World Health Organization (WHO) Nipah Virus Research & Development (R&D) Roadmap
Taskforce Meeting
July 31 & August 1, 2023
Wellcome Trust, London, UK
Summary

Table of Contents

Background and Meeting Objectives

The Nipah Research and Development (R&D) Roadmap provides a 6-year framework beginning in 2024 for identifying the vision, underpinning strategic goals, and prioritizing areas and activities for accelerating the collaborative development of medical countermeasures (MCMs) – diagnostics, therapeutics, and vaccines – against Nipah virus infection. The roadmap is a key component of the World Health Organization's (WHO's) R&D Blueprint Initiative, and was first drafted in 2017/2018 with input from subject matter experts, including a core group of taskforce members. WHO now aims to finalize and formally launch the Nipah R&D Roadmap, and the draft has been updated to incorporate recent scientific advances and research. The roadmap will be delivered to WHO in late 2023 for publication on the WHO website.

The meeting objectives include the following:

1. Briefly recap each of the four topic areas of the Nipah R&D Roadmap (cross-cutting, diagnostics, therapeutics, and vaccines).
2. Review the goals and milestones in each section and develop consensus on the wording and timelines for each milestone, as time allows.
3. Identify the milestones or issues that are highest priority.
4. Discuss challenges and opportunities for implementing the roadmap goals and milestones.

Meeting Participants and Observers

Meeting participants and observers joined both in-person and virtually. Those who participated virtually are noted with an asterisk (*). Sushmita Barmen was also present in-person as the meeting organizer for Wellcome.

Meeting Participants		
Christopher Broder	Tabitha Kazaglis*	Michael Osterholm
Emmie de Wit	Eve Lackritz	Julie Ostrowsky
Petra Fay	Stephen Luby	Shahana Parveen
Alex Freiberg	Alison Mack	Marie-Pierre Preziosi
Pierre Formenty*	Anje Mehr*	Mahmudur Rahman
Josie Golding	Joel Montgomery	Christina Spiropoulou
Emily Gurley	Kristine Moore	Anaelia Siya Temu*
Kim Halpin	Nicolina Moua*	Angela Ulrich

Guest Observers		
Zakiul Hassan	Cathy Roth	Laura Mazzola

Cross-Cutting Issues in the Nipah R&D Roadmap

Emily Gurley served as the facilitator for discussion of cross-cutting issues in the draft roadmap.

Emily began the session with a review of important advances, barriers, challenges, and key needs for Nipah (NiV) vaccines. Key points from that discussion:

- Various entities (e.g., the National Institute of Allergy and Infectious Diseases [NIAID]) have been providing financial support for this work (Spiropoulou, Gurley).
- Researchers and developers have made significant contributions to NiV vaccines in the last 5 years; that's been the main R&D push, but we're now coming to a bit of a roadblock (Spiropoulou).
- The discovery of other henipaviruses, such as Langya, raises the importance of NiV and henipaviruses in general (Montgomery).
- Surveillance is lacking (Montgomery); the more we look for henipaviruses, the more we'll find and they will continue to be a global problem (Broder).
- The Centers for Disease Control and Prevention (CDC) supports NiV activities, but not to the same extent as NIAID; for example, surveillance isn't adequately supported in Bangladesh, India, or Southeast Asia (Montgomery). CDC's investment in Bangladesh has been crucial, but more effort is needed (Luby).
- More surveillance is needed in Bangladesh and India as well as other countries (e.g., Philippines, Malaysia). Undiagnosed NiV infections likely are occurring and we need to better understand the burden of disease and transmission; we are potentially missing a lot of cases (Montgomery, Luby).
- We also need better surveillance of bats to improve our ecological understanding, including in SE Asia, where there are likely more strains of NiV circulating in wildlife than we are currently aware of (Montgomery).
- CDC is working on modifying case definitions and respiratory surveillance. We are missing cases because our surveillance is not good enough, and this affects diagnostics and other MCMs. Identifying cases earlier in illness (e.g., respiratory phase) is critical but not yet accomplished (Montgomery).
- Surveillance for Japanese encephalitis (JE) is ongoing in Bangladesh, including the collection and characterization of blood samples. These samples could potentially also be tested for NiV if funding can be made available (Rahman).
- In the past, incident-based surveillance was conducted, but funding has weakened and now only large clusters of infections are identified, missing sporadic cases. The JE surveillance program could be leveraged, and this is being pushed by the WHO South-East Asia Regional Office (SEARO), along with JE vaccination (Rahman).
- Surveillance is the key to making a business case for development of NiV MCMs (Gurley).
- Minimally invasive diagnostic methods are needed that avoid cultural reluctance for postmortem exams (Halpin).
- Bangladesh has made significant advancements over the last 5 years in postmortem exams through minimally invasive sampling. These updates could possibly be added to the epidemiology/surveillance section of the roadmap (Gurley).

- Risk communication is important and potentially a cross-cutting issue; it should be addressed somewhere in the roadmap. The roadmap also should address the need to involve media, policymakers, and the general public in NiV prevention efforts (Rahman).
- Political buy-in is important for surveillance, reporting, and prevention (Gurley).
- We should consider linking NiV to other surveillance efforts, including influenza and postmortem work. If we can create a common platform and case definitions, we can identify cases for further testing (Parveen).
- The Coalition for Epidemic Preparedness Innovations (CEPI) is engaged in discussion with regulatory authorities on advancements in licensure and approval of NiV MCMs (Rahman).
- The long-term goal is to have a rapid, bedside diagnostic test. Antibodies/antigens are available that could be used to develop such a test, but investment is lacking (multiple participants).

Emily then led a discussion of the draft roadmap strategic goals and milestones for cross-cutting issues. Discussion highlights are detailed in the tables below.

Cross-Cutting Issues: Strategic Goal 1 and Aligned Milestones		
Strategic Goal or Milestone	**Discussion highlights**	**Suggested actions**
Strategic Goal 1: Identify additional and ongoing sources of private- and public-sector funding and develop appropriate incentives and competitions to promote R&D of NiV MCMs.	• No comments.	• No edits suggested.
Milestone 1: By 2025, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2) outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.	• Persuading people that this issue is a reasonable investment is challenging, given few recognized cases (Luby). • It might be worth emphasizing the risks posed by gain-of-function research with NiV, especially given the democratization of synthetic biological tools (Luby). All disease roadmaps should acknowledge this risk (Gurley). • The COVID-19 pandemic showed what can happen and how either humans or nature can make viruses bigger threats. Even without nefarious actors, nature will give us more challenging viruses; roadmaps should acknowledge potential for enhanced transmission (Osterholm). • Three quarters of the world's population is at risk from NiV and henipaviruses, not just SE Asia. Henipaviruses	• The group agreed that the value proposition is still needed (and should remain a milestone). • Add phrasing to the Introduction to acknowledge recent experience with coronaviruses to capture the point about nature and humans both capable of more challenging viruses. • Remove "potential" from point #1 of the milestone; emphasize that this is a global threat that requires

	should be emphasized as the virus being focused on, as it is more inclusive (Montgomery). - While milestones under this Strategic Goal are important and should be addressed soon, no timelines should be earlier than 2024, as the roadmap will not be published until 2024 (Moore).	global engagement (Luby, Gurley). - Modify milestone language to the “global threat of NiV and related henipaviruses” (Moore, Gurley). - Add a comment to the Introduction about the risk to the global population. - Change the timeline from 2025 to 2024.
Milestone 2: By 2026, create a funding plan based on the value proposition for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.	- Since 2017, the funding situation has improved (e.g., CEPI, Gates Foundation). The shortfall of indirect funds is the major current roadblock (Broder). - An expert able to provide economic calculations to inform a clearly-articulated value proposition is important for NiV MCMs (Preziosi). - A value proposition has been developed for Lassa fever therapeutics; the group could consider reaching out to the team that developed that proposition (Hassan). - In addition to a solid economic calculation for NiV MCMs, we need the vision and explanation of importance from NiV experts (Gurley).	- Change the timeline from 2026 to 2025 (Gurley, Moore).
Milestone 3: By 2026, develop a coordinated strategy for promoting and incentivizing greater industry engagement in R&D for NiV MCMs.	- CEPI and pharmaceutical companies in Bangladesh are discussing stockpiling vaccines; they might also be interested in stockpiling monoclonal antibodies (mAbs) (Rahman). - At a CEPI meeting in June 2023, concern was expressed that mAb therapies are not feasible due to expense, even though their cost has been reduced drastically the last 5-6 years. Because NiV and Hendra do not mutate a lot, mAbs could be useful for a longer period of time and they could be combined in cocktails (of >1 antibody) to prevent viral escape (Broder).	- Add mention of indirect costs and shortfalls. - Add in-country industry partners. - Change the timeline from 2026 to 2025 (Gurley, Moore).

	• Indirect costs and shortfalls are lacking but needed for industry partners to produce GMP products that are ready; the money is not currently there (Broder). • Industry interest in NiV MCMs may have changed from what it was previously as a result of the COVID-19 pandemic (Roth). • In addition to industry work on MCMs, there are US federal scientists and industry partners who will produce countermeasures for the public benefit. It is important to promote that the technology for the MCMs is available and that it be given to affected countries so those countries can evaluate and manufacture for their own use (Broder). • Participants raised the importance of engagement of in-country industry partners.	

Cross-Cutting Issues: Strategic Goal 2 and Aligned Milestones		
Strategic Goal or Milestone	**Discussion highlights**	**Suggested actions**
Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to better define the disease burden, risk factors for infection, and risk of spillover events in affected countries.	• Instead of “affected” countries, use “countries at risk” or “countries with appropriate reservoir hosts” (Gurley, Rahman, Moore).	• Change goal language from “affected” countries to “at-risk” countries and include reservoirs in the revised Strategic Goal (Moore).
Milestone 1: By 2025, develop a plan for enhancing human NiV surveillance in India and Bangladesh outside of existing surveillance areas (i.e., where cases previously have been identified). This should include securing funding, identifying additional surveillance catchment areas, engaging key partners in those areas, generating standardized surveillance protocols, and conducting training for implementation.	• Discussion for milestones 1 and 2 (which currently separate development and initiation of a NiV surveillance plan) had significant overlap, and the group agreed that they should be combined. • Consider adding leveraging of existing surveillance platforms for other disease, such JE (Rahman). • It is also important to collaborate with organizations already in place, e.g., CDC and WHO (Parveen). • Surveillance should not be restricted to human surveillance; instead, this should include all relevant	• Combine milestones 1 and 2; the revised milestone timeline should be 2025 (Gurley, Moore). *[Note: In the edited version, original milestone 1 is now milestone 3.]* • Add a new milestone on human surveillance outside of India and Bangladesh with

Milestone 2: By 2026, initiate enhanced human NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), promote early case detection, and better define the disease burden in India and Bangladesh, particularly outside of areas where cases previously have been identified.	efforts, such as surveillance in domestic animals and wildlife (Roth). • Surveillance must be clearly embedded in comprehensive strategies for prevention and control. We want India and Bangladesh to lead in surveillance and extend their leadership to other countries (Formenty). This highlights the importance of broadening surveillance to include henipaviruses, and the importance of disease prevention (Gurley). • One Health issues are important in relation to surveillance for spillover into domestic animals and livestock (Broder). Such issues are an important part of a value proposition (Gurley). Tests for some diseases are required of certain species for international transportation (Halpin). • Instead of using the word “Nipah” throughout the roadmap, it should say “Nipah and Nipah-like” or “Henipavirus” (Gurley, Broder). • Hendra virus genotype 2 (HeV-g2) taught us that PCR tests will miss related viruses, and therefore we need serology on samples (Broder). • Add a milestone on conducting human surveillance in areas other than India and Bangladesh.	a timeline of 2025. *[Note: In the edited version this new milestone is now milestone 4.]* • Add a milestone on conducting surveillance outside of India and Bangladesh in animals with a timeline of 2025. *[Note: In the edited version this new milestone is now milestone 5.]* • Expand language in the roadmap, as appropriate, from just “Nipah” to include Nipah-like and/or Henipaviruses (Gurley, Broder).
Milestone 3: By 2026, generate and implement standardized protocols for case investigation that are aimed at identifying risk factors for primary NiV infection and at conducting case-contact studies to better understand chains of transmission ([Hedge 2023]()).	• Incorporate One Health for this milestone (Rahman, Gurley). • Bangladesh already has a protocol for this, and the milestone could be moved to 2024 (Rahman). However, it might take time for India to meet this milestone (Luby). • WHO could help by hosting a standardized protocol and, if spillovers happen in other countries, they could go through WHO to avoid inter-country tension (Luby). • WHO has developed several standardized protocols for other diseases, such as Crimean Congo Hemorrhagic Fever (CCHF). Part of that work involves WHO developing a standardized protocol for appropriate and in-depth case	• Change the timeline from 2026 to 2024. • This will now be milestone 1 in the edited version because of the date change. • Add One Health language to the milestone.

	investigation. This is needed well before 2026 (Formenty). • Bangladesh and India have protocols in place; the push is to share, modify, and expand into other countries, and to have funding for that work (Montgomery). • "Standardizing" includes adaptability to individual countries/regions (Gurley, Osterholm).	
Milestone 4: By 2026, develop plans for conducting additional research in India and Bangladesh to identify the potential for and drivers of spillover events, particularly in areas where NiV cases have not yet been identified.	• Additional research should not be restricted to India and Bangladesh; for example, Malaysia has requested work on such protocols (Formenty, Gurley).	• Change the timeline from 2026 to 2025. • Revise milestone so it is not restricted to India and Bangladesh (Formenty, Gurley). Instead, refer to at-risk countries. *[Milestone 6 in the edited version.]*
Additional considerations	• The following comment was made in another section: Country-level capacity will need to be assessed and gaps identified as part of standard clinical protocol development (Parveen). This work could be included in one of the surveillance-related issues (Gurley). • Later in the discussion, participants suggested the following milestone (originally milestone 4 under Strategic Goa 4) be moved to this goal: By 2026, establish capacity at selected surveillance sites in India and Bangladesh to investigate NiV-related deaths by using post-mortem minimally invasive tissue sampling to enhance understanding of NiV disease pathogenesis (Bassat 2021).	• Consider adding the following milestone to this goal: "By 2025, assess country-level capacity in affected countries to implement standardized clinical protocols for case investigation and address key gaps in implementation." *[Milestone 2 in the edited version.]* • Move the following milestone to this goal: "By 2026, establish capacity at selected surveillance sites in India and Bangladesh to investigate NiV-related deaths by using post-mortem minimally invasive tissue sampling to enhance

		understanding of NiV disease pathogenesis ([Bassat 2021](#)).” *[Milestone 7 in the edited version.]*

Cross-Cutting Issues: Strategic Goal 3 and Aligned Milestones

Strategic Goal or Milestone	Discussion highlights	Suggested actions
Strategic Goal 3: Determine the requirements for clinical trials, regulatory pathways, and other considerations that will affect licensure or approval of NiV MCMs by engaging an international regulatory working group representing NRAs in affected areas and other key international stakeholders.	• No comments.	• No edits suggested (although the comment below on changing the wording from an international regulatory group also applies to the wording of the goal).
Milestone 1: By 2024, conduct scenario planning to clarify the regulatory procedures and determine the acceptable pathways for approval and emergency use authorization of NiV MCMs (including vaccines, novel candidate therapeutics, repurposed therapeutics, and diagnostics) in countries at highest risk for NiV outbreaks (i.e., Bangladesh and India) through an international NiV-focused regulatory group.	Discussion and comments for Milestones 1 and 2 are combined in the following bullets: • The group touched on CEPI’s accomplishments specific to vaccines, but noted that this milestone is broader than just vaccines (Gurley, Moore). • In 2018, NIAID and country partners (e.g., Bangladesh) created a protocol for use of mAbs. However, this was not the work of an established international regulatory group (Broder). • Regulatory issues are major barriers to industry engagement and private sector participation. It would be helpful to understand these issues better and have an advocacy strategy to overcome those issues (Luby). • Look to WHO’s work with the African Vaccine Regulatory Forum (AVAREF), which allows for interfacing with regulators. It might be possible to create a subgroup from that group for relevant discussions (Roth). • WHO’s work with African regulators to involve the regulators on reviewing protocols and dossiers – mostly for vaccines – has been very positive, allowing for	• Replace “international NiV-focused regulatory group” with “international forum of regulators” or similar language (Moore, Preziosi). • Marie-Pierre Preziosi will ask a colleague at WHO for input on this milestone wording. • Milestone language should clarify that this is scenario planning to identify gaps (Moore, Gurley). • Remove “countries at highest risk for NiV outbreaks (i.e.,)” and “through an international focused regulatory group.” • No change to timeline.
Milestone 2: By 2025, determine if any key gaps exist for regulatory approval		• Milestone 2 should be reworded to “develop

and emergency use authorization of candidate NiV MCMs in affected countries and develop strategies to address those gaps, with specified timelines for completion.	progress made on regulatory harmonization. Broader efforts are being led now, such as working on mAbs (Preziosi). • The regulatory agencies in India and Pakistan are already involved, and therefore the focus should first be with them, followed by engaging others more broadly. There is a potential for bottlenecks if the work goes too broad at first (Gurley). • What constitutes a regulatory body (Gurley)? Examples provided were FDA, EMA, national regulatory agencies (Moore). • International regulatory groups cannot focus on individual diseases; their reviews are thematic. As such, the milestone wording should be adjusted and also expanded to include fast review of adaptive platform trials (Preziosi). • We need engagement from the countries themselves (Formenty). • An understanding of how this work is coordinated should be linked to this milestone, perhaps through WHO. For example, the WHO portal could be adapted for this purpose (Parveen, Gurley, Rahman, Preziosi).	strategies" and focus on developing strategies to address the gaps identified as part of milestone 1 (Moore, Gurley). • No change to timeline.
Milestone 3: By 2026, ensure that any issues affecting approval and emergency use of candidate MCMs in affected countries have been resolved and that consensus has been achieved on the necessary regulatory steps and procedures.	• The group noted that this milestone may not be realistic. It may be better for focus on a system for monitoring regulatory issues. • Assessing the need/capacity to conduct clinical trials must be included; it does not exist now (Hassan). • Capacity is a "key gap," so consider having a nod to capacity here, as this is a cross-cutting issue (Gurley). A milestone on plans/protocols for emergency use of candidate NiV MCMs is needed.	• Revise this milestone to creating a system for monitoring regulatory issues for licensure and use of candidate NiV MCMs. • Add another milestone on developing plans for emergency use of candidate NiV MCMs. • Add another milestone on assessing capacity to conduct clinical trials and field studies

		of MCMs, particularly during outbreaks.

Cross-Cutting Issues: Strategic Goal 4 and Aligned Milestones

Strategic Goal or Milestone	Discussion highlights	Suggested actions
Strategic Goal 4: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.	• Consider expanding to include non-animal models, such as organoids. Several countries have non-animal models in place, mainly for basic research (Halpin). • Possible edits suggested include adding "non-animal models" to the goal language and editing the language to "in vitro and in vivo models" (Gurley, de Wit). Instead, the group agreed to revise the goal by just shortening the language to remove reference to animal models.	• Delete "in human and animal models" (Gurley, Moore). • Consider adding non-animal models activities (e.g., organoids, using AI technology, etc.) to the additional research priorities.
Milestone 1: By 2025, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.	• CEPI, NIAID, and CDC are already doing this work (multiple participants). • Unclear whether this milestone should be kept or if it should be moved to research priorities (Gurley). • We should not lock into challenge strain, etc.; we need to know more about epidemiology (de Wit). • We need standardized assays, reagents, etc., for clinical trials, but these are continually improved and revised. These resources are needed now; some are available and some are in-progress (multiple participants).	• Change timeline from 2025 to 2024.
Milestone 2: By 2025, conduct additional research to further optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs.	• Consider changing to "standardized" animal models, since they are well-defined already (Freiberg). • Milestone could potentially be combined with an earlier milestone on assay standardization (Freiberg). • Discussion on whether we do or do not know which animal model is the best for MCM development, and whether it is the African green monkey (AGM) or if the AGM is just the best that we have currently (Broder, de Wit). • There is a lack of understanding on pathogenesis in humans (de Wit), but that is data we may never have (Broder).	• Leave the milestone as is for now. • Consider adding a new milestone on better understanding human pathology (Gurley, Moore). Wording related to this could potentially be "pathogenesis investigation protocol" or "standardized human pathology investigation" (Gurley). *[New milestone 4.]*

	- Any pathogenesis investigation has to be linked to surveillance: picking up cases early, developing MCMs to address early disease, understanding disease progression, optimizing animal models, etc. (Broder). - We need to do better clinical investigation to better optimize animal models of early-stage disease/pathophysiology (Montgomery). - The International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC) developed clinical characterization protocols for a number of diseases. They are designed to be simple, capture evolution, natural history of disease, and can be made targeted and sophisticated. They were widely used for COVID-19 and other diseases. Such an approach would fit both surveillance and identifying cases where they happen (Roth). - Country-level capacity will need to be assessed and gaps identified as part of standard clinical protocol development (Parveen). This work could be included in one of the surveillance-related issues (Gurley).	
Milestone 3: By 2026, conduct sequencing of NiV strains from existing clinical samples obtained from past NiV cases to assess variability of NiV strains in India and Bangladesh (CEPI 2023a).	- This is an ongoing activity (Gurley).	- Delete this milestone (Gurley) and instead add to additional research priorities.
Milestone 4: By 2026, establish capacity at selected surveillance sites in India and Bangladesh to investigate NiV-related deaths by using post-mortem minimally invasive tissue sampling to enhance understanding of NiV disease pathogenesis (Bassat 2021).	- Participants suggested that this milestone be moved to Strategic Goal 2.	- Move this milestone to the surveillance-focused Strategic Goal 2 (Moore).
Milestone 5: By 2028, conduct research in animal models to determine if strain variability impacts efficacy of promising	- The timeline for this milestone seems far off (Gurley). - Much of this may not require animal models (de Wit).	- Change milestone language to de-emphasize animal models, i.e., “conduct

NiV MCMs or the accuracy of diagnostic tests.		research to determine if strain variability…" (Moore). • Move up the timeline by one year.

Diagnostics in the Nipah R&D Roadmap

Joel Montgomery served as facilitator for discussion on diagnostics in the draft roadmap.

Joel led the group in a review of important advances, barriers, challenges, and key needs for NiV diagnostics. Key points from that discussion:

- At the previous meeting of this group, two diagnostic platforms were discussed: a gene expert platform developed in India, possibly being moved to Bangladesh, and Linfa Wang's lateral flow platform (Gurley). Meeting participants were not aware of those diagnostic platforms progressing further (i.e., no one was aware of additional announcements or updates).
- Challenges for NiV diagnostics include lack of RDTs (e.g., lateral flow tests) or bedside diagnostics. Of note, bedside diagnostics would require changes to infection control practices.
- The CDC serology assay is low-cost and could be helpful in ecological studies, but supporting research has not yet been published; also, this assay can't differentiate IgM from IgG antibodies. CDC is also working with FIND to evaluate rapid diagnostic tests (RDTs); progress with RDTs will be driven by the perceived need for these tests in the US or Europe (Montgomery).
- Even severe cases of NiV are often not diagnosed; regular use of an RDT for severely ill patients could be justified (Gurley).
- Improved diagnostics are needed for the following reasons: (1) improve early detection when therapeutic intervention is viable; (2) ensure adequate infection prevention and control (IPC) practices; and (3) enhance surveillance to better understand the burden of disease. Point-of-care (POC) diagnostics are particularly useful for outbreaks and IPC implementation. RDTs can be used in rural settings that lack adequate surveillance or specimen transportation. Diagnostics can also be useful in postmortem surveillance (Broder).
- RDTs, despite limitations, are useful in remote locations, such as where NiV outbreaks have occurred. Tests that have longer shelf lives and resist heat and humidity (e.g., patch technologies) are being pursued. However, there is no market for rapid POC tests that would save frontline healthcare workers (HCWs) during an outbreak (Roth, Broder).
- POC tests for henipaviruses (i.e., broader than just tests for NiV) would increase the geographic area where the tests could be used (Gurley).
- Serially testing of contacts during an outbreak could be used to gather data for developing tests for early diagnosis (Montgomery, Broder).
- Patients generally do not present to the hospital before day 4 of illness, at which point they are severely ill. We want tests to work early, but we have no way to evaluate those tests. One approach would be to retest (2 days after initial testing) suspected cases that initially test negative if they are still symptomatic (Gurley).

Joel then led a discussion of the draft roadmap strategic goals and milestones for NiV diagnostics. Discussion highlights are detailed in the tables below.

Diagnostics: Strategic Goal 1 and Aligned Milestones		
Strategic Goal or Milestone	**Discussion highlights**	**Suggested actions**
Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.	• Some participants were unclear on what was meant by a virtual repository.	• Delete the words "virtual reference" in front of repository.
Milestone 1: By 2026, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).	Discussion of milestones 1 and 2 was as follows: • Discussion on what would be needed with a "virtual reference repository" highlighted the following: centralized registry for samples located in/owned by multiple countries; requests can be made but not necessarily granted; location is known and documented; control over samples is maintained in-country; bilateral agreements between individual researchers (Montgomery, Broder, Rahman, Moore, Osterholm). • The repository of samples "to be collected in future outbreaks" in milestone 2 is centralized within countries, whereas in milestone 1 the samples remain in labs and their locations are known through an online registry/catalogue. For the repository in milestone 1, a governance structure dictates rules for gaining access to samples (Broder, Mazzola, Osterholm). • The goal is to have samples accessible for diagnostic assay evaluation; a repository of well-characterized samples (Montgomery). • A governance structure is critical for several reasons, including that sample sharing must conform to the Nagoya Protocol and a prioritization of sharing requests for limited samples. This will not just involve India and Bangladesh, but also CDC (Rahman, Mazzola, Montgomery).	• Remove the words "virtual reference" and change to "repositories" (Moore, Rahman, Gurley). • The milestone should note that the samples are "well-documented" (i.e., full clinical history of patient), as well as "well-characterized" (multiple participants). • Potential milestone language to address the previous bullet: "well-characterized with a recommended set of metadata (i.e., age, sex, days since symptom onset)" (Moore, Gurley). • The milestone should also include both acute and convalescent samples (multiple participants). • Change milestone timeline from 2026 to 2024.

Milestone 2: By 2027, identify sustainable, long-term funding, determine sites for sample storage, and initiate creation of the virtual reference repository in Bangladesh and India, with samples to be collected during future outbreaks.	• CEPI created a reference panel, but its usefulness for validating rapid or POC diagnostics is limited (Preziosi). • Determining repository location should be determined by a governance structure; creating the governance structure will be a hurdle (Gurley, Montgomery, Osterholm). • Repository location will raise issues of biosecurity and security in the home countries and where samples are shared (multiple participants). • A WHO workgroup could be involved with the governance structure (Preziosi) and it would need to be wider than NiV alone (e.g., henipaviruses) (Montgomery). • Repository samples would need to be well-characterized, requiring a minimum set of metadata on samples (e.g., gender, age, onset date) (Gurley, Montgomery). However, excluding samples without that information might discourage sample sharing (Gurley).	• Revise this milestone to be appropriate with changes made to milestone 1 (e.g., remove “virtual”) (Rahman, Gurley, Moore). • “Repository” language should stay in this milestone, since locations is detailed (i.e., Bangladesh, India) (Rahman, Gurley, Moore). • Change milestone timeline from 2026 to 2025.

Diagnostics: Strategic Goal 2 and Aligned Milestones

Strategic Goal or Milestone	Discussion highlights	Suggested actions
Strategic Goal 2: Continue to develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are suitable for use in peripheral settings and that have minimal requirements for biosafety precautions and staff training.	• Milestone should be POC “and” near-patient, not “or” (Gurley). • We want tests that a community worker can perform with minimal biosafety risks (Montgomery). • Pan-henipavirus testing is the ultimate goal, but we need a NiV diagnostic now (Gurley). • In addition to “suitable for use,” we want to specify sustained storage/shelf life of tests (Roth). • Test affordability is the key to POC adoption (Montgomery). • The target product profile (TPP) for these tests is vague, so it is worthwhile to state “extended shelf life” or they might have a short shelf life, which impacts affordability (Roth).	• Change goal language from “point-of-care or near-patient” to “point-of-care and near-patient” (Gurley) and include language on extended shelf life (Roth).
Milestone 1: By 2025, engage appropriate regulatory agencies and	• “Commercialization” is intended to mean test approval and that tests are made commercially available. The	• Change timeline from 2025 to 2024.

NRAs to inform commercialization pathways for NiV diagnostic assays. This effort should include clarifying regulatory pathways for approval (including approval for emergency use) of NiV diagnostics.	milestone describes a discussion with regulators about what is needed to put a product on the market (Gurley, Broder, Moore). • Work towards this milestone can begin with existing samples (i.e., does not need to wait until repositories detailed under Strategic Goal 1 are created) (multiple participants). • NiV diagnostics might qualify for the Expert Review Panel for Diagnostics (ERPD) pathway hosted by WHO. Decisions would be made in light of difficulty to obtain clinical samples (Preziosi, Mazzola). • The existing use cases and TTPs for NiV diagnostics have not yet been finalized, so a new milestone should be added to accomplish this in 2024 (Mazzola).	• Add a new milestone for 2024 to finalize the draft TTPs and use cases for NiV diagnostics.
Milestone 2: By 2026, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP and can be used in peripheral sites.	• “Preclinical evaluation” is a FIND term that means laboratory work, not clinical samples. Consider changing to “analytical evaluation” or other term (Gurley, Montgomery, Moore). • Milestone timeline has to follow after the repository activities detailed under Strategic Goal 1 (multiple participants). • Participants were not aware of promising candidates with potential to seek approval in 2025 or 2026. • Technologies that can be applied to POC testing may advance in the next 2 years (Osterholm). Participants recommended that the milestone timeline stay at 2026, with recognition that there may be technological advancements that could be leveraged for NiV diagnostics by that time (Luby, Montgomery). • A suggestion was made to add a new milestone calling for the acceleration of POC and near-patient testing using existing technologies (Mazzola, Montgomery). • Matchmaking between diagnostic test developers/platforms and available reagents (e.g., mAbs)	• No change to the timeline o wording. • Create a new milestone (which will be a new milestone 2) that calls for the acceleration of POC and near-patient testing using existing technologies.

	could be done (e.g., as FIND did with Duke University) (Montgomery, Mazzola, Roth). • For milestones 2 and 3: WHO sets international reference standards and is creating an antibody standard. Standards have to be completed before the preclinical evaluation, so the order for milestones 2 and 3 should be reversed (standards [milestone 3] by 2025, preclinical work [milestone 2] by 2026) (Mazzola, Gurley, Moore, Montgomery).	
Milestone 3: By 2026, create international reference standards for calibrating and harmonizing NiV diagnostic assays.	• The milestone timeline has to follow after the repository activities detailed under Strategic Goal 1 (multiple participants). • For original milestones 2 and 3: WHO sets international reference standards and is creating an antibody standard for NiV. Standards have to be completed before the preclinical evaluation, so the order for milestones 2 and 3 should be reversed (standards [original milestone 3] by 2025, preclinical work [original milestone 2] by 2026) (Mazzola, Gurley, Moore, Montgomery).	• Change timeline from 2026 to 2025 (this will also change the order of original milestones 2 and 3, as milestone 3 will remain 2026).
Milestone 4: By 2026, develop a minimum protocol or set of best practices (that biosafety committees will accept) for inactivation of clinical samples from humans and animals that are being tested for NiV.	• Remove the word “minimum” from the milestone and change the timeline to 2024 (Rahman, Gurley, Moore). • Questions related to this have likely been addressed before, such as with PCR for suspected NiV patients in Bangladesh (Luby). However, new technologies (e.g., those on the horizon that would be considered “plug-and-play”) require consideration (Montgomery). • Standardized methods for inactivation would be desired (Gurley). • Every inactivation method has to be tested for use in the US. For companies, deactivation information is usually proprietary information and divulged only to regulatory agencies (de Wit).	• Revise the milestone: remove “minimum” and change the timeline to 2024 (Rahman, Gurley, Moore).
Milestone 5: By 2027, complete clinical validation of performance and operational suitability for at least two of	• No comments.	• No change to the timeline or wording.

the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP and can be used in peripheral sites.		
Milestone 6: By 2028, obtain regulatory approval for at least one rapid, point-of-care or near-patient care NiV diagnostic test that can be commercialized and standardized.	• Milestone wording leaves standardization up to the developer (Mazzola). • This is an aspirational milestone (Montgomery). • The company Molbio has emergency use authorization (EUA) in India for its Truenat test, but that test might not be used currently. While an EUA isn't regulatory approval, it can continue to be used for a long time (e.g., Ebola test) (Mazzola, Moore). • Change "obtain" to "promote" and/or "support" (Mazzola, Moore); leave the timeline at 2028 since milestone 5 is for 2027.	• Change "obtain" to "promote" and/or "support" (Mazzola, Moore).

Diagnostics: Strategic Goal 3 and Aligned Milestones		
Strategic Goal or Milestone	**Discussion highlights**	**Suggested actions**
Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known spillover risk to promote early detection of NiV.	• No comments.	• No edits suggested.
Milestone 1: By 2026, expand national laboratory networks for NiV detection in the primary affected countries (Bangladesh and India) that include plans for enhancing laboratory preparedness to enable earlier and timely detection of NiV infection during future outbreaks.	• As discussed previously, the milestone should refer to leveraging existing platforms and infrastructure, particularly given what was established for COVID (Gurley, de Wit, Rahman). • This needs to happen quickly to keep systems online. One strategy would be to assess post-COVID genomic activities related to materials and personnel, and seek alternative funding to keep this running, not just for NiV but for any potential pandemic threat (Preziosi, multiple participants). *[Note: This was not added as a milestone to the roadmap, as this seems to be more of an implementation issue.]* • Use "at-risk countries" instead of "affected countries" (Rahman).	• Remove "India and Bangladesh" from the milestone (Moore). • Change "affected countries" to "at-risk countries" (Rahman). • Change timeline from 2026 to 2025. • Verify that any related milestones in the cross-cutting section are revised, if needed, per diagnostics discussions.

	• Staffing is the key and there needs to be a system in place to keep places running. It is difficult to get funding for surveillance and detection activities (Roth, multiple participants). • Biosafety can be an issue (Montgomery). • Vigilance, safety, and training are necessary. We want active virus for some applications (Gurley, Montgomery). • Using serology to detect spillovers in humans and inform acute surveillance might be useful in other countries (Montgomery). • Consider adding other countries given need for lab capacity to diagnose NiV (for milestones 1-3) (Moore).	
Milestone 2: By 2027, generate well-characterized and up-to-date proficiency panels for NiV diagnostic testing to be used in selected laboratories in Bangladesh and India.	• This work might be done earlier than 2026 in India and Bangladesh; the timeline represents other at-risk countries. • Consider adding other countries (i.e., at-risk countries) given need for lab capacity to diagnose NiV (for milestones 1-3) (Moore).	• Remove “India and Bangladesh” from the milestone (Moore). • Revise to “…proficiency panels and network quality controls for NiV diagnostic testing.” • Add at-risk countries. • Change timeline from 2027 to 2026.
Milestone 3: By 2029, implement routine EQA monitoring of NiV diagnostic testing at selected laboratories in Bangladesh and India.	• Consider adding other countries given need for lab capacity to diagnose NiV (for milestones 1-3) (Moore).	• Remove “India and Bangladesh” from the milestone (Moore). • Add at-risk countries. • Change timeline from 2029 to 2026.

Joel concluded the diagnostics section with a facilitated discussion on roadmap implementation, including barriers to implementation and ideas for implementation. Key points from the discussion:

- Barriers:
    - Financial support and coordination (Roth)
    - In-country leadership attention/support (Gurley)
    - The lack of a sense of urgency (Gurley)

    - The lack of in-country champions (Rahman)
- Ideas for implementation:
    - WHO's role is critical.
    - A sense of urgency and buy-in is needed, specifically from:
        - Community and the affected/vulnerable populations (Rahman, Lackritz)
        - Political leadership in affected countries (Formenty, Osterholm)
    - Involving clinicians in overcoming barriers to sample sharing (Gurley)
        - Physicians would likely get behind this effort (Gurley); people already give samples to iccdr,b (which has decades of trust/presence in the community) (Rahman, Lackritz).
    - Funding should be internationally sourced by global public-private partnerships; this is a global pandemic prevention issue and we shouldn't ask the countries that are already stretched thin to protect wealthy countries.

Therapeutics in the Nipah R&D Roadmap

Emmie de Wit served as facilitator for discussion on therapeutics in the draft roadmap.

Emmie led the group in a review of important advances, barriers, challenges, and key needs for NiV therapeutics. Key points from that discussion focused on current challenges in the therapeutics field:

- Funding clinical trials is a challenge (multiple participants).
- IV administration of mAbs is also a challenge (Broder, Montgomery).
- NIAID funded grants for NiV antiviral discovery, for which Christopher Broder's group partnered with Novartis.
- In Bangladesh, patients often do not present until day 4 after symptom onset (Gurley). Because of that, a potent anti-NiV monoclonal likely to prevent significant mortality associated with diagnosed disease would be useful (Broder).
- With therapeutics, more patients would likely survive NiV, but would have sequelae unless an agent crosses the blood-brain barrier or cases are treated upon suspicion, like with rabies (de Wit, Broder). Patients would be surviving with neurological deficits (Luby).
- It's not clear whether mRNA therapeutics would be successful unless there is gene therapy (Broder).
- Expense will be a barrier, as was seen with COVID therapeutics (Rahman).
- The few numbers of patients presenting each year is a huge barrier to therapeutics development; this could maybe be overcome with better surveillance, although that is somewhat unlikely (Luby).
- Numerous challenges exist with developing NiV therapeutics; however, we should be considering the fact that the critical target here is to have therapeutics not just to treat current patients, but to have drugs available in case of a catastrophic pandemic caused by NiV or a related virus (Luby).
- Guidelines for supportive care are needed that can apply whether or not clinical trials are successful (Gurley).

Emmie then led a discussion of the draft roadmap strategic goals and milestones for NiV therapeutics. Discussion highlights are detailed in the tables below:

Therapeutics: Strategic Goal 1 and Aligned Milestones		
Strategic Goal or Milestone	**Discussion highlights**	**Suggested actions**
Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.	• No comments.	• No edits suggested, other than expanding to include related viruses (per earlier discussions).
Milestone 1: By 2024, convene a consortium of key stakeholders—in affected areas and internationally—to address the key challenges with conducting clinical trials of therapeutic agents during future NiV outbreaks. This consortium could potentially be modeled after the West Africa Lassa Fever Consortium (WALC) (ISARIC 2023).	• Clinical trial guidelines for Bangladesh and India should come first, but other affected countries should be included (multiple participants).	• Add related viruses (per earlier discussions). • No change in the timeline.
Milestone 2: By 2025, develop NiV standard of care guidelines to be used in affected countries, disseminate the guidelines, and conduct outreach to clinicians as appropriate.	• Based on Lassa and CCHF experience of developing and implementing training modules for physicians in Africa, consider how to raise awareness of symptoms and standards of care in affected regions. For the time being, consider adapting standards of care for other infectious diseases (Formenty). • We need to develop a network/critical mass of clinicians to adopt these standards of care if we want to enhance NiV detection (Formenty). • Consider adding another milestone on clinician awareness/training on standards of care; infection control could be tied to that (de Wit). Training is needed at the university level (Formenty). • Shahana Parveen noted that a training module that includes infection control was developed; she can share that.	• Revise milestone to add "infection control and standard of care guidelines" (Gurley, Moore). • Change timeline from 2025 to 2024. • Create a new milestone on training clinicians regarding infection control and standards of care guidelines, with a 2025 target date (de Wit, Moore).

