Summer) per budget period.

Year (YYYY)	Person Months(##.##)
3. 2022	0.6 calendar
4. 2023	0.6 calendar

Title: Epidemiology, Immunology, and Clinical Characteristics of Emerging Infectious Diseases with Pandemic Potential (EpICC-EID)