	• In Bangladesh, family members provide most of the hands-on care in hospitals. That creates closed loops that limit hospital-wide outbreaks. As health systems develop, there are more opportunities for transmission (Gurley). Family members providing patient care need to be instructed in infection control (Parveen). • Training is easy compared with supply chains and running water for infection control (Gurley).	
Milestone 3: By 2025, complete an agreed-upon generic prepositioned protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates (mAbs and small molecules, including repurposed drugs) to be implemented in NiV-affected areas during outbreaks and develop plans for operationalizing the protocol.	• WHO is working on a rolling protocol (Roth). • COVID has changed the way such activities are approached and can serve as an example; as such, the dates can be moved up (multiple participants). • NIAID developed a generic protocol for mAbs with an intent that it could be used for other therapeutics. This could be reinvigorated. It was written for post-exposure prophylaxis (PEP) but could be modified to include pre-exposure prophylaxis (PREP) (Moore, Broder, de Wit, Gurley). • Semantics of pre- and post-exposure can be tricky: if you have been exposed but it is not detected, it is pre-exposure. • In an outbreak with pandemic potential, both those with known exposure and likely exposure should be treated (Osterholm).	• Change timeline from 2025 to 2024.
Milestone 4: By 2025, complete an agreed-upon generic prepositioned protocol for conducting PEP trials of promising therapeutic candidates (mAbs and small molecules, including repurposed drugs) to be implemented in NiV-affected areas during outbreaks and develop plans for operationalizing the protocol.		• Change timeline from 2025 to 2024. • Add PREP to this milestone.
Milestone 5: By 2026, complete a broader, harmonized regional protocol (to be used across Bangladesh and India) for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during outbreaks or potentially during periods of endemic disease (if comparable data can be generated over	• Milestone 3 and 5 are essentially the same; the group agreed to remove milestone 5.	• Remove this milestone.

time and across different clinical sites) and develop plans for operationalizing the protocol.		
Milestone 6: By 2026, generate a reliable source or stockpile of a mAB (m102.4 or other mAb) to be used in outbreak-related clinical trials for both PEP and early clinical treatment.	• CEPI is working on this, but does not support enough indirect costs to make production feasible. There are people ready to do this work if there was sufficient funding (Broder). • mAbs have long shelf lives (Gurley, Broder).	• No change to timeline or wording.

Therapeutics: Strategic Goal 2 and Aligned Milestones		
Strategic Goal or Milestone	**Discussion highlights**	**Suggested actions**
Strategic Goal 2: Develop and evaluate therapeutic agents for the treatment of NiV infection and for PEP to prevent NiV infection.	• No comments.	• No edits suggested.
Milestone 1: By 2025, create and implement a prioritization process for determining which promising NiV therapeutic candidates should be further evaluated in clinical trials, once adequate animal data demonstrating safety and efficacy are available.	• This should be done as quickly as possible to determine qualifying animal data (de Wit). • This timeline works well with the current NIH Antiviral Drug Discovery (AViDD) Centers for Pathogens of Pandemic Concern, which have 2 years of funding left (Freiberg).	• Add a reference to a “governance structure” in the milestone. • No change to timeline.
Milestone 2: By 2026, complete preclinical evaluation in animal models—with administration of the therapeutic agent more than 24 hours after challenge and potentially after symptom onset—of the preliminary safety, tolerability, and efficacy of at least two promising small-molecule therapeutic candidates or combination therapies for the treatment of NiV infection.	• AViDD Centers should be pushing out antivirals; the 2026 timeline is realistic (de Wit).	• No change to the wording or timeline.
Milestone 3: By 2027, further explore in animal models whether two or three of the most promising small-molecule	• This milestone can be removed (de Wit).	• Remove this milestone.

therapeutic candidates are likely suitable for PEP and, therefore, should be assessed as PEP in clinical trials.		
Milestone 4: By 2027, determine the most cost-effective and feasible routes of administration for use in real-world settings for at least two promising small-molecule therapeutic candidates.	• This milestone can be removed (de Wit).	• Remove this milestone.
Milestone 5: By 2027, complete at least one additional clinical trial (phase 2 or 2/3) in a NiV-affected area of m102.4 or other suitable mAb to further assess safety, tolerability, and efficacy (if NiV incidence allows efficacy assessment).	• Revise the milestone so it is not focused on m102.4 specifically (multiple participants). • The group agreed that this milestone should be changed to a phase 1 trial. • Then develop a new milestone on phase 2 or phase 2/3 trials for a mAb or mAb cocktail; this milestone should have a later timeline (de Wit).	• Change the milestone to; “complete one additional phase 1 clinical trial of a monoclonal antibody” (i.e., do not specify 102.4) (Moore). • With language revision, allow for a mAb cocktail, e.g., “mAb(s)” (Broder, Roth). • Change the timeline from 2027 to 2025 (Preziosi). • Create a new milestone on phase 2 or 2/3 trials for mAbs with a timeline of 2027.
Milestone 6: By 2028, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising small-molecule therapeutic candidates or combination therapies for the treatment of NiV infection.	• The group agreed with the language “combination therapies”; there is no need to specify monoclonal antibodies. • Consider a separate milestone for combination therapeutic trials; alternatively, that could be two arms of the same phase 1 trial (Moore, Preziosi, Gurley). This milestone might be maintained with revisions to the language (vs. creating a new milestone).	• Possible revision: “By 2028, complete at least one phase 1 clinical trial of at least two small molecule therapeutic agents or combination therapies …” *[Note: The language was not finalized during the meeting and will be revised based on written feedback from the group].* • No change to the timeline.

Emmie concluded the therapeutics section with a facilitated discussion on roadmap implementation, including barriers to implementation and ideas for implementation. Key points from the discussion:

- Barriers:
    - Money
    - Lack of coordination
    - Lack of urgency
    - Time
    - Delays in ethical clearance; phase 1 trials would mitigate this, given acceptance of results from other countries (clinical trial harmonization).
    - Therapeutics for NiV are not going to make money, they're mainly for pandemic preparedness.
    - The number of detected cases is small, which is a barrier to drug R&D.
- Ideas for implementation:
    - Synergy with other efforts (e.g., JE work) (Preziosi).
    - Use existing capacity for conducting clinical trials in affected countries (Bangladesh and India); leverage existing clinical trial infrastructure (Preziosi).
    - Build capacity for participating hospitals/facilities:
        - Find ways to improve overall quality of care as part of trials, rather than funding high-expense treatment for a few patients (Gurley).
        - There must be continuity for enrolled patients in all circumstances (Hassan).

Vaccines in the Nipah R&D Roadmap

Christopher Broder served as facilitator for discussion.

Chris began the session with a review of important advances, barriers, challenges, and key needs for NiV vaccines. Key points from that discussion focused on recent advancements in the vaccine field:

- The measles NIV construct vaccine from the University of Tokyo is a candidate of note (Luby).
- Another vaccine candidate of note is the ChAdOx1 NiV vaccine, with a phase 1 trial starting by December 2023 (Broder).
- It has been amazing to see a robust set of vaccine candidates in the last 5 years, with much thanks to CEPI (Luby).
- Vaccines currently in phase 1 trials are: the NIH-Moderna mRNA vaccine, an rVSV vaccine that expresses the envelope glycoproteins of both Ebola virus (EBOV) and NiV, and a soluble G protein vaccine (Preziosi, Broder).
- Stocks are available and standardized at this stage (Preziosi).

- Elements still needed for the soluble G program include a correlate of protection (CoP) study, challenge strain selection, and identification of who will conduct the studies (Broder).
- The SG protein candidate is the furthest along; researchers are now characterizing polyclonal immune responses from subjects (Broder).
- A subunit vaccine could be ready quickly, which could help stop an outbreak from spreading, as well as be used for laboratory workers and first responders (Broder).

Chris then led a discussion of the draft roadmap strategic goals and milestones for NiV vaccines. Discussion highlights are detailed in the tables below.

Vaccines: Strategic Goal 1 and Aligned Milestones		
Strategic Goal or Milestone	**Discussion highlights**	**Suggested actions**
Strategic Goal 1: Develop the tools and policies necessary for evaluating and potentially approving one or more NiV candidate vaccines through a nontraditional regulatory pathway.	• No comments.	• No edits suggested.
Milestone 1: By 2024, generate a fully characterized and controlled virus challenge stock (or potentially one each for NiV-M and NiV-B) for assessing candidate vaccines in animal models.	• Other than the mRNA vaccine, all candidate vaccines are based on the G protein, which is nearly identical between the Malaysian and Bangladesh strains, and therefore multiple strains are not needed for challenge studies (Broder). • One challenge strain from NiV-B is apparently established (Broder, de Wit). • All NiV strains are 98% identical. Hendra (at 20% divergent) is 100% protective against both NiV-B and NiV-M, which is a proof of concept for using a single challenge strain in an animal model vaccine efficacy trial (Broder). • It would be helpful for this group to share what makes the most sense for the field. NiV-B is responsible for more outbreaks, spillovers, and appears more transmissible and causes more severe disease. As such, the challenge stock should be NiV-B. There might be disagreement on that suggestion, but that choice would be focused and achievable (Luby).	• Remove "(or potentially one each for NiV-M and NiV-B)." • Add (preferably a NiV-B strain). . .

Milestone 2: By 2024, establish benchmark parameters (e.g., route of challenge, timing of challenge, and challenge dose) for testing of NiV candidate vaccines in animal models, with particular focus toward meeting criteria necessary for approval via a nontraditional pathway.	Discussion for milestones 2 and 3 is combined as follows: • This timeline (2024) seems too soon, unless a program funding vaccine development wants this path forward. So far, there are limited experiments in primates with aerosolized devices. The model must be interpretable in a small number of animals (Broder). • An animal challenge model must be coordinated with regulatory authorities because of the expense (de Wit). • Repeated testing has not been performed by many different routes. There is one (intertracheal and internasal) that is accepted; other models on aerosol exposure are being pursued (Broder). • It is possible that the existing serum neutralizing IgG antibody will be the CoP. • We will never be done characterizing animal models (Broder). • There is significant overlap between milestones 2 and 3. They can be merged and given a timeline of 2025. CEPI is aiming for Accelerated Approval, so we need a good surrogate marker; this will be easier than the Animal Rule pathway (de Wit, Broder, Moore). • With accelerated approval, the animal model will most likely be the African green monkey (Broder).	• Change timeline from 2024 to 2025. • Add language that the work in this milestone be done “in conjunction with regulatory authorities” (Moore). • Add language to specify a “well-characterized animal model” (Moore). • Add surrogate markers per discussion of the next milestone.
Milestone 3: By 2024, further characterize as needed at least one animal model suitable for determining surrogate markers that correlate with vaccine efficacy.		• Remove milestone 3 (given overlap with milestone 2) and add determining surrogate markers to the previous milestone (Moore).
Milestone 4: By 2025, define the protective threshold against NiV infection for serum neutralizing IgG antibodies (as a CoP or surrogate marker), which can be used in animal studies and for immunobridging to humans.	• Traditionally, we do not see high neutralizing titers early on. With our intranasal vaccine, we see good antibody response and good protection in hamsters. We are moving to nonhuman primates (NHPs) in September 2023 (Spiropoulou). • The challenge route and the animal model are going to be different each time. But for vaccines used in human trials, antibody response in serum will be measured (Broder). • The group discussed whether neutralizing antibodies should be the sole CoP. • Avoid language in the milestone that locks into serum neutralizing antibodies despite its prominence as a likely	• Change language to include “serum neutralizing antibodies or other functional CoPs” (Broder, Spiropoulou, Moore). • No change to timeline.

	CoP. Include "other" CoPs due to the ability to induce T-cell responses.	
Milestone 5: By 2025, convene a group of key stakeholders to agree on, through a consensus approach, the most suitable assays (e.g., assays that are developed using live NiV vs. assays developed using pseudoviruses) for determining serum neutralizing IgG antibody titers for NiV vaccine R&D and develop a strategy for standardizing those assays.	• A WHO anti-NiV antibody standard is already developed and due for publication in October 2023. This milestone may not be needed (Broder).	• Remove this milestone.
Milestone 6: By 2026, generate standardized assays to measure neutralizing IgG antibodies for NiV vaccine R&D, with a particular focus on assays to be used for regulatory approval via nontraditional pathways.	• This should be antibodies in general, not specifically "neutralizing" (Spiropoulou). • The WHO antibody standard is forthcoming and should be used; therefore, this milestone is essentially done (multiple participants).	• Remove the word "neutralizing" from the milestone. • Change timeline from 2026 to 2024 and reorder the milestones.

Vaccines: Strategic Goal 2 and Aligned Milestones

Strategic Goal or Milestone	**Discussion highlights**	**Suggested actions**
Strategic Goal 2: Continue to move the current NiV vaccine pipeline forward toward licensure.	• Based on group discussion around milestones 4-6, consider revising Strategic Goal 2 to be on moving the pipeline forward (i.e., using language from milestones 1 and 2), and the other milestones remaining in this section would be part of that revised Strategic Goal.	• Revise the Strategic Goal as detailed in the discussion column.
Milestone 1: By 2024, complete current phase 1 clinical trials for at least three promising NiV candidate vaccines.	• This work is underway. Keep this as "at least three" as written currently (Broder, de Wit).	• No changes to timeline or wording.
Milestone 2: By 2024, define use cases for NiV vaccines to inform vaccine deployment and manufacturing plans.	• We need to understand which vaccines will come through phase 2 for this work (Gurley).	• Change timeline from 2024 to 2025.
Milestone 3: By 2026, further assess vaccine safety and immunogenicity through additional phase 1 and initial phase 2 clinical trials (preferably in affect	• The CEPI trial in Bangladesh with a subunit vaccine will likely begin before 2026, as they plan to start phase 2 in 2024 (Broder).	• Revise milestone to "initiate phase 2 trials by 2025" (multiple participants).

areas) for at least two of the most promising NiV candidate vaccines.	• The VSV vaccine might start phase 2 in Bangladesh in 2024, and the subunit vaccine would follow. Not many patients are needed, but approval will take some time. Two clinical phase 2 trials by 2026 is realistic (Luby). • The financial support and commitment are there (Luby). • This milestone is not entirely dependent on CEPI, as NIAID also could do phase 2 trials (de Wit).	
Milestone 4: By 2027, complete immunogenicity and efficacy studies in a well-characterized animal model for at least one cross-protective NiV vaccine candidate and define a surrogate marker that demonstrates likely clinical benefit of candidate vaccines.	• The group agreed that this milestone should be removed because this is covered in Strategic Goal 1 of this section.	• Remove this milestone.
Milestone 5: By 2029, conduct well-controlled clinical trials (preferably in affected areas) to assess a surrogate endpoint in human subjects for at least one NiV candidate vaccine.	• Trials for a surrogate endpoint might be necessary to repeat in affected areas with different populations (Broder, Preziosi). • Going back to Strategic Goal 1, and then following the progression of activities, we have 1) characterizing the virus stock, 2) establishing benchmark parameters for well-characterized animal model, 3) defining protective thresholds to be used in animal studies for immunobridging, 4) generate/use WHO standard NiV assay, and then 5) clinical trials. • This milestone date is currently for completely trials; could be changed to initiating trials (and date moved up) (Moore). Completing phase 2 trials could be done faster than by 2029 if initiated by 2025; they could be done by 2027 (Broder). • We may need to do more than one phase 2 trial (e.g., children in Bangladesh). If these are going to be only human studies with efficacy via bridging, questions will be raised, including by regulators, who will want more than initial phase 2 or a more robustly powered trial. It is hard to anticipate an area that has few precedents, but	• Revise language: for at least two candidates (instead of one) and remove "preferably." Additionally, see discussion highlights for possible other revisions (e.g., additional clinical trials including vulnerable populations). • Ensure that the milestone is clearly for phase 2 (i.e., appropriate phase 2 context). • Keep the current timeline.

	expectations should not be for "normal" vaccine development (Luby, Preziosi). Given that, a 2029 date is appropriate (Moore). • Trials will already include humans, and the language should be expanded to detail certain populations. Specifically, children, pregnant women, and women of childbearing age should be noted (Broder, Roth, Luby, Osterholm). We would be compromised in an outbreak without data on pregnant women (Luby). • Discussion on milestone rewording included a few recommendations, including: keep the 2029 date and add additional clinical trials including children and pregnant women; detail at least two vaccines; "in affected area" should be a requirement, not "preferably".	
Milestone 6: By 2030, complete a regulatory dossier for at least one NiV vaccine candidate based on a suitable animal model with subsequent immunobridging to humans for review via a nontraditional approval pathway.	• By 2030 is reasonable for this milestone, but it is unclear if this is for licensure or EUA (Broder, Preziosi).	• Add language on "(for licensure or emergency use)" to the milestone (Moore).

Chris concluded the vaccines section with a facilitated discussion on roadmap implementation, including barriers to implementation and ideas for implementation. Key points from the discussion:

- Barriers:
    - Money
    - Lack of stakeholder engagement and buy-in
    - Lack of readiness/coordination for trials during outbreaks
        - Consider adding a milestone in the cross-cutting section, applying to vaccines, therapeutics, and diagnostics (e.g., Strategic Goal 3) (Luby)
            - Include research protocol development (Gurley)
            - There are lessons learned from Ebola that apply; consider use of universal protocols beyond currently affected countries for pandemic prevention (Montgomery)
        - *[Note: We added a milestone in the cross-cutting section on developing protocols for emergency use of candidate NiV MCMs during outbreaks.]*
    - Regulatory uncertainty, given alternate pathways (Rahman, Luby)

  - Requirements for stockpiling
- Ideas for implementation:
  - A lot of forward movement currently exists, with huge strides since 2017; keep up the momentum (Gurley)
  - CEPI is committed to take these vaccines through phase 2 (Rahman, Broder)
  - Stockpiling and plans for use
  - Advocacy plans among stakeholders within affected countries
  - Ensure that trials are conducted in affected countries

Roadmap Implementation

Marie-Pierre Preziosi led a facilitated discussion on roadmap implementation, with questions to panelists Shahana Parveen and Mahmudur Rahman and open discussion to all participants.

- Question: Given the discussions from the last 2 days, what are the most important issues for Bangladesh specifically that align with the goals and milestones for moving NiV diagnostics, therapeutics, and vaccines forward?
  - To deal with small outbreaks, we need POC diagnostics, followed by therapeutics and vaccines (Rahman).
  - Vaccines will come first if the situation changes and there is a large outbreak (Rahman).
  - Rapid tests, especially for hospitalized patients, are the most pressing need (Parveen).
  - Vaccine stockpiles are important, but the vaccines shouldn’t remain stockpiled until a major outbreak. It would be better to use the vaccines, even in a research protocol, or offer them to healthcare and laboratory workers for prevention (Gurley).
    - The mistake for mpox (which we can avoid with NiV) is that the vaccine was stockpiled but not released to healthcare workers and laboratory workers who were at risk (Broder). This also happened with Ebola (Roth).
  - Enable voluntary preventive use of vaccines to prevent pandemics; don’t wait until a pandemic starts (Gurley).
  - Countries should have a vaccination strategy that prioritizes who gets vaccines, such as healthcare workers (Rahman).
  - Countries need to improve patient outcomes now with supportive care. There is a need to improve clinical care capacity, along with laboratory and research capacity, and in support of clinical trials (Hassan).
  - WHO is currently revising treatment guidelines and long-term care for people with neurological sequelae and brain infections (Preziosi).
- Question: What are the most critical resources that you need in Bangladesh to support development of NiV diagnostics, therapeutics, and vaccines?
  - Strong collaboration with CDC and WHO; we need a common platform and collaboration with existing efforts at country-level (Parveen).
  - Technology transfer to countries to enable development of MCMs (Rahman).
  - Consider taking advantage of the money that is moving through One Health efforts now, including from the World Bank (Rahman).
  - There should be a mapping initiative (Rahman, Preziosi).
  - Countries need investment in research; WHO is a potential organizer of such support (Lackritz).

  - SEARO is engaged in helping at-risk countries. It is easier for national institutions to push for surveillance and diagnostics. There are many cases going undiagnosed and we could change that (Formenty).
- Question: What role do you see WHO playing in promoting R&D of NiV MCMs and implementing the goals and milestones in the NiV roadmap?
  - WHO should oversee the development and implementation of an action plan to accomplish roadmap milestones, and designate who will accomplish the milestones. WHO can play an important role in initiating/collaborating on regulatory issues. WHO can initiate international collaborations, and specifically between India and Bangladesh (Parveen).
  - WHO must have a coordinating role in Bangladesh for multiple players, including CDC, CEPI, and the EcoHealth Alliance. An example is the Asia Pacific Strategy for Emerging Diseases and Public Health Emergencies (APSED III, formerly APSED) (Rahman).
  - Regarding a follow-up question as to whether other stakeholders (e.g., agriculture, veterinary) should be involved (Preziosi):
    - In Bangladesh, One Health is institutionalized. Other ministries will come forward during outbreaks. World Bank is also an important partner, as are UNICEF, CDC, and the Bill & Melinda Gates Foundation (Rahman).
    - Stakeholder mapping needs to be done (Rahman).
  - We can ask WHO to play a role, but the technical experts on NiV are responsible for advancing this agenda. It is great if Wellcome, the Bill & Melinda Gates Foundation, etc. fund this work generously, but the reality is that those contributions are incremental. We have to continue to push on the value of this agenda throughout our work and networks (Luby).
  - Champions are needed; we can assemble a group to make the investment case for NiV MCMs (Preziosi).
  - SEARO is developing strategy documents to prepare countries in the region for NiV outbreaks, including MCM R&D along with surveillance. We need to push for this beyond SEARO and the Western Pacific Regional Office (WPRO), notably in Africa (Formenty).
  - Governments need to fund NiV R&D, as well as development partners. Within countries, NiV researchers need to be networked (Rahman).
  - While grateful for the work CEPI is doing to push NiV vaccine development, there needs to be similar funding support for therapeutic development (Formenty).
  - From the One Health consideration, we need rapid, field-based diagnostics that can be used in species other than humans (Gurley).
    - This consideration could be added as a TPP-focused milestone (Preziosi).
    - While scientifically a simple issue, the application of such a diagnostic is complex with regard to different agencies involved at the country level (e.g., agriculture, health) (Gurley).
    - *[Note: Diagnostics for animal species was not added to the roadmap, as the taskforce had decided originally (in 2017-18) that issues related to animals were out of scope for the R&D roadmap.]*
  - The roadmap has milestones that include protocols and epidemiological studies, but we should verify that they adequately/explicitly mention continuing epidemiological studies (Rahman, Gurley).
- Question: Who do you think are the most important external partners and what do you think are the most critical roles for those partners in R&D of NiV MCMs?

    - In Bangladesh, the national government, specifically the Ministry of Health, is the central resource for engaging external partners, connecting with in-country experts, and engaging with external groups. This applies to the stakeholder mapping that we hope to accomplish, and other activities, such as those related to One Health (Parveen).
    - A consortium for engagement based on the One Health platform could be created, potentially by early 2024 (Preziosi, Parveen).
- Question: What is the best way to encourage other in-country experts on issues related to NiV MCMs, including WHO regional representatives?
    - Bangladesh has a One Health Forum, initiated in 2007, now with more than 1000 members. It regularly convenes and has an executive committee representing animal, human, and environmental health. The forum acts as a catalyst to push the government to work. There is also a One Health steering committee at the inter-ministerial level; both can be leveraged toward NiV MCMs (Rahman).
- Question: What are the best ways to promote regional coordination between India and Bangladesh?
    - There should be a memorandum of understanding (MOU) between India and Bangladesh regarding validation. We had this in the past for leishmaniasis, and included Nepal. We tried [to have these] for avian influenza and anthrax, but failed. These MOUs must be negotiated at the highest government level and are effective because they become an obligation for each country and work well at the local level. They would be useful for MCMs, regional coordination, and cooperation. There are, however, challenges in getting these set up (Rahman). [Note: Mahmudur Rahman agreed to provide the leishmaniasis MOU to Marie-Pierre Preziosi.]
    - SEARO is a potential forum for engagement between India and Bangladesh, to encourage bilateral exchanges (Luby).
    - Engaging at the community level is challenging, but communities can be leveraged carefully (Rahman).

Publication Process

Kristine Moore shared an overview on next steps for the roadmap and an accompanying manuscript. Key points:

- The roadmap will be revised per this meeting, finalized, and published on the WHO website in early 2024.
- Once the updated draft roadmap is ready (i.e., following revisions from this meeting), it will be shared with the taskforce and select other experts (e.g., CEPI) to sign off.
- A manuscript will also be developed. Group comments on the manuscript:
    - A journal for publishing should be selected with policymakers and funders in mind; we want to make it easy for them to recognize the roadmap's purpose and goals (Golding).
    - We should consider more than one publication, with different objectives for different target audiences (e.g., One Health community, development world/development banks beyond World Bank, etc.). Many groups would take a wider interest in short, clear, nontechnical publications that lay out problems and benefits relevant to the roadmap. This is a promotion, not just a single publication (Roth). This could include WHO promotion two-pager (Preziosi) and/or policy briefs (Roth).
    - A full communication package, including sizeable, usable versions of the roadmap that is useful for graphics and seminar presentations, could be shared with stakeholders, via targeted webinars, etc. This would be part of a one-year communication that WHO would develop (Golding).

  - Journals suggested by group members for manuscript publication consideration included: PLOS Neglected Tropical Diseases, BMJ Global Health, and Emerging Infectious Diseases.

APPENDIX: Nipah R&D Roadmap Taskforce Meeting Agenda

Nipah R&D Roadmap Taskforce Meeting
July 31 & August 1, 2023
London, UK

Agenda times listed in British Standard Time (BST)

Day 1: Monday, July 31

8:45 am *Registration, tea, coffee, and light breakfast*

Session 1: Welcome, Introductions, and Overview

9:15 am Welcome (Josie Golding, Wellcome)

9:20 am Introductions (Michael Osterholm, Center for Infectious Disease Research and Policy [CIDRAP])

9:30 am Update on the WHO Blueprint Initiative (Marie-Pierre Preziosi, WHO)

9:40 am Overview and meeting objectives (Kristine Moore, CIDRAP)

Session 2: Nipah Cross-Cutting Issues
Session Facilitator: Emily Gurley, Johns Hopkins Bloomberg School of Public Health

9:50 am General comments on Nipah cross-cutting issues in the current roadmap draft
- Key progress in the past 5 years
- Critical areas where additional efforts are needed

10:10 am Review the Nipah cross-cutting goals and milestones

10:30 am *Break*

10:45 am Review the Nipah cross-cutting goals and milestones (continued)

11:45 am Concluding comments for Nipah cross-cutting issues

- Barriers to implementing the goals and milestones
- Ideas for Roadmap implementation for this section

Session 3: Nipah Diagnostics
Session Facilitator: Joel Montgomery, US Centers for Disease Control and Prevention (US CDC)

12:05 pm General comments on Nipah diagnostics in the current roadmap draft
- Key progress in the past 5 years
- Critical areas where additional efforts are needed

12:30 pm *Lunch*

1:30 pm Review the Nipah diagnostics goals and milestones

2:50 pm *Break*

3:05 pm Concluding comments for Nipah diagnostics
- Barriers to implementing the goals and milestones
- Ideas for Roadmap implementation for this section

Session 4: Nipah Therapeutics
Session Facilitator: Emmie de Wit, US National Institute of Allergy and Infectious Diseases (NIAID)

3:25 pm General comments on Nipah therapeutics in the current roadmap draft
- Key progress in the past 5 years
- Critical areas where additional efforts are needed

3:45 pm Review the Nipah therapeutics goals and milestones

5:10 pm Concluding comments for Nipah therapeutics
- Barriers to implementing the goals and milestones
- Ideas for Roadmap implementation for this section

5:30 pm *Adjourn Day 1*
Drinks and reception

6:00 pm Dinner

Day 2: Tuesday, August 1

8:45 am *Registration, tea, coffee, and light breakfast*

9:15 am Welcome for Day 2 (Michael Osterholm, CIDRAP)

Session 5: Nipah Vaccines

Session Facilitator: Christopher Broder, Uniformed Services University of the Health Sciences

9:20 am	General comments on Nipah vaccines in the current roadmap draft • Key progress in the past 5 years • Critical areas where additional efforts are needed
9:40 am	Review the Nipah vaccines goals and milestones
10:15 am	*Break*
10:30 am	Review the Nipah vaccines goals and milestones (continued)
11:10 am	Concluding comments for Nipah vaccines • Barriers to implementing the goals and milestones • Ideas for Roadmap implementation for this section

Session 6: Nipah R&D Roadmap Implementation and Next Steps

11:30 am	Discussion: Roadmap implementation (Marie-Pierre Preziosi, WHO) Discussion panelists: • Shahana Parveen, International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b) • Mahmudur Rahman, Eastern Mediterranean Public Health Network (EMPHNET)
12:15 pm	Discussion: Publication process (Kristine Moore, CIDRAP)
12:25 pm	Wrap up and next steps (Michael Osterholm, CIDRAP)
12:30 pm	*Meeting close*
12:30 pm	*Lunch*

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 6-year framework beginning in 2024 for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs)—diagnostics, therapeutics, and vaccines—against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999 (Chew 2000, Chua 1999, Chua 2010, Parashar 2000, Paton 1999). As part of that outbreak, 265 human cases of NiV disease (NiVD) were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiVD was subsequently recognized, however, in Bangladesh in 2001, and nearly annual outbreaks have occurred in that country since (Hsu 2004, WHO 2018, Agrawal 2023). NiVD has also been identified periodically in eastern India (in 2001 and 2007) and, in 2018, an outbreak occurred for the first time in southern India (Arunkumar 2019, Chadha 2006, Chattu 2018, Sharma 2018, Soman Pillai 2020). Additionally, one case was reported from Kerala state in 2019 (Sudeep 2021). Case-fatality rates during outbreaks in Bangladesh and India have generally ranged from 50% to 100% (Sharma 2018). NiV infection in humans results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae (Goh 2000, Hossain 2008, Tan 2002). A summary of 14 years of NiVD investigations in Bangladesh found no evidence of asymptomatic infection (Nikolay 2019).

The primary natural reservoir host for NiV in South Asia, where cases continue to occur, is *Pteropus* bats. A recent study suggests that discrete multiannual local epizootics in bat populations contribute to the ongoing sporadic nature of human NiV outbreaks in South Asia (Epstein 2020). The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock and other domestic animals, which can serve as a source of exposure to humans (Islam 2023). Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in *Pteropus* bats and several other related bat species in Southeast Asia, the Western Pacific, and Africa (Anderson 2019, Breed 2010, Epstein 2008, Hasebe 2012, Iehlé 2007, Plowright 2019, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, Yob 2001). In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, dogs were found to be infected with NiV on the farms involved in the outbreak (Field 2001). In outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role to date, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission (Arunkumar 2019, Gurley 2007, Islam

2016, Luby 2009, Nikolay 2019, Rahman 2008). However, a recent study in Bangladesh found NiV antibodies in cattle, dogs, and cats from six sites where spillover human NiV infection cases occurred during 2013–2015 (Islam 2023), suggesting the potential of zoonotic spread via intermediary hosts. Respiratory transmission via droplet spread may play an important role in propagating outbreaks (Nikolay 2019, Spiropoulou 2019). The virus could have pandemic potential if a more human-adapted strain, with greater person-to-person transmission emerges (Luby 2013).
~~The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock and other domestic animals, which can serve as a source of exposure to humans (Islam 2023).~~ NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen—Hendra virus (HeV)—which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia (Murray 1995, Selvey 1995). To date, at least 66 spillover events—all in Australia—involving more than 100 horses and seven humans have been identified (Wang 2023). Changes in bat behavior related to habitat loss and climate change appear to have increased the spillover risk of HeV from bats to horses (Eby 2023). Another henipavirus (Langya virus) was recently identified as the probable cause of febrile illness among a group of people in China (Zhang 2022). An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014 (Ching 2015). This outbreak likely involved spillover of the virus into horses and subsequent disease in humans following consumption of contaminated horsemeat; disease also occurred in healthcare workers who cared for infected patients. Detailed genomic information for this virus is limited.

Several other henipaviruses have been identified, although the zoonotic and pathogenic potential of such viruses remains unknown (Li H 2023) and additional research is needed to better understand the global health threat of these viruses. Since additional bat species (particularly in Africa) and potentially other animals may serve as reservoir hosts for henipaviruses, the risk of spillover to humans may encompass up to three-fourths of the world's population. Although this roadmap is primarily focused on NiV, many of the issues identified also apply to other henipaviruses. While the current incidence of detected disease caused by henipaviruses is low, the COVID-19 pandemic clearly demonstrated that viruses can transform into serious global threats without significant warning; therefore, vigilance is needed to better understand the epidemiology of henipaviruses and to monitor their global occurrence.

Genomic sequencing has demonstrated that there are two main clades of NiV: the M genotype, which comprises the Malaysian NiV isolates (NiV-M), and the B genotype, which includes Bangladesh (NiV-B) and India NiV isolates (NiV-I) (Liew 2022, Yadav 2019). These three strains share a high percentage of homology (NiV-M and NiV-B strains share 91.8% homology, and NiV-I strains share 85.14to 96.15% homology with both NiV-M and NiV-B). Some strain-related differences, however, have been noted in the clinical features of infection in humans and experimentally infected non-human primates, with strains of the B clade appearing to be more pathogenic than those of the M clade (Mire 2016). Recent data indicate that strains from Bangladesh are segregated into two additional distinct sublineages that have intermingled geographically and temporally in that area over time (Rahman 2021, Whitmer 2020). At this time, however, the molecular epidemiology of NiV remains somewhat unclear and issues around strain diversity and strain evolution require further elucidation (Rahman 2021). One recent summary involving the most comprehensive analysis of available genomic data to date suggests that only about 15% of the overall NiV genetic diversity has been uncovered. Moreover, findings from that analysis demonstrated co-circulation of distinct lineages among bats, coupled with slow migration over large spatial areas (Cortés Azuero 2023).

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of MCMs to enable effective and timely emergency response to infectious disease epidemics. NiVD is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist) (WHO 2023). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this roadmap ranges from basic research to late-stage development of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply broadly to more than one MCM category), diagnostics, therapeutics, and vaccines. (*Note*: These topics are not presented in order of public health priority.) Each section includes barriers (inherent obstacles or technical challenges that may influence the likelihood of success for development of NiV MCMs) and gaps (key needs or unresolved limitations in knowledge that are critical to the development of new NiV MCMs). These are followed by strategic goals and milestones, which build on the gaps and barriers and are focused on achievements for the next 6 years (beginning in 2024) that are necessary for moving NiV MCMs forward. The roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed. Each section also includes additional ongoing priorities that should be considered for NiV MCM R&D.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include minimizing zoonotic NiV transmission, improving use of personal protective equipment (PPE), ensuring adequate hand hygiene and environmental hygiene, promoting effective community engagement, implementing adequate infection prevention and control practices, developing adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and promoting workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of this R&D roadmap, but need to be addressed as part of a broader public health control strategy. Further research of NiV and related henipaviruses in animal species, including development of appropriate MCMs targeted to animal populations (such as vaccines [McLean 2019]), also is needed, since disease in animals may amplify occurrence of NiV (or a related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

VISION

Robust MCMs to detect, prevent, treat, and control human outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or

potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care or near patient diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Barriers and Gaps

Barriers

- Securing funding for NiV/henipavirus research represents a substantial challenge, since economic incentives to invest in NiV research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with small and sporadic outbreaks (Gómez Román 2020). The development of a sustainable value proposition for industry and international philanthropic public-private partnerships is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition should be informed by a robust assessment of the risk of future outbreaks of NiV and related henipaviruses and the economic, societal, and health impacts that such outbreaks could generate.
- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand (Gouglas 2018). In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- National regulatory authorities in countries where NiV/henipavirus outbreaks are likely to occur have different regulatory requirements for authorization, licensure, or emergency use of NiV medical countermeasures, which complicates the approval process, particularly for candidate vaccines and therapeutics (Gómez Román 2022). Engagement of international regulators ~~An international, NiV-focused regulatory group has been created and~~ will be an important mechanism for coordinating regulatory issues as NiV MCMs are moved forward (Gómez Román 2020).
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (biosafety level 4 [BSL-4]) conditions (Geisbert 2020, Gómez Román 2022), which can increase the cost and complexity of MCM development.
- To date, NiV spillovers to human communities have been identified most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The primary natural reservoir for NiV and henipaviruses is fruit bats of the *Pteropus* genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar (Bruno 2022). Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV or related viruses; such bats can be found across Africa and parts of the Middle East (Bruno 2022). This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where

the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to the lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.

- The development and accessibility of animal models that recapitulate human NiV disease are critical for NiV MCM development, given the limitations on clinical samples and the infeasibility of traditional clinical efficacy trials. While ferrets and Syrian golden hamsters are well-established animal models for NiV research, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans (Foster 2022, Geisbert 2010, Geisbert 2020, Geisbert 2021, Johnston 2015, Price 2021, van Doremalen 2022, Woolsey 2023). Studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways; however, costs, space requirements (particularly in BSL-4 containment facilities) and ethical concerns constrain their use (Arnason 2020, Bossart 2012, Geisbert 2010, Johnston 2015).
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection occurs in relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate MCM efficacy with adequate statistical power (Gómez Román 2020). It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks; however, it is likely that at least vaccines will need to be licensed via nontraditional regulatory pathways.
- Patients usually present late in the clinical course of disease and disease progression is often rapid, making it difficult to collect clinical samples before patients succumb to the disease. Additionally, autopsies are often not the standard of care in affected areas, which further reduces opportunities to collect clinical specimens. These barriers hinder the ability to understand disease pathogenesis and immunologic responses to infection, which are important for MCM R&D (Amaya 2020, Arunkumar 2019, Gurley 2020, Liew 2022, Mazzola 2019).
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV vaccines and therapeutics.

Gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of NiV/henipavirus MCMs, as well as other preventive measures, depend on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of human disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas (Bruno 2022, Singhai 2021). Improved surveillance might also support the business case for investment in NiV MCMs by identifying a higher incidence of disease than previously demonstrated and revealing a broader geographic range of risk.

- Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of *Pteropus* bats and potentially other bat species around the globe (Gómez Román 2020, Plowright 2019).
- Additional research is needed to optimize and further characterize relevant animal challenge models (particularly ferret, Syrian golden hamster, and AGM models) for promoting development and evaluation of NiV MCMs (Geisbert 2020, Gómez Román 2020, Price 2021, Rockx 2014). Examples of additional issues involving animal models include the following (Dhondt 2013, Gómez Román 2020, Johnston 2015, Mathieu 2015, Mire 2019, Price 2021):
    - Determine the appropriate animal model(s) for screening assay development.
    - Standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development.
    - Determine when after-challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans.
    - Identify the best models for studying chronic (relapsing) infection.
    - Determine if different animal models are needed for different clinical endpoints such as infection, disease, and transmission.
    - Determine if models perform differently based on the route of virus administration.
    - Improve overall standardization of the models.
- Other research needs include the following:
    - Improved understanding of the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs (Gurley 2020, Liew 2022). This includes evaluating the pathophysiologic differences between different NiV strains, determining the mechanisms that allow NiV to escape immunologic clearance and cause delayed onset or recurrent encephalitis, and identifying factors influencing the development of permanent neurologic sequelae.
    - Ongoing phylogenetic and evolutionary analyses of NiV strains to monitor viral heterogeneity and antigenic changes that may affect the epidemiologic and clinical features of disease over time and thereby influence MCM development (Cortés Azuero 2023, Gurley 2020, McKee 2022, Rahman 2021).
    - Additional research to determine if: (1) NiV strain variations influence the ability to detect NiV infections; (2) different strains have different phenotypic characteristics, such as different clinical manifestations or transmission dynamics, and (3) if strain variability impacts efficacy of vaccines or therapeutics (CEPI 2023a, Gurley 2020, Whitmer 2020).
    - Whole-genome sequencing of NiV isolates to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses (CEPI 2023a).
    - Sociological and anthropological research to understand how to best engage populations at high risk of exposure (such as persons who consume date palm sap, healthcare workers, and workers at the human-animal interface) and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially

if therapeutics and vaccines do not consistently prevent disease (Singhai 2021, Lancet 2018).
    - Prospective serosurveillance of henipavirus exposure from susceptible animal species and proximate human populations in areas of predicted risk to assess the potential of human spillover and to build preparedness for detection of human cases and for limiting exposure (Daszak 2020, Deka 2018, Gómez Román 2020, Plowright 2019).
    - Expanded use of machine-learning approaches can facilitate an improved understanding of the risk of NiV/henipavirus spillover events (Plowright 2019). Ecological studies are also needed to enhance understanding of the dynamics governing prevalence and shedding of NiV and other henipaviruses in bats (Plowright 2019).
- Other important needs include the following:
    - Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop and manufacture NiV MCMs (Gómez Román 2020).
    - Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control (Bruno 2022).
    - Advocacy to policy makers in affected countries and to global stakeholders to ensure they understand the potential health, societal, and economic benefits of devoting resources to improving NiV surveillance, detection, prevention, and control measures (Gómez Román 2020).
    - Scenario planning to clarify regulatory pathways for product approval in countries where NiV/henipavirus outbreaks are likely to occur, including determining whether or not efficacy data from animal models is sufficient for regulatory approval. Such planning should take into consideration the local epidemiology of NiV infection and the different requirements of local national regulatory authorities for product approval and emergency use authorization (Gómez Román 2022). Regulatory pathways and NRA capabilities vary between countries; therefore, early engagement, potentially with support from WHO and other key international stakeholders, is essential to identify country-specific considerations. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.
    - Standardized and well-characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection (Rampling 2019, Satterfield 2016). Assays that can be used at lower biosafety levels are an important priority. WHO international standards should be used (when available) as calibrators and reported in units/ml to harmonize assay results.
    - Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical

management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection (Singhai 2021).

- Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
- Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and strengthen disease prevention and preparedness activities. This effort could potentially involve linking NiV surveillance with other surveillance efforts, such as surveillance for Japanese encephalitis (JE). Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
- Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.
- Efforts to reduce the cost of medical countermeasure development and ongoing production.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify additional and ongoing sources of private- and public-sector funding and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2024~~5~~, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the ~~potential~~ global threat of NiV and related henipaviruses (including the risk of gain-of-function research involving such viruses), (2) demonstrates the need for global engagement to address the threat, and (3) outlines the global social and economic benefits of generating accessible and affordable NiV MCMs.~~, and (3) details the positive impact on the health systems in affected areas.~~.
2. By 2025~~6~~, create a funding plan based on the global value proposition for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.
3. By 2025~~6~~, develop a coordinated strategy (to include addressing indirect costs and shortfalls) for promoting and incentivizing greater industry engagement in R&D for NiV MCMs, particularly in affected countries.

Strategic Goal 2: Improve understanding of ~~NiV~~ the epidemiology and ecology of NiV and related henipaviruses to better define the disease burden, risk factors for infection, reservoir hosts, and risk of spillover events in ~~affected~~ at-risk countries.

Milestones:

1. By 2024~~6~~, generate and implement standardized protocols for case investigation in at-risk countries, using a One Health approach, that are aimed at identifying risk factors for primary NiV

infection and at conducting case-contact studies to better understand chains of transmission (Hedge 2023).

2. By 2025, assess country-level capacity in at-risk countries for implementing standardized clinical protocols for case investigation, and develop plans for addressing key gaps in implementation.

~~1.~~3. By 2025, develop and initiate a plan for enhancing human ~~NiV~~ surveillance for NiV and related henipaviruses in India and Bangladesh outside of existing surveillance areas (i.e., where cases previously have been identified). This should include securing funding, identifying additional surveillance catchment areas, engaging key partners in those areas, generating standardized surveillance protocols, ~~and~~ conducting training for implementation, and leveraging other surveillance activities (such as surveillance for JE).

~~2. By 2026, initiate enhanced human NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), promote early case detection, and better define the disease burden in India and Bangladesh, particularly outside of areas where cases previously have been identified.~~

~~3.~~4. By 2025, develop plans for conducting human surveillance for NiV and related henipaviruses in at-risk countries other than India and Bangladesh.

5. By 2025, develop plans for conducting animal surveillance for NiV and related henipaviruses in at-risk countries other than India and Bangladesh.

6. By 2025~~6~~, develop plans for conducting additional research in at-risk countries ~~India and Bangladesh~~ to identify the potential for and drivers of spillover events for NiV and related henipaviruses, using a One Health approach, particularly in areas where NiV cases have not yet been identified.

~~4.~~7. By 2026, establish capacity at selected surveillance sites in India and Bangladesh to investigate NiV-related deaths by using post-mortem minimally invasive tissue sampling to enhance understanding of NiV disease pathogenesis (Bassat 2021).

Strategic Goal 3: Determine the requirements for clinical trials, regulatory pathways, and other considerations that will affect licensure or approval of NiV MCMs by engaging ~~an~~ international ~~regulatory working group~~ regulators representing NRAs in affected areas and other key international stakeholders.

Milestones:

1. By 2024, conduct scenario planning to identify gaps, clarify ~~the~~ regulatory procedures, and determine the acceptable pathways for approval and emergency use authorization of NiV MCMs (including vaccines, novel candidate therapeutics, repurposed therapeutics, and diagnostics) in countries at highest risk for NiV outbreaks ~~(i.e., Bangladesh and India)~~ through an international ~~NiV-focused regulatory group.~~ forum of regulators.

~~2.~~ By 2025, ~~determine if any key gaps exist for regulatory approval and emergency use authorization of candidate NiV MCMs in affected countries and~~ develop strategies to address

~~those~~ gaps in regulatory approval and emergency use authorization of candidate NiV MCMs, with specified timelines for completion.

2. By 2025, assess capacity in affected countries to conduct clinical trials and field studies of MCMs, particularly during outbreaks.

3. By 2026, create a system for monitoring regulatory issues related to licensure or use of candidate NiV MCMs over time. ~~ensure that any issues affecting approval and emergency use of candidate MCMs in affected countries have been resolved and that consensus has been achieved on the necessary regulatory steps and procedures.~~

~~3.~~ By 2026, develop protocols for emergency use of candidate NiV MCMs during outbreaks.

Strategic Goal 4: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection~~ in humans and animal models~~.

Milestones:

1. By 2024~~5~~, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
2. By 2025, conduct additional research to further optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs.

~~3.1. By 2026, conduct sequencing of NiV strains from existing clinical samples obtained from past NiV cases to assess variability of NiV strains in India and Bangladesh (CEPI 2023a).~~

3. ~~By 2026, establish capacity at selected surveillance sites in India and Bangladesh to investigate NiV-related deaths by using post-mortem minimally invasive tissue sampling to enhance understanding of NiV disease pathogenesis (Bassat 2021).~~

4. By 2026, develop a standardized human pathology investigation protocol for improving understanding of NiV pathogenesis.

5. By 2027~~8~~, conduct research ~~in animal models~~ to determine if strain variability impacts efficacy of promising NiV MCMs or the accuracy of diagnostic tests.

Additional Priority Areas/Activities

Research

- **Continue to expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach. Such research should include serosurveys in different animal species and ecologic studies in bats, and should utilize computational approaches, such as machine-learning.
- **Continue to perform** phylogenetic and evolutionary analyses, using whole-genome sequencing, of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- ~~By 2026,~~ **Continue to conduct** sequencing of NiV strains from existing clinical samples obtained from past NiV cases to assess variability of NiV strains in India and Bangladesh (CEPI 2023a).

- **Incorporate**, on an ongoing basis, additional NiV strains into preclinical research as newer strains become available.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Continue to explore** alternative strategies to using animal models for research (e.g., use of organoids, other in-vitro approaches, computational modeling).
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability of henipaviruses to improve understanding of their global distribution.
- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection, including potential regulatory pathways for MCM licensure and approval.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** an open-access shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in ~~endemic~~ affected and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas. These should include efforts to reduce production costs and ensure equitable global access as needed.

- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an “affordable and fair” price is one that can reasonably be paid by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

DIAGNOSTICS

Barriers and Gaps

Barriers

- Initial signs and symptoms of NiV infection are nonspecific, and infection is often not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent infection can last for months to years after initial exposure, which can complicate epidemiologic investigation (CDC 2020).
- The accuracy of laboratory results can be affected by a variety of factors, such as clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory (WHO 2019, Mazzola 2019).
- The time required to perform diagnostic testing using conventional laboratory methods is problematic, given the potential for rapid disease progression of NiV infection (Sayed 2019).
- Diagnostic needs vary across the latent, acute, and convalescent phases of NiV infection (Bruno 2023).
- Limited laboratory infrastructure and diagnostic capabilities in peripheral settings can lead to delays in diagnosis and in outbreak investigation and response (Berge 2019, Bruno 2022, Chua 2013, Wang 2012, WHO 2019).
- Owing to the high biosafety precautions necessary when working with NiV, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis (Watanabe 2020, Widerspick 2022).
- Limited NiV-positive clinical samples are available, which are important for validation of diagnostic tests (Mazzola 2019).
- *Pteropus* species (and likely other bat species) may carry other henipaviruses in addition to NiV and HeV, some of which could be pathogenic in humans and livestock. Antibodies to different henipaviruses appear to be highly cross-reactive, making it difficult to discriminate the particular henipaviruses that are in circulation using serologic assays, which is critical to ensuring diagnostic preparedness to respond to future outbreaks (Mazzola 2019, Wang 2012, WHO 2019, Yang 2022).

Gaps

- Further research is needed to:

  - Improve understanding of the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease (Arunkumar 2019, Berge 2019, Mazzola 2019, Thakur 2019).
  - Determine criteria for test performance and further evaluate performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as rapid diagnostic tests) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
  - Continue to develop commercialized or standardized rapid nucleic acid tests that can quickly confirm active NiV infection at the point of care or at the level of near-patient care (Berge 2019, Pollack 2023, WHO 2019). This effort may require clarification of the regulatory pathways for commercialization of NiV diagnostic tests. To date, one rapid test has been approved for emergency use in India during an outbreak that occurred in 2018 (Yadav 2021).
  - Generate international reference standards to calibrate diagnostic assays to ensure proficiency testing of new diagnostics (Berge 2019, WHO 2019).
  - Clinically validate the performance and operational suitability of new promising diagnostics, particularly rapid diagnostic tests, in endemic geographic regions (Berge 2019, Pollack 2023).
  - Continue to assess and operationally validate safe and simple methods of sample inactivation that do not interfere with diagnosis and that can be used at peripheral sites (Pollack 2023, WHO 2019, Watanabe 2020, Widerspick 2022, Yadav 2021).
  - Establish operational suitability at the point of care (i.e., at peripheral community settings) for NiV diagnostic tests by developing an integrated approach to facilitate rapid, accurate, and safe testing procedures (Pollack 2023).This could include a minimal protocol or best practices approach for sample inactivation before testing (WHO 2019).
- Other needs include the following:
  - Development of a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples to assess and validate diagnostic tests (Berge 2019, WHO 2019). As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6) identify who would have access to the samples; (7) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)

  - Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection (Berge 2019, WHO 2019).
  - In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
  - Systems for external quality assessment (EQA) monitoring of tests using up-to-date clinical specimen panels and reference standards (Mazzola 2019).
  - A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for NiV diagnostics, particularly given the costs of regulatory approval.
  - Improvement of diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses as they arise (Wang 2012).
  - Ongoing efforts to develop affordable and easy-to-use multiplex panels for detection of a range of pathogens using a syndromic approach, if such panels can be deemed cost-saving (Mazzola 2019).
- Use cases and target product profiles (TPPs) have been ~~developed~~ drafted for NiV diagnostics (WHO 2019); however, these need to be finalized and the criteria may need to be modified over time as new lineages are identified (Mazzola 2019).
- Since NiV strains are continuing to evolve, it's possible that current diagnostic tests could fail to detect an emergent variant of NiV. Recently, a novel strain of HeV was identified in Australia that was not detected through conventional PCR testing owing to gene sequence mismatches (Annand 2022). Diagnostic tools that can detect a broader range of NiV, HeV, or related viruses capable of spillover may be needed to advance the ability to forecast spillover risks and to detect emergent viruses (Peel 2022).

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of ~~reference repository~~ repositories of clinical samples from NiV-infected patients.

Milestones:

1. By 2024~~6~~, develop and standardize plans and protocols (including the governance structure) for creating ~~a virtual reference repository~~repositories of well-characterized acute and convalescent clinical samples to include a recommended set of metadata (i.e., age, sex, days since symptom onset), as feasible, and to be maintained in the two primary NiV-affected countries (Bangladesh and India).

2. By 2025~~7~~, identify sustainable, long-term funding, determine sites for sample storage, and initiate creation of the ~~virtual reference repository~~repositories in Bangladesh and India, with ~~samples~~ samples and associated metadata to be collected during future outbreaks.

Strategic Goal 2: Continue to develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care and~~or~~ near-patient NiV diagnostic tests that are suitable for use in peripheral settings, have extended shelf lives, and ~~that~~ have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2024, finalize the draft use cases and TPPs for NiV diagnostics.

2. By 2024~~5~~, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays. This effort should include clarifying regulatory pathways for approval (including approval for emergency use) of NiV diagnostics.

~~1.~~3. By 2024, generate a call to accelerate the development of point-of-care and near-patient diagnostic testing for NiV.

4. By 2024, develop a protocol or set of best practices (that biosafety committees will accept) for inactivation of clinical samples from humans and animals that are being tested for NiV.

5. By 2025, create international reference standards for calibrating and harmonizing NiV diagnostic assays.

~~2.~~6. By 2026, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP and can be used in peripheral sites.

~~3. By 2026, create international reference standards for calibrating and harmonizing NiV diagnostic assays.~~

~~4. By 2026, develop a minimum protocol or set of best practices (that biosafety committees will accept) for inactivation of clinical samples from humans and animals that are being tested for NiV.~~

~~5.~~7. By 2027, complete clinical validation of performance and operational suitability for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP and can be used in peripheral sites.

~~6.~~8. By 2028, ~~obtain~~ promote regulatory approval for at least one rapid, point-of-care or near-patient~~-~~care NiV diagnostic test that can be commercialized and standardized.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known spillover risk to promote early detection of NiV.

Milestones:

1. By 2025~~6~~, continue to expand national laboratory networks for NiV detection in ~~the primary affected~~ at-risk countries ~~(Bangladesh and India)~~ that include plans for enhancing laboratory preparedness to enable earlier and timely detection of NiV infection during future outbreaks.

2. By 2026~~7~~, generate well-characterized and up-to-date proficiency panels and network quality controls for NiV diagnostic testing to be used in selected laboratories in ~~Bangladesh and India~~at-risk countries.

3. By 2026~~9~~, implement routine EQA monitoring of NiV diagnostic testing at selected laboratories in ~~Bangladesh and India.~~at-risk countries.

Additional Priority Areas/Activities

Research

- **Continue to explore** new diagnostic approaches that may allow earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** criteria for test performance and **continue to evaluate** performance characteristics for promising new assays for diagnosis of NiV infection.
- **Continue to conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection as they become available.
- **Continue to research** methods of diagnostic testing that are able to differentiate between various pathogenic henipaviruses.
- **Continue to develop** affordable and easy-to-use multiplex panels for detection of a range of pathogens using a syndromic approach.
- **Consider** development of diagnostic tools that can detect a broader range of NiV, HeV, or related viruses capable of spillover.

Product development

- **Refine** over time, as needed, criteria in the existing TPPs to include identification of different NiV lineages/strains.
- **Continue to develop and evaluate** point-of-care and~~or~~ near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their intended use), can capture antigenically diverse strains of the virus, and can be performed accurately and safely in peripheral settings under a variety of circumstances.
- **Expand** diagnostic test development for other henipaviruses over time.

Key capacities

- **Establish** operational suitability in peripheral laboratories of rapid diagnostic tests over time, as new tests become available.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed.

Policy and commercialization

- **Develop** guidance on optimal strategies for the deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

THERAPEUTICS

Barriers and Gaps

Barriers

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.

- A limiting constraint to assessing the effectiveness of promising therapeutics is the number of patients with NiV infection who can be enrolled in clinical trials over time, given the small number of cases that are identified annually.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment of patients and PEP for exposed persons, which can significantly impact clinical evaluation of therapeutic candidates.
- NiV can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in affected countries often do not have adequate infection control–programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.
- One promising therapy is the monoclonal antibody (mAb) m102.4; however, the projected cost per patient for this agent is expected to be more than $1,000 (Gómez Román 2022); this high cost poses an important barrier to its use.

Gaps

- Patients may benefit from optimal supportive care, independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials to inform best-practice guidelines and evidence-based policy decisions. Standard of care guidelines will be important for conducting clinical efficacy trials of therapeutic agents.
- During the 1998-99 NiV outbreak in Malaysia, clinicians used ribavirin to treat 140 patients. Outcomes data revealed a lower mortality rate among treated patients (Chong 2001), but the findings may have been biased by the use of historical controls. No additional clinical studies of ribavirin have been conducted, and limited studies in animals have not demonstrated efficacy of ribavirin following NiV or Hendra virus challenge (Georges-Courbot 2006, Rockx 2010). Ribavirin, however, may prove useful for PEP (Banerjee 2019); therefore, further challenge studies in animal models should considered to explore this possibility.
- Studies in animals have evaluated the usefulness of several agents (including remdesivir, favipiravir, and fusion inhibitory peptides) when delivered prior to disease onset or early during the disease course (Dawes 2018, Lo 2019, Mathieu 2018). One recent study showed that AGMs were only partially protected when remdesivir was administered 3 days post-inoculation; therefore, early administration seems critical for effective treatment (de Wit 2023). Patients with NiV infection are often detected late in the clinical course, which creates challenges for predicting how well a therapeutic agent will work in the field. Additional challenge studies in animals, therefore, are needed to: (1) assess the clinical benefit of these therapeutics as treatment options when administered after symptom onset or at least more than 24 hours after initial exposure, (2) determine whether these agents may be appropriate for PEP, and (3) clarify the most feasible and cost-effective route of administration (e.g., oral, intranasal, intravenous)

appropriate for real-world conditions, particularly if being considered for mass prophylaxis in an outbreak setting (Gómez Román 2022).

- m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV (Broder 2012, Guillaume 2004, Playford 2020). Several other mAbs have also been assessed in animal models and appear promising (Gómez Román 2022). A phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia during 2015 and 2016 (Playford 2020). In that trial, m102.4 was well tolerated and safe, with no evidence of an immunogenic response.
- Additional research needs for mAbs as treatment or PEP for NiV infection include:
    - Additional clinical trials in endemic areas to further assess the safety, tolerability, efficacy, and pharmacokinetic parameters of m102.4 (and possibly other mAbs with adequate preclinical data) for PEP and potentially early treatment of clinical disease (CEPI 2023b).
    - Additional research to determine the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with m102.4, it may be necessary to consider mAb cocktails (Borisevich 2016, Playford 2020).
    - Animal studies to determine if mAb cocktails that combine several different mAbs into one formulation are more efficacious than administering one mAb alone (Dang 2021).
    - Future studies to ascertain the efficacy of m102.4 for treatment and prophylaxis against different viral strains of NiV and Hendra viruses, particularly among populations living in settings where there is the potential for an outbreak.
    - Adequate stockpiles of m102.4 (or potentially other mAbs) to ensure urgent access at the onset of a NiV outbreak.
- Given the limited number of NiV cases identified each year, a transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials and how best to allocate scarce resources for conducting such trials.
- A prepositioned, agreed-upon protocol for conducting clinical trials of promising therapeutics during NiV outbreaks would be of value in advancing clinical evaluation of such agents (Spiropoulou 2019).
- Diagnostic criteria and standardized testing are needed for including patients in clinical trials of therapeutics.
- Additional research needs include the following:
    - Further research to broaden the number of novel antiviral candidates (including repurposed drugs) for treatment of NiV infection and strengthen the therapeutic pipeline. Computational aided drug design is one tool that can be useful for this discovery (Yang 2023).
    - Additional data to establish the pharmacokinetic/pharmacodynamic (PK/PD) relationship of promising therapeutic candidates.
    - Additional data to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP stockpiling and

distribution in both affected and at-risk areas, particularly Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.

- Additional information to determine whether or not strain differences will affect the response to therapeutic candidates and results from clinical trials.
- Additional data to determine the therapeutic windows for promising therapeutics for the different NiV strains, as highlighted by a recent study in AGMs that showed that the therapeutic window for m102.4 against a strain from Bangladesh/India was shorter than for a strain from Malaysia (Mire 2016).

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future outbreaks of NiV or related viruses. ~~outbreaks.~~

Milestones:

1. By 2024, convene a consortium of key stakeholders—in affected areas and internationally—to address the key challenges with conducting clinical trials of therapeutic agents during future ~~NiV~~ outbreaks of NiV or related viruses. This consortium could potentially be modeled after the West Africa Lassa Fever Consortium (WALC) (ISARIC 2023).
2. By 2024~~5~~, develop NiV infection control and standard of care guidelines to be used in affected countries and ~~,~~disseminate the guidelines. ~~, and conduct outreach to clinicians as appropriate~~.
3. By 2024~~5~~, complete an agreed-upon generic prepositioned protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates (mAbs and small molecules, including repurposed drugs) to be implemented in NiV-affected areas during outbreaks and develop plans for operationalizing the protocol.
4. By 2024~~5~~, complete an agreed-upon generic prepositioned protocol for conducting PEP (and potentially pre-exposure prophylaxis [PREP]) trials of promising therapeutic candidates (mAbs and small molecules, including repurposed drugs) to be implemented in NiV-affected areas during outbreaks and develop plans for operationalizing the protocol.
5. By 2025, conduct outreach and training to clinicians on the NiV infection control and standard of care guidelines in India and Bangladesh.

~~1. By 2026, complete a broader, harmonized regional protocol (to be used across Bangladesh and India) for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during outbreaks or potentially during periods of endemic disease (if comparable data can be generated over time and across different clinical sites) and develop plans for operationalizing the protocol.~~

6. By 2026, generate a reliable source or stockpile of a mAB (m102.4 or other mAb) to be used in outbreak-related clinical trials for ~~both~~ PEP, possibly PREP, and early clinical treatment.

Strategic Goal 2: Develop and evaluate therapeutic agents for treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2025, create and implement a prioritization process, with a governance structure, for determining which promising NiV therapeutic candidates should be further evaluated in clinical trials, once adequate animal data demonstrating safety and efficacy are available.

2. By 2026, complete preclinical evaluation in animal models—with administration of the therapeutic agent more than 24 hours after challenge and potentially after symptom onset—of the preliminary safety, tolerability, and efficacy of at least two promising small-molecule therapeutic candidates or combination therapies for the treatment of NiV infection.

~~3. By 2027, further explore in animal models whether two or three of the most promising small-molecule therapeutic candidates are likely suitable for PEP and, therefore, should be assessed as PEP in clinical trials.~~

~~4. By 2027, determine the most cost-effective and feasible routes of administration for use in real-world settings for at least two promising small-molecule therapeutic candidates.~~

3. By 2025~~7~~, complete at least one additional phase 1 clinical trial ~~(phase 2 or 2/3)~~ in a NiV-affected area of ~~m102.4 or other suitable~~ a promising mAb or mAb cocktail to ~~further~~ assess safety and ~~,~~ tolerability. ~~, and efficacy (if NiV incidence allows efficacy assessment).~~

~~5.~~4. By 2027, complete at least one phase 2/3 clinical trial in a NiV-affected area of a promising mAb or mAb cocktail to further assess safety, tolerability, and potentially efficacy (if NiV incidence allows efficacy assessment).

~~6.~~5. By 2028, complete at least one phase 1 clinical ~~evaluation~~ trial of the preliminary safety~~,~~ and tolerability ~~, and (possibly) efficacy~~ of at least two promising small-molecule therapeutic candidates or combination therapies for the treatment of NiV infection.

Additional Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as m102.4, other mAbs, remdesivir, and favipiravir) for treating and preventing NiV infection, including conducting additional studies in animal models and clinical trials as appropriate and feasible. This should include determining the therapeutic windows for use of therapeutic agents as treatment or PEP.
- **Clarify,** in animal models, the potential for development of escape mutants from use of mAbs.
- **Continue to conduct** preclinical research on mAbs other than m102.4 and on mAb cocktails to assess safety, tolerability, and efficacy for treating NiV infection
- **Continue to expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation, potentially using pseudotyped viruses for initial screening of compounds (Li T 2023).
- **Consider conducting** additional challenge studies in animal models to assess whether or not ribavirin may be suitable for PEP following NiV exposure.

- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Continue to develop, evaluate, and license** safe and effective therapeutic agents for the treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized in advance of outbreaks, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in affected areas to improve clinical management and supportive care of patients with NiV infection and to improve infection control practices to limit person-to-person spread.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- **Explore** strategies for decreasing the costs associated with m102.4 or other mAbs, such as exploring the possibility of administering mAbs subcutaneously rather than intravenously.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

VACCINES

Barriers and Gaps

Barriers

- Large clinical efficacy trials, which typically are required for vaccine licensure, will likely not be feasible for NiV vaccines, owing to the sporadic and unpredictable nature of NiV outbreaks and the low case numbers usually involved (Gómez Román 2022, Nikolay 2021, Satterfield 2016).
- In the absence of large clinical efficacy trials, authorization and licensure will likely involve nontraditional regulatory pathways to guide the evaluation of safety and efficacy (Gómez Román 2022). However, experience is limited with these routes (such as the US FDA's Animal Rule or Accelerated Approval Program, the EMA's conditional market authorization, and authorization under exceptional circumstances) and there are few successful models for vaccine authorization and approval.
- The limited commercial value of NiV vaccines may impede industry's involvement in developing and producing NiV vaccines without significant financial support (e.g., through partnerships with organizations such as CEPI, PATH, and high-income country government agencies) (Gómez Román 2022).

- The affordability of creating and maintaining a NiV vaccine stockpile and deploying vaccines during outbreaks is a key issue for low- and middle-income countries; supplementary funding will likely be required to ensure vaccine preparedness for NiV outbreaks (Gómez Román 2022).
- The absence of improved diagnostic assays for the timely diagnosis of infection creates an important challenge by delaying implementation of a rapid reactive vaccination strategy for NiV outbreak control.

Gaps

- NiV vaccines are needed that: (1) are readily accessible with adequate supply chains, particularly in low-resourced areas, (2) can protect against different NiV strains, and (3) provide rapid onset of immunity to adequately prevent and control outbreaks in a timely manner.
- Use cases for NiV vaccines need to be better defined, as how vaccines are to be used will affect vaccine deployment and manufacturing plans.
- Reference standards for NiV antibodies are needed to evaluate candidate NiV vaccines.
- Expanded partnerships among researchers, funders, and regulators are needed to advance the development of promising NiV vaccine candidates (Amaya 2020, Gómez Román 2022). NiV vaccine candidates in preclinical development target the F/G glycoproteins and a variety of platform technologies are being considered (e.g., virus vectors, protein subunits, mRNA, and virus-like particles) (Amaya 2020, Geisbert 2021, Gómez Román 2022, Loomis 2021, Monath 2022). NiV vaccine candidates based on three different platforms (protein subunits, mRNA, and viral vectors) are currently in phase 1 clinical trials (Auro Vaccines 2022, NIAID 2023, Public Health Vaccines 2023).
- Demonstrating vaccine-induced protection against NiV infection or disease in an animal model will require an immune correlate of protection (CoP) or immune surrogate that can predict the likelihood of protective efficacy and that reflects the protective immune responses generated in humans (Amaya 2020, Escudero-Pérez 2023, Price 2021).
    - Accurate and reliable CoPs for determining the protective efficacy of NiV vaccines have not yet been identified (Loomis 2021). Neutralizing IgG is generally used as a CoP, although the protective threshold still needs to be defined to allow additional vaccine testing in animal challenge models and eventual immunobridging of antibody responses to humans, through phase 1/2 clinical studies (Escudero-Pérez 2023, Price 2021).
    - Once the protective threshold for neutralizing IgG antibodies is determined, the most appropriate and feasible assays (e.g., assays that are developed using live NiV vs. assays developed using pseudoviruses expressing the NiV F and G glycoproteins [Luo 2023]) need to be identified and standardized for use in animal models (Price 2021).
    - Different types or titers of CoPs may ultimately be needed for different vaccine platforms, antigens, clinical outcomes (e.g., protection against infection, severe disease, chronic disease, or death) and potentially host or population characteristics to support the assessment of candidate NiV vaccines using immunogenicity and efficacy data from preclinical studies.
    - Other humoral immune responses that may be relevant as COPs include specific titers of IgM, antibodies and numbers of plasmablasts and activated B cells (Escudero-Pérez

  2023). With regard to cellular immune responses, CD8+ T cell measurements may be useful as a CoP (Escudero-Pérez 2023). Additional research is needed to better define these potential CoPs, which may be particularly important for next-generation vaccines.

- Most current NiV vaccine candidates target the immunodominant fusion (F) and attachment (G) glycoproteins, which elicit potent neutralizing antibody responses (Byrne 2023, Geisbert 2021, Ithinji 2022, Loomis 2020, Loomis 2021, van Doremalen 2022, Wang 2022, Woolsey 2023). Data are needed on the potential role of additional immunogens, such as nucleoproteins and other non-enveloped proteins, in stimulating B and T cell responses that contribute to viral clearance, cross-protection, or immune memory. Robust vaccine-induced humoral and cell-mediated immunity to NiV might include protective antibodies with durable immunologic memory and rapid and efficient effector functions (Escudero-Pérez 2023).
- Additional immunologic research is needed to assess the following key elements of protective immunity against NiV infection and disease:
    - The relative contributions of innate, cell-mediated, and humoral immune responses that lead to protective immunity against NiV.
    - Specific cell types and interactions between different immune compartments in achieving viral clearance, surviving acute disease, and modulating chronic infection (Escudero-Pérez 2023, Liew 2022).
    - The roles of neutralizing and non-neutralizing or binding antibodies in protection against NiV (Liew 2022).
    - Mechanisms and cell subsets of cellular immune responses (e.g., CD8 T cell activation) that play a role in cross-neutralizing (heterologous) protection against co-circulating NiV strains (e.g., NiV-M, NiV-B, and NiV-I) (Amaya 2020, Arunkumar 2019, Escudero-Pérez 2023, Liew 2022).
- If researchers and regulators agree that a nontraditional regulatory pathway is appropriate for licensure of NiV vaccines, then a number of issues need to be addressed, such as the following (Price 2021):
    - Generate a fully characterized and controlled virus challenge stock (or potentially one each for NiV-M and NiV-B) for assessing candidate vaccines in animal models.
    - Further characterize, as needed, at least one animal model suitable for vaccine efficacy evaluation.
    - Standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development. Challenge strains used in experimental research also need to be compared against any circulating strains in humans (CEPI 2023a).
    - Determine the most appropriate CoP or surrogate marker (e.g., IgG neutralizing antibodies) for measuring protection and generate standardized assays for measurement.
    - Bridge NiV vaccine efficacy data from animal models to humans, including identifying thresholds of vaccine protection, to determine appropriate human vaccine doses.

  - If the accelerated approval process is deemed an acceptable regulatory approval pathway for NiV vaccines, then plans will be needed to conduct well-controlled clinical trials to establish that vaccines have an effect on an appropriate surrogate endpoint that is likely to predict clinical benefit against NiVD.
  - Post-licensure clinical trials will also be needed to confirm the clinical benefit of any NiV vaccines that are approved via nontraditional pathways.
- Additional research is also needed to address the following areas:
  - Clarification of vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
  - Alternative vaccine delivery approaches, such as oral tablets or transdermal patches, to facilitate rapid NiV vaccine deployment in response to NiV outbreaks in low-resource settings.
  - Further evaluation of optimal NiV antigen combinations (e.g., including stabilized prefusion F protein trimers, multimeric G constructs, and chimeric proteins containing both pre-F and G glycoproteins), and antigen/vaccine platform combinations for generating rapid and durable protective responses to NiV infection (Byrne 2023, Loomis 2020, Loomis 2021, Srivastava 2023).
  - Research in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- Mathematical modelling and forecasting may be useful in (Nikolay 2021): (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.
- Researchers should consider efforts toward developing pan-henipavirus vaccines to maximize potential benefit, similar to projects aimed at developing pan-coronavirus vaccines or universal influenza vaccines (Tan 2023). One strategy for developing broadly protective henipavirus vaccines involves identifying conserved epitopes or cross-reactive antibodies targeting Henipavirus F proteins (Byrne 2023, Ithinji 2022). Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.
- Once vaccines are available, the following will be needed:
  - Guidance on the use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
  - Enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.

  - Strategic planning for stockpiling and deploying NiV vaccines.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Develop the tools and policies necessary for evaluating and potentially approving one or more NiV candidate vaccines through a nontraditional regulatory pathway.

Milestones:

1. By 2024, generate a fully characterized and controlled virus challenge stock (preferably using a NiV-B strain) ~~(or potentially one each for NiV-M and NiV-B)~~ for assessing candidate vaccines in animal models.

2. By 2024~~6~~, generate standardized assays to measure ~~neutralizing~~ IgG antibodies for NiV vaccine R&D, with a particular focus on assays to be used for regulatory approval via nontraditional pathways.

~~2.~~3. By 2025~~4~~, in conjunction with regulatory authorities, establish benchmark parameters (e.g., route of challenge, timing of challenge, and challenge dose) for testing of NiV candidate vaccines in well-characterized animal models, with particular focus toward meeting criteria necessary for approval via a nontraditional pathway, including identifying surrogate markers that correlate with vaccine efficacy.

~~3. By 2024, further characterize as needed at least one animal model suitable for determining surrogate markers that correlate with vaccine efficacy.~~

4. By 2025, define the protective threshold against NiV infection for serum neutralizing IgG antibodies or other functional CoPs, ~~(as a CoP or surrogate marker),~~ which can be used in animal studies and for immunobridging to humans.

~~5. By 2025, convene a group of key stakeholders to agree on, through a consensus approach, the most suitable assays (e.g., assays that are developed using live NiV vs. assays developed using pseudoviruses) for determining serum neutralizing IgG antibody titers for NiV vaccine R&D and develop a strategy for standardizing those assays.~~

~~6.~~1. ~~By 2026, generate standardized assays to measure neutralizing IgG antibodies for NiV vaccine R&D, with a particular focus on assays to be used for regulatory approval via nontraditional pathways.~~

Strategic Goal 2: Continue to move the current NiV vaccine pipeline forward through clinical trials. ~~toward licensure.~~

Milestones:

1. By 2024, complete current phase 1 clinical trials for at least three promising NiV candidate vaccines.

2. By 2025~~4~~, define use cases for NiV vaccines to inform vaccine deployment and manufacturing plans.

3. By 2025~~6~~, ~~further assess vaccine safety and immunogenicity through~~initiate ~~additional phase 1 and initial~~ phase 2 clinical trials (preferably in affect areas) to further assess immunogenicity and safety for at least two of the most promising NiV candidate vaccines.

~~4. By 2027, complete immunogenicity and efficacy studies in a well-characterized animal model for at least one cross-protective NiV vaccine candidate and define a surrogate marker that demonstrates likely clinical benefit of candidate vaccines.~~

~~5.~~4. By 2029, conduct additional well-controlled phase 2 clinical trials ~~(preferably~~ in affected areas~~)~~ to assess a surrogate endpoint in human subjects (to include children and pregnant women) for at least two~~one~~ NiV candidate vaccines.

~~6.~~5. By 2030, complete a regulatory dossier (for licensure or emergency use) for at least one NiV vaccine candidate based on a suitable animal model with subsequent immunobridging to humans for review via a nontraditional approval pathway.

Additional Priority Areas/Activities

Research

- **Improve understanding** of humoral (e.g., NiV-specific IgG and IgM antibodies) and cellular (e.g., CD8 T cell) immune responses to NiV infection in animal models to inform the design of vaccines and the identification of correlates of protection (Arunkumar 2019, Escudero-Pérez 2023).
- **Improve understanding** of innate immune responses (e.g., involving interferon impairment and pro-inflammatory cytokine release) in relation to humoral and cellular immune responses to NiV infection (Escudero-Pérez 2023).
- **Continue research** on identifying the key NiV antigens (including surface glycoproteins and internal proteins) that modulate the host immune response to NiV infection to inform future vaccine design (Escudero-Pérez 2023).
- **Continue to research** different types of CoPs (both humoral and cell-mediated) for NiV vaccines that are currently in the R&D pipeline and next-generation vaccines, taking into consideration different vaccine platforms, antigens, and clinical outcomes.
- **Generate** international reference standards to calibrate serologic assays for vaccine potency analyses.
- **Continue to conduct** preclinical evaluation of promising candidate NiV vaccines (current and future vaccines) for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.
- **Explore** the possibility of creating pan-henipavirus vaccines that will protect against NiV, HeV, and other henipaviruses.

Product development

- **Continue to develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans.
- **Expand** partnerships among researchers, government agencies, and industry to provide the resources necessary for ongoing R&D of NiV vaccines.
- **Define** vaccine attributes (such as time from administration to immune protection, durability of protection, and the need for booster doses) for the most promising candidate vaccines.

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Support** plans for adequate manufacturing and stockpiling of NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptance and promotion within the community.
- **Consider** developing a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if a NiV strain emerges with increased capacity for person-to-person transmission and potential for faster spread.

Subject: Summary report from the Nipah R&D Roadmap Taskforce meeting and revised Nipah R&D Roadmap for your review
Date: Tuesday, August 29, 2023 5:43:08 PM
Attachments: Nipah Roadmap TF Meeting Summary.Final.docx
Nipah RD Roadmap.PostMeetingRevision.August2023.docx

Dear colleagues: First, I want to thank all of you who participated in the Nipah R&D Roadmap Taskforce meeting on July 31 and August 1, 2023. The discussions were highly productive and your input was extremely valuable. Also, it was great to see so many of you in person.

I would also like to again thank those of you who facilitated the meeting: Emily Gurley, Joel Montgomery, Emmie de Wit, Chris Broder, and Marie-Pierre Preziosi—you all did a great job!

Attached please find a summary report of the meeting and a revised version of the Nipah Virus R&D Roadmap that includes all of the changes that were made based on discussions at the meeting (track changes are included). We also added a couple of additional references.

We would very much appreciate your review of the attached roadmap and any edits or comments that you may have. During the meeting, we mainly focused on the goals and milestones, and that's where the majority of the edits are, but we would very much appreciate your review of the whole document at this point in the process. **Please send any feedback on the document no later than September 15, 2023.**

Also, if you see any glaring omissions or inaccuracies in the summary report, please let me know (although we certainly don't expect you to review and comment on the meeting summary—we are providing it to you for your information only).

Over the coming weeks, I'll be preparing a manuscript about the roadmap and will be sending that to you for your review—tentatively in early October.

Again, thank you all for your support of this important project and for sharing your extensive expertise with us.

Kind regards,

Kris

Nipah Research and Development (R&D) Roadmap

Roadmap purpose: To provide a 6-year framework beginning in 2024 for identifying the vision, underpinning strategic goals, and prioritizing areas and activities (from basic research toward advanced development, licensure, manufacture, acceptance and deployment, and assessment) for accelerating the collaborative development of medical countermeasures (MCMs)—diagnostics, therapeutics, and vaccines—against Nipah virus infection.

INTRODUCTION

Nipah virus (NiV) is a paramyxovirus that was first identified as a zoonotic pathogen after an outbreak involving respiratory illness in pigs and severe encephalitic disease in humans occurred in Malaysia and Singapore in 1998 and 1999 (Chew 2000, Chua 1999, Chua 2010, Parashar 2000, Paton 1999). As part of that outbreak, 265 human cases of NiV disease (NiVD) were identified in Malaysia, and 11 abattoir workers in Singapore became ill following contact with imported pigs, with an overall case fatality rate of 40%. No new outbreaks have been reported in these countries since May 1999. NiVD was subsequently recognized, however, in Bangladesh in 2001, and nearly annual outbreaks have occurred in that country since (Hsu 2004, WHO 2018, Agrawal 2023). NiVD has also been identified periodically in eastern India (in 2001 and 2007) and, in 2018, an outbreak occurred for the first time in southern India (Arunkumar 2019, Chadha 2006, Chattu 2018, Sharma 2018, Soman Pillai 2020). Additionally, one case was reported from Kerala state in 2019 (Sudeep 2021). Case-fatality rates during outbreaks in Bangladesh and India have generally ranged from 50% to 100% (Sharma 2018). NiV infection in humans results in neurologic and respiratory syndromes, with fever, headache, altered mental state or unconsciousness, dizziness, cough, and vomiting as the primary presenting clinical features. NiV infection may result in late-onset encephalitis and relapsing encephalitis, and survivors may experience long-term neurological sequelae (Goh 2000, Hossain 2008, Tan 2002). A summary of 14 years of NiVD investigations in Bangladesh found no evidence of asymptomatic infection (Nikolay 2019).

The primary natural reservoir host for NiV in South Asia, where cases continue to occur, is *Pteropus* bats. A recent study suggests that discrete multiannual local epizootics in bat populations contribute to the ongoing sporadic nature of human NiV outbreaks in South Asia (Epstein 2020). Other regions may be at risk for NiV infection, as serologic evidence for NiV has been found in *Pteropus* bats and several other related bat species in Southeast Asia, the Western Pacific, and Africa (Anderson 2019, Breed 2010, Epstein 2008, Hasebe 2012, Iehlé 2007, Plowright 2019, Reynes 2005, Sendow 2013, Wacharapluesadee 2005, Yob 2001). In the 1998-99 Malaysia outbreak, NiV spillover occurred from bats to pigs, which led to pig-to-pig, pig-to-human, and suspected, although limited, human-to-human NiV transmission. Additionally, dogs were found to be infected with NiV on the farms involved in the outbreak (Field 2001). In outbreaks in Bangladesh, intermediary hosts between bat and human have not played a major role to date, with the primary modes of NiV transmission being human consumption of bat-contaminated raw date palm sap and subsequent person-to-person transmission (Arunkumar 2019, Gurley 2007, Islam 2016, Luby 2009, Nikolay 2019, Rahman 2008). However, a recent study in Bangladesh found NiV antibodies in cattle, dogs, and cats from six sites where spillover human NiV infection cases occurred during 2013–2015 (Islam 2023), suggesting the potential of zoonotic spread via intermediary hosts. Respiratory transmission via droplet spread may play an important role in propagating outbreaks (Nikolay 2019, Spiropoulou 2019). The virus could have pandemic potential if a more human-adapted strain, with greater person-to-person transmission emerges (Luby 2013).

The zoonotic potential of NiV is significant, particularly because of its ability to amplify in livestock and other domestic animals, which can serve as a source of exposure to humans (Islam 2023). NiV is part of the Henipavirus genus; this genus also includes another zoonotic pathogen—Hendra virus (HeV)—which predominantly causes infection in horses and also can lead to human disease (usually following contact with infected horses). HeV was initially recognized in 1994, following an outbreak of fatal cases of severe respiratory disease in horses and humans in the Brisbane suburb of Hendra in Queensland, Australia (Murray 1995, Selvey 1995). To date, at least 66 spillover events—all in Australia—involving more than 100 horses and seven humans have been identified (Wang 2023). Changes in bat behavior related to habitat loss and climate change appear to have increased the spillover risk of HeV from bats to horses (Eby 2023). An outbreak of an unidentified henipavirus (possibly NiV or a closely related virus) occurred among horses and humans in the Philippines in 2014 (Ching 2015). This outbreak likely involved spillover of the virus into horses and subsequent disease in humans following consumption of contaminated horsemeat; disease also occurred in healthcare workers who cared for infected patients. Detailed genomic information for this virus is limited.

Genomic sequencing has demonstrated that there are two main clades of NiV: the M genotype, which comprises the Malaysian NiV isolates (NiV-M), and the B genotype, which includes Bangladesh (NiV-B) and India NiV isolates (NiV-I) (Liew 2022, Yadav 2019). These three strains share a high percentage of homology (NiV-M and NiV-B strains share 91.8% homology, and NiV-I strains share 85.14to 96.15% homology with both NiV-M and NiV-B). Some strain-related differences, however, have been noted in the clinical features of infection in humans and experimentally infected non-human primates, with strains of the B clade appearing to be more pathogenic than those of the M clade (Mire 2016). Recent data indicate that strains from Bangladesh are segregated into two additional distinct sublineages that have intermingled geographically and temporally in that area over time (Rahman 2021, Whitmer 2020). At this time, however, the molecular epidemiology of NiV remains somewhat unclear and issues around strain diversity and strain evolution require further elucidation (Rahman 2021).

The R&D roadmap for NiV infection is a key component of the WHO R&D Blueprint initiative for accelerating research and product development of MCMs to enable effective and timely emergency response to infectious disease epidemics. NiVD is identified in the Blueprint's list of "priority diseases" (defined as diseases that are likely to cause severe outbreaks in the near future and for which few or no MCMs exist) (WHO 2023). The Blueprint calls for the development of R&D roadmaps for the priority diseases to align and stimulate R&D of new or improved countermeasures, such as rapid diagnostic assays, novel therapeutics, and effective vaccines. The scope of R&D addressed in this roadmap ranges from basic research to late-stage development of MCMs to prevent and control NiV outbreaks and endemic disease in humans. The roadmap is organized into four main sections: cross-cutting issues (for areas that apply broadly to more than one MCM category), diagnostics, therapeutics, and vaccines.

(*Note*: These topics are not presented in order of public health priority.) Each section includes barriers (inherent obstacles or technical challenges that may influence the likelihood of success for development of NiV MCMs) and gaps (key needs or unresolved limitations in knowledge that are critical to the development of new NiV MCMs). These are followed by strategic goals and milestones, which build on the gaps and barriers and are focused on achievements for the next 6 years (beginning in 2024) that are necessary for moving NiV MCMs forward. The roadmap milestones will be tracked over time, with periodic assessment of progress and updating as needed. Each section also includes additional ongoing priorities that should be considered for NiV MCM R&D.

Other aspects of public health preparedness and response, in addition to R&D for diagnostics, therapeutics, and vaccines, are critical to successful NiV infection prevention and control. Examples include minimizing zoonotic NiV transmission, improving use of personal protective equipment (PPE), ensuring adequate hand hygiene and environmental hygiene, promoting effective community engagement, implementing adequate infection prevention and control practices, developing adequate infrastructure (such as cold-chain maintenance) to deploy MCMs, and promoting workforce development and training in endemic and at-risk regions. Many of these issues are beyond the scope of this R&D roadmap, but need to be addressed as part of a broader public health control strategy. Further research of NiV and related henipaviruses in animal species, including development of appropriate MCMs targeted to animal populations (such as vaccines [McLean 2019]), also is needed, since disease in animals may amplify occurrence of NiV (or a related henipavirus species) in humans and virus transmission can occur at the human-animal interface.

VISION

Robust MCMs to detect, prevent, treat, and control human outbreaks of NiV infection (and other closely related henipaviruses) that are readily available and accessible for use in areas of known or potential NiV spillover. These MCMs include: (1) rapid and accurate, point-of-care or near patient diagnostics; (2) safe and effective treatment and post-exposure prophylaxis (PEP); and (3) safe and effective vaccines to prevent disease, disability, and death.

CROSS-CUTTING ISSUES

Barriers and Gaps

Barriers

- Securing funding for NiV research represents a substantial challenge, since economic incentives to invest in NiV research are not readily apparent because the disease primarily occurs in under-resourced areas of South Asia and reported disease incidence has, so far, been low with small and sporadic outbreaks (Gómez Román 2020). The development of a sustainable value proposition for industry and international philanthropic public-private partnerships is needed to secure funding to complete development, licensure, manufacture, and deployment of NiV MCMs. The value proposition should be informed by a robust assessment of the risk of future outbreaks and the economic, societal, and health impacts that such outbreaks could generate.

- Demonstrating whether or not a product provides meaningful benefit without undue risk, which is a key aspect of any regulatory approval pathway, can be prohibitively expensive for product developers in the absence of a predictable demand (Gouglas 2018). In addition, licensure of vaccines and therapeutics using alternative regulatory pathways can be very costly, given the regulatory requirements for such approval.
- National regulatory authorities in countries where NiV outbreaks are likely to occur have different regulatory requirements for authorization, licensure, or emergency use of NiV medical countermeasures, which complicates the approval process, particularly for candidate vaccines and therapeutics (Gómez Román 2022). An international, NiV-focused regulatory group has been created and will be an important mechanism for coordinating regulatory issues as NiV MCMs are moved forward (Gómez Román 2020).
- High-level biocontainment requirements may pose an impediment to research on NiV pathogenesis and development of MCMs, as certain materials must be generated under the highest biosafety level (biosafety level 4 [BSL-4]) conditions (Geisbert 2020, Gómez Román 2022), which can increase the cost and complexity of MCM development.
- To date, NiV spillovers to human communities have been identified most commonly in rural communities in Bangladesh and India; the healthcare facilities that serve these communities have limited laboratory and clinical infrastructure for diagnosis and treatment.
- The natural reservoir for NiV is fruit bats of the *Pteropus* genus; these bats have a wide geographic range that stretches across much of the Western Pacific region, Southeast and South Asia, and Madagascar (Bruno 2022). Evidence also suggests that other fruit bats of the Pteropodidae family may harbor NiV or related viruses; such bats can be found across Africa and parts of the Middle East (Bruno 2022). This broad host range increases the likelihood of additional spillover events from bats to humans or livestock in new areas where the disease has not yet been detected, which may make accurate and timely diagnosis, disease recognition, and treatment more difficult owing to the lack of clinical experience with the condition, lack of available laboratory testing, and the occurrence of other diseases that have similar clinical presentations.
- The development and accessibility of animal models that recapitulate human NiV disease are critical for NiV MCM development, given the limitations on clinical samples and the infeasibility of traditional clinical efficacy trials. While ferrets and Syrian golden hamsters are well-established animal models for NiV research, the African green monkey (AGM) is regarded as the most relevant animal model for evaluation of candidate therapeutics and vaccines intended for use in humans (Foster 2022, Geisbert 2010, Geisbert 2020, Geisbert 2021, Johnston 2015, Price 2021, van Doremalen 2022, Woolsey 2023). Studies involving the AGM model may be required for licensure of MCMs via alternative regulatory pathways; however, costs, space requirements (particularly in BSL-4 containment facilities) and ethical concerns constrain their use (Arnason 2020, Bossart 2012, Geisbert 2010, Johnston 2015).
- Phase 1 and 2 clinical trials can be conducted in non-endemic regions or in endemic regions; however, phase 3 clinical efficacy trials will need to be conducted in endemic areas. Because NiV infection occurs in relatively small, focal outbreaks, the low disease incidence poses a major challenge for conducting such trials, in terms of achieving a sufficient sample size to estimate

MCM efficacy with adequate statistical power (Gómez Román 2020). It may be possible to address this issue by enhancing case detection through improved surveillance and by combining clinical trial data over time, including across outbreaks; however, it is likely that at least vaccines will need to be licensed via nontraditional regulatory pathways.

- Patients usually present late in the clinical course of disease and disease progression is often rapid, making it difficult to collect clinical samples before patients succumb to the disease. Additionally, autopsies are often not the standard of care in affected areas, which further reduces opportunities to collect clinical specimens. These barriers hinder the ability to understand disease pathogenesis and immunologic responses to infection, which are important for MCM R&D (Amaya 2020, Arunkumar 2019, Gurley 2020, Liew 2022, Mazzola 2019).
- Sociocultural issues may hinder trust in the formal healthcare and public health systems, which could reduce acceptance of NiV vaccines and therapeutics.

Gaps

- Continued R&D, improved manufacturing processes, deployment, and assessment of NiV MCMs, as well as other preventive measures, depend on accurate and current information on the ecology and epidemiology of NiV infection, using a One Health approach. Improved surveillance (or dedicated prospective research with a surveillance focus) is needed to determine the true incidence of human disease in endemic areas and to monitor the occurrence of spillover incidents from bats to humans or livestock in new geographic areas (Bruno 2022, Singhai 2021).
- Additionally, continued research is needed to better define and assess the occurrence of NiV and other henipaviruses, including drivers of infection, in the natural reservoir of *Pteropus* bats and potentially other bat species around the globe (Gómez Román 2020, Plowright 2019).
- Additional research is needed to optimize and further characterize relevant animal challenge models (particularly ferret, Syrian golden hamster, and AGM models) for promoting development and evaluation of NiV MCMs (Geisbert 2020, Gómez Román 2020, Price 2021, Rockx 2014). Examples of additional issues involving animal models include the following (Dhondt 2013, Gómez Román 2020, Johnston 2015, Mathieu 2015, Mire 2019, Price 2021):
    - Determine the appropriate animal model(s) for screening assay development.
    - Standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development.
    - Determine when after-challenge MCMs should be administered in animal models to best mimic realistic timing of MCM use in humans.
    - Identify the best models for studying chronic (relapsing) infection.
    - Determine if different animal models are needed for different clinical endpoints such as infection, disease, and transmission.
    - Determine if models perform differently based on the route of virus administration.
    - Improve overall standardization of the models.
- Other research needs include the following:
    - Improved understanding of the virology, immunology, and pathogenesis of NiV in humans and animals to inform development of NiV MCMs (Gurley 2020, Liew 2022). This includes evaluating the pathophysiologic differences between different NiV strains,

  determining the mechanisms that allow NiV to escape immunologic clearance and cause delayed onset or recurrent encephalitis, and identifying factors influencing the development of permanent neurologic sequelae.
  - Ongoing phylogenetic and evolutionary analyses of NiV strains to monitor viral heterogeneity and antigenic changes that may affect the epidemiologic and clinical features of disease over time and thereby influence MCM development (Gurley 2020, McKee 2022, Rahman 2021).
  - Additional research to determine if: (1) NiV strain variations influence the ability to detect NiV infections; (2) different strains have different phenotypic characteristics, such as different clinical manifestations or transmission dynamics, and (3) if strain variability impacts efficacy of vaccines or therapeutics (CEPI 2023a, Gurley 2020, Whitmer 2020).
  - Whole-genome sequencing of NiV isolates to generate a comprehensive phylogenetic mapping of the global genetic variability among henipaviruses (CEPI 2023a).
  - Sociological and anthropological research to understand how to best engage populations at high risk of exposure (such as persons who consume date palm sap, healthcare workers, and workers at the human-animal interface) and vulnerable populations (such as children, immunocompromised individuals, and pregnant women) for participation in clinical trials and to ensure acceptance of new NiV MCMs, especially if therapeutics and vaccines do not consistently prevent disease (Singhai 2021, Lancet 2018).
  - Prospective serosurveillance of henipavirus exposure from susceptible animal species and proximate human populations in areas of predicted risk to assess the potential of human spillover and to build preparedness for detection of human cases and for limiting exposure (Daszak 2020, Deka 2018, Gómez Román 2020, Plowright 2019).
  - Expanded use of machine-learning approaches can facilitate an improved understanding of the risk of NiV spillover events (Plowright 2019).Ecological studies are also needed to enhance understanding of the dynamics governing prevalence and shedding of NiV and other henipaviruses in bats (Plowright 2019).
- Other important needs include the following:
  - Funding sources (such as public-private partnerships, government agencies, and philanthropic organizations) and industry incentives and competitions for non-dilutive funding to encourage innovation and secure private-sector commitments to develop and manufacture NiV MCMs (Gómez Román 2020).
  - Enhanced clinical, laboratory, and public health infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, surveillance, and implementation of vaccination programs for NiV prevention and control (Bruno 2022).
  - Advocacy to policy makers in affected countries and to global stakeholders to ensure they understand the potential health, societal, and economic benefits of devoting resources to improving NiV surveillance, detection, prevention, and control measures (Gómez Román 2020).

  - Scenario planning to clarify regulatory pathways for product approval in countries where NiV outbreaks are likely to occur, including determining whether or not efficacy data from animal models is sufficient for regulatory approval. Such planning should take into consideration the local epidemiology of NiV infection and the different requirements of local national regulatory authorities for product approval and emergency use authorization (Gómez Román 2022). Regulatory pathways and NRA capabilities vary between countries; therefore, early engagement, potentially with support from WHO and other key international stakeholders, is essential to identify country-specific considerations. While it is critical to focus on approaches that make ethical and scientifically valid clinical trials feasible whenever possible, alternative regulatory pathways may need to be considered for licensure of NiV vaccines or therapeutics, if classic clinical trial designs (e.g., randomized controlled trials [RCTs]) are not feasible.
  - Standardized and well-characterized assays (to be further defined based on end use), reagents, antibodies, nucleic acids, and stocks of NiV challenge strains for R&D of MCMs for NiV infection (Rampling 2019, Satterfield 2016). Assays that can be used at lower biosafety levels are an important priority. WHO international standards should be used (when available) as calibrators and reported in units/ml to harmonize assay results.
  - Outreach and education to clinicians and community health workers to improve NiV awareness, training, and outbreak preparedness (e.g., disease diagnosis, clinical management, and infection prevention and control) and to ensure availability of diagnostic tools in endemic areas to increase the likelihood of accurate and timely diagnosis and treatment of NiV infection (Singhai 2021).
  - Enhanced capacity for data sharing and analysis (particularly of NiV sequence data) to support collaborative clinical research, including methods for collecting, standardizing, and sharing clinical data.
  - Collaboration between public health authorities in endemic and at-risk areas and international development partners to support NiV surveillance and strengthen disease prevention and preparedness activities. Human health, animal health, and wildlife officials should be engaged as part of a long-term collaborative effort.
  - Clarification regarding the potential for and possible strategies to promote technology transfer for NiV MCM development and manufacturing to endemic and at-risk areas.
  - Efforts to reduce the cost of medical countermeasure development and ongoing production.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Identify additional and ongoing sources of private- and public-sector funding and develop appropriate incentives and competitions to promote R&D of NiV MCMs.

Milestones:

1. By 2025, develop a public value proposition to effectively advocate for the development and sustainability of NiV MCMs that: (1) articulates the potential global threat of NiV infection, (2)

outlines the social and economic benefits of generating accessible and affordable NiV MCMs, and (3) details the positive impact on the health systems in affected areas.

2. By 2026, create a funding plan based on the value proposition for moving NiV diagnostics, therapeutics, and vaccines toward clinical evaluation, licensure/approval, acceptance, and sustainable access.
3. By 2026, develop a coordinated strategy for promoting and incentivizing greater industry engagement in R&D for NiV MCMs.

Strategic Goal 2: Improve understanding of NiV epidemiology and ecology to better define the disease burden, risk factors for infection, and risk of spillover events in affected countries.

Milestones:

1. By 2025, develop a plan for enhancing human NiV surveillance in India and Bangladesh outside of existing surveillance areas (i.e., where cases previously have been identified). This should include securing funding, identifying additional surveillance catchment areas, engaging key partners in those areas, generating standardized surveillance protocols, and conducting training for implementation.
2. By 2026, initiate enhanced human NiV surveillance to better characterize NiV epidemiology (including the potential for spillover events), promote early case detection, and better define the disease burden in India and Bangladesh, particularly outside of areas where cases previously have been identified.
3. By 2026, generate and implement standardized protocols for case investigation that are aimed at identifying risk factors for primary NiV infection and at conducting case-contact studies to better understand chains of transmission (Hedge 2023).
4. By 2026, develop plans for conducting additional research in India and Bangladesh to identify the potential for and drivers of spillover events, particularly in areas where NiV cases have not yet been identified.

Strategic Goal 3: Determine the requirements for clinical trials, regulatory pathways, and other considerations that will affect licensure or approval of NiV MCMs by engaging an international regulatory working group representing NRAs in affected areas and other key international stakeholders.

Milestones:

1. By 2024, conduct scenario planning to clarify the regulatory procedures and determine the acceptable pathways for approval and emergency use authorization of NiV MCMs (including vaccines, novel candidate therapeutics, repurposed therapeutics, and diagnostics) in countries at highest risk for NiV outbreaks (i.e., Bangladesh and India) through an international NiV-focused regulatory group.

2. By 2025, determine if any key gaps exist for regulatory approval and emergency use authorization of candidate NiV MCMs in affected countries and develop strategies to address those gaps, with specified timelines for completion.
3. By 2026, ensure that any issues affecting approval and emergency use of candidate MCMs in affected countries have been resolved and that consensus has been achieved on the necessary regulatory steps and procedures.

Strategic Goal 4: Support basic science research to improve understanding of NiV virology, pathogenesis, and the immune response to infection in humans and animal models.

Milestones:

1. By 2025, generate standardized and well-characterized assays, reagents, antibodies, nucleic acids, and stocks of NiV challenge strains to facilitate R&D of NiV MCMs.
2. By 2025, conduct additional research to further optimize animal models that recapitulate disease in humans for use in preclinical studies of NiV MCMs.
3. By 2026, conduct sequencing of NiV strains from existing clinical samples obtained from past NiV cases to assess variability of NiV strains in India and Bangladesh (CEPI 2023a).
4. By 2026, establish capacity at selected surveillance sites in India and Bangladesh to investigate NiV-related deaths by using post-mortem minimally invasive tissue sampling to enhance understanding of NiV disease pathogenesis (Bassat 2021).
5. By 2028, conduct research in animal models to determine if strain variability impacts efficacy of promising NiV MCMs or the accuracy of diagnostic tests.

Additional Priority Areas/Activities

Research

- **Continue to expand** research to further understand the ecology and epidemiology of NiV and other pathogenic henipaviruses in human and animal populations (wild and domestic) over time and across geographic areas, using a One Health approach. Such research should include serosurveys in different animal species and ecologic studies in bats, and should utilize computational approaches, such as machine-learning approaches.
- **Continue to perform** phylogenetic and evolutionary analyses, using whole-genome sequencing, of NiV strains to monitor antigenic changes and characterize genetic diversity over time.
- **Incorporate**, on an ongoing basis, additional NiV strains into preclinical research as newer strains become available.
- **Continue to conduct** basic science research on the virology, pathogenesis, and immunology of NiV infections to inform development of MCMs.
- **Determine** key differences in pathogenesis for different NiV strains that may have implications for the development of safe and effective NiV vaccines or therapies.
- **Conduct** research studies to enable a more comprehensive mapping of genetic variability of henipaviruses to improve understanding of their global distribution.

- **Conduct** social science research to determine strategies for engaging communities for participation in clinical trials and to support acceptance of MCMs for NiV infection as they become available.

Product development

- **Promote** early communication between developers and appropriate NRAs for clarity and guidance on the regulatory aspects of MCM development for NiV infection, including potential regulatory pathways for MCM licensure and approval.

Key capacities

- **Create** international partnerships to fund, support, and promote enhanced laboratory capacity, public health surveillance capacity, and infrastructure in endemic and at-risk areas to promote early diagnosis, treatment, and implementation of vaccination programs for NiV prevention and control.
- **Improve** active and passive surveillance capacity to: (1) better define the incidence of disease in NiV-endemic and at-risk areas and (2) promote targeted research in non-endemic areas to identify evidence of spillover of NiV or other related henipaviruses from the natural reservoir to human or animal populations.
- **Develop** an open-access shared data platform to facilitate sharing of NiV sequence and strain data.
- **Collaborate** with local government authorities (including human health, animal health, and wildlife representatives) to support NiV surveillance and disease prevention activities in endemic and at-risk areas.
- **Promote** community-based outreach programs that transfer skills and knowledge for the prevention and early recognition of NiV disease in areas of known or potential NiV spillover risk.
- **Strengthen** infrastructure and capacity for post-marketing pharmacovigilance of licensed NiV therapeutics and vaccines.

Policy and commercialization

- **Support** plans for adequate manufacturing and subsequent distribution of NiV diagnostics, therapeutics, and vaccines to endemic and at-risk areas. These should include efforts to reduce production costs and ensure equitable global access as needed.
- **Support** the development of affordable pricing mechanisms to promote accessibility of NiV MCMs in low- and middle-income at-risk countries. (*Note*: According to WHO, an “affordable and fair” price is one that can reasonably be paid by patients and health budgets and simultaneously sustains research and development, production, and distribution within a country.)
- **Clarify** the potential for and possible strategies to promote technology transfer for development and manufacturing of MCMs for NiV infection.

DIAGNOSTICS

Barriers and Gaps

Barriers

- Initial signs and symptoms of NiV infection are nonspecific, and infection is often not suspected at the time of presentation. This can hinder accurate diagnosis and creates challenges in outbreak detection and implementation of effective and timely infection control measures and outbreak response activities. Additionally, latent infection can last for months to years after initial exposure, which can complicate epidemiologic investigation (CDC 2020).
- The accuracy of laboratory results can be affected by a variety of factors, such as clinical sample quality, quantity, type, timing of collection, and the time necessary to transfer the sample from the patient to the laboratory (WHO 2019, Mazzola 2019).
- The time required to perform diagnostic testing using conventional laboratory methods is problematic, given the potential for rapid disease progression of NiV infection (Sayed 2019).
- Diagnostic needs vary across the latent, acute, and convalescent phases of NiV infection (Bruno 2023).
- Limited laboratory infrastructure and diagnostic capabilities in peripheral settings can lead to delays in diagnosis and in outbreak investigation and response (Berge 2019, Bruno 2022, Chua 2013, Wang 2012, WHO 2019).
- Owing to the high biosafety precautions necessary when working with NiV, diagnostic testing of clinical specimens for NiV poses safety and logistical challenges in under-resourced areas with regard to collection, handling, transport, and laboratory analysis (Watanabe 2020, Widerspick 2022).
- Limited NiV-positive clinical samples are available, which are important for validation of diagnostic tests (Mazzola 2019).
- *Pteropus* species (and likely other bat species) may carry other henipaviruses in addition to NiV and HeV, some of which could be pathogenic in humans and livestock. Antibodies to different henipaviruses appear to be highly cross-reactive, making it difficult to discriminate the particular henipaviruses that are in circulation using serologic assays, which is critical to ensuring diagnostic preparedness to respond to future outbreaks (Mazzola 2019, Wang 2012, WHO 2019, Yang 2022).

Gaps

- Further research is needed to:
    - Improve understanding of the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids (e.g., urine and respiratory secretions), and tissue samples to enhance the ability to diagnose infection at different stages of disease (Arunkumar 2019, Berge 2019, Mazzola 2019, Thakur 2019).
    - Determine criteria for test performance and further evaluate performance characteristics (including sensitivity, specificity, limits of detection, cross-reactivity, and quantitative vs. qualitative data) for NiV assays, particularly for newer tests (such as rapid diagnostic tests) and tests that are designed to detect more than one henipavirus. Further testing of diagnostics should be conducted in animal models before field trials in humans are pursued.
    - Continue to develop commercialized or standardized rapid nucleic acid tests that can quickly confirm active NiV infection at the point of care or at the level of near-patient

    care (Berge 2019, Pollack 2023, WHO 2019). This effort may require clarification of the regulatory pathways for commercialization of NiV diagnostic tests. To date, one rapid test has been approved for emergency use in India during an outbreak that occurred in 2018 (Yadav 2021).
  - Generate international reference standards to calibrate diagnostic assays to ensure proficiency testing of new diagnostics (Berge 2019, WHO 2019).
  - Clinically validate the performance and operational suitability of new promising diagnostics, particularly rapid diagnostic tests, in endemic geographic regions (Berge 2019, Pollack 2023).
  - Continue to assess and operationally validate safe and simple methods of sample inactivation that do not interfere with diagnosis and that can be used at peripheral sites (Pollack 2023, WHO 2019, Watanabe 2020, Widerspick 2022, Yadav 2021).
  - Establish operational suitability at the point of care (i.e., at peripheral community settings) for NiV diagnostic tests by developing an integrated approach to facilitate rapid, accurate, and safe testing procedures (Pollack 2023).This could include a minimal protocol or best practices approach for sample inactivation before testing (WHO 2019).
- Other needs include the following:
  - Development of a virtual repository (with specimens being held and maintained in the countries of origin) of clinical samples to assess and validate diagnostic tests (Berge 2019, WHO 2019). As part of this process, a clear approach is needed to: (1) determine what clinical samples should be collected, based on what would be most useful (e.g., plasma, whole blood, urine, cerebrospinal fluid); (2) outline the purposes of sample collection; (3) determine what organizations will be responsible for the activities related to creating and maintaining the repositories; (4) establish standardized protocols for sample collection and maintenance; (5) establish an appropriate governance structure; (6) identify who would have access to the samples; (7) prioritize use of samples and sample distribution; and (8) ensure that material transfer agreements (MTAs) are in place. (Samples obtained from laboratory animals also can be used to assess diagnostic assays during the timeframe when the virtual repository is being created.)
  - Optimal deployment strategies for diagnostics in different geographic areas based on the risk and epidemiology of NiV infection (Berge 2019, WHO 2019).
  - In-country laboratories able to conduct proficiency testing to monitor reproducibility and performance of NiV diagnostic assays in the field.
  - Systems for external quality assessment (EQA) monitoring of tests using up-to-date clinical specimen panels and reference standards (Mazzola 2019).
  - A sufficient number of laboratories committed to using the diagnostics on a regular basis to support the business case for NiV diagnostics, particularly given the costs of regulatory approval.
  - Improvement of diagnostic preparedness in at-risk areas to detect NiV, HeV, and other emergent henipaviruses as they arise (Wang 2012).

  - Ongoing efforts to develop affordable and easy-to-use multiplex panels for detection of a range of pathogens using a syndromic approach, if such panels can be deemed cost-saving (Mazzola 2019).
- Use cases and target product profiles (TPPs) have been developed for NiV diagnostics (WHO 2019); however, the criteria may need to be modified over time as new lineages are identified (Mazzola 2019).
- Since NiV strains are continuing to evolve, it's possible that current diagnostic tests could fail to detect an emergent variant of NiV. Recently, a novel strain of HeV was identified in Australia that was not detected through conventional PCR testing owing to gene sequence mismatches (Annand 2022). Diagnostic tools that can detect a broader range of NiV, HeV, or related viruses capable of spillover may be needed to advance the ability to forecast spillover risks and to detect emergent viruses (Peel 2022).

Strategic Goals and Aligned Milestones

Strategic Goal 1: Support development of diagnostic assays through creation of a virtual reference repository of clinical samples from NiV-infected patients.

Milestones:

1. By 2026, develop and standardize plans and protocols (including the governance structure) for creating a virtual reference repository of well-characterized clinical samples to be maintained in the two primary NiV-affected countries (Bangladesh and India).
2. By 2027, identify sustainable, long-term funding, determine sites for sample storage, and initiate creation of the virtual reference repository in Bangladesh and India, with samples to be collected during future outbreaks.

Strategic Goal 2: Continue to develop and assess affordable, highly sensitive and specific (as needed depending on intended use), point-of-care or near-patient NiV diagnostic tests that are suitable for use in peripheral settings and that have minimal requirements for biosafety precautions and staff training.

Milestones:

1. By 2025, engage appropriate regulatory agencies and NRAs to inform commercialization pathways for NiV diagnostic assays. This effort should include clarifying regulatory pathways for approval (including approval for emergency use) of NiV diagnostics.
2. By 2026, complete preclinical evaluation for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP and can be used in peripheral sites.
3. By 2026, create international reference standards for calibrating and harmonizing NiV diagnostic assays.
4. By 2026, develop a minimum protocol or set of best practices (that biosafety committees will accept) for inactivation of clinical samples from humans and animals that are being tested for NiV.

5. By 2027, complete clinical validation of performance and operational suitability for at least two of the most promising NiV point-of-care or near-patient diagnostic assays that align with the TPP and can be used in peripheral sites.
6. By 2028, obtain regulatory approval for at least one rapid, point-of-care or near-patient care NiV diagnostic test that can be commercialized and standardized.

Strategic Goal 3: Enhance laboratory diagnostic preparedness in areas of known spillover risk to promote early detection of NiV.

Milestones:

1. By 2026, expand national laboratory networks for NiV detection in the primary affected countries (Bangladesh and India) that include plans for enhancing laboratory preparedness to enable earlier and timely detection of NiV infection during future outbreaks.
2. By 2027, generate well-characterized and up-to-date proficiency panels for NiV diagnostic testing to be used in selected laboratories in Bangladesh and India.
3. By 2029, implement routine EQA monitoring of NiV diagnostic testing at selected laboratories in Bangladesh and India.

Additional Priority Areas/Activities

Research

- **Continue to explore** new diagnostic approaches that may allow earlier detection of infection.
- **Further evaluate** the kinetics of NiV detection in cerebrospinal fluid, blood, saliva, other body fluids, and tissue samples to enhance the ability to diagnose NiV infection at different stages of disease.
- **Determine** criteria for test performance and **continue to evaluate** performance characteristics for promising new assays for diagnosis of NiV infection.
- **Continue to conduct** field evaluation studies to assess and validate new diagnostic tests for NiV infection as they become available.
- **Continue to research** methods of diagnostic testing that are able to differentiate between various pathogenic henipaviruses.
- **Continue to develop** affordable and easy-to-use multiplex panels for detection of a range of pathogens using a syndromic approach.
- **Consider** development of diagnostic tools that can detect a broader range of NiV, HeV, or related viruses capable of spillover.

Product development

- **Refine** over time, as needed, criteria in the existing TPPs to include identification of different NiV lineages/strains.
- **Continue to develop and evaluate** point-of-care or near-patient rapid diagnostic tests for NiV infection that are affordable, highly sensitive and specific (as needed, depending on their

intended use), can capture antigenically diverse strains of the virus, and can be performed accurately and safely in peripheral settings under a variety of circumstances.

Key capacities

- **Establish** operational suitability in peripheral laboratories of rapid diagnostic tests over time, as new tests become available.
- **Enhance** diagnostic preparedness in areas of known or potential henipavirus spillover risk to promote early detection of NiV, HeV, and other emergent henipaviruses as needed.

Policy and commercialization

- **Develop** guidance on optimal strategies for the deployment and use of new NiV diagnostic tests across different geographic areas, as such tests become available.

THERAPEUTICS

Barriers and Gaps

Barriers

- Patients typically present late in the clinical course of disease, which decreases the likelihood of successful treatment.
- A limiting constraint to assessing the effectiveness of promising therapeutics is the number of patients with NiV infection who can be enrolled in clinical trials over time, given the small number of cases that are identified annually.
- The absence of improved diagnostic assays for timely diagnosis and surveillance of infection creates an important challenge in providing early treatment of patients and PEP for exposed persons, which can significantly impact clinical evaluation of therapeutic candidates.
- NiV can infect the central nervous system (CNS), which creates challenges for generating therapeutic agents that cross the blood-brain barrier to inhibit viral replication and prevent severe neurologic disease.
- Healthcare systems in affected countries often do not have adequate infection control– programs in place to prevent person-to-person transmission. They also lack the ability to rapidly identify contacts most likely to benefit from PEP therapy.
- One promising therapy is the monoclonal antibody (mAb) m102.4; however, the projected cost per patient for this agent is expected to be more than $1,000 (Gómez Román 2022); this high cost poses an important barrier to its use.

Gaps

- Patients may benefit from optimal supportive care, independent of treatment with specific NiV therapeutic agents. Key research areas include obtaining data on the safety and efficacy of components of supportive care for NiV, such as optimal fluid and respiration management strategies, diagnosis and treatment of organ dysfunction, and the use of empiric antibiotics and/or antimalarials to inform best-practice guidelines and evidence-based policy decisions. Standard of care guidelines will be important for conducting clinical efficacy trials of therapeutic agents.

- During the 1998-99 NiV outbreak in Malaysia, clinicians used ribavirin to treat 140 patients. Outcomes data revealed a lower mortality rate among treated patients (Chong 2001), but the findings may have been biased by the use of historical controls. No additional clinical studies of ribavirin have been conducted, and limited studies in animals have not demonstrated efficacy of ribavirin following NiV or Hendra virus challenge (Georges-Courbot 2006, Rockx 2010). Ribavirin, however, may prove useful for PEP (Banerjee 2019); therefore, further challenge studies in animal models should considered to explore this possibility.
- Studies in animals have evaluated the usefulness of several agents (including remdesivir, favipiravir, and fusion inhibitory peptides) when delivered prior to disease onset or early during the disease course (Dawes 2018, Lo 2019, Mathieu 2018). One recent study showed that AGMs were only partially protected when remdesivir was administered 3 days post-inoculation; therefore, early administration seems critical for effective treatment (de Wit 2023). Patients with NiV infection are often detected late in the clinical course, which creates challenges for predicting how well a therapeutic agent will work in the field. Additional challenge studies in animals, therefore, are needed to: (1) assess the clinical benefit of these therapeutics as treatment options when administered after symptom onset or at least more than 24 hours after initial exposure, (2) determine whether these agents may be appropriate for PEP, and (3) clarify the most feasible and cost-effective route of administration (e.g., oral, intranasal, intravenous) appropriate for real-world conditions, particularly if being considered for mass prophylaxis in an outbreak setting (Gómez Román 2022).
- m102.4 has demonstrated protection against lethal NiV challenge in animal models and has been provided under compassionate use programs for a small number of individuals exposed to either HeV or NiV (Broder 2012, Guillaume 2004, Playford 2020). Several other mAbs have also been assessed in animal models and appear promising (Gómez Román 2022). A phase 1 clinical trial for m102.4 with 40 human participants was completed in Australia during 2015 and 2016 (Playford 2020). In that trial, m102.4 was well tolerated and safe, with no evidence of an immunogenic response.
- Additional research needs for mAbs as treatment or PEP for NiV infection include:
    - Additional clinical trials in endemic areas to further assess the safety, tolerability, efficacy, and pharmacokinetic parameters of m102.4 (and possibly other mAbs with adequate preclinical data) for PEP and potentially early treatment of clinical disease (CEPI 2023b).
    - Additional research to determine the likelihood of escape mutants with mAb use. While evidence of escape mutants has not been found to date with m102.4, it may be necessary to consider mAb cocktails (Borisevich 2016, Playford 2020).
    - Animal studies to determine if mAb cocktails that combine several different mAbs into one formulation are more efficacious than administering one mAb alone (Dang 2021).
    - Future studies to ascertain the efficacy of m102.4 for treatment and prophylaxis against different viral strains of NiV and Hendra viruses, particularly among populations living in settings where there is the potential for an outbreak.
    - Adequate stockpiles of m102.4 (or potentially other mAbs) to ensure urgent access at the onset of an NiV outbreak.

- Given the limited number of NiV cases identified each year, a transparent and collaborative process is needed to determine which agents are most appropriate for study in future clinical trials and how best to allocate scarce resources for conducting such trials.
- A prepositioned, agreed-upon protocol for conducting clinical trials of promising therapeutics during NiV outbreaks would be of value in advancing clinical evaluation of such agents (Spiropoulou 2019).
- Diagnostic criteria and standardized testing are needed for including patients in clinical trials of therapeutics.
- Additional research needs include the following:
    - Further research to broaden the number of novel antiviral candidates (including repurposed drugs) for treatment of NiV infection and strengthen the therapeutic pipeline. Computational aided drug design is one tool that can be useful for this discovery (Yang 2023).
    - Additional data to establish the pharmacokinetic/pharmacodynamic (PK/PD) relationship of promising therapeutic candidates.
    - Additional data to determine the role of PEP and to inform development of guidance on the types of exposures that warrant such intervention and the most appropriate agents to administer. This determination should include feasibility for PEP stockpiling and distribution in both affected and at-risk areas, particularly Bangladesh, which has hundreds of potentially exposed persons annually that could be candidates for PEP.
    - Additional information to determine whether or not strain differences will affect the response to therapeutic candidates and results from clinical trials.
    - Additional data to determine the therapeutic windows for promising therapeutics for the different NiV strains, as highlighted by a recent study in AGMs that showed that the therapeutic window for m102.4 against a strain from Bangladesh/India was shorter than for a strain from Malaysia (Mire 2016).

Strategic Goals and Aligned Milestones

Strategic Goal 1: Enhance preparedness to conduct clinical trials of therapeutic agents during future NiV outbreaks.

Milestones:

1. By 2024, convene a consortium of key stakeholders—in affected areas and internationally—to address the key challenges with conducting clinical trials of therapeutic agents during future NiV outbreaks. This consortium could potentially be modeled after the West Africa Lassa Fever Consortium (WALC) (ISARIC 2023).

2. By 2025, develop NiV standard of care guidelines to be used in affected countries, disseminate the guidelines, and conduct outreach to clinicians as appropriate.

3. By 2025, complete an agreed-upon generic prepositioned protocol for conducting safety and efficacy clinical trials of promising therapeutic candidates (mAbs and small molecules, including

repurposed drugs) to be implemented in NiV-affected areas during outbreaks and develop plans for operationalizing the protocol.

4. By 2025, complete an agreed-upon generic prepositioned protocol for conducting PEP trials of promising therapeutic candidates (mAbs and small molecules, including repurposed drugs) to be implemented in NiV-affected areas during outbreaks and develop plans for operationalizing the protocol.
5. By 2026, complete a broader, harmonized regional protocol (to be used across Bangladesh and India) for conducting clinical trials of promising therapeutic candidates to be implemented in NiV-affected areas during outbreaks or potentially during periods of endemic disease (if comparable data can be generated over time and across different clinical sites) and develop plans for operationalizing the protocol.
6. By 2026, generate a reliable source or stockpile of an mAB (m102.4 or other mAb) to be used in outbreak-related clinical trials for both PEP and early clinical treatment.

Strategic Goal 2: Develop and evaluate therapeutic agents for the treatment of NiV infection and for PEP to prevent NiV infection.

Milestones:

1. By 2025, create and implement a prioritization process for determining which promising NiV therapeutic candidates should be further evaluated in clinical trials, once adequate animal data demonstrating safety and efficacy are available.
2. By 2026, complete preclinical evaluation in animal models—with administration of the therapeutic agent more than 24 hours after challenge and potentially after symptom onset—of the preliminary safety, tolerability, and efficacy of at least two promising small-molecule therapeutic candidates or combination therapies for the treatment of NiV infection.
3. By 2027, further explore in animal models whether two or three of the most promising small-molecule therapeutic candidates are likely suitable for PEP and, therefore, should be assessed as PEP in clinical trials.
4. By 2027, determine the most cost-effective and feasible routes of administration for use in real-world settings for at least two promising small-molecule therapeutic candidates.
5. By 2027, complete at least one additional clinical trial (phase 2 or 2/3) in an NiV-affected area of m102.4 or other suitable mAb to further assess safety, tolerability, and efficacy (if NiV incidence allows efficacy assessment).
6. By 2028, complete clinical evaluation of the preliminary safety, tolerability, and (possibly) efficacy of at least two promising small-molecule therapeutic candidates or combination therapies for the treatment of NiV infection.

Additional Priority Areas/Activities

Research

- **Continue to research** the safety, tolerability, and efficacy of available investigational therapies (such as m102.4, remdesivir, and favipiravir) for treating and preventing NiV infection, including conducting additional studies in animal models and clinical trials as appropriate and feasible. This should include determining the therapeutic windows for use of therapeutic agents as treatment or PEP.
- **Clarify,** in animal models, the potential for development of escape mutants from use of mAbs.
- **Continue to conduct** preclinical research on mAbs other than m102.4 and on mAb cocktails to assess safety, tolerability, and efficacy for treating NiV infection
- **Continue to expand** the pipeline of new therapeutic options for treating and preventing NiV infection that should undergo further evaluation, potentially using pseudotyped viruses for initial screening of compounds (Li 2023).
- **Consider conducting** additional challenge studies in animal models to assess whether or not ribavirin may be suitable for PEP following NiV exposure.
- **Research** optimal treatment and supportive care strategies for NiV infection and determine best-practice guidelines.

Product development

- **Continue to develop, evaluate, and license** safe and effective therapeutic agents for the treatment of NiV infection that are active against different NiV strains and other henipaviruses, and that can cross the blood-brain barrier to treat or prevent CNS disease.
- **Identify** therapeutic approaches for PEP that are broadly active against different NiV strains and other pathogenic henipaviruses that may emerge.

Key capacities

- **Ensure** that clinical trial protocols are in place and are ready to be operationalized, including obtaining appropriate approvals and conducting necessary training.
- **Promote** enhancements to the healthcare delivery systems in affected areas to improve clinical management and supportive care of patients with NiV infection and to improve infection control practices to limit person-to-person spread.
- **Ensure** that mechanisms are in place to finance, generate, and maintain stockpiles of NiV therapeutics for further clinical testing and outbreak control.

Policy and commercialization

- **Explore** strategies for decreasing the costs associated with m102.4, such as exploring the possibility of administering mAbs subcutaneously rather than intravenously.
- **Develop** guidance for the use of therapeutics for disease treatment and PEP, as new therapies become available.

VACCINES

Barriers and Gaps

Barriers

- Large clinical efficacy trials, which typically are required for vaccine licensure, will likely not be feasible for NiV vaccines, owing to the sporadic and unpredictable nature of NiV outbreaks and the low case numbers usually involved (Gómez Román 2022, Nikolay 2021, Satterfield 2016).
- In the absence of large clinical efficacy trials, authorization and licensure will likely involve nontraditional regulatory pathways to guide the evaluation of safety and efficacy (Gómez Román 2022). However, experience is limited with these routes (such as the US FDA's Animal Rule or Accelerated Approval Program, the EMA's conditional market authorization, and authorization under exceptional circumstances) and there are few successful models for vaccine authorization and approval.
- The limited commercial value of NiV vaccines may impede industry's involvement in developing and producing NiV vaccines without significant financial support (e.g., through partnerships with organizations such as CEPI, PATH, and high-income country government agencies) (Gómez Román 2022).
- The affordability of creating and maintaining an NiV vaccine stockpile and deploying vaccines during outbreaks is a key issue for low- and middle-income countries; supplementary funding will likely be required to ensure vaccine preparedness for NiV outbreaks (Gómez Román 2022).
- The absence of improved diagnostic assays for the timely diagnosis of infection creates an important challenge by delaying implementation of a rapid reactive vaccination strategy for NiV outbreak control.

Gaps

- NiV vaccines are needed that: (1) are readily accessible with adequate supply chains, particularly in low-resourced areas, (2) can protect against different NiV strains, and (3) provide rapid onset of immunity to adequately prevent and control outbreaks in a timely manner.
- Use cases for NiV vaccines need to be better defined, as how vaccines are to be used will affect vaccine deployment and manufacturing plans.
- Reference standards for NiV antibodies are needed to evaluate candidate NiV vaccines.
- Expanded partnerships among researchers, funders, and regulators are needed to advance the development of promising NiV vaccine candidates (Amaya 2020, Gómez Román 2022). NiV vaccine candidates in preclinical development target the F/G glycoproteins and a variety of platform technologies are being considered (e.g., virus vectors, protein subunits, mRNA, and virus-like particles) (Amaya 2020, Geisbert 2021, Gómez Román 2022, Loomis 2021, Monath 2022). NiV vaccine candidates based on three different platforms (protein subunits, mRNA, and viral vectors) are currently in phase 1 clinical trials (Auro Vaccines 2022, NIAID 2023, Public Health Vaccines 2023).
- Demonstrating vaccine-induced protection against NiV infection or disease in an animal model will require an immune correlate of protection (CoP) or immune surrogate that can predict the likelihood of protective efficacy and that reflects the protective immune responses generated in humans (Amaya 2020, Escudero-Pérez 2023, Price 2021).
    - Accurate and reliable CoPs for determining the protective efficacy of NiV vaccines have not yet been identified (Loomis 2021). Neutralizing IgG is generally used as a CoP, although the protective threshold still needs to be defined to allow additional vaccine

  testing in animal challenge models and eventual immunobridging of antibody responses to humans, through phase 1/2 clinical studies (Escudero-Pérez 2023, Price 2021).
  - Once the protective threshold for neutralizing IgG antibodies is determined, the most appropriate and feasible assays (e.g., assays that are developed using live NiV vs. assays developed using pseudoviruses expressing the NiV F and G glycoproteins [Luo 2023]) need to be identified and standardized for use in animal models (Price 2021).
  - Different types or titers of CoPs may ultimately be needed for different vaccine platforms, antigens, clinical outcomes (e.g., protection against infection, severe disease, chronic disease, or death) and potentially host or population characteristics to support the assessment of candidate NiV vaccines using immunogenicity and efficacy data from preclinical studies.
  - Other humoral immune responses that may be relevant as COPs include specific titers of IgM, antibodies and numbers of plasmablasts and activated B cells (Escudero-Pérez 2023). With regard to cellular immune responses, CD8+ T cell measurements may be useful as a CoP (Escudero-Pérez 2023). Additional research is needed to better define these potential CoPs, which may be particularly important for next-generation vaccines.
- Most current NiV vaccine candidates target the immunodominant fusion (F) and attachment (G) glycoproteins, which elicit potent neutralizing antibody responses (Byrne 2023, Geisbert 2021, Ithinji 2022, Loomis 2020, Loomis 2021, van Doremalen 2022, Wang 2022, Woolsey 2023). Data are needed on the potential role of additional immunogens, such as nucleoproteins and other non-enveloped proteins, in stimulating B and T cell responses that contribute to viral clearance, cross-protection, or immune memory. Robust vaccine-induced humoral and cell-mediated immunity to NiV might include protective antibodies with durable immunologic memory and rapid and efficient effector functions (Escudero-Pérez 2023).
- Additional immunologic research is needed to assess the following key elements of protective immunity against NiV infection and disease:
  - The relative contributions of innate, cell-mediated, and humoral immune responses that lead to protective immunity against NiV.
  - Specific cell types and interactions between different immune compartments in achieving viral clearance, surviving acute disease, and modulating chronic infection (Escudero-Pérez 2023, Liew 2022).
  - The roles of neutralizing and non-neutralizing or binding antibodies in protection against NiV (Liew 2022).
  - Mechanisms and cell subsets of cellular immune responses (e.g., CD8 T cell activation) that play a role in cross-neutralizing (heterologous) protection against co-circulating NiV strains (e.g., NiV-M, NiV-B, and NiV-I) (Amaya 2020, Arunkumar 2019, Escudero-Pérez 2023, Liew 2022).
  - If researchers and regulators agree that a nontraditional regulatory pathway is appropriate for licensure of NiV vaccines, then a number of issues need to be addressed, such as the following (Price 2021):
    - Generate a fully characterized and controlled virus challenge stock (or potentially one each for NiV-M and NiV-B) for assessing candidate vaccines in animal models.

  - Further characterize, as needed, at least one animal model suitable for vaccine efficacy evaluation.
  - Standardize the challenge strain and dose, and determine the most appropriate lethal NiV dose for MCM development. Challenge strains used in experimental research also need to be compared against any circulating strains in humans (CEPI 2023a).
  - Determine the most appropriate CoP or surrogate marker (e.g., IgG neutralizing antibodies) for measuring protection and generate standardized assays for measurement.
  - Bridge NiV vaccine efficacy data from animal models to humans, including identifying thresholds of vaccine protection, to determine appropriate human vaccine doses.
  - If the accelerated approval process is deemed an acceptable regulatory approval pathway for NiV vaccines, then plans will be needed to conduct well-controlled clinical trials to establish that vaccines have an effect on an appropriate surrogate endpoint that is likely to predict clinical benefit against NiVD.
  - Post-licensure clinical trials will also be needed to confirm the clinical benefit of any NiV vaccines that are approved via nontraditional pathways.
- Additional research is also needed to address the following areas:
  - Clarification of vaccine attributes (such as time from administration to immune protection, duration of immunity, and the need for booster doses) and to determine safety profiles of candidate vaccines.
  - Alternative vaccine delivery approaches, such as oral tablets or transdermal patches, to facilitate rapid NiV vaccine deployment in response to NiV outbreaks in low-resource settings.
  - Further evaluation of optimal NiV antigen combinations (e.g., including stabilized prefusion F protein trimers, multimeric G constructs, and chimeric proteins containing both pre-F and G glycoproteins), and antigen/vaccine platform combinations for generating rapid and durable protective responses to NiV infection (Byrne 2023, Loomis 2020, Loomis 2021, Srivastava 2023).
  - Research in animal models to determine if vaccine candidates are cross-protective between different NiV strains, including recently identified strains; only a few studies demonstrating cross-protection have been performed to date.
- Mathematical modelling and forecasting may be useful in (Nikolay 2021): (1) assessing whether or not disease incidence is high enough in endemic areas for conducting clinical trials of candidate vaccines, (2) simulating various epidemiologic scenarios for development of vaccination strategies, (3) estimating the potential impact of NiV vaccines (once vaccines become available), (4) estimating disease risk based on risk behaviors and practices in communities or specific population groups, and (5) estimating the vaccine quantity that may be necessary to maintain vaccine stockpiles.
- Researchers should consider efforts toward developing pan-henipavirus vaccines to maximize potential benefit, similar to projects aimed at developing pan-coronavirus

vaccines or universal influenza vaccines (Tan 2023). One strategy for developing broadly protective henipavirus vaccines involves identifying conserved epitopes or cross-reactive antibodies targeting Henipavirus F proteins (Byrne 2023, Ithinji 2022). Public communication outreach strategies that address possible vaccine uptake hesitancy in target populations and guidance for community sensitization to vaccine acceptation and promotion within the community.

- Once vaccines are available, the following will be needed:
  - Guidance on the use of NiV vaccines to include vaccination strategies for special populations (such as children, immunocompromised individuals, and pregnant women); different epidemiologic scenarios; and different vaccine attributes.
  - Enhanced surveillance capacity to assess the impact of vaccination programs and to refine vaccination strategies over time.
  - Strategic planning for stockpiling and deploying NiV vaccines.

Strategic Goals and Aligned Milestones

Strategic Goal 1: Develop the tools and policies necessary for evaluating and potentially approving one or more NiV candidate vaccines through a nontraditional regulatory pathway.

1. By 2024, generate a fully characterized and controlled virus challenge stock (or potentially one each for NiV-M and NiV-B) for assessing candidate vaccines in animal models.
2. By 2024, establish benchmark parameters (e.g., route of challenge, timing of challenge, and challenge dose) for testing of NiV candidate vaccines in animal models, with particular focus toward meeting criteria necessary for approval via a nontraditional pathway.
3. By 2024, further characterize as needed at least one animal model suitable for determining surrogate markers that correlate with vaccine efficacy.
4. By 2025, define the protective threshold against NiV infection for serum neutralizing IgG antibodies (as a CoP or surrogate marker), which can be used in animal studies and for immunobridging to humans.
5. By 2025, convene a group of key stakeholders to agree on, through a consensus approach, the most suitable assays (e.g., assays that are developed using live NiV vs. assays developed using pseudoviruses) for determining serum neutralizing IgG antibody titers for NiV vaccine R&D and develop a strategy for standardizing those assays.
6. By 2026, generate standardized assays to measure neutralizing IgG antibodies for NiV vaccine R&D, with a particular focus on assays to be used for regulatory approval via nontraditional pathways.

Strategic Goal 2: Continue to move the current NiV vaccine pipeline forward toward licensure.

Milestones:

1. By 2024, complete current phase 1 clinical trials for at least three promising NiV candidate vaccines.
2. By 2024, define use cases for NiV vaccines to inform vaccine deployment and manufacturing plans.
3. By 2026, further assess vaccine safety and immunogenicity through additional phase 1 and initial phase 2 clinical trials (preferably in affect areas) for at least two of the most promising NiV candidate vaccines.
4. By 2027, complete immunogenicity and efficacy studies in a well-characterized animal model for at least one cross-protective NiV vaccine candidate and define a surrogate marker that demonstrates likely clinical benefit of candidate vaccines.
5. By 2029, conduct well-controlled clinical trials (preferably in affected areas) to assess a surrogate endpoint in human subjects for at least one NiV candidate vaccine.
6. By 2030, complete a regulatory dossier for at least one NiV vaccine candidate based on a suitable animal model with subsequent immunobridging to humans for review via a nontraditional approval pathway.

Additional Priority Areas/Activities

Research

- **Improve understanding** of humoral (e.g., NiV-specific IgG and IgM antibodies) and cellular (e.g., CD8 T cell) immune responses to NiV infection in animal models to inform the design of vaccines and the identification of correlates of protection (Arunkumar 2019, Escudero-Pérez 2023).
- **Improve understanding** of innate immune responses (e.g., involving interferon impairment and pro-inflammatory cytokine release) in relation to humoral and cellular immune responses to NiV infection (Escudero-Pérez 2023).
- **Continue research** on identifying the key NiV antigens (including surface glycoproteins and internal proteins) that modulate the host immune response to NiV infection to inform future vaccine design (Escudero-Pérez 2023).
- **Continue to research** different types of CoPs (both humoral and cell-mediated) for NiV vaccines that are currently in the R&D pipeline and next-generation vaccines, taking into consideration different vaccine platforms, antigens, and clinical outcomes.
- **Generate** international reference standards to calibrate serologic assays for vaccine potency analyses.
- **Continue to conduct** preclinical evaluation of promising candidate NiV vaccines (current and future vaccines) for safety, immunogenicity, efficacy in animal models, correlates of protection, and durability.
- **Further study** cross protection of various vaccine candidates against different NiV strains, and between NiV strains and HeV strains.
- **Conduct** mathematical modelling to estimate the potential impact of NiV vaccines and inform strategies for vaccine use.

- **Explore** the possibility of creating pan-henipavirus vaccines that will protect against NiV, HeV, and other henipaviruses.

Product development

- **Continue to develop and clinically evaluate** safe and effective monovalent NiV vaccines for humans.
- **Expand** partnerships among researchers, government agencies, and industry to provide the resources necessary for ongoing R&D of NiV vaccines.
- **Define** vaccine attributes (such as time from administration to immune protection, durability of protection, and the need for booster doses) for the most promising candidate vaccines.

Key capacities

- **Improve** surveillance capabilities to assess the impact of vaccine use and vaccination strategies (once vaccines become available).
- **Support** plans for adequate manufacturing and stockpiling of NiV vaccines for further clinical evaluation and use when outbreaks occur.

Policy and commercialization

- **Provide** guidance on vaccination strategies for various target populations and epidemiologic scenarios that align with vaccine attributes, once vaccines are available.
- **Develop** guidance for community sensitization to vaccine acceptance and promotion within the community.
- **Consider** developing a strategy for vaccine surge capacity to rapidly ramp up the vaccine supply, if NiV is used as a bioterrorism agent or if an NiV strain emerges with increased capacity for person-to-person transmission and potential for faster spread.

Nipah R&D Roadmap Taskforce Meeting
July 31 & August 1, 2023

Background

The Nipah Research and Development (R&D) Roadmap provides a 6-year framework beginning in 2024 for identifying the vision, underpinning strategic goals, and prioritizing areas and activities for accelerating the collaborative development of medical countermeasures – diagnostics, therapeutics, and vaccines – against Nipah virus infection. The roadmap is a key component of the World Health Organization's (WHO's) R&D Blueprint Initiative, and was first drafted in 2017/2018 with input from subject matter experts, including a core group of taskforce members. WHO now aims to finalize and formally launch the Nipah R&D Roadmap, and the draft has been updated to incorporate recent scientific advances and research. The roadmap will be delivered to WHO in late 2023 for publication on the WHO website.

Meeting Objectives

The meeting objective include the following:

1. Briefly recap each of the four topic areas of the Nipah R&D Roadmap (cross-cutting, diagnostics, therapeutics, and vaccines).
2. Review the goals and milestones in each section and develop consensus on the wording and timelines for each milestone, as time allows.
3. Identify the milestones or issues that are highest priority.
4. Discuss challenges and opportunities for implementing the roadmap goals and milestones.

Meeting Format

The meeting will be held in a hybrid format; participants will join either in person at Wellcome in London, UK, or virtually. Presentations and facilitated discussions will be used throughout the 1.5-day meeting.

Meeting Agenda

Agenda times listed in British Standard Time (BST)

Day 1: Monday, July 31

8:45 am *Registration, tea, coffee, and light breakfast*

Session 1: Welcome, Introductions, and Overview

9:15 am Welcome (Josie Golding, Wellcome)

9:20 am Introductions (Michael Osterholm, Center for Infectious Disease Research and Policy [CIDRAP])

9:30 am Update on the WHO Blueprint Initiative (Marie-Pierre Preziosi, WHO)

9:40 am Overview and meeting objectives (Kristine Moore, CIDRAP)

Session 2: Nipah Cross-Cutting Issues

Session Facilitator: Emily Gurley, Johns Hopkins Bloomberg School of Public Health

9:50 am General comments on Nipah cross-cutting issues in the current roadmap draft

- Key progress in the past 5 years
- Critical areas where additional efforts are needed

10:10 am Review the Nipah cross-cutting goals and milestones

10:30 am *Break*

10:45 am Review the Nipah cross-cutting goals and milestones (continued)

11:45 am Concluding comments for Nipah cross-cutting issues

- High-priority milestones
- Barriers to implementing the goals and milestones
- Ideas Roadmap implementation for this section

Session 3: Nipah Diagnostics

Session Facilitator: Joel Montgomery, US Centers for Disease Control and Prevention (US CDC)

12:05 pm General comments on Nipah diagnostics in the current roadmap draft

- Key progress in the past 5 years
- Critical areas where additional efforts are needed

12:30 pm *Lunch*

1:30 pm Review the Nipah diagnostics goals and milestones

2:50 pm *Break*

3:05 pm Concluding comments for Nipah diagnostics

- High-priority milestones
- Barriers to implementing the goals and milestones
- Ideas Roadmap implementation for this section

Session 4: Nipah Therapeutics

Session Facilitator: Emmie de Wit, US National Institute of Allergy and Infectious Diseases (US NIAID)

3:25 pm General comments on Nipah therapeutics in the current roadmap draft

- Key progress in the past 5 years
- Critical areas where additional efforts are needed

3:45 pm Review the Nipah therapeutics goals and milestones

5:10 pm Concluding comments for Nipah therapeutics

- High-priority milestones

  - Barriers to implementing the goals and milestones
  - Ideas Roadmap implementation for this section

5:30 pm *Adjourn Day 1*
Drinks and reception

6:00 pm Dinner

Day 2: Tuesday, August 1

8:45 am *Registration, tea, coffee, and light breakfast*

9:15 am Welcome for Day 2 (Michael Osterholm, CIDRAP)

Session 5: Nipah Vaccines

Session Facilitator: Pending

9:20 am General comments on Nipah vaccines in the current roadmap draft
  - Key progress in the past 5 years
  - Critical areas where additional efforts are needed

9:40 am Review the Nipah vaccines goals and milestones

10:15 am *Break*

10:30 am Review the Nipah vaccines goals and milestones (continued)

11:10 am Concluding comments for Nipah vaccines
  - High-priority milestones
  - Barriers to implementing the goals and milestones
  - Ideas Roadmap implementation for this section

Session 6: Nipah R&D Roadmap Implementation and Next Steps

11:30 am Discussion: Roadmap implementation (Marie-Pierre Preziosi, WHO)

12:15 pm Discussion: Publication process (Kristine Moore, CIDRAP)

12:25 pm Wrap up and next steps (Michael Osterholm, CIDRAP)

12:30 pm *Meeting close*

12:30 pm *Lunch*

Subject: Revised version of the Nipah R&D roadmap and near-final agenda for the July 31 and August 1 meeting at Wellcome in London
Date: Thursday, July 13, 2023 2:55:19 PM
Attachments: Nipah RD Roadmap.Revision.July2023.ForTFReview.docx
Nipah_Agenda_NearFinal.Draft.docx

Dear Colleagues: Attached please find the revised version of the Nipah R&D Roadmap for your review. This version contains extensive updates from progress made over the past 5 years and includes many additional references from the recent literature.

Please review this version **in advance** of the Nipah taskforce meeting. In the interest of time, during the meeting **we will focus primarily on discussing the goals and milestones**. We would also like to spend some time discussing roadmap implementation.

Following the meeting, we will revise the roadmap and will send it out to taskforce members for your written feedback and comments.

We have also included a near-final agenda of the meeting for your information.

Thank you, again, for your involvement in this important effort. I look forward to seeing many of you either in-person or virtually at the end of the month.

Kind regards,

Kris

A. BACKGROUND AND SIGNIFICANCE. Paramyxoviruses, nairoviruses, and arenaviruses are widely distributed RNA viruses that cause severe human syndromes. Because of their geographical distribution and expansion, changes in human demographics and increased exposures to wild animals including rodents and bats, and their capacity for human-to-human spread, these viruses have the potential to cause pandemics. Together with the other investigators in **PABVAX**, we have selected several important prototype paramyxoviruses, nairoviruses, and arenaviruses to study to learn the rules governing immunity to these pathogens. The work on the pathogens selected is justified based on their prevalence and severity alone, but also because of their ability to serve as prototypes for genetically related viruses. We chose the viruses for focus in this RP4 on human antibody development because of their clinical relevance and because several will be studied as prototypes for vaccine development in **RP1** (arenaviruses, nairoviruses) and **RP2** (paramyxoviruses). Among the arenaviruses, we will target Lassa virus (LASV) and Machupo virus (MACV), and among the nairoviruses, we will study Crimean–Congo hemorrhagic fever virus (CCHFV). In tandem with the vaccine project in **RP2** focused on paramyxoviruses, we will study Nipah virus (NiV) and Hendra virus (HeV) as the prototypes. Information about the principles we discover about critical neutralizing epitopes identified here in **RP4** with prototype viruses can feed back into all other **Projects** that address the subsequent plug and play test cases in later years (Lujo, Chapare, Kasokero, Langya).

LASV is an Old World arenavirus (OWAV) with a single-stranded RNA virus belonging to the Arenaviridae family. Infection in humans is often the result of exposure to infected excreta from the rodent reservoir, *Mastomys natalensis* where up to 500,000 cases and an estimated 5,000 deaths occur annually in West Africa[2]. While rodent infection is largely benign, human infection can result in severe hemorrhagic disease with neurological complications and long-term hearing and vision sequelae[3,4]. There are no approved vaccines or treatments for LASV infection. **MACV** is a New World Arenavirus (NWAV) and the causative agent of Bolivian Hemorrhagic fever. Humans are infected after exposure to excreta from the reservoir, *Calomys callosus,* the large vesper mouse. Disease in humans has a slow onset, but can progress to severe hemorrhagic fever coupled to insidious neurological complications including tremors, seizures, and paralysis[5]. There are no approved vaccines or therapies approved for MACV. **CCHFV** is a highly pathogenic tick-borne virus classified under the Nairovirus genus within the Bunyaviridae family[6]. CCHF outbreaks have a case fatality rate of up to 40%, and there are no vaccines or treatments approved for human use. **NiV/HeV.** Bat-borne, NiV and HeV are enveloped, negative-sense, single-stranded RNA viruses belonging to the Henipavirus genus within the Paramyxoviridae family[7]. These emerging zoonotic viruses pose a significant threat to human and animal health due to their high fatality rates and broad host range. As with the other prototype virus in the **PABAX** Center, there are no vaccines or treatments against henipaviruses licensed for human use.

Antibodies (Abs) are important correlates of protection for paramyxoviruses, nairoviruses, and arenaviruses. Immune sera against members of each of these groups of viruses has been shown to exhibit protective efficacy *in vivo*, which supports the use for Abs as treatment options. However, the specificity, functional properties, and other attributes of protective antibodies are poorly defined for most of these viruses. MAbs to the attachment and fusion surface proteins of paramyxoviruses (such as the G and F proteins of Hendra/Nipah[8,9] and the GP proteins of the arenaviruses like LASV[10,11]) can neutralize and protect against infection in rodent models. CCHFV is a bit of a conundrum in that ultrapotent human neutralizing antibodies to the related Rift Valley fever virus surface proteins are highly protective *in vivo*[12,13], but CCHFV neutralizing antibodies are not protective. In contrast, some non-neutralizing antibodies do protect partially for CCHFV[14]. Clearly, there is a lot to learn about the rules of immunity to these viruses, and the genetic, molecular, and structural basis of antibody-mediated protection for viruses like CCHFV. Based on these data, we propose the use of mAbs as treatment options to learn the rule of how to protect against emerging paramyxoviruses, nairoviruses, and arenaviruses and to develop candidate antibody countermeasures for translational development with **Core D**. To do so, we will further develop our technical methods for rapidly discovering mAbs, in the case of a future unexpected epidemic caused by viruses of these families. Most importantly, we will define the principles governing combination antibody therapy to prevent virus escape from treatment or prevention and to optimize the efficacy of the beneficial effects conferred by passive immunity.

B. SCIENTIFIC PREMISE. The work proposed here in **RP4** is based on the extensive basic, translational, and clinical trial data on the role of neutralizing Abs in protection against infection and disease caused by paramyxoviruses, nairoviruses, and arenaviruses. Although a significant amount of data supports the use of mAbs to prevent or control paramyxovirus, nairovirus, and arenavirus infection, many questions remain, such as the ideal epitopes to target with mAb combination therapy to improve upon neutralization potency, *in vivo* efficacy, and resistance to viral escape. Identifying these epitopes can help inform vaccine design to elicit optimal protective polyclonal responses (in **RP1** and **RP2**, especially with designs for test cases in years 4 and 5). Here we aim to refine our understanding of the correlates of mAb protection against paramyxoviruses, nairoviruses, and arenaviruses to enable the design of a modular "plug-and-play" workflow to rapidly respond to potential

pandemics by generating optimized combinations of vaccine-like mAbs with an extended half-life that could be used for long-term prophylaxis (> 6 months) and therapy.

C. INNOVATION. RP4 has many innovative conceptual and technical features including: Conceptual. **(1)** determining the principles that govern optimal combinations of human mAbs against paramyxoviruses, nairoviruses, and arenaviruses for protection and resistance to viral escape; **(2)** the development of a clear workflow that generates therapeutic or preventative antibodies (long half-life mAbs that serve as vaccine surrogates) against emerging or new paramyxoviruses, nairoviruses, and arenaviruses with pandemic potential. Our goal is to define the principles and features, including epitope, combination ratios, and mechanisms of action, that result in optimal efficacy of mAbs against paramyxoviruses, nairoviruses, and arenaviruses in animal models and create a higher barrier for resistance. These studies will serve as paradigms for rapid antibody discovery in response to future paramyxovirus, nairovirus, and arenavirus pandemic threats. Technical. **(3)** large-scale B cell repertoire sequencing with customized methods and software; (**4**) use of humanized (Alloy) mice and novel immunogens from **RP1** and **RP2** and **Core D**; **(5)** single B cell functional (neutralization) assays performed on a Beacon instrument; **(6)** development of high-throughput real-time label-free virus neutralization assays (xCELLigence platform); and **(7)** use of *simultaneous* in parallel screening with several different high-throughput virus-specific B cell isolation approaches (Beacon, 10X Genomics, Rhapsody) to generate and validate best-in-class human mAbs as candidate medical countermeasures.

D. LINKAGE TO OTHER PABVAX PROJECTS AND CORES. The group will focus on developing a modular test case platform for rapid selection of highly neutralizing and/or protective mAbs against paramyxoviruses, nairoviruses, and arenaviruses. Members of our group have active collaborations with most members of the **PABVAX Center** as reflected in previous collaborations and publications (see **Overall** document). We will interact extensively with the Animal Model and Preclinical Evaluation Core (**Core E)** to study neutralization against authentic viruses and to test for protection in small and large animals as well as with **RP3** for testing paramyxovirus mAbs. The knowledge gained from our studies on the structure-function relationships of neutralizing mAb combinations can be applied to rational vaccine design for **RP 1** and **RP2** in later years of the effort when we pivot to apply the lessons learned to the same test case targets as **RP1** and **RP2.** Numerous antigens will be made available to our RP. Finally, long-half-life Fc mutations are now available based on engineering of human IgG1 for enhanced binding to the neonatal Fc receptor (FcRn) such as LS (M428L /N434S)[15], or YTE (M252Y/S254T/T256E)[16] mutations. With ≥ 90 days half-life in humans, our approach will generate mAbs with vaccine-like properties that remain effective for months during a virus epidemic and thus provides a platform for response to future paramyxovirus, nairovirus, and arenavirus pandemic threats, a key goal of our **PABVAX Center.** *Our laboratory previously validated this vaccine surrogate concept when we isolated the human mAbs that formed the basis for Evusheld with YTE long-half-life Fc mutations (used in 70 countries and millions of people) that exhibited > 6 months protective levels in humans after single IM injections*.

E. APPROACH

E.1. Specific Aim 1. Discover potently neutralizing arenavirus mAb combination therapies. For the prototypes, we will focus on LASV, an Old-World virus and MACV, a New-World virus. We will investigate the principles underlying antibody-mediated arenavirus protection. Preliminary evidence suggests that potent virus neutralization is a mechanistic correlate of protection for arenaviruses[17,18]. **RP1/Core D** will provide optimized antigens for mAb selection for the Prototype LASV and MACV (or subsequent Test Cases). We will use a workflow for rapid identification of potently neutralizing mAb combinations for LASV and MACV. We will generate mAbs from individuals with prior natural infection or use transgenic mice with human antibody repertoires. A large panel of human anti-LASV and anti-MACV mAbs will be generated using multiple approaches (immune human B cells and immunized humanized mice), and highly neutralizing mAbs will be evaluated to identify optimal combinations. The best mAb combinations will be assessed to determine the minimal effective dose for protection, and the lead mAb combination therapy(ies) will be transferred to **Core E** for further evaluation and ultimately testing in an NHP model of LASV or MACV infection. Leads will be transferred to **Core D** for further translational development as medical countermeasures. The prototype LASV and MACV will be studied in years 1 to 3, followed by mAb discovery efforts for Test Cases Lujo and Chapare viruses based on the established principles in years 4-5.

Preliminary Data. ***(a) Potently neutralizing human anti-arenavirus mAbs.*** The Crowe laboratory has previously characterized panels of neutralizing human anti-viral human mAbs from virus-immune or vaccinated individuals for about 50 viruses, mostly RNA viruses. Isolated peripheral blood mononuclear cells (PBMCs) are used to generate hybridomas or alternatively antigen-sorted at single B cell level and antibody variable genes sequenced to generate mAbs recombinantly. Panels of human anti-viral mAbs are produced rapidly (we recently reported isolation of 15,000 mAb gene pairs from single Ebola-virus-specific human B cells from a single blood sample of an immune individual[19]. Previous studies by others clearly show that representative neutralizing and protective human antibodies can be isolated from LASV-immune subjects[20-24]. In this Aim, we will refine the approaches we have developed previously for other RNA viruses in a proof-of-concept study by identifying potently neutralizing combinations of anti-LASV and anti-MACV human mAbs. We will rapidly discover human anti-LASV mAbs from LASV-immune individuals and human anti-MACV mAbs by immunizing Alloy transgenic mice. Synergy studies will be performed to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify optimal anti-LASV and anti-MACV mAb combinations and further advance the discovery platform for rapid response against emerging arenaviruses.

(b) Advanced mAb technologies. The Crowe laboratory has developed some of the highest yield systems to isolate naturally occurring human mAbs using human hybridoma or advanced single-cell RNA-seq methods (**Fig 1**). We have used sorting of antigen-specific cells with recombinant viral surface protein antigens (like the GP1 and GP2 proteins we will use here), cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. One variation we will use is to capture Ab genes directly from viral glycoprotein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), as we have done for Ebola virus[19,25] and SARS-CoV-2[1,26-31]. These single-cell techniques enhance the capture of rare antigen-specific B cells.

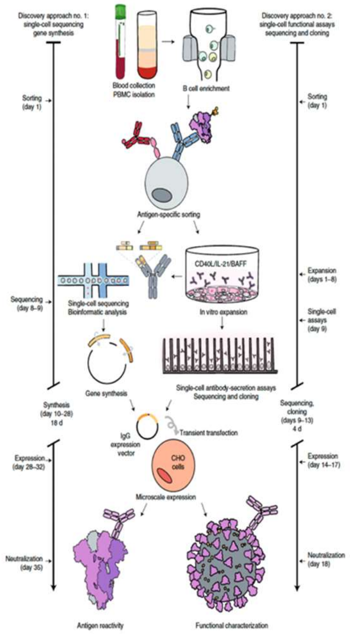

Figure 1. Single cell mAb discovery. PBMC samples are used to enrich for B cells, which can be sorted for antigen-specific B cells. Expansion allows us to further assess the functionality of the B cells or for antibody sequencing. Recombinant mAb expression validates the mAb sequence and functional activity. Figure is adapted from [1].

E.1.1. Rapid isolation of human anti-LASV and anti-MACV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from one previously LASV-infected individual who was medically managed previously by Emory University in their infectious diseases containment unit. This person has a documented robust neutralizing serum antibody response, suggesting isolation of neutralizing human mAbs from these PBMC aliquots will be straightforward for us. Our colleagues in **RP1** have ongoing field operations for over a decade in Sierra Leone, Liberia, and Nigeria. This work is currently in association with the NIH-Centers for Research on Emerging Infectious Diseases (CREID) with a heavy focus on the study of LASV ecology, epidemiology, and host responses. **RP4** is currently working with **RP1** on obtaining PBMCs from ~10 individuals with prior laboratory-confirmed cases of LASV. The acquisition of these samples is being managed by the Vanderbilt Vaccine Center Biorepository with separate institutional funding to be de-identified prior to use in the studies proposed here. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies have been approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples will be deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded. For anti-MACV mAbs, as a human PBMC source is not readily available, we will immunize Alloy humanized mice. These animals yield PBMCs that secrete fully human mAbs. Alloy mice are used routinely in the Crowe lab workflow.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-LASV and anti-MACV mAbs in a rapid manner to mimic a pandemic response to an outbreak. We will single-cell sort antigen-specific B cells using recombinant LASV or MACV proteins (*e.g.*, **Table 1)** or non-infectious viral particles as bait. These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including LASV and MACV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe GP protein or virus-particle binding to single B cells. These cells are exported for sequencing of the variable gene regions and analysis using the PyIR software developed in the Crowe laboratory. We will select a panel of up to 500 neutralizing anti-LASV mAbs and a similar number of anti-MACV mAbs to express recombinantly and advance for further characterization. We can easily conduct multiple approaches simultaneously in parallel[1,32].

Table 1. Antigens from Core D
Lassa Josiah NP
Lassa Josiah GPe
Machupo GPe
Machupo NP

(c) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using a custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors.

(d) Micro-scale mAb expression. The Crowe laboratory has the capacity for large-throughput micro-scale mAb expression and purification. The lower end of this range allows expression of thousands of mAbs, which will feed into automated mAb purification platforms. This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(e) A CPE-based LASV and MACV neutralization assay using RTCA. We have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of cytopathic effect (CPE). Here, we will apply this method to assess neutralization of LASV. Recently, we validated the inclusion of simultaneous live-cell fluorescence microscopy into this real-time CPE-based screening platform (xCelligence RTCA eSight). These capabilities expand the platform to screen viruses that may or may not induce CPE, allowing us to also use a replication-competent vesicular stomatitis virus (VSV) LASV surrogate that expresses LASV surface proteins and causes CPE[33]. Currently, we have a VSV-LASV-Josiah (lineage IV)[33] and a Sauerwald version (lineage II) of these recombinants. Making additional LASV VSV-LASVs is not difficult, and **RP1** will make the other missing lineages or needed arenaviruses based on the same approaches as previously published. **RP1** also can easily make versions of these VSVs that express the green fluorescent protein (GFP) reporter gene. Existing VSV-CCHFV, VSV-NiV, and VSV-HeV vectors[34-36] will be provided by Dr. Geisbert overall PI and Lead of **Core E**. We already have Vanderbilt IBC approval for use of these constructs. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression if used will identify mAbs with neutralizing activity against LASV. These mAbs will be moved forward for additional studies to identify an optimal anti-LASV mAb combination. Similar processes will be followed to determine neutralization capacity of MACV mAb candidates.

E.1.2. Identifying LASV and MACV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind LASV or MACV and validate their epitopes. We will perform competition-binding studies with GP or subunit proteins (as above) or virus-like particles (VLPs)[37] available from **Core E** at UTMB. **Core E** will also inactivate LASV and MACV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from previously reported antibodies for the identification of mAbs that can concurrently bind LASV or MACV with a goal of finding more potent clones at those sites or clones that complement these inhibitory mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-LASV or anti-MACV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations for each virus, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key residues binding residues of human anti-LASV and anti-MACV mAbs.*** To determine the key residues for binding of down-selected mAbs, we will perform deep mutational scanning[38]. Briefly, all amino acids of the GP proteins will be mutated to the other 19 amino acids with a unique barcode using PCR-based mutagenesis. The LASV or MACV GP protein library will be incubated with the appropriate mAbs to identify residues with loss-of-binding phenotypes. A sequence 'logo' showing the relative contributions of each amino acid mutation will identify residues critical for binding. Multiple amino acid substitutions can then be assessed by reverse genetics at UTMB to confirm the epitopes recognized by the down-selected mAbs. This method also serves as a surrogate for *in vitro* neutralization escape studies. ***(d) Neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-LASV or VSV-MACV constructs at BSL2 in the presence of saturating concentrations of mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Confirmatory reverse genetics studies will be performed by introducing mutations into an infectious cDNA clone of LASV or MACV by **RP1** to test neutralization. We hypothesize that escape will be less likely in the presence of mAb combinations than single mAbs. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of escape variants in the presence of mAbs.

E.1.3. Structural basis of neutralization by mAb combinations. The studies above should identify optimal anti-LASV and anti-MACV mAb combinations that simultaneously bind, neutralize, and increase the barrier for viral escape under mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb

combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for arenavirus by identifying key epitope targets (**RP1**).

E.1.4. Protective efficacy of human anti-arenavirus mAbs. ***(a) Studies in guinea pigs***. MAbs that satisfy the criteria stated above and that display stage-appropriate manufacturability characteristics will advance to *in vivo* testing. We will use established models of LASV[11,39] and MACV[40,41] infection in guinea pigs. PABVAX **Core E** has access to many strains from different LASV and MACV lineages, which will be tested. For prioritization, we will focus on LASV lineage II, III, and IV strains and MACV lineage I, II, and VIII strains for which uniformly lethal models are available. Groups of 6 outbred Hartley guinea pigs will be treated with low, medium, and high doses of single or combinations of anti-LASV or anti-MACVs mAb, or isotype controls at day +1 after inoculation with the LASVs or MACVs This approach allows us to determine whether combinations provide advantage over the best monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-LASV and anti-MACV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements (blood) at day 5 or 6 after LASV or MACV challenge and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal LASV and MACV mAb pairs that are comparable to or outperform previously reported mAbs for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-LASV and anti-MACV mAb combination against LASV or MACV in NHPs. As a final test of an optimal anti-LASV and anti-MACV mAb combinations, we will assess protective efficacy of the lead anti-LASV mAb pair in NHPs as well as the anti-MACV mAb pair in NHPs. These anti-LASV and anti-MACV mAb pairs will be selected based on the *in vitro* and guinea pig data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys will only be considered pending success in the guinea pig studies and consultation with the external Scientific Advisory Board (SAB) and NIAID program staff.

E.1.5. Applying lessons learned in LASV and MACV research with the selected test case pathogens for mAb generation: Lujo and Chapare mAbs. Once we have completed the LASV and MACV discovery campaigns, will turn to the test case pathogens to see if we can use the prototype pathogen approach to related viruses, Lujo (LUJV) and Chapare (CHAPV). We do not have access to human PBMCs from LUJV - or CHAPV-immune donors. As an alternative approach, we will use humanized mouse models as a source of B cells encoding fully human monoclonal antibodies. The Vanderbilt core investigators have an established fully executed agreement to use Alloy human antibody mice for this purpose (See Letter of Support). The Alloy ATX-Gx™ mouse is one of the most effective *in vivo* human antibody discovery platforms, with over 140 partners and counting. This mouse system was originally invented and validated inside a major pharma company and then further developed by Alloy. This foundational suite of highly immunocompetent transgenic mice is engineered to drive the greatest potential diversity of unique human antibodies binding to the viral target of interest, with broad epitopic coverage. The comprehensive functional human antibody repertoire in these mice is optimized for human Ab sequence developability and diversity. Alloy and Vanderbilt have already executed a simple licensing process for use of the ATX-Gx platform, and as an established partner the Vanderbilt core team will access the expanding portfolio of transgenic Alloy strains designed to address a range of discovery challenges (including diverse Ab isotypes). Mice will be immunized with conformationally correct recombinant protein antigens (**Table 2**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for the target of interest. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for LASV and MACV.

<u>**Anticipated results, potential problems, and alternative approaches**</u>**.** In this Aim, we will identify human anti-LASV and anti-MACV mAb combinations with optimal neutralizing and protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging LASV, MACV, or related arenaviruses. Given our previous ability to generate human antiviral mAbs, we do not anticipate problems in isolating anti-LASV or anti-MACV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently neutralizing anti-LASV or anti-MACV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody™) on enriched B cells (*i.e.*, memory B cells) isolated from human LASV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in LASV-immune PBMC samples and identify clonal lineages, including

siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-LASV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-LASV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-LASV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-LASV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the high-throughput Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E2. Specific Aim 2. Discover a protective CCHF virus mAb combination therapy. Establishing the generality of protection approaches against nairoviruses, we will perform a mAb discovery proof-of-concept campaign for the Prototype CCHFV. Preliminary studies have identified human anti-CCHF mAbs with varying levels of protection in experimentally infected animals[14,42,43]. We will isolate a large panel of human anti-CCHFV mAbs and determine the rules governing optimal mAb combinations through competition-binding, epitope mapping, neutralization, and viral escape studies. Lead antibodies with acceptable manufacturability characteristics (**Core D**) and the highest capacity to overcome resistance while maintaining potency of protection will be selected. The structural basis of their activity will be established using structural biology techniques (electron microscopy and crystallography). Lead mAb cocktail therapies will be evaluated for *in vivo* protective efficacy in STAT1$^{-/-}$ mice (with **Core E).** As a final test of an optimal anti-CCHFV mAb combination, we will assess protective efficacy of the lead anti-CCHFV mAb pair in NHPs, to be selected based on the *in vitro* and mouse data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys studies would only be considered pending success in the mouse studies and consultation with the external Scientific Advisory Board and NIAID program staff. In years 4-5, we will apply the lessons learned to the plug and play test case Kasokero virus (KASV) in collaboration with **RP1**, **Core D**, and **Core E**.

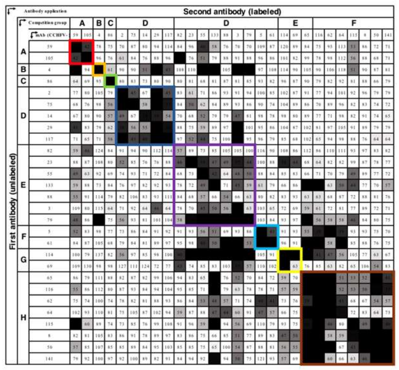

Figure 2. Competition assessment of human Abs to CCHFV using M-segment expressing cells. We tested 28 mAbs in competition assays. MAbs are displayed in 8 groups (A-H) based on their ability to compete for binding. Values shown are the % of binding that occurred during competition compared to non-competed binding of the mAb. This value was normalized to 100%. The values are also indicated by the box fill color; darker colors toward black indicate higher competition and lighter colors toward white indicate less competition, on a gradient scale.

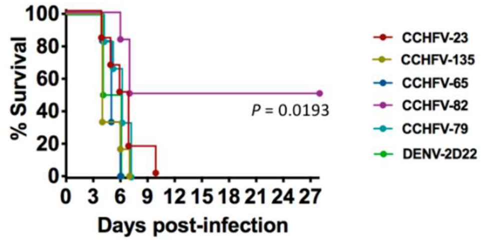

Figure 3. Human mAb CCHF-82 provides partial protection as a post-exposure prophylaxis against the Turkish strain of CCHFV in the STAT1$^{-/-}$ mouse model. A single dose of mAb was administered by the IP route to mice (n=6 per group (3 male, 3 female)) at 30 min post infections. A lethal dose of Turkish strain of CCHFV was administered. CCHF mAbs or DENV-2D22 (an isotype-matched negative control mAb) were tested in a single dose of 250 µg per mouse. Kaplan-Meier survival curves were statistically analyzed using a log-rank (Mantel-Cox) test where mAb-treated animals (*P* value shown in figure) were compared to animals treated with the DENV-2D22 negative control mAb. Unpublished data.

<u>Preliminary Data</u>. ***(a) Potently neutralizing and non-neutralizing human anti-CCHFV mAbs.*** In this Aim, we will rapidly discover human anti-CCHFV mAbs from CCHFV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify an optimal anti-CCHFV mAb combination and further advance the discovery platform for rapid response against emerging nairoviruses. In preliminary experiments in collaboration with investigators in **RP1** and **Core E**, the Crowe laboratory has previously isolated and characterized panels of neutralizing human anti-CCHFV human mAbs from individuals who were convalescent after naturally-acquired laboratory-confirmed infection in Spain or Turkey. We isolated a panel of antibodies against CCHFV that recognize the M-segment in transfected cells, and they exhibit a diversity of recognition patterns in that they fall into multiple competition-binding groups (**Fig 2**). This panel contains cross-binding and cross-neutralizing antibodies for diverse strains. We observed a human mAb designated CCHF-82 competing with competition group 1 and group 2 antibodies from the previously isolated GP38-reactive murine antibodies. CCHF-82 showed some protection in a STAT1$^{-/-}$ mouse model of infection conducted by investigators in **RP1 (Fig 3)**. Further investigation with this antibody in the IbAr10200 prophylaxis and therapeutic models is warranted. In contrast, the CCHFV-neutralizing mAbs that we isolated and tested *in vivo* did not perform well in the Turkish strain STAT1$^{-/-}$ mouse model. We now know protection in this model is possible, given the work from Fels *et al*., 2021 who showed that potent antibodies against various sites on the Gc surface can afford protection in this model[42]. However, in their study they did not test GP38-reactive antibodies. To our knowledge, our preliminary

data is the first indication that a human GP38-targeting antibody can provide some protection in this mouse model.

Non-neutralizing murine mAbs protect in mouse models of infection[14], but it is unknown if the human antibody response could provide similar levels of protection. Murine mAb 13G8 binds to GP38 and does not neutralize CCHFV. This mAb provides protection against lethal challenge as a prophylaxis and a therapeutic against CCHFV. In preliminary experiments we sought to understand if human survivors of CCHFV infection possess B cells encoding mAbs that bind a similar epitope as 13G8 and provide protection. CCHF-82 competes for binding with 13G8 to preGn-transfected cells containing GP38. This antibody offered some protection as a post-exposure prophylaxis against the Turkish strain of CCHFV (**Fig 3**). Human antibodies like this should be further studied and the frequency of these clones should be elucidated to understand if this is a feasible strategy for future vaccine efforts for humans. The epitope that 13G8 and CCHF-82 identifies could inform vaccine design if these antibodies offer protection in larger animal models. Understanding how non-neutralizing antibodies function is critical in efforts to validate the GP38-binding class of antibodies. Golden *et al.* undertook a study to understand the mechanisms 13G8 functioned and observed that complement activation contributes to the protective capacity of this antibody[14]. Here, in studies of CCHF-82, we also will assess complement activation in mouse models of infection to fully understand the function of this mAb *in vivo*. Furthermore, if this mAb protects in the CCHFV IbAr10200 strain challenge model, assessing its mechanism is warranted. Together with **Core D**, we will assess IgG molecules with complement knockout ("KA") and Fc gamma receptor knockout (LALA-PG) mutations in the Fc domain to study this matter. Human mAb CCHF-82 displayed limited cross-protection against experimental infection with the Turkish strain of CCHFV. Our antibody isolation here will aim to identify cross-protective non-neutralizing antibodies reactive with GP38. Recently, vaccinating with NP was shown to be another way to elicit non- neutralizing antibodies[44]. The NP of CCHFV is more conserved than the glycoproteins and might also be a non-canonical target for the identification of cross-protective non-neutralizing antibodies[44].

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant viral surface protein antigens, cloning of Ab variable genes, and then expression of mAbs as as described above in Specific Aim 1.

E.2.1. Rapid isolation of human anti-CCHFV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from a number of previously CCHFV-infected individuals. One was a health care survivor who was infected while caring for a patient in Spain[45]. We also collected a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Turkey, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples were only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies were approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples were deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-CCHFV mAbs rapidly, as if we had to respond to a nairovirus outbreak in real time. Our ability to respond rapidly in the setting of outbreaks is well-documented in the lay press (60 Minutes features and others) and the scientific literature, e.g., 78 days from sample to protection of NHPs for Zika virus[32], and 25 days from PBMC sample receipt to delivery of the antibody genes for the approved COVID-19 drug Evusheld to AstraZeneca[1]. Here, we will single-cell sort antigen-specific B cells using recombinant CCHFV proteins (GP38, Gc, Gn, Gc/Gn) or non-infectious particles as bait as described in Specific Aim 1. We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D**, (**Table 3**) or by **RP1 (Table 4)**.

(c) Recombinant mAb cloning. As described in Specific Aim 1 above.

(d) Micro-scale mAb expression. As described in Specific Aim 1 above.

(e) A CPE-based CCHFV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of CCHFV. We will use a rVSV CCHFV surrogate that expresses CCHFV surface proteins and causes CPE[35]. Investigators in **RP1** have the VSV-CCHFV-GFP versions of clades 1 through 7 based on this publication. We will obtain these VSV constructs from investigators in **PABVAX**. Existing VSV vectors will be provided by investigators in **RP1 and Core E**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against CCHFV. These mAbs will be moved forward for additional studies to identify an optimal anti-CCHFV mAb combination. GP38-reactive clones will be advanced based on avidity ranking since they are not likely to be neutralizing but may be protective *in vivo*.

E.2.2. Identifying CCHFV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind CCHFV surface proteins and validate their epitopes. We will perform competition-binding studies with CCHFV Gc/Gn or subunit proteins (as above) or CCHFV virus-like particles (VLPs) made from a replicon system in hand. **Core E** will inactivate CCHFV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site. Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from some of the mAbs shown in the unpublished preliminary data above for the identification of mAbs that can concurrently bind CCHFV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-CCHFV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. GP-38-reactive clones will be screened for synergistic binding as they are not expected to be neutralizing. ***(c) Identification of key binding residues of human anti-CCHFV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-CCHFV constructs at BSL2 in the presence of saturating concentrations of CCHFV mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of VSV-CCHFV escape variants in the presence of mAbs.

E.2.3. Structural basis of neutralization by anti-CCHFV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.2.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies in STAT1$^{-/-}$ mouse models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (Core D), will advance to *in vivo* testing. We will use an established STAT1$^{-/-}$ mouse model of CCHFV infection that the **RP1** and **Core E** investigators have deployed[35]. To benchmark our mAbs, a separate set of STAT1$^{-/-}$ mice will be treated with CCHF-82, which we showed in unpublished preliminary data above confers substantial but incomplete protection (**Fig 3**). The **Core E** laboratory has access to strains representing all 6 clades that can be tested. Groups of 6-8 STAT1$^{-/-}$ mice will be treated with low, medium, and high doses) of single or combinations of anti-CCHFV mAb, or isotype controls at day +1 after inoculation with CCHFVs. This approach allows us to determine whether combinations provide advantage over the best CCHFV monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after CCHFV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal CCHFV mAb pairs that are comparable to or outperform the mAbs we reported above. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-CCHFV mAb combination against CCHFV in NHPs. As a final test of an optimal anti-CCHFV mAb combination, we will assess efficacy of the lead anti-CCHFV mAb pair in NHPs (**Core E**), to be selected based on the *in vitro,* STAT1$^{-/-}$ mice, and manufacturability data (**Core D**). Down-selection for testing in cynomolgus monkeys would only be considered with success in the STAT1$^{-/-}$ mouse studies and in consultation with the external SAB and NIAID program staff.

E.2.5. Applying lessons learned in CCHFV research to Kasokero mAbs. Once we have completed the CCHFV discovery campaigns, will turn to the test case pathogen Kasokero virus to see if we can use the prototype pathogen approach for this virus. We do not have access to human PBMCs from Kasokero-immune donors. We will use Alloy humanized mouse models as a source of B cells encoding fully human mAbs, as described above. Mice will be immunized with conformationally correct recombinant protein antigens (**Table 5**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Kasokero. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for CCHFV.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-CCHFV mAb combinations with optimal protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging CCHFV or related nairoviruses. Given our previous ability to generate human anti-CCHFV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-CCHFV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-CCHFV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (i.e., memory B cells) isolated from human CCHFV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in CCHFV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-CCHFV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-CCHFV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-CCHFV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-CCHFV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E3. Specific Aim 3. Establish optimal mAb combination therapies against henipaviruses Hendra (HeV) and Nipah (NiV) viruses. We will use a large panel of potent anti-henipavirus mAbs that we previously made from the memory B cells of immune individuals and generate new antibodies targeting the fusion (F) protein. **RP2** will provide new antigens for mAb selection and BSL-2-compatible viruses for neutralization screens including Cedar virus constructs displaying HeV and NiV F and G proteins. We will identify optimal mAb combinations to enhance henipavirus therapy, minimize viral escape, and improve treatment efficacy through synergy. *In vitro* competition-binding, neutralization, and mechanistic studies will be conducted, including authentic virus neutralization with **PABVAX Core E**. We will refine the recognized epitopes and investigate the structural basis for optimal combination neutralization of henipaviruses using HeV and NiV as prototypes. *In vivo* assessment of mAb combinations will determine the minimal effective dose for protection and the ability to prevent *in vivo* escape. Protective efficacy of lead mAb combinations will be assessed in hamster models of NiV and HeV infection with **Core E**. Leads will be transferred to **Core D**. As a final test of optimal henipavirus mAb combinations, we will assess protective efficacy of the lead henipavirus mAb pairs in NHPs, to be selected based on the *in vitro* and hamster data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in African green monkey (AGM) henipavirus model studies would only be considered pending success in the hamster studies and consultation with the external SAB and NIAID program staff. The HeV and NiV studies will be conducted in years 1-3 and then applied to the plug-and-play test case Langya virus in years 2-5. If **RP2** and **Core E** cannot rescue recombinant Langya virus, the lessons learned in Years 1-3 will be applied to the alternate "plug and play" test viruses Angavokely or Sosuga (SOSV) virus. Preliminary data on SOSV mAbs are provided.

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-NIV/HeV mAbs.*** In this Aim, we will further adapt approaches we have developed in preliminary experiments with henipavirus mAb studies by identifying a potently protective combination of anti-NiV/HeV human mAbs. Through these studies, we aim to identify an optimal anti-NiV+HeV mAb combination and further advance the discovery platform for rapid response against emerging paramyxoviruses, especially henipaviruses. In previous experiments in collaboration with investigators in **RP2** and **Core E**, the Crowe laboratory has isolated characterized panels of neutralizing human anti-G NiV/HeV human mAbs from an individual with G-based immunity following occupational exposure to an equine HeV G subunit vaccine. Isolated peripheral blood mononuclear cells (PBMCs) were used to generate human B cell hybridomas secreting human mAbs to G, and antibody variable genes were sequenced to generate mAbs recombinantly. We isolated a panel of antibodies against the G protein that recognize the HeV G, NiV Bangladesh G, and NiV Malaysia G proteins. The mAbs exhibited a diversity of recognition patterns in that they fall into multiple competition-binding groups. This panel contains cross-binding and cross-neutralizing antibodies for diverse NiV and HeV strains. In the work proposed here, we will rapidly discover human NiV/HeV anti-F mAbs from NiV-immune individuals and outstanding potency anti-G antibodies with extensive characterization, including synergistic neutralization.

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant henipavirus F protein antigens, as described above in Specific Aim 1.

E.3.1. Rapid isolation of human anti-HeV/NiV mAbs. ***(a) Immune cells.*** We are obtaining human PBMCs from a number of previously NiV-infected individuals who acquired immunity following natural infection in collaboration with the **icddr,b**, an international health research institute based in Dhaka, Bangladesh. We are collecting a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Bangladesh, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies are approved by the icddr,b and Vanderbilt University Medical Center IRBs. PBMCs isolated from the blood samples are deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their use in this **RP4,** if funded. ***(b) Applying mAb technologies for new mAb isolation***. We will use sorting of antigen-specific B cells, cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), and this may be helpful for rarer antigen-specific B cells. We will sort soluble fusion (sF) or attachment (G) protein-specific cells with recombinant viral surface protein antigens from **Core D** (**Table 6**).

(c) Ab screening and sequence analysis. Our goal is to identify human anti-NiV/HeV mAbs rapidly, as if we had to respond to a paramyxovirus outbreak in real time. We will single-cell sort antigen-specific B cells using recombinant HeV and NiV proteins (sF or G) as bait as described in Specific Aim 1 above.

(d) Recombinant mAb cloning. As described in Specific Aim 1 above.

(e) Micro-scale mAb expression. As described in Specific Aim 1 above.

Hendra sF
NiV G

(f) CPE-based HeV/NiV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of HeV and NiV. We will use rVSV HeV and NiV surrogates that expresses henipaviurs surface proteins and cause CPE. Investigators in **RP2 and RP3** have VSV-NiV F and VSV-NiV G with GFP[34], VSV-NiV G without GFP[36] and VSV-HeVG (Geisbert and Cross, unpublished). We will obtain these all these VSV constructs from investigators in **PABVAX**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against HeV and NiV. We also can use Cedar virus constructs for neutralization assays as the have reduced pathogenicity[46] and can be used in high-throughput screening assays for henipavirus antiviral discovery[47]. Cedar viruses will be provided by Dr. Broder of **RP2**. The mAbs with most potent activity will be moved forward for additional studies to identify an optimal anti-HeV/NiV mAb combination.

E.3.2. Identifying HeV/NiV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind HeV/NiV surface proteins and validate their epitopes. We will perform competition-binding studies with HeV/NiV sF or G proteins (as above). We will include positive controls made recombinantly from some of the mAbs shown in the preliminary data above for the identification of mAbs that can concurrently bind HeV/NiV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti- HeV/NiV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key binding residues of human anti-HeV/NiV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-NiV F, VSV-NiV G and VSV-HeV G constructs at BSL-2 in the presence of saturating concentrations of HeV/NiV mAbs (single or combination) using RTCA to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test the level of infection of VSV-HeV/NiV escape variants in the presence of mAbs.

E.3.3. Structural basis of neutralization by anti-HeV/NiV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.3.4. Protective efficacy of human anti-henipavirus mAbs. ***(a) Studies in hamsters***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (**Core D**), will advance to *in vivo* testing. We will use an established hamster model of NiV or HeV infection that the **Core E** investigators have deployed. To

benchmark our mAbs, a separate set of hamsters will be treated with G mAbs HENV-103+HENV-117, which we showed in previous data above confers substantial protection[8]. Groups of 6-8 hamsters will be treated with low, medium, or high IgG doses) of single or combinations of anti-HeV/NiV mAbs, or isotype controls at day +1 after inoculation with HeV or NiV. This approach allows us to determine whether combinations provide advantage over the best HeV or NiV mAb monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-HeV and anti-NiV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after HeV or NiV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal HeV/NiV mAb pairs that are comparable to or outperform the mAbs we reported previously. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-HeV/NiV mAb combination against HeV and NiV in NHPs. As a final test of an optimal anti-HeV/NiV mAb combination, we may assess efficacy of the lead anti-HeV/NiV mAb pair in NHPs (**Core E**), selected based on the *in vitro,* hamster data, and manufacturability data (**Core D**). Down-selection for testing in AGMs would only be considered with success in the hamster studies and in consultation with the external SAB and NIAID program staff.

E.3.5. Applying lessons learned in HeV/NiV research to Langya, Angavokely and Sosuga viruses. Once we have completed the HeV/NiV discovery campaigns, will turn to the test case pathogen Langya (or alternate Angavokely and Sosuga (SOSV) viruses) to see if we can use the prototype pathogen approach for this virus. We have plenty of human PBMCs from the sole identified SOSV-immune individual and have already shown that it is possible to obtain HN- and F-specific neutralizing antibodies from this individual's B cells[48] and **Fig 4**. We also have already prepared recombinant SOSV prefusion F and HN proteins[48]. We do not have access to human PBMCs from Langya- or Angavokely-immune donors. For those mAb discovery campaigns, we will use Alloy humanized mouse models as a source of B cells encoding human mAbs, as above. Mice will be immunized with recombinant protein antigens (**Table 7**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Langya or Angavokely. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above using single-cell RNAseq or human hybridoma methods. The development will follow as for Hev/NiV described above.

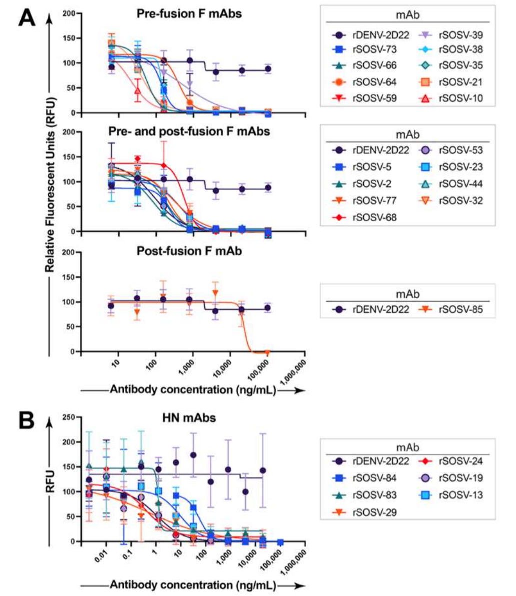

Figure 4. Neutralization assay of SOSV mAbs against live virus. SOSV mAbs were tested for inhibition of authentic rSOSV-ZsG in quadruplicate on Vero-E6 cell culture monolayers. (A) Neutralization data for anti-F mAbs. Data are grouped according to the pattern of antigen-reactivity: pre-fusion F, pre- and post-fusion F, or post-fusion F protein. (B) Neutralization data for the HN-specific mAbs.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-HeV/NiV mAb combinations with optimal protective activity. These mAb combinations will be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging HeV/NiV or related paramyxoviruses. Given our previous ability to generate human anti- HeV/NiV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-HeV/NiV mAbs. We may observe that new mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-HeV/NiV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells *(i.e., memory B cells) isolated from human NiV-immune PBMC samples. In addition, we can deep sequence the B* cell repertoires present in NiV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-HeV/NiV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-HeV/NiV mAb combinations that can inform vaccine design (**RP2**) for related viruses used as test cases in years 2 through 5.

F. Scientific rigor. ***Experimental design.*** Experiments will include biological and technical replicates, and results will be analyzed by parametric or non-parametric analyses (depending on data distribution) and corrections for multiple comparisons. EC_{50} (binding) and IC_{50} (neutralization) values will be reported only following at least 3 identically conducted experiments. All mAb screening will incorporate appropriate + and - controls. Positive signals in binding assays will be defined as >3 SD above background. ***Protein quality.*** We have a high capacity to purify proteins using a Protein Maker workstation that allows purification chromatography on 24 parallel columns. We perform QC on protein reagents using a Maurice instrument with capillary electrophoresis technology to automate our protein profiling either by size or charge, providing cIEF and CE-SDS data. Animal ***studies*** will be performed blinded with independent replicates and include negative (*e.g.*, placebo), and positive (when available) controls. We will use power calculations (**Data Management Core B**) to determine sample sizes. For virological studies, power analysis was performed using accepted values for type I error (0.05) and power (80%). The values for population variance (15×) are based on existing data sets and our experience with rodent challenge studies. We will perform experiments at least 2-3 independent times (n = 4-5 each) to attain n = 12-15 per arm. Smaller group sizes can be used if differences are larger than expected.

G. Relevant biological variables. The human mAbs are derived from immune human donors or Alloy mice. Humans. Human Abs will be isolated for biological, structural, and functional studies at a clonal level. The sample size is not powered for large scale epidemiologic or clinical study conclusions. There is no evidence that sex, age, body mass index, or underlying health conditions other than immunodeficiency or immunosuppressive treatments alters the activity of cloned Abs in structure/function studies. The samples are de-identified without patient specific identifiers to protect the health information of the donors; thus, research with these samples is considered *Not Human Subjects Research* category activity. Mice, hamsters, guinea pigs, NHP, and viruses are also biological systems used in this application. Conventional animal housing conditions will be used because there is no evidence that altered room temperatures and light/dark cycles influence paramyxovirus, nairovirus, or arenavirus pathogenesis. Mice, hamsters, guinea pigs, and NHPs of both sexes will be used, and phenotypes will be monitored for sex-based differences. Virus stocks will be either low passage seed stocks from natural isolates or generated from existing cDNA clones and sequence-confirmed prior to use for infection studies.

H. Milestones and quantitative Go/No-Go criteria. Through **Aims 1-3**, we have proposed experiments that will advance our knowledge of the mAb-mediated mechanisms of action against paramyxoviruses, nairoviruses, and arenaviruses. In each Aim, we will use down-selection criteria (as below) to advance mAb combinations or variants for additional studies. By year 3, we will have defined the principles that govern optimal mAb combinations for paramyxoviruses, nairoviruses, and arenaviruses and the rational approaches needed to select mAbs for potency and breadth. We will use the following metrics to advance mAbs: ***(a) Neutralizing activity.*** All mAbs will have neutralizing potency < 10 ng/mL, EC_{50} value; ***(b) Binding affinity***. MAbs will be of high affinity to surface proteins or virions (K_D < 5 nM). ***(c) Protein stability and production quality.*** MAbs must produce at high levels without optimization (> 100 mg/L) and show biochemical/functional stability at 4°C or -80°C (>90% retention of binding and neutralization activity at 30 d). ***(d) Synergy***. Combinations of 2 mAbs against a given virus ideally will show synergy of neutralization *in vitro* or at a minimum, additive inhibition (no antagonism); ***(e) Epitopes***. To avoid resistance, mAbs in combination will bind 2 epitopes (determined by competition binding (<20% reduction in binding), mapping, and structural studies. ***(f) Resistance*** against mAbs will be assessed for virus escape. Deep sequencing of viruses that emerge from cells or animals treated with mAbs will inform prioritization. Combinations of mAbs with high genetic barriers to resistance (<10× loss in EC_{50}) will be advanced. ***(g) Protection in mice, hamsters, guinea pigs, or NHPs.*** The following metrics can be used: (i) Protection against lethal challenge by homologous virus (>90% survival; (ii) Protection against clinical disease by homologous virus (>80%); (iii) Protection against infection by homologous virus (>100-fold reduction in viral titers in multiple organs). ***(h) pK measurements***. For lead protective mAbs with mutations that should confer extended half-life, we will perform pK studies in NHPs (with **Core D** and **E**) to assess levels over time with a goal of a human predicted serum half-life of >6 months.

Timeline for RP4	Year 1	Year 2	Year 3		Year 4	Year 5

A. BACKGROUND AND SIGNIFICANCE. Paramyxoviruses, nairoviruses, and arenaviruses are widely distributed RNA viruses that cause severe human syndromes. Because of their geographical distribution and expansion, changes in human demographics and increased exposures to wild animals including rodents and bats, and their capacity for human-to-human spread, these viruses have the potential to cause pandemics. Together with the other investigators in **PABVAX**, we have selected several important prototype paramyxoviruses, nairoviruses, and arenaviruses to study to learn the rules governing immunity to these pathogens. The work on the pathogens selected is justified based on their prevalence and severity alone, but also because of their ability to serve as prototypes for genetically related viruses. We chose the viruses for focus in this RP4 on human antibody development because of their clinical relevance and because several will be studied as prototypes for vaccine development in **RP1** (arenaviruses, nairoviruses) and **RP2** (paramyxoviruses). Among the arenaviruses, we will target Lassa virus (LASV) and Machupo virus (MACV), and among the nairoviruses, we will study Crimean–Congo hemorrhagic fever virus (CCHFV). In tandem with the vaccine projects in **RP2** focused on paramyxoviruses, we will study Nipah virus (NiV) and Hendra virus (HeV) as the prototypes. Information about the principles we discover about critical neutralizing epitopes identified here in **RP4** with prototype viruses can feed back into all other **Projects** that address the subsequent plug and play test cases in later years (Lujo, Chapare, Kasokero, Langya).

LASV is an Old World arenavirus (OWAV) with a single-stranded RNA virus belonging to the Arenaviridae family. Infection in humans is often the result of exposure to infected excreta from the rodent reservoir, *Mastomys natalensis* where up to 500,000 cases and an estimated 5,000 deaths occur annually in West Africa[2]. While rodent infection is largely benign, human infection can result in severe hemorrhagic disease with neurological complications and long-term hearing and vision sequelae[3,4]. There are no approved vaccines or treatments for LASV infection. **MACV** is a New World Arenavirus (NWAV) and the causative agent of Bolivian Hemorrhagic fever. Humans are infected after exposure to excreta from the reservoir, *Calomys callosus,* the large vesper mouse. Disease in humans has a slow onset, but can progress to severe hemorrhagic fever coupled to insidious neurological complications including tremors, seizures, and paralysis[5]. There are no approved vaccines or therapies approved for MACV. **CCHFV** is a highly pathogenic tick-borne virus classified under the Nairovirus genus within the Bunyaviridae family[6]. CCHF outbreaks have a case fatality rate of up to 40%, and there are no vaccines or treatments approved for human use. **NiV/HeV.** Bat-borne, NiV and HeV are enveloped, negative-sense, single-stranded RNA viruses belonging to the Henipavirus genus within the Paramyxoviridae family[7]. These emerging zoonotic viruses pose a significant threat to human and animal health due to their high fatality rates and broad host range. As with the other prototype virus in the **PABAX** Center, there are no vaccines or treatments against henipaviruses licensed for human use.

Antibodies (Abs) are important correlates of protection for paramyxoviruses, nairoviruses, and arenaviruses. Immune sera against members of each of these groups of viruses has been shown to exhibit protective efficacy *in vivo*, which supports the use for Abs as treatment options. However, the specificity, functional properties, and other attributes of protective antibodies are poorly defined for most of these viruses. MAbs to the attachment and fusion surface proteins of paramyxoviruses (such as the G and F proteins of Hendra/Nipah[8,9] and the GP proteins of the arenaviruses like LASV[10,11]) can neutralize and protect against infection in rodent models. CCHFV is a bit of a conundrum in that ultrapotent human neutralizing antibodies to the related Rift Valley fever virus surface proteins are highly protective *in vivo*[12,13], but CCHFV neutralizing antibodies are not protective. In contrast, some non-neutralizing antibodies do protect partially for CCHFV[14]. Clearly, there is a lot to learn about the rules of immunity to these viruses, and the genetic, molecular, and structural basis of antibody-mediated protection for viruses like CCHFV. Based on these data, we propose the use of mAbs as treatment options to learn the rule of how to protect against emerging paramyxoviruses, nairoviruses, and arenaviruses and to develop candidate antibody countermeasures for translational development with **Core D**. To do so, we will further develop our technical methods for rapidly discovering mAbs, in the case of a future unexpected epidemic caused by viruses of these families. Most importantly, we will define the principles governing combination antibody therapy to prevent virus escape from treatment or prevention and to optimize the efficacy of the beneficial effects conferred by passive immunity.

B. SCIENTIFIC PREMISE. The work proposed here in **RP4** is based on the extensive basic, translational, and clinical trial data on the role of neutralizing Abs in protection against infection and disease caused by paramyxoviruses, nairoviruses, and arenaviruses. Although a significant amount of data supports the use of mAbs to prevent or control paramyxovirus, nairovirus, and arenavirus infection, many questions remain, such as the ideal epitopes to target with mAb combination therapy to improve upon neutralization potency, *in vivo* efficacy, and resistance to viral escape. Identifying these epitopes can help inform vaccine design to elicit optimal protective polyclonal responses (in **RP1** and **RP2**, especially with designs for test cases in years 4 and 5). Here we aim to refine our understanding of the correlates of mAb protection against paramyxoviruses, nairoviruses, and arenaviruses to enable the design of a modular “plug-and-play” workflow to rapidly respond to potential

pandemics by generating optimized combinations of vaccine-like mAbs with an extended half-life that could be used for long-term prophylaxis (> 6 months) and therapy.

C. INNOVATION. RP4 has many innovative conceptual and technical features including: Conceptual. **(1)** determining the principles that govern optimal combinations of human mAbs against paramyxoviruses, nairoviruses, and arenaviruses for protection and resistance to viral escape; **(2)** the development of a clear workflow that generates therapeutic or preventative antibodies (long half-life mAbs that serve as vaccine surrogates) against emerging or new paramyxoviruses, nairoviruses, and arenaviruses with pandemic potential. Our goal is to define the principles and features, including epitope, combination ratios, and mechanisms of action, that result in optimal efficacy of mAbs against paramyxoviruses, nairoviruses, and arenaviruses in animal models and create a higher barrier for resistance. These studies will serve as paradigms for rapid antibody discovery in response to future paramyxovirus, nairovirus, and arenavirus pandemic threats. Technical. **(3)** large-scale B cell repertoire sequencing with customized methods and software; (**4**) use of humanized (Alloy) mice and novel immunogens from **RP1** and **RP2** and **Core D**; **(5)** single B cell functional (neutralization) assays performed on a Beacon instrument; **(6)** development of high-throughput real-time label-free virus neutralization assays (xCELLigence platform); and **(7)** use of *simultaneous* in parallel screening with several different high-throughput virus-specific B cell isolation approaches (Beacon, 10X Genomics, Rhapsody) to generate and validate best-in-class human mAbs as candidate medical countermeasures.

D. LINKAGE TO OTHER PABVAX PROJECTS AND CORES. The group will focus on developing a modular test case platform for rapid selection of highly neutralizing and/or protective mAbs against paramyxoviruses, nairoviruses, and arenaviruses. Members of our group have active collaborations with most members of the **PABVAX Center** as reflected in previous collaborations and publications (see **Overall** document). We will interact extensively with the Animal Model and Preclinical Evaluation Core (**Core E)** to study neutralization against authentic viruses and to test for protection in small and large animals as well as with **RP3** for testing paramyxovirus mAbs. The knowledge gained from our studies on the structure-function relationships of neutralizing mAb combinations can be applied to rational vaccine design for **RP 1** and **RP2** in later years of the effort when we pivot to apply the lessons learned to the same test case targets as **RP1** and **RP2.** Numerous antigens will be made available to our RP. Finally, long-half-life Fc mutations are now available based on engineering of human IgG1 for enhanced binding to the neonatal Fc receptor (FcRn) such as LS (M428L /N434S)[15], or YTE (M252Y/S254T/T256E)[16] mutations. With ≥ 90 days half-life in humans, our approach will generate mAbs with vaccine-like properties that remain effective for months during a virus epidemic and thus provides a platform for response to future paramyxovirus, nairovirus, and arenavirus pandemic threats, a key goal of our **PABVAX Center.** *Our laboratory previously validated this vaccine surrogate concept when we isolated the human mAbs that formed the basis for Evusheld with YTE long-half-life Fc mutations (used in 70 countries and millions of people) that exhibited > 6 months protective levels in humans after single IM injections*.

E. APPROACH

E.1. Specific Aim 1. Discover potently neutralizing arenavirus combination therapies. For the prototypes, we will focus on LASV, an Old-World virus and MACV, a New-World virus. We will investigate the principles underlying antibody-mediated arenavirus protection. Preliminary evidence suggests that potent virus neutralization is a mechanistic correlate of protection for arenaviruses[17,18]. **RP1/Core D** will provide optimized antigens for mAb selection for the Prototype LASV and MACV (or subsequent Test Cases). We will use a workflow for rapid identification of potently neutralizing mAb combinations for LASV and MACV. We will generate mAbs from individuals with prior natural infection or use transgenic mice with human antibody repertoires. A large panel of human anti-LASV and anti-MACV mAbs will be generated using multiple approaches (immune human B cells and immunized humanized mice), and highly neutralizing mAbs will be evaluated to identify optimal combinations. The best mAb combinations will be assessed to determine the minimal effective dose for protection, and the lead mAb combination therapy(ies) will be transferred to **Core E** for further evaluation and ultimately testing in an NHP model of LASV or MACV infection. Leads will be transferred to **Core D** for further translational development as medical countermeasures. The prototype LASV and MACV will be studied in years 1 to 3, followed by mAb discovery efforts for Test Cases Lujo and Chapare viruses based on the established principles in years 4-5.

Preliminary Data. ***(a) Potently neutralizing human anti-LASV and anti-MACV mAbs.*** The Crowe laboratory has previously characterized panels of neutralizing human anti-viral human mAbs from virus-immune or vaccinated individuals for about 50 viruses, mostly RNA viruses. Isolated peripheral blood mononuclear cells (PBMCs) are used to generate hybridomas or alternatively antigen-sorted at single B cell level and antibody variable genes sequenced to generate mAbs recombinantly. Panels of human anti-viral mAbs are produced rapidly (we recently reported isolation of 15,000 mAb gene pairs from single Ebola-virus-specific human B cells from a single blood sample of an immune individual[19]. Previous studies by others clearly show that representative neutralizing and protective human antibodies can be isolated from LASV-immune subjects[20-24]. In this Aim, we will refine the approaches we have developed previously for other RNA viruses in a proof-of-concept study by identifying potently neutralizing combinations of anti-LASV and anti-MACV human mAbs. We will rapidly discover human anti-LASV mAbs from LASV-immune individuals and human anti-MACV mAbs by immunizing Alloy transgenic mice. Synergy studies will be performed to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify optimal anti-LASV and anti-MACV mAb combinations and further advance the discovery platform for rapid response against emerging arenaviruses.

(b) Advanced mAb technologies. The Crowe laboratory has developed some of the highest yield systems to isolate naturally occurring human mAbs using human hybridoma or advanced single-cell RNA-seq methods (**Fig 1**). We have used sorting of antigen-specific cells with recombinant viral surface protein antigens (like the GP1 and GP2 proteins we will use here), cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. One variation we will use is to capture Ab genes directly from viral glycoprotein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), as we have done for Ebola virus[19,25] and SARS-CoV-2[1,26-31]. These single-cell techniques enhance the capture of rare antigen-specific B cells.

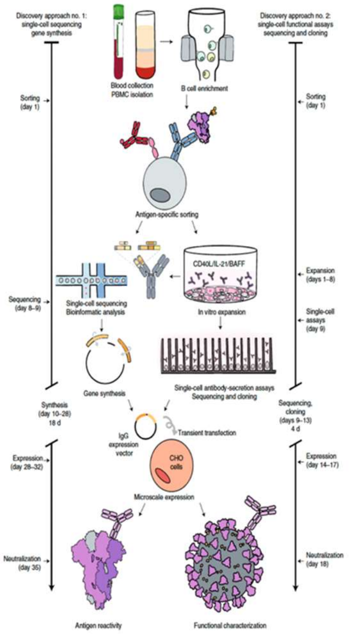

Figure 1. Single cell mAb discovery. PBMC samples are used to enrich for B cells, which can be sorted for antigen-specific B cells. Expansion allows us to further assess the functionality of the B cells or for antibody sequencing. Recombinant mAb expression validates the mAb sequence and functional activity. Figure is adapted from [1].

E.1.1. Rapid isolation of human anti-LASV and anti-MACV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from one previously LASV-infected individual who was medically managed previously by Emory University in their infectious diseases containment unit. This person has a documented robust neutralizing serum antibody response, suggesting isolation of neutralizing human mAbs from these PBMC aliquots will be straightforward for us. Our colleagues in **RP1** have ongoing field operations for over a decade in Sierra Leone, Liberia, and Nigeria. This work is currently in association with the NIH-Centers for Research on Emerging Infectious Diseases (CREID) with a heavy focus on the study of LASV ecology, epidemiology, and host responses. **RP4** is currently working with **RP1** on obtaining PBMCs from ~10 individuals with prior laboratory-confirmed cases of LASV. The acquisition of these samples is being managed by the Vanderbilt Vaccine Center Biorepository with separate institutional funding to be de-identified prior to use in the studies proposed here. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies have been approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples will be deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded. For anti-MACV mAbs, as a human PBMC source is not readily available, we will immunize Alloy humanized mice. These animals yield PBMCs that secrete fully human mAbs. Alloy mice are used routinely in the Crowe lab workflow.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-LASV and anti-MACV mAbs in a rapid manner to mimic a pandemic response to an outbreak. We will single-cell sort antigen-specific B cells using recombinant LASV or MACV proteins (*e.g.*, **Table 1)** or non-infectious viral particles as bait. These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including LASV and MACV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe GP protein or virus-particle binding to single B cells. These cells are exported for sequencing of the variable gene regions and analysis using the PyIR software developed in the Crowe laboratory. We will select a panel of up to 500 neutralizing anti-LASV mAbs and a similar number of anti-MACV mAbs to express recombinantly and advance for further characterization. We can easily conduct multiple approaches simultaneously in parallel[1,32].

Table 1. Antigens from Core D
Lassa Josiah NP
Lassa Josiah GPe
Machupo GPe
Machupo NP

(c) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using a custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors.

(d) Micro-scale mAb expression. The Crowe laboratory has the capacity for large-throughput micro-scale mAb expression and purification. The lower end of this range allows expression of thousands of mAbs, which will feed into automated mAb purification platforms. This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(e) A CPE-based LASV and MACV neutralization assay using RTCA. We have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of cytopathic effect (CPE). Here, we will apply this method to assess neutralization of LASV. Recently, we validated the inclusion of simultaneous live-cell fluorescence microscopy into this real-time CPE-based screening platform (xCelligence RTCA eSight). These capabilities expand the platform to screen viruses that may or may not induce CPE, allowing us to also use a replication-competent vesicular stomatitis virus (VSV) LASV surrogate that expresses LASV surface proteins and causes CPE[33]. Currently, we have a VSV-LASV-Josiah (lineage IV)[33] and a Sauerwald version (lineage II) of these recombinants. Making additional LASV VSV-LASVs is not difficult, and **RP1** will make the other missing lineages or needed arenaviruses based on the same approaches as previously published. **RP1** also can easily make versions of these VSVs that express the green fluorescent protein (GFP) reporter gene. Existing VSV-CCHFV, VSV-NiV, and VSV-HeV vectors[34-36] will be provided by Dr. Geisbert overall PI and Lead of **Core E**. We already have Vanderbilt IBC approval for use of these constructs. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression if used will identify mAbs with neutralizing activity against LASV. These mAbs will be moved forward for additional studies to identify an optimal anti-LASV mAb combination. Similar processes will be followed to determine neutralization capacity of MACV mAb candidates.

E.1.2. Identifying LASV and MACV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind LASV or MACV and validate their epitopes. We will perform competition-binding studies with GP or subunit proteins (as above) or virus-like particles (VLPs)[37] available from **Core E** at UTMB. **Core E** will also inactivate LASV and MACV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from previously reported antibodies for the identification of mAbs that can concurrently bind LASV or MACV with a goal of finding more potent clones at those sites or clones that complement these inhibitory mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-LASV or anti-MACV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations for each virus, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key residues binding residues of human anti-LASV and anti-MACV mAbs.*** To determine the key residues for binding of down-selected mAbs, we will perform deep mutational scanning[38]. Briefly, all amino acids of the GP proteins will be mutated to the other 19 amino acids with a unique barcode using PCR-based mutagenesis. The LASV or MACV GP protein library will be incubated with the appropriate mAbs to identify residues with loss-of-binding phenotypes. A sequence ‘logo’ showing the relative contributions of each amino acid mutation will identify residues critical for binding. Multiple amino acid substitutions can then be assessed by reverse genetics at UTMB to confirm the epitopes recognized by the down-selected mAbs. This method also serves as a surrogate for *in vitro* neutralization escape studies. ***(d) Neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-LASV or VSV-MACV constructs at BSL2 in the presence of saturating concentrations of mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Confirmatory reverse genetics studies will be performed by introducing mutations into an infectious cDNA clone of LASV or MACV by **RP1** to test neutralization. We hypothesize that escape will be less likely in the presence of mAb combinations than single mAbs. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of escape variants in the presence of mAbs.

E.1.3. Structural basis of neutralization by mAb combinations. The studies above should identify optimal anti-LASV and anti-MACV mAb combinations that simultaneously bind, neutralize, and increase the barrier for viral escape under mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb

combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for arenavirus by identifying key epitope targets (**RP1**).

E.1.4. Protective efficacy of human anti-arenavirus mAbs. ***(a) Studies in guinea pigs***. MAbs that satisfy the criteria stated above and that display stage-appropriate manufacturability characteristics will advance to *in vivo* testing. We will use established models of LASV[11,39] and MACV[40,41] infection in guinea pigs. PABVAX **Core E** has access to many strains from different LASV and MACV lineages, which will be tested. For prioritization, we will focus on LASV lineage II, III, and IV strains and MACV lineage I, II, and VIII strains for which uniformly lethal models are available. Groups of 6 outbred Hartley guinea pigs will be treated with low, medium, and high doses of single or combinations of anti-LASV or anti-MACVs mAb, or isotype controls at day +1 after inoculation with the LASVs or MACVs This approach allows us to determine whether combinations provide advantage over the best monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-LASV and anti-MACV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements (blood) at day 5 or 6 after LASV or MACV challenge and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal LASV and MACV mAb pairs that are comparable to or outperform previously reported mAbs for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-LASV and anti-MACV mAb combination against LASV or MACV in NHPs. As a final test of an optimal anti-LASV and anti-MACV mAb combinations, we will assess protective efficacy of the lead anti-LASV mAb pair in NHPs as well as the anti-MACV mAb pair in NHPs. These anti-LASV and anti-MACV mAb pairs will be selected based on the *in vitro* and guinea pig data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys will only be considered pending success in the guinea pig studies and consultation with the external Scientific Advisory Board (SAB) and NIAID program staff.

E.1.5. Applying lessons learned in LASV and MACV research with the selected test case pathogens for mAb generation: Lujo and Chapare mAbs. Once we have completed the LASV and MACV discovery campaigns, will turn to the test case pathogens to see if we can use the prototype pathogen approach to related viruses, Lujo (LUJV) and Chapare (CHAPV). We do not have access to human PBMCs from LUJV - or CHAPV-immune donors. As an alternative approach, we will use humanized mouse models as a source of B cells encoding fully human monoclonal antibodies. The Vanderbilt core investigators have an established fully executed agreement to use Alloy human antibody mice for this purpose (See Letter of Support). The Alloy ATX-Gx™ mouse is one of the most effective *in vivo* human antibody discovery platforms, with over 140 partners and counting. This mouse system was originally invented and validated inside a major pharma company and then further developed by Alloy. This foundational suite of highly immunocompetent transgenic mice is engineered to drive the greatest potential diversity of unique human antibodies binding to the viral target of interest, with broad epitopic coverage. The comprehensive functional human antibody repertoire in these mice is optimized for human Ab sequence developability and diversity. Alloy and Vanderbilt have already executed a simple licensing process for use of the ATX-Gx platform, and as an established partner the Vanderbilt core team will access the expanding portfolio of transgenic Alloy strains designed to address a range of discovery challenges (including diverse Ab isotypes). Mice will be immunized with conformationally correct recombinant protein antigens (**Table 2**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for the target of interest. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for LASV and MACV.

<u>**Anticipated results, potential problems, and alternative approaches**</u>**.** In this Aim, we will identify human anti-LASV and anti-MACV mAb combinations with optimal neutralizing and protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging LASV, MACV, or related arenaviruses. Given our previous ability to generate human antiviral mAbs, we do not anticipate problems in isolating anti-LASV or anti-MACV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently neutralizing anti-LASV or anti-MACV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody™) on enriched B cells (*i.e.*, memory B cells) isolated from human LASV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in LASV-immune PBMC samples and identify clonal lineages, including

siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-LASV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-LASV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-LASV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-LASV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the high-throughput Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E2. Specific Aim 2. Discover a protective CCHF virus mAb combination therapy. Establishing the generality of protection approaches against nairoviruses, we will perform a mAb discovery proof-of-concept campaign for the Prototype CCHFV. Preliminary studies have identified human anti-CCHF mAbs with varying levels of protection in experimentally infected animals[14,42,43]. We will isolate a large panel of human anti-CCHFV mAbs and determine the rules governing optimal mAb combinations through competition-binding, epitope mapping, neutralization, and viral escape studies. Lead antibodies with acceptable manufacturability characteristics (**Core D**) and the highest capacity to overcome resistance while maintaining potency of protection will be selected. The structural basis of their activity will be established using structural biology techniques (electron microscopy and crystallography). Lead mAb cocktail therapies will be evaluated for *in vivo* protective efficacy in STAT1$^{-/-}$ mice (with **Core E).** As a final test of an optimal anti-CCHFV mAb combination, we will assess protective efficacy of the lead anti-CCHFV mAb pair in NHPs, to be selected based on the *in vitro* and mouse data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys studies would only be considered pending success in the mouse studies and consultation with the external Scientific Advisory Board and NIAID program staff. In years 4-5, we will apply the lessons learned to the plug and play test case Kasokero virus (KASV) in collaboration with **RP1**, **Core D**, and **Core E**.

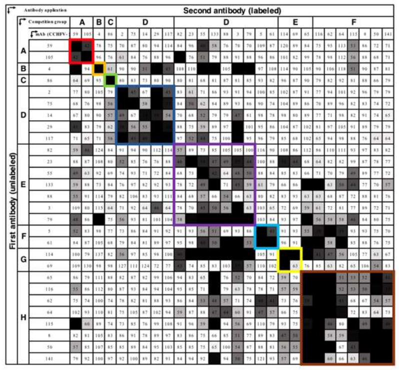

Figure 2. Competition assessment of human Abs to CCHFV using M-segment expressing cells. We tested 28 mAbs in competition assays. MAbs are displayed in 8 groups (A-H) based on their ability to compete for binding. Values shown are the % of binding that occurred during competition compared to non-competed binding of the mAb. This value was normalized to 100%. The values are also indicated by the box fill color; darker colors toward black indicate higher competition and lighter colors toward white indicate less competition, on a gradient scale.

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-CCHFV mAbs.*** In this Aim, we will rapidly discover human anti-CCHFV mAbs from CCHFV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify an optimal anti-CCHFV mAb combination and further advance the discovery platform for rapid response against emerging nairoviruses. In preliminary experiments in collaboration with investigators in **RP1** and **Core E**, the Crowe laboratory has previously isolated and characterized panels of neutralizing human anti-CCHFV human mAbs from individuals who were convalescent after naturally-acquired laboratory-confirmed infection in Spain or Turkey. We isolated a panel of antibodies against CCHFV that recognize the M-segment in transfected cells, and they exhibit a diversity of recognition patterns in that they fall into multiple competition-binding groups (**Fig 2**). This panel contains cross-binding and cross-neutralizing antibodies for diverse strains. We observed a human mAb designated CCHF-82 competing with competition group 1 and group 2 antibodies from the previously isolated GP38-reactive murine antibodies. CCHF-82 showed some protection in a STAT1$^{-/-}$ mouse model of infection conducted by investigators in **RP1 (Fig 3)**. Further investigation with this antibody in the IbAr10200 prophylaxis and therapeutic models is warranted. In contrast, the CCHFV-neutralizing mAbs that we isolated and tested *in vivo* did not perform well in the Turkish strain STAT1$^{-/-}$ mouse model. We now know protection in this model is possible, given the work from Fels *et al*., 2021 who showed that potent antibodies against various sites on the Gc surface can afford protection in this model[42]. However, in their study they did not test GP38-reactive antibodies. To our knowledge, our preliminary

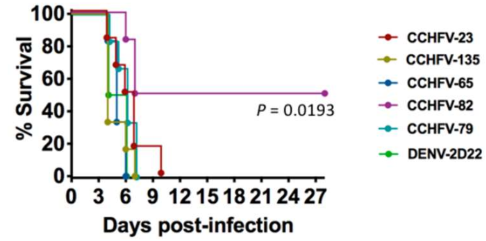

Figure 3. Human mAb CCHF-82 provides partial protection as a post-exposure prophylaxis against the Turkish strain of CCHFV in the STAT1$^{-/-}$ mouse model. A single dose of mAb was administered by the IP route to mice (n=6 per group (3 male, 3 female)) at 30 min post infections. A lethal dose of Turkish strain of CCHFV was administered. CCHF mAbs or DENV-2D22 (an isotype-matched negative control mAb) were tested in a single dose of 250 µg per mouse. Kaplan-Meier survival curves were statistically analyzed using a log-rank (Mantel-Cox) test where mAb-treated animals (*P* value shown in figure) were compared to animals treated with the DENV-2D22 negative control mAb. Unpublished data.

data is the first indication that a human GP38-targeting antibody can provide some protection in this mouse model.

Non-neutralizing murine mAbs protect in mouse models of infection[14], but it is unknown if the human antibody response could provide similar levels of protection. Murine mAb 13G8 binds to GP38 and does not neutralize CCHFV. This mAb provides protection against lethal challenge as a prophylaxis and a therapeutic against CCHFV. In preliminary experiments we sought to understand if human survivors of CCHFV infection possess B cells encoding mAbs that bind a similar epitope as 13G8 and provide protection. CCHF-82 competes for binding with 13G8 to preGn-transfected cells containing GP38. This antibody offered some protection as a post-exposure prophylaxis against the Turkish strain of CCHFV (**Fig 3**). Human antibodies like this should be further studied and the frequency of these clones should be elucidated to understand if this is a feasible strategy for future vaccine efforts for humans. The epitope that 13G8 and CCHF-82 identifies could inform vaccine design if these antibodies offer protection in larger animal models. Understanding how non-neutralizing antibodies function is critical in efforts to validate the GP38-binding class of antibodies. Golden *et al.* undertook a study to understand the mechanisms 13G8 functioned and observed that complement activation contributes to the protective capacity of this antibody[14]. Here, in studies of CCHF-82, we also will assess complement activation in mouse models of infection to fully understand the function of this mAb *in vivo*. Furthermore, if this mAb protects in the CCHFV IbAr10200 strain challenge model, assessing its mechanism is warranted. Together with **Core D**, we will assess IgG molecules with complement knockout ("KA") and Fc gamma receptor knockout (LALA-PG) mutations in the Fc domain to study this matter. Human mAb CCHF-82 displayed limited cross-protection against experimental infection with the Turkish strain of CCHFV. Our antibody isolation here will aim to identify cross-protective non-neutralizing antibodies reactive with GP38. Recently, vaccinating with NP was shown to be another way to elicit non- neutralizing antibodies[44]. The NP of CCHFV is more conserved than the glycoproteins and might also be a non-canonical target for the identification of cross-protective non-neutralizing antibodies[44].

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant viral surface protein antigens, cloning of Ab variable genes, and then expression of mAbs as as described above in Specific Aim 1.

E.2.1. Rapid isolation of human anti-CCHFV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from a number of previously CCHFV-infected individuals. One was a health care survivor who was infected while caring for a patient in Spain[45]. We also collected a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Turkey, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples were only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies were approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples were deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-CCHFV mAbs rapidly, as if we had to respond to a nairovirus outbreak in real time. Our ability to respond rapidly in the setting of outbreaks is well-documented in the lay press (60 Minutes features and others) and the scientific literature, e.g., 78 days from sample to protection of NHPs for Zika virus[32], and 25 days from PBMC sample receipt to delivery of the antibody genes for the approved COVID-19 drug Evusheld to AstraZeneca[1]. Here, we will single-cell sort antigen-specific B cells using recombinant CCHFV proteins (GP38, Gc, Gn, Gc/Gn) or non-infectious particles as bait as described in Specific Aim 1. We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D**, (**Table 3**) or by **RP1 (Table 4)**.

CCHF Turkey GnGc
CCHF Turkey GP38
CCHF NP

(c) Recombinant mAb cloning. As described in Specific Aim 1 above.

(d) Micro-scale mAb expression. As described in Specific Aim 1 above.

(e) A CPE-based CCHFV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of CCHFV. We will use a rVSV CCHFV surrogate that expresses CCHFV surface proteins and causes CPE[35]. Investigators in **RP1** have the VSV-CCHFV-GFP versions of clades 1 through 7 based on this publication. We will obtain these VSV constructs from investigators in **PABVAX**. Existing VSV vectors will be provided by investigators in **RP1 and Core E**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against CCHFV. These mAbs will be moved forward for additional studies to identify an optimal anti-CCHFV mAb combination. GP38-reactive clones will be advanced based on avidity ranking since they are not likely to be neutralizing but may be protective *in vivo*.

E.2.2. Identifying CCHFV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind CCHFV surface proteins and validate their epitopes. We will perform competition-binding studies with CCHFV Gc/Gn or subunit proteins (as above) or CCHFV virus-like particles (VLPs) made from a replicon system in hand. **Core E** will inactivate CCHFV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site. Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from some of the mAbs shown in the unpublished preliminary data above for the identification of mAbs that can concurrently bind CCHFV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-CCHFV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. GP-38-reactive clones will be screened for synergistic binding as they are not expected to be neutralizing. ***(c) Identification of key binding residues of human anti-CCHFV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-CCHFV constructs at BSL2 in the presence of saturating concentrations of CCHFV mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of VSV-CCHFV escape variants in the presence of mAbs.

E.2.3. Structural basis of neutralization by anti-CCHFV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.2.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies in STAT1$^{-/-}$ mouse models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (Core D), will advance to *in vivo* testing. We will use an established STAT1$^{-/-}$ mouse model of CCHFV infection that the **RP1** and **Core E** investigators have deployed[35]. To benchmark our mAbs, a separate set of STAT1$^{-/-}$ mice will be treated with CCHF-82, which we showed in unpublished preliminary data above confers substantial but incomplete protection (**Fig 3**). The **Core E** laboratory has access to strains representing all 6 clades that can be tested. Groups of 6-8 STAT1$^{-/-}$ mice will be treated with low, medium, and high doses) of single or combinations of anti-CCHFV mAb, or isotype controls at day +1 after inoculation with CCHFVs. This approach allows us to determine whether combinations provide advantage over the best CCHFV monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after CCHFV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal CCHFV mAb pairs that are comparable to or outperform the mAbs we reported above. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-CCHFV mAb combination against CCHFV in NHPs. As a final test of an optimal anti-CCHFV mAb combination, we will assess efficacy of the lead anti-CCHFV mAb pair in NHPs (**Core E**), to be selected based on the *in vitro,* STAT1$^{-/-}$ mice, and manufacturability data (**Core D**). Down-selection for testing in cynomolgus monkeys would only be considered with success in the STAT1$^{-/-}$ mouse studies and in consultation with the external SAB and NIAID program staff.

E.2.5. Applying lessons learned in CCHFV research to Kasokero mAbs. Once we have completed the CCHFV discovery campaigns, will turn to the test case pathogen Kasokero virus to see if we can use the prototype pathogen approach for this virus. We do not have access to human PBMCs from Kasokero-immune donors. We will use Alloy humanized mouse models as a source of B cells encoding fully human mAbs, as described above. Mice will be immunized with conformationally correct recombinant protein antigens (**Table 5**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Kasokero. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for CCHFV.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-CCHFV mAb combinations with optimal protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging CCHFV or related nairoviruses. Given our previous ability to generate human anti-CCHFV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-CCHFV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-CCHFV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (i.e., memory B cells) isolated from human CCHFV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in CCHFV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-CCHFV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-CCHFV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-CCHFV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-CCHFV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E3. Specific Aim 3. Establish optimal mAb combination therapies against henipaviruses Hendra (HeV) and Nipah (NiV) viruses. We will use a large panel of potent anti-henipavirus mAbs that we previously made from the memory B cells of immune individuals and generate new antibodies targeting the fusion (F) protein. **RP2** will provide new antigens for mAb selection and BSL-2-compatible viruses for neutralization screens including Cedar virus constructs displaying HeV and NiV F and G proteins. We will identify optimal mAb combinations to enhance henipavirus therapy, minimize viral escape, and improve treatment efficacy through synergy. *In vitro* competition-binding, neutralization, and mechanistic studies will be conducted, including authentic virus neutralization with **PABVAX Core E**. We will refine the recognized epitopes and investigate the structural basis for optimal combination neutralization of henipaviruses using HeV and NiV as prototypes. *In vivo* assessment of mAb combinations will determine the minimal effective dose for protection and the ability to prevent *in vivo* escape. Protective efficacy of lead mAb combinations will be assessed in hamster models of NiV and HeV infection with **Core E**. Leads will be transferred to **Core D**. As a final test of optimal henipavirus mAb combinations, we will assess protective efficacy of the lead henipavirus mAb pairs in NHPs, to be selected based on the *in vitro* and hamster data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in African green monkey (AGM) henipavirus model studies would only be considered pending success in the hamster studies and consultation with the external SAB and NIAID program staff. The HeV and NiV studies will be conducted in years 1-3 and then applied to the plug-and-play test case Langya virus in years 2-5. If **RP2** and **Core E** cannot rescue recombinant Langya virus, the lessons learned in Years 1-3 will be applied to the alternate “plug and play” test viruses Angavokely or Sosuga (SOSV) virus. Preliminary data on SOSV mAbs are provided.

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-NIV/HeV mAbs.*** In this Aim, we will further adapt approaches we have developed in preliminary experiments with henipavirus mAb studies by identifying a potently protective combination of anti-NiV/HeV human mAbs. Through these studies, we aim to identify an optimal anti-NiV+HeV mAb combination and further advance the discovery platform for rapid response against emerging paramyxoviruses, especially henipaviruses. In previous experiments in collaboration with investigators in **RP2** and **Core E**, the Crowe laboratory has isolated characterized panels of neutralizing human anti-G NiV/HeV human mAbs from an individual with G-based immunity following occupational exposure to an equine HeV G subunit vaccine. Isolated peripheral blood mononuclear cells (PBMCs) were used to generate human B cell hybridomas secreting human mAbs to G, and antibody variable genes were sequenced to generate mAbs recombinantly. We isolated a panel of antibodies against the G protein that recognize the HeV G, NiV Bangladesh G, and NiV Malaysia G proteins. The mAbs exhibited a diversity of recognition patterns in that they fall into multiple competition-binding groups. This panel contains cross-binding and cross-neutralizing antibodies for diverse NiV and HeV strains. In the work proposed here, we will rapidly discover human NiV/HeV anti-F mAbs from NiV-immune individuals and outstanding potency anti-G antibodies with extensive characterization, including synergistic neutralization.

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant henipavirus F protein antigens, as described above in Specific Aim 1.

E.3.1. Rapid isolation of human anti-HeV/NiV mAbs. ***(a) Immune cells.*** We are obtaining human PBMCs from a number of previously NiV-infected individuals who acquired immunity following natural infection in collaboration with the **icddr,b**, an international health research institute based in Dhaka, Bangladesh. We are collecting a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Bangladesh, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies are approved by the icddr,b and Vanderbilt University Medical Center IRBs. PBMCs isolated from the blood samples are deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their use in this **RP4,** if funded. ***(b) Applying mAb technologies for new mAb isolation***. We will use sorting of antigen-specific B cells, cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), and this may be helpful for rarer antigen-specific B cells. We will sort soluble fusion (sF) or attachment (G) protein-specific cells with recombinant viral surface protein antigens from **Core D** (**Table 6**).

(c) Ab screening and sequence analysis. Our goal is to identify human anti-NiV/HeV mAbs rapidly, as if we had to respond to a paramyxovirus outbreak in real time. We will single-cell sort antigen-specific B cells using recombinant HeV and NiV proteins (sF or G) as bait as described in Specific Aim 1 above.

(d) Recombinant mAb cloning. As described in Specific Aim 1 above.

(e) Micro-scale mAb expression. As described in Specific Aim 1 above.

(f) CPE-based HeV/NiV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of HeV and NiV. We will use rVSV HeV and NiV surrogates that expresses henipaviurs surface proteins and cause CPE. Investigators in **RP2 and RP3** have VSV-NiV F and VSV-NiV G with GFP[34], VSV-NiV G without GFP[36] and VSV-HeVG (Geisbert and Cross, unpublished). We will obtain these all these VSV constructs from investigators in **PABVAX**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against HeV and NiV. We also can use Cedar virus constructs for neutralization assays as the have reduced pathogenicity[46] and can be used in high-throughput screening assays for henipavirus antiviral discovery[47]. Cedar viruses will be provided by Dr. Broder of **RP2**. The mAbs with most potent activity will be moved forward for additional studies to identify an optimal anti-HeV/NiV mAb combination.

E.3.2. Identifying HeV/NiV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind HeV/NiV surface proteins and validate their epitopes. We will perform competition-binding studies with HeV/NiV sF or G proteins (as above). We will include positive controls made recombinantly from some of the mAbs shown in the preliminary data above for the identification of mAbs that can concurrently bind HeV/NiV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti- HeV/NiV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key binding residues of human anti-HeV/NiV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-NiV F, VSV-NiV G and VSV-HeV G constructs at BSL-2 in the presence of saturating concentrations of HeV/NiV mAbs (single or combination) using RTCA to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test the level of infection of VSV-HeV/NiV escape variants in the presence of mAbs.

E.3.3. Structural basis of neutralization by anti-HeV/NiV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.3.4. Protective efficacy of human anti-henipavirus mAbs. ***(a) Studies in hamsters***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (**Core D**), will advance to *in vivo* testing. We will use an established hamster model of NiV or HeV infection that the **Core E** investigators have deployed. To

benchmark our mAbs, a separate set of hamsters will be treated with G mAbs HENV-103+HENV-117, which we showed in previous data above confers substantial protection[8]. Groups of 6-8 hamsters will be treated with low, medium, or high IgG doses) of single or combinations of anti-HeV/NiV mAbs, or isotype controls at day +1 after inoculation with HeV or NiV. This approach allows us to determine whether combinations provide advantage over the best HeV or NiV mAb monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-HeV and anti-NiV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after HeV or NiV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal HeV/NiV mAb pairs that are comparable to or outperform the mAbs we reported previously. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-HeV/NiV mAb combination against HeV and NiV in NHPs. As a final test of an optimal anti-HeV/NiV mAb combination, we may assess efficacy of the lead anti-HeV/NiV mAb pair in NHPs (**Core E**), selected based on the *in vitro,* hamster data, and manufacturability data (**Core D**). Down-selection for testing in AGMs would only be considered with success in the hamster studies and in consultation with the external SAB and NIAID program staff.

E.3.5. Applying lessons learned in HeV/NiV research to Langya, Angavokely and Sosuga viruses. Once we have completed the HeV/NiV discovery campaigns, will turn to the test case pathogen Langya (or alternate Angavokely and Sosuga (SOSV) viruses) to see if we can use the prototype pathogen approach for this virus. We have plenty of human PBMCs from the sole identified SOSV-immune individual and have already shown that it is possible to obtain HN- and F-specific neutralizing antibodies from this individual's B cells[48] and **Fig 4**. We also have already prepared recombinant SOSV prefusion F and HN proteins[48]. We do not have access to human PBMCs from Langya- or Angavokely-immune donors. For those mAb discovery campaigns, we will use Alloy humanized mouse models as a source of B cells encoding human mAbs, as above. Mice will be immunized with recombinant protein antigens (**Table 7**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Langya or Angavokely. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above using single-cell RNAseq or human hybridoma methods. The development will follow as for Hev/NiV described above.

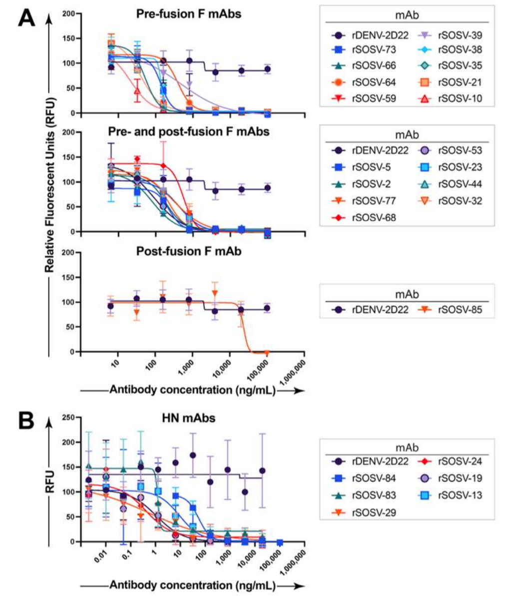

Figure 4. Neutralization assay of SOSV mAbs against live virus. SOSV mAbs were tested for inhibition of authentic rSOSV-ZsG in quadruplicate on Vero-E6 cell culture monolayers. (A) Neutralization data for anti-F mAbs. Data are grouped according to the pattern of antigen-reactivity: pre-fusion F, pre- and post-fusion F, or post-fusion F protein. (B) Neutralization data for the HN-specific mAbs.

<u>Anticipated results, potential problems, and alternative approaches</u>. In this Aim, we will identify human anti-HeV/NiV mAb combinations with optimal protective activity. These mAb combinations will be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging HeV/NiV or related paramyxoviruses. Given our previous ability to generate human anti- HeV/NiV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-HeV/NiV mAbs. We may observe that new mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-HeV/NiV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells *(i.e., memory B cells) isolated from human NiV-immune PBMC samples. In addition, we can deep sequence the B* cell repertoires present in NiV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-HeV/NiV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-HeV/NiV mAb combinations that can inform vaccine design (**RP2**) for related viruses used as test cases in years 2 through 5.

F. Scientific rigor. ***Experimental design.*** Experiments will include biological and technical replicates, and results will be analyzed by parametric or non-parametric analyses (depending on data distribution) and corrections for multiple comparisons. EC$_{50}$ (binding) and IC$_{50}$ (neutralization) values will be reported only following at least 3 identically conducted experiments. All mAb screening will incorporate appropriate + and - controls. Positive signals in binding assays will be defined as >3 SD above background. ***Protein quality.*** We have a high capacity to purify proteins using a Protein Maker workstation that allows purification chromatography on 24 parallel columns. We perform QC on protein reagents using a Maurice instrument with capillary electrophoresis technology to automate our protein profiling either by size or charge, providing cIEF and CE-SDS data. Animal ***studies*** will be performed blinded with independent replicates and include negative (*e.g.*, placebo), and positive (when available) controls. We will use power calculations (**Data Management Core B**) to determine sample sizes. For virological studies, power analysis was performed using accepted values for type I error (0.05) and power (80%). The values for population variance (15×) are based on existing data sets and our experience with rodent challenge studies. We will perform experiments at least 2-3 independent times (n = 4-5 each) to attain n = 12-15 per arm. Smaller group sizes can be used if differences are larger than expected.

G. Relevant biological variables. The human mAbs are derived from immune human donors or Alloy mice. Humans. Human Abs will be isolated for biological, structural, and functional studies at a clonal level. The sample size is not powered for large scale epidemiologic or clinical study conclusions. There is no evidence that sex, age, body mass index, or underlying health conditions other than immunodeficiency or immunosuppressive treatments alters the activity of cloned Abs in structure/function studies. The samples are de-identified without patient specific identifiers to protect the health information of the donors; thus, research with these samples is considered *Not Human Subjects Research* category activity. Mice, hamsters, guinea pigs, NHP, and viruses are also biological systems used in this application. Conventional animal housing conditions will be used because there is no evidence that altered room temperatures and light/dark cycles influence paramyxovirus, nairovirus, or arenavirus pathogenesis. Mice, hamsters, guinea pigs, and NHPs of both sexes will be used, and phenotypes will be monitored for sex-based differences. Virus stocks will be either low passage seed stocks from natural isolates or generated from existing cDNA clones and sequence-confirmed prior to use for infection studies.

H. Milestones and quantitative Go/No-Go criteria. Through **Aims 1-3**, we have proposed experiments that will advance our knowledge of the mAb-mediated mechanisms of action against paramyxoviruses, nairoviruses, and arenaviruses. In each Aim, we will use down-selection criteria (as below) to advance mAb combinations or variants for additional studies. By year 3, we will have defined the principles that govern optimal mAb combinations for paramyxoviruses, nairoviruses, and arenaviruses and the rational approaches needed to select mAbs for potency and breadth. We will use the following metrics to advance mAbs: ***(a) Neutralizing activity.*** All mAbs will have neutralizing potency < 10 ng/mL, EC$_{50}$ value; ***(b) Binding affinity***. MAbs will be of high affinity to surface proteins or virions (K$_D$ < 5 nM). ***(c) Protein stability and production quality.*** MAbs must produce at high levels without optimization (> 100 mg/L) and show biochemical/functional stability at 4°C or -80°C (>90% retention of binding and neutralization activity at 30 d). ***(d) Synergy***. Combinations of 2 mAbs against a given virus ideally will show synergy of neutralization *in vitro* or at a minimum, additive inhibition (no antagonism); ***(e) Epitopes***. To avoid resistance, mAbs in combination will bind 2 epitopes (determined by competition binding (<20% reduction in binding), mapping, and structural studies. ***(f) Resistance*** against mAbs will be assessed for virus escape. Deep sequencing of viruses that emerge from cells or animals treated with mAbs will inform prioritization. Combinations of mAbs with high genetic barriers to resistance (<10× loss in EC$_{50}$) will be advanced. ***(g) Protection in mice, hamsters, guinea pigs, or NHPs.*** The following metrics can be used: (i) Protection against lethal challenge by homologous virus (>90% survival; (ii) Protection against clinical disease by homologous virus (>80%); (iii) Protection against infection by homologous virus (>100-fold reduction in viral titers in multiple organs). ***(h) pK measurements***. For lead protective mAbs with mutations that should confer extended half-life, we will perform pK studies in NHPs (with **Core D** and **E**) to assess levels over time with a goal of a human predicted serum half-life of >6 months.

Timeline for RP4	**Year 1**	**Year 2**	**Year 3**		**Year 4**	**Year 5**
Prototype mAb generation and testing: **LASV and MACV mAbs**	X	X	X		X	
Test case mAb generation and testing: **Lujo and Chapare mAbs**			X		X	X
Prototype mAb generation and testing: **CCHFV mAbs**	X	X	X		X	
Test case mAb generation and testing: **Kasokero mAbs**			X		X	X
Prototype mAb generation and testing: **NiV/HeV mAbs**	X	X	X			
Test case mAb generation: **Langya, Angavokely/Sosuga mAbs**		X	X		X	X
In vivo efficacy studies with **Core E**	X	X	X		X	X
Translational activities with **Core D**	X	X	X		X	X

A. BACKGROUND AND SIGNIFICANCE. Paramyxoviruses, nairoviruses, and arenaviruses are widely distributed RNA viruses that cause severe human syndromes. Because of their geographical distribution and expansion, changes in human demographics and increased exposures to wild animals including rodents and bats, and their capacity for human-to-human spread, these viruses have the potential to cause pandemics. Together with the other investigators in **PABVAX**, we have selected several important prototype paramyxoviruses, nairoviruses, and arenaviruses to study to learn the rules governing immunity to these pathogens. The work on the pathogens selected is justified based on their prevalence and severity alone, but also because of their ability to serve as prototypes for genetically related viruses. We chose the viruses for focus in this RP4 on human antibody development because of their clinical relevance and because several will be studied as prototypes for vaccine development in **RP1** (arenaviruses, nairoviruses) and **RP2** (paramyxoviruses). Among the arenaviruses, we will target Lassa virus (LASV) and Machupo virus (MACV), and among the nairoviruses, we will study Crimean–Congo hemorrhagic fever virus (CCHFV). In tandem with the vaccine projects in **RP2** focused on paramyxoviruses, we will study Nipah virus (NiV) and Hendra virus (HeV) as the prototypes. Information about the principles we discover about critical neutralizing epitopes identified here in **RP4** with prototype viruses can feed back into all other **Projects** that address the subsequent plug and play test cases in later years (Lujo, Chapare, Kasokero, Langya).

LASV is an Old World arenavirus (OWAV) with a single-stranded RNA virus belonging to the Arenaviridae family. Infection in humans is often the result of exposure to infected excreta from the rodent reservoir, *Mastomys natalensis* where up to 500,000 cases and an estimated 5,000 deaths occur annually in West Africa[2]. While rodent infection is largely benign, human infection can result in severe hemorrhagic disease with neurological complications and long-term hearing and vision sequelae[3,4]. There are no approved vaccines or treatments for LASV infection. **MACV** is a New World Arenavirus (NWAV) and the causative agent of Bolivian Hemorrhagic fever. Humans are infected after exposure to excreta from the reservoir, *Calomys callosus,* the large vesper mouse. Disease in humans has a slow onset, but can progress to severe hemorrhagic fever coupled to insidious neurological complications including tremors, seizures, and paralysis[5]. There are no approved vaccines or therapies approved for MACV. **CCHFV** is a highly pathogenic tick-borne virus classified under the Nairovirus genus within the Bunyaviridae family[6]. CCHF outbreaks have a case fatality rate of up to 40% and there are no vaccines or treatments approved for human use. **NiV/HeV.** Bat borne, NiV and HeV are enveloped, negative-sense, single-stranded RNA viruses belonging to the Henipavirus genus within the Paramyxoviridae family[7]. These emerging zoonotic viruses pose a significant threat to human and animal health due to their high fatality rates and broad host range. As with the other prototype virus in the **PABAX** Center there are no vaccines or treatments against henipaviruses licensed for human use.

Antibodies (Abs) are important correlates of protection for paramyxoviruses, nairoviruses, and arenaviruses. Immune sera against members of each of these groups of viruses has been shown to exhibit protective efficacy *in vivo*, which supports the use for Abs as treatment options. However, the specificity, functional properties, and other attributes of protective antibodies are poorly defined for most of these viruses. MAbs to the attachment and fusion surface proteins of paramyxoviruses (such as the G and F proteins of Hendra/Nipah[8,9] and the GP proteins of the arenaviruses like LASV[10,11]) can neutralize and protect against infection in rodent models. CCHFV is a bit of a conundrum in that ultrapotent human neutralizing antibodies to the related Rift Valley fever virus surface proteins are highly protective *in vivo*[12,13], but CCHFV neutralizing antibodies are not protective. In contrast, some non-neutralizing antibodies do protect partially for CCHFV[14]. Clearly, there is a lot to learn about the rules of immunity to these viruses, and the genetic, molecular, and structural basis of antibody-mediated protection for viruses like CCHFV. Based on these data, we propose the use of mAbs as treatment options to learn the rule of how to protect against emerging paramyxoviruses, nairoviruses, and arenaviruses and to develop candidate antibody countermeasures for translational development with **Core D**. To do so, we will further develop our technical methods for rapidly discovering mAbs, in the case of a future unexpected epidemic caused by viruses of these families. Most importantly, we will define the principles governing combination antibody therapy to prevent virus escape from treatment or prevention and to optimize the efficacy of the beneficial effects conferred by passive immunity.

B. SCIENTIFIC PREMISE. The work proposed here in **RP4** is based on the extensive basic, translational, and clinical trial data on the role of neutralizing Abs in protection against infection and disease caused by paramyxoviruses, nairoviruses, and arenaviruses. Although a significant amount of data supports the use of mAbs to prevent or control paramyxovirus, nairovirus, and arenavirus infection, many questions remain, such as the ideal epitopes to target with mAb combination therapy to improve upon neutralization potency, *in vivo* efficacy, and resistance to viral escape. Identifying these epitopes can help inform vaccine design to elicit optimal protective polyclonal responses (in **RP1** and **RP2**, especially with designs for test cases in years 4 and 5). Here we aim to refine our understanding of the correlates of mAb protection against paramyxoviruses, nairoviruses, and arenaviruses to enable the design of a modular “plug-and-play” workflow to rapidly respond to potential

pandemics by generating optimized combinations of vaccine-like mAbs with an extended half-life that could be used for long-term prophylaxis (> 6 months) and therapy.

C. INNOVATION. RP4 has many innovative conceptual and technical features including: Conceptual. **(1)** determining the principles that govern optimal combinations of human mAbs against paramyxoviruses, nairoviruses, and arenaviruses for protection and resistance to viral escape; **(2)** the development of a clear workflow that generates therapeutic or preventative antibodies (long half-life mAbs that serve as vaccine surrogates) against emerging or new paramyxoviruses, nairoviruses, and arenaviruses with pandemic potential. Our goal is to define the principles and features, including epitope, combination ratios, and mechanisms of action, that result in optimal efficacy of mAbs against paramyxoviruses, nairoviruses, and arenaviruses in animal models and create a higher barrier for resistance. These studies will serve as paradigms for rapid antibody discovery in response to future paramyxovirus, nairovirus, and arenavirus pandemic threats. Technical. **(3)** large-scale B cell repertoire sequencing with customized methods and software; **(4**) use of humanized (Alloy) mice and novel immunogens from **RP1** and **RP2** and **Core D**; **(5)** single B cell functional (neutralization) assays performed on a Beacon instrument; **(6)** development of high-throughput real-time label-free virus neutralization assays (xCELLigence platform); and **(7)** use of *simultaneous* in parallel screening with several different high-throughput virus-specific B cell isolation approaches (Beacon, 10X Genomics, Rhapsody) to generate and validate best-in-class human mAbs as candidate medical countermeasures.

D. LINKAGE TO OTHER PABVAX PROJECTS AND CORES. The group will focus on developing a modular test case platform for rapid selection of highly neutralizing and/or protective mAbs against paramyxoviruses, nairoviruses, and arenaviruses. Members of our group have active collaborations with most members of the **PABVAX Center** as reflected in previous collaborations and publications (see **Overall** document). We will interact extensively with the Animal Model and Preclinical Evaluation Core (**Core E)** to study neutralization against authentic viruses and to test for protection in small and large animals as well as with **RP3** for testing paramyxovirus mAbs. The knowledge gained from our studies on the structure-function relationships of neutralizing mAb combinations can be applied to rational vaccine design for **RP 1** and **RP2** in later years of the effort when we pivot to apply the lessons learned to the same test case targets as **RP1** and **RP2.** Numerous antigens will be made available to our RP. Finally, long-half-life Fc mutations are now available based on engineering of human IgG1 for enhanced binding to the neonatal Fc receptor (FcRn) such as LS (M428L /N434S)[15], or YTE (M252Y/S254T/T256E)[16] mutations. With ≥ 90 days half-life in humans, our approach will generate mAbs with vaccine-like properties that remain effective for months during a virus epidemic and thus provides a platform for response to future paramyxovirus, nairovirus, and arenavirus pandemic threats, a key goal of our **PABVAX Center.** *Our laboratory previously validated this vaccine surrogate concept when we isolated the human mAbs that formed the basis for Evusheld with YTE long-half-life Fc mutations (used in 70 countries and millions of people) that exhibited > 6 months protective levels in humans after single IM injections*.

E. APPROACH

E.1. Specific Aim 1. Discover potently neutralizing arenavirus combination therapies. For the prototypes, we will focus on LASV, an Old World virus and MACV, a New World virus. We will investigate the principles underlying antibody-mediated arenavirus protection. Preliminary evidence suggests that potent virus neutralization is a mechanistic correlate of protection for arenaviruses[17,18]. **RP1/Core D** will provide optimized antigens for mAb selection for the Prototype LASV and MACV (or subsequent Test Cases). We will use a workflow for rapid identification of potently neutralizing mAb combinations for LASV and MACV. We will generate mAbs from individuals with prior natural infection or use transgenic mice with human antibody repertoires. A large panel of human anti-LASV and anti-MACV mAbs will be generated using multiple approaches (immune human B cells and immunized humanized mice), and highly neutralizing mAbs will be evaluated to identify optimal combinations. The best mAb combinations will be assessed to determine the minimal effective dose for protection, and the lead mAb combination therapy(ies) will be transferred to **Core E** for further evaluation and ultimately testing in an NHP model of LASV or MACV infection. Leads will be transferred to **Core D** for further translational development as medical countermeasures. The prototype LASV and MACV will be studied in years 1 to 3, followed by mAb discovery efforts for Test Cases Lujo and Chapare viruses based on the established principles in years 4-5.

Preliminary Data. ***(a) Potently neutralizing human anti-LASV and anti-MACV mAbs.*** The Crowe laboratory has previously characterized panels of neutralizing human anti-viral human mAbs from virus-immune or vaccinated individuals for about 50 viruses, mostly RNA viruses. Isolated peripheral blood mononuclear cells (PBMCs) are used to generate hybridomas or alternatively antigen-sorted at single B cell level and antibody variable genes sequenced to generate mAbs recombinantly. Panels of human anti-viral mAbs are produced rapidly (we recently reported isolation of 15,000 mAb gene pairs from single Ebola-virus-specific human B cells from a single blood sample of an immune individual[19]. Previous studies by others clearly show that representative neutralizing and protective human antibodies can be isolated from LASV-immune subjects[20-24]. In this Aim, we will refine the approaches we have developed previously for other RNA viruses in a proof-of-concept study by identifying potently neutralizing combinations of anti-LASV and anti-MACV human mAbs. We will rapidly discover human anti-LASV mAbs from LASV-immune individuals and human anti-MACV mAbs by immunizing Alloy transgenic mice. Synergy studies will be performed to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify optimal anti-LASV and anti-MACV mAb combinations and further advance the discovery platform for rapid response against emerging arenaviruses.

(b) Advanced mAb technologies. The Crowe laboratory has developed some of the highest yield systems to isolate naturally occurring human mAbs using human hybridoma or advanced single-cell RNA-seq methods (**Fig 1**). We have used sorting of antigen-specific cells with recombinant viral surface protein antigens (like the GP1 and GP2 proteins we will use here), cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. One variation we will use is to capture Ab genes directly from viral glycoprotein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), as we have done for Ebola virus[19,25] and SARS-CoV-2[1,26-31]. These single-cell techniques enhance the capture of rare antigen-specific B cells.

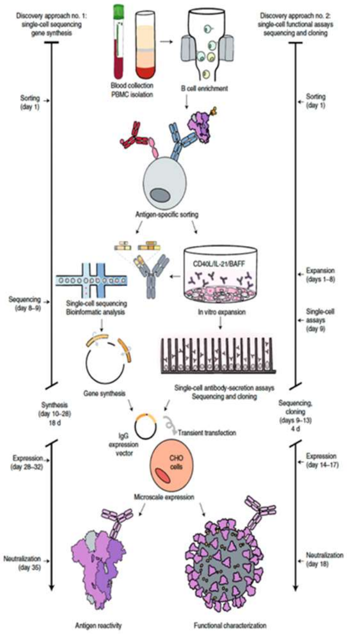

Figure 1. Single cell mAb discovery. PBMC samples are used to enrich for B cells, which can be sorted for antigen-specific B cells. Expansion allows us to further assess the functionality of the B cells or for antibody sequencing. Recombinant mAb expression validates the mAb sequence and functional activity. Figure is adapted from [1].

E.1.1. Rapid isolation of human anti-LASV and anti-MACV mAbs. *(a) Immune cells.* We have obtained human PBMCs from one previously LASV-infected individual who was medically managed previously by Emory University in their infectious diseases containment unit. This person has a documented robust neutralizing serum antibody response, suggesting isolation of neutralizing human mAbs from these PBMC aliquots will be straightforward for us. Our colleagues in **RP1** have ongoing field operations for over a decade in Sierra Leone, Liberia, and Nigeria. This work is currently in association with the NIH-Centers for Research on Emerging Infectious Diseases (CREID) with a heavy focus on the study of LASV ecology, epidemiology, and host responses. **RP4** is currently working with **RP1** on obtaining PBMCs from ~10 individuals with prior laboratory-confirmed cases of LASV. The acquisition of these samples is being managed by the Vanderbilt Vaccine Center Biorepository with separate institutional funding to be de-identified prior to use in the studies proposed here. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies have been approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples will be deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded. For anti-MACV mAbs, as a human PBMC source is not readily available, we will immunize Alloy humanized mice. These animals yield PBMCs that secrete fully human mAbs. Alloy mice are used routinely in the Crowe lab workflow.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-LASV and anti-MACV mAbs in a rapid manner to mimic a pandemic response to an outbreak. We will single-cell sort antigen-specific B cells using recombinant LASV or MACV proteins (*e.g.*, **Table 1)** or non-infectious viral particles as bait. These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including LASV and MACV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe GP protein or virus-particle binding to single B cells. These cells are exported for sequencing of the variable gene regions and analysis using the PyIR software developed in the Crowe laboratory. We will select a panel of up to 500 neutralizing anti-LASV mAbs and a similar number of anti-MACV mAbs to express recombinantly and advance for further characterization. We can easily conduct multiple approaches simultaneously in parallel[1,32].

(c) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using a custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors.

(d) Micro-scale mAb expression. The Crowe laboratory has the capacity for large-throughput micro-scale mAb expression and purification. The lower end of this range allows expression of thousands of mAbs, which will feed into automated mAb purification platforms. This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(e) A CPE-based LASV and MACV neutralization assay using RTCA. We have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of cytopathic effect (CPE). Here, we will apply this method to assess neutralization of LASV. Recently, we validated the inclusion of simultaneous live-cell fluorescence microscopy into this real-time CPE-based screening platform (xCelligence RTCA eSight). These capabilities expand the platform to screen viruses that may or may not induce CPE, allowing us to also use a replication-competent vesicular stomatitis virus (VSV) LASV surrogate that expresses LASV surface proteins and causes CPE[33]. Currently, we have a VSV-LASV-Josiah (lineage IV)[33] and a Sauerwald version (lineage II) of these recombinants. Making additional LASV VSV-LASVs is not difficult, and **RP1** will make the other missing lineages or needed arenaviruses based on the same approaches as previously published. **RP1** also can easily make versions of these VSVs that express the green fluorescent protein (GFP) reporter gene. Existing VSV-CCHFV, VSV-NiV, and VSV-HeV vectors[34-36] will be provided by Dr. Geisbert overall PI and Lead of **Core E**. We already have Vanderbilt IBC approval for use of these constructs. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression if used will identify mAbs with neutralizing activity against LASV. These mAbs will be moved forward for additional studies to identify an optimal anti-LASV mAb combination. Similar processes will be followed to determine neutralization capacity of MACV mAb candidates.

E.1.2. Identifying LASV and MACV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind LASV or MACV and validate their epitopes. We will perform competition-binding studies with GP or subunit proteins (as above) or virus-like particles (VLPs)[37] available from **Core E** at UTMB. **Core E** will also inactivate LASV and MACV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from previously reported antibodies for the identification of mAbs that can concurrently bind LASV or MACV with a goal of finding more potent clones at those sites or clones that complement these inhibitory mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-LASV or anti-MACV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations for each virus, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key residues binding residues of human anti-LASV and anti-MACV mAbs.*** To determine the key residues for binding of down-selected mAbs, we will perform deep mutational scanning[38]. Briefly, all amino acids of the GP proteins will be mutated to the other 19 amino acids with a unique barcode using PCR-based mutagenesis. The LASV or MACV GP protein library will be incubated with the appropriate mAbs to identify residues with loss-of-binding phenotypes. A sequence 'logo' showing the relative contributions of each amino acid mutation will identify residues critical for binding. Multiple amino acid substitutions can then be assessed by reverse genetics at UTMB to confirm the epitopes recognized by the down-selected mAbs. This method also serves as a surrogate for *in vitro* neutralization escape studies. ***(d) Neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-LASV or VSV-MACV constructs at BSL2 in the presence of saturating concentrations of mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Confirmatory reverse genetics studies will be performed by introducing mutations into an infectious cDNA clone of LASV or MACV by **RP1** to test neutralization. We hypothesize that escape will be less likely in the presence of mAb combinations than single mAbs. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of escape variants in the presence of mAbs.

E.1.3. Structural basis of neutralization by mAb combinations. The studies above should identify optimal anti-LASV and anti-MACV mAb combinations that simultaneously bind, neutralize, and increase the barrier for viral escape under mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb

combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for arenavirus by identifying key epitope targets (**RP1**).

E.1.4. Protective efficacy of human anti-arenavirus mAbs. ***(a) Studies in guinea pigs***. MAbs that satisfy the criteria stated above and that display stage-appropriate manufacturability characteristics will advance to *in vivo* testing. We will use established models of LASV[11,39] and MACV[40,41] infection in guinea pigs. PABVAX **Core E** has access to many strains from different LASV and MACV lineages, which will be tested. For prioritization, we will focus on LASV lineage II, III, and IV strains and MACV lineage I, II, and VIII strains for which uniformly lethal models are available. Groups of 6 outbred Hartley guinea pigs will be treated with low, medium, and high doses of single or combinations of anti-LASV or anti-MACVs mAb, or isotype controls at day +1 after inoculation with the LASVs or MACVs This approach allows us to determine whether combinations provide advantage over the best monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-LASV and anti-MACV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements (blood) at day 5 or 6 after LASV or MACV challenge and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal LASV and MACV mAb pairs that are comparable to or outperform previously reported mAbs for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-LASV and anti-MACV mAb combination against LASV or MACV in NHPs. As a final test of an optimal anti-LASV and anti-MACV mAb combinations, we will assess protective efficacy of the lead anti-LASV mAb pair in NHPs as well as the anti-MACV mAb pair in NHPs. These anti-LASV and anti-MACV mAb pairs will be selected based on the *in vitro* and guinea pig data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys will only be considered pending success in the guinea pig studies and consultation with the external Scientific Advisory Board (SAB) and NIAID program staff.

E.1.5. Applying lessons learned in LASV and MACV research with the selected test case pathogens for mAb generation: Lujo and Chapare mAbs. Once we have completed the LASV and MACV discovery campaigns, will turn to the test case pathogens to see if we can use the prototype pathogen approach to related viruses, Lujo (LUJV) and Chapare (CHAPV). We do not have access to human PBMCs from LUJV - or CHAPV-immune donors. As an alternative approach, we will use humanized mouse models as a source of B cells encoding fully human monoclonal antibodies. The Vanderbilt core investigators have an established fully executed agreement to use Alloy human antibody mice for this purpose (See Letter of Support). The Alloy ATX-Gx™ mouse is one of the most effective *in vivo* human antibody discovery platforms, with over 140 partners and counting. This mouse system was originally invented and validated inside a major pharma company and then further developed by Alloy. This foundational suite of highly immunocompetent transgenic mice is engineered to drive the greatest potential diversity of unique human antibodies binding to the viral target of interest, with broad epitopic coverage. The comprehensive functional human antibody repertoire in these mice is optimized for human Ab sequence developability and diversity. Alloy and Vanderbilt have already executed a simple licensing process for use of the ATX-Gx platform, and as an established partner the Vanderbilt core team will access the expanding portfolio of transgenic Alloy strains designed to address a range of discovery challenges (including diverse Ab isotypes). Mice will be immunized with conformationally correct recombinant protein antigens (**Table 2**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for the target of interest. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for LASV and MACV.

<u>**Anticipated results, potential problems, and alternative approaches**</u>**.** In this Aim, we will identify human anti-LASV and anti-MACV mAb combinations with optimal neutralizing and protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging LASV, MACV, or related arenaviruses. Given our previous ability to generate human antiviral mAbs, we do not anticipate problems in isolating anti-LASV or anti-MACV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently neutralizing anti-LASV or anti-MACV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody™) on enriched B cells (*i.e.*, memory B cells) isolated from human LASV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in LASV-immune PBMC samples and identify clonal lineages, including

siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-LASV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-LASV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-LASV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-LASV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the high-throughput Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E2. Specific Aim 2. Discover a protective CCHF virus mAb combination therapy. Establishing the generality of protection approaches against nairoviruses, we will perform a mAb discovery proof-of-concept campaign for the Prototype CCHFV. Preliminary studies have identified human anti-CCHF mAbs with varying levels of protection in experimentally infected animals[14,42,43]. We will isolate a large panel of human anti-CCHFV mAbs and determine the rules governing optimal mAb combinations through competition-binding, epitope mapping, neutralization, and viral escape studies. Lead antibodies with acceptable manufacturability characteristics (**Core D**) and the highest capacity to overcome resistance while maintaining potency of protection will be selected. The structural basis of their activity will be established using structural biology techniques (electron microscopy and crystallography). Lead mAb cocktail therapies will be evaluated for *in vivo* protective efficacy in STAT1$^{-/-}$ mice (with **Core E).** As a final test of an optimal anti-CCHFV mAb combination, we will assess protective efficacy of the lead anti-CCHFV mAb pair in NHPs, to be selected based on the *in vitro* and mouse data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys studies would only be considered pending success in the mouse studies and consultation with the external Scientific Advisory Board and NIAID program staff. In years 4-5, we will apply the lessons learned to the plug and play test case Kasokero virus (KASV) in collaboration with **RP1**, **Core D**, and **Core E**.

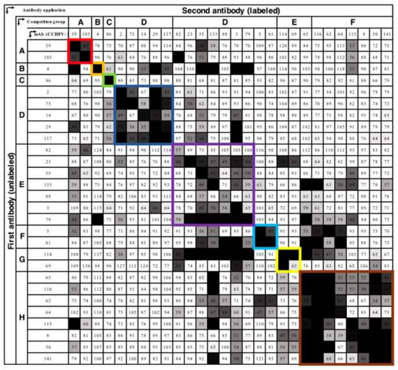

Figure 2. Competition assessment of human Abs to CCHFV using M-segment expressing cells. We tested 28 mAbs in competition assays. MAbs are displayed in 8 groups (A-H) based on their ability to compete for binding. Values shown are the % of binding that occurred during competition compared to non-competed binding of the mAb. This value was normalized to 100%. The values are also indicated by the box fill color; darker colors toward black indicate higher competition and lighter colors toward white indicate less competition, on a gradient scale.

<u>Preliminary Data</u>. ***(a) Potently neutralizing and non-neutralizing human anti-CCHFV mAbs.*** In this Aim, we will rapidly discover human anti-CCHFV mAbs from CCHFV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify an optimal anti-CCHFV mAb combination and further advance the discovery platform for rapid response against emerging nairoviruses. In preliminary experiments in collaboration with investigators in **RP1** and **Core E**, the Crowe laboratory has previously isolated and characterized panels of neutralizing human anti-CCHFV human mAbs from individuals who were convalescent after naturally-acquired laboratory-confirmed infection in Spain or Turkey. We isolated a panel of antibodies against CCHFV that recognize the M-segment in transfected cells, and they exhibit a diversity of recognition patterns in that they fall into multiple competition-binding groups (**Fig 2**). This panel contains cross-binding and cross-neutralizing antibodies for diverse strains. We observed a human mAb designated CCHF-82 competing with competition group 1 and group 2 antibodies from the previously isolated GP38-reactive murine antibodies. CCHF-82 showed some protection in a STAT1$^{-/-}$ mouse model of infection conducted by investigators in **RP1 (Fig 3)**. Further investigation with this antibody in the IbAr10200 prophylaxis and therapeutic models is warranted. In contrast, the CCHFV-neutralizing mAbs that we isolated and tested *in vivo* did not perform well in the Turkish strain STAT1$^{-/-}$ mouse model. We now know protection in this model is possible, given the work from Fels *et al*., 2021 who showed that potent antibodies against various sites on the Gc surface can afford protection in this model[42]. However, in their study they did not test GP38-reactive antibodies. To our knowledge, our preliminary

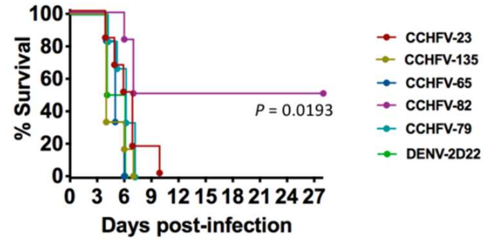

Figure 3. Human mAb CCHF-82 provides partial protection as a post-exposure prophylaxis against the Turkish strain of CCHFV in the STAT1$^{-/-}$ mouse model. A single dose of mAb was administered by the IP route to mice (n=6 per group (3 male, 3 female)) at 30 min post infections. A lethal dose of Turkish strain of CCHFV was administered. CCHF mAbs or DENV-2D22 (an isotype-matched negative control mAb) were tested in a single dose of 250 µg per mouse. Kaplan-Meier survival curves were statistically analyzed using a log-rank (Mantel-Cox) test where mAb-treated animals (*P* value shown in figure) were compared to animals treated with the DENV-2D22 negative control mAb. Unpublished data.

data is the first indication that a human GP38-targeting antibody can provide some protection in this mouse model.

Non-neutralizing murine mAbs protect in mouse models of infection[14], but it is unknown if the human antibody response could provide similar levels of protection. Murine mAb 13G8 binds to GP38 and does not neutralize CCHFV. This mAb provides protection against lethal challenge as a prophylaxis and a therapeutic against CCHFV. In preliminary experiments we sought to understand if human survivors of CCHFV infection possess B cells encoding mAbs that bind a similar epitope as 13G8 and provide protection. CCHF-82 competes for binding with 13G8 to preGn-transfected cells containing GP38. This antibody offered some protection as a post-exposure prophylaxis against the Turkish strain of CCHFV (**Fig 3**). Human antibodies like this should be further studied and the frequency of these clones should be elucidated to understand if this is a feasible strategy for future vaccine efforts for humans. The epitope that 13G8 and CCHF-82 identifies could inform vaccine design if these antibodies offer protection in larger animal models. Understanding how non-neutralizing antibodies function is critical in efforts to validate the GP38-binding class of antibodies. Golden *et al.* undertook a study to understand the mechanisms 13G8 functioned and observed that complement activation contributes to the protective capacity of this antibody[14]. Here, in studies of CCHF-82, we also will assess complement activation in mouse models of infection to fully understand the function of this mAb *in vivo*. Furthermore, if this mAb protects in the CCHFV IbAr10200 strain challenge model, assessing its mechanism is warranted. Together with **Core D**, we will assess IgG molecules with complement knockout ("KA") and Fc gamma receptor knockout (LALA-PG) mutations in the Fc domain to study this matter. Human mAb CCHF-82 displayed limited cross-protection against experimental infection with the Turkish strain of CCHFV. Our antibody isolation here will aim to identify cross-protective non-neutralizing antibodies reactive with GP38. Recently, vaccinating with NP was shown to be another way to elicit non- neutralizing antibodies[44]. The NP of CCHFV is more conserved than the glycoproteins and might also be a non-canonical target for the identification of cross-protective non-neutralizing antibodies[44].

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant viral surface protein antigens, cloning of Ab variable genes, and then expression of mAbs as as described above in Specific Aim 1.

E.2.1. Rapid isolation of human anti-CCHFV mAbs. *(a) Immune cells.* We have obtained human PBMCs from a number of previously CCHFV-infected individuals. One was a health care survivor who was infected while caring for a patient in Spain[45]. We also collected a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Turkey, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples were only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies were approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples were deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-CCHFV mAbs rapidly, as if we had to respond to a nairovirus outbreak in real time. Our ability to respond rapidly in the setting of outbreaks is well-documented in the lay press (60 Minutes features and others) and the scientific literature, e.g., 78 days from sample to protection of NHPs for Zika virus[32], and 25 days from PBMC sample receipt to delivery of the antibody genes for the approved COVID-19 drug Evusheld to AstraZeneca[1]. Here, we will single-cell sort antigen-specific B cells using recombinant CCHFV proteins (GP38, Gc, Gn, Gc/Gn) or non-infectious particles as bait as described in Specific Aim 1. We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D**, (**Table 3**) or by **RP1 (Table 4)**.

Table 3. Core D CCHFV antigens
CCHF Turkey GnGc
CCHF Turkey GP38
CCHF NP

(c) Recombinant mAb cloning. As described in Specific Aim 1 above.

(d) Micro-scale mAb expression. As described in Specific Aim 1 above.

(e) A CPE-based CCHFV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of CCHFV. We will use a rVSV CCHFV surrogate that expresses CCHFV surface proteins and causes CPE[35]. Investigators in **RP1** have the VSV-CCHFV-GFP versions of clades 1 through 7 based on this publication. We will obtain these VSV constructs from investigators in **PABVAX**. Existing VSV vectors will be provided by investigators in **RP1 and Core E**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against CCHFV. These mAbs will be moved forward for additional studies to identify an optimal anti-CCHFV mAb combination. GP38-reactive clones will be advanced based on avidity ranking since they are not likely to be neutralizing but may be protective *in vivo*.

E.2.2. Identifying CCHFV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind CCHFV surface proteins and validate their epitopes. We will perform competition-binding studies with CCHFV Gc/Gn or subunit proteins (as above) or CCHFV virus-like particles (VLPs) made from a replicon system in hand. **Core E** will inactivate CCHFV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site. Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from some of the mAbs shown in the unpublished preliminary data above for the identification of mAbs that can concurrently bind CCHFV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-CCHFV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. GP-38-reactive clones will be screened for synergistic binding as they are not expected to be neutralizing. ***(c) Identification of key binding residues of human anti-CCHFV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-CCHFV constructs at BSL2 in the presence of saturating concentrations of CCHFV mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of VSV-CCHFV escape variants in the presence of mAbs.

E.2.3. Structural basis of neutralization by anti-CCHFV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.2.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies in STAT1$^{-/-}$ mouse models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (Core D), will advance to *in vivo* testing. We will use an established STAT1$^{-/-}$ mouse model of CCHFV infection that the **RP1** and **Core E** investigators have deployed[35]. To benchmark our mAbs, a separate set of STAT1$^{-/-}$ mice will be treated with CCHF-82, which we showed in unpublished preliminary data above confers substantial but incomplete protection (**Fig 3**). The **Core E** laboratory has access to strains representing all 6 clades that can be tested. Groups of 6-8 STAT1$^{-/-}$ mice will be treated with low, medium, and high doses) of single or combinations of anti-CCHFV mAb, or isotype controls at day +1 after inoculation with CCHFVs. This approach allows us to determine whether combinations provide advantage over the best CCHFV monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after CCHFV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal CCHFV mAb pairs that are comparable to or outperform the mAbs we reported above. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-CCHFV mAb combination against CCHFV in NHPs. As a final test of an optimal anti-CCHFV mAb combination, we will assess efficacy of the lead anti-CCHFV mAb pair in NHPs (**Core E**), to be selected based on the *in vitro,* STAT1$^{-/-}$ mice, and manufacturability data (**Core D**). Down-selection for testing in cynomolgus monkeys would only be considered with success in the STAT1$^{-/-}$ mouse studies and in consultation with the external SAB and NIAID program staff.

E.2.5. Applying lessons learned in CCHFV research to Kasokero mAbs. Once we have completed the CCHFV discovery campaigns, will turn to the test case pathogen Kasokero virus to see if we can use the prototype pathogen approach for this virus. We do not have access to human PBMCs from Kasokero-immune donors. We will use Alloy humanized mouse models as a source of B cells encoding fully human mAbs, as described above. Mice will be immunized with conformationally correct recombinant protein antigens (**Table 5**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Kasokero. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for CCHFV.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-CCHFV mAb combinations with optimal protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging CCHFV or related nairoviruses. Given our previous ability to generate human anti-CCHFV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-CCHFV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-CCHFV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (i.e., memory B cells) isolated from human CCHFV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in CCHFV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-CCHFV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-CCHFV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-CCHFV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-CCHFV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E3. Specific Aim 3. Establish optimal mAb combination therapies against henipaviruses Hendra (HeV) and Nipah (NiV) viruses. We will use a large panel of potent anti-henipavirus mAbs that we previously made from the memory B cells of immune individuals and generate new antibodies targeting the fusion (F) protein. **RP2** will provide new antigens for mAb selection and BSL-2-compatible viruses for neutralization screens including Cedar virus constructs displaying HeV and NiV F and G proteins. We will identify optimal mAb combinations to enhance henipavirus therapy, minimize viral escape, and improve treatment efficacy through synergy. *In vitro* competition-binding, neutralization, and mechanistic studies will be conducted, including authentic virus neutralization with **PABVAX Core E**. We will refine the recognized epitopes and investigate the structural basis for optimal combination neutralization of henipaviruses using HeV and NiV as prototypes. *In vivo* assessment of mAb combinations will determine the minimal effective dose for protection and the ability to prevent *in vivo* escape. Protective efficacy of lead mAb combinations will be assessed in hamster models of NiV and HeV infection with **Core E**. Leads will be transferred to **Core D**. As a final test of optimal henipavirus mAb combinations, we will assess protective efficacy of the lead henipavirus mAb pairs in NHPs, to be selected based on the *in vitro* and hamster data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in African green monkey (AGM) henipavirus model studies would only be considered pending success in the hamster studies and consultation with the external SAB and NIAID program staff. The HeV and NiV studies will be conducted in years 1-3 and then applied to the plug-and-play test case Langya virus in years 2-5. If **RP2** and **Core E** cannot rescue recombinant Langya virus, the lessons learned in Years 1-3 will be applied to the alternate "plug and play" test viruses Angavokely or Sosuga (SOSV) virus. Preliminary data on SOSV mAbs are provided.

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-NIV/HeV mAbs.*** In this Aim, we will further adapt approaches we have developed in preliminary experiments with henipavirus mAb studies by identifying a potently protective combination of anti-NiV/HeV human mAbs. Through these studies, we aim to identify an optimal anti-NiV+HeV mAb combination and further advance the discovery platform for rapid response against emerging paramyxoviruses, especially henipaviruses. In previous experiments in collaboration with investigators in **RP2** and **Core E**, the Crowe laboratory has isolated characterized panels of neutralizing human anti-G NiV/HeV human mAbs from an individual with G-based immunity following occupational exposure to an equine HeV G subunit vaccine. Isolated peripheral blood mononuclear cells (PBMCs) were used to generate human B cell hybridomas secreting human mAbs to G, and antibody variable genes were sequenced to generate mAbs recombinantly. We isolated a panel of antibodies against the G protein that recognize the HeV G, NiV Bangladesh G, and NiV Malaysia G proteins. The mAbs exhibited a diversity of recognition patterns in that they fall into multiple competition-binding groups. This panel contains cross-binding and cross-neutralizing antibodies for diverse NiV and HeV strains. In the work proposed here, we will rapidly discover human NiV/HeV anti-F mAbs from NiV-immune individuals and outstanding potency anti-G antibodies with extensive characterization, including synergistic neutralization.

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant henipavirus F protein antigens, as described above in Specific Aim 1.

E.3.1. Rapid isolation of human anti-HeV/NiV mAbs. ***(a) Immune cells.*** We are obtaining human PBMCs from a number of previously NiV-infected individuals who acquired immunity following natural infection in collaboration with the **icddr,b**, an international health research institute based in Dhaka, Bangladesh. We are collecting a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Bangladesh, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies are approved by the icddr,b and Vanderbilt University Medical Center IRBs. PBMCs isolated from the blood samples are deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their use in this **RP4,** if funded. ***(b) Applying mAb technologies for new mAb isolation***. We will use sorting of antigen-specific B cells, cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), and this may be helpful for rarer antigen-specific B cells. We will sort soluble fusion (sF) or attachment (G) protein-specific cells with recombinant viral surface protein antigens from **Core D** (**Table 6**).

(c) Ab screening and sequence analysis. Our goal is to identify human anti-NiV/HeV mAbs rapidly, as if we had to respond to a paramyxovirus outbreak in real time. We will single-cell sort antigen-specific B cells using recombinant HeV and NiV proteins (sF or G) as bait as described in Specific Aim 1 above.

(d) Recombinant mAb cloning. As described in Specific Aim 1 above.

(e) Micro-scale mAb expression. As described in Specific Aim 1 above.

(f) CPE-based HeV/NiV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of HeV and NiV. We will use rVSV HeV and NiV surrogates that expresses henipaviurs surface proteins and cause CPE. Investigators in **RP2 and RP3** have VSV-NiV F and VSV-NiV G with GFP[34], VSV-NiV G without GFP[36] and VSV-HeVG (Geisbert and Cross, unpublished). We will obtain these all these VSV constructs from investigators in **PABVAX**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against HeV and NiV. We also can use Cedar virus constructs for neutralization assays as the have reduced pathogenicity[46] and can be used in high-throughput screening assays for henipavirus antiviral discovery[47]. Cedar viruses will be provided by Dr. Broder of **RP2**. The mAbs with most potent activity will be moved forward for additional studies to identify an optimal anti-HeV/NiV mAb combination.

E.3.2. Identifying HeV/NiV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind HeV/NiV surface proteins and validate their epitopes. We will perform competition-binding studies with HeV/NiV sF or G proteins (as above). We will include positive controls made recombinantly from some of the mAbs shown in the preliminary data above for the identification of mAbs that can concurrently bind HeV/NiV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti- HeV/NiV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key binding residues of human anti-HeV/NiV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-NiV F, VSV-NiV G and VSV-HeV G constructs at BSL-2 in the presence of saturating concentrations of HeV/NiV mAbs (single or combination) using RTCA to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test the level of infection of VSV-HeV/NiV escape variants in the presence of mAbs.

E.3.3. Structural basis of neutralization by anti-HeV/NiV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.3.4. Protective efficacy of human anti-henipavirus mAbs. ***(a) Studies in hamsters***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (**Core D**), will advance to *in vivo* testing. We will use an established hamster model of NiV or HeV infection that the **Core E** investigators have deployed. To

benchmark our mAbs, a separate set of hamsters will be treated with G mAbs HENV-103+HENV-117, which we showed in previous data above confers substantial protection[8]. Groups of 6-8 hamsters will be treated with low, medium, or high IgG doses) of single or combinations of anti-HeV/NiV mAbs, or isotype controls at day +1 after inoculation with HeV or NiV. This approach allows us to determine whether combinations provide advantage over the best HeV or NiV mAb monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-HeV and anti-NiV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after HeV or NiV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal HeV/NiV mAb pairs that are comparable to or outperform the mAbs we reported previously. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-HeV/NiV mAb combination against HeV and NiV in NHPs. As a final test of an optimal anti-HeV/NiV mAb combination, we may assess efficacy of the lead anti-HeV/NiV mAb pair in NHPs (**Core E**), selected based on the *in vitro,* hamster data, and manufacturability data (**Core D**). Down-selection for testing in AGMs would only be considered with success in the hamster studies and in consultation with the external SAB and NIAID program staff.

E.3.5. Applying lessons learned in HeV/NiV research to Langya, Angavokely and Sosuga viruses. Once we have completed the HeV/NiV discovery campaigns, will turn to the test case pathogen Langya (or alternate Angavokely and Sosuga (SOSV) viruses) to see if we can use the prototype pathogen approach for this virus. We have plenty of human PBMCs from the sole identified SOSV-immune individual and have already shown that it is possible to obtain HN- and F-specific neutralizing antibodies from this individual's B cells[48]. We also have already prepared recombinant SOSV prefusion F and HN proteins[48]. We do not have access to human PBMCs from Langya- or Angavokely-immune donors. For those mAb discovery campaigns, we will use Alloy humanized mouse models as a source of B cells encoding human mAbs, as above. Mice will be immunized with recombinant protein antigens (**Table 7**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Langya or Angavokely. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for Hev/NiV described above.

Angavokely sF
Langya sF

<u>Anticipated results, potential problems, and alternative approaches</u>. In this Aim, we will identify human anti-HeV/NiV mAb combinations with optimal protective activity. These mAb combinations will be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging HeV/NiV or related paramyxoviruses. Given our previous ability to generate human anti-HeV/NiV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-HeV/NiV mAbs. We may observe that new mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-HeV/NiV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody™) on enriched B cells *(i.e., memory B cells) isolated from human NiV-immune PBMC samples. In addition, we can deep sequence the B* cell repertoires present in NiV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-HeV/NiV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-HeV/NiV mAb combinations that can inform vaccine design (**RP2**) for related viruses being used as test cases in years 2 through 5.

F. Scientific rigor. *<u>Experimental design</u>.* Experiments will include biological and technical replicates, and results will be analyzed by parametric or non-parametric analyses (depending on data distribution) and corrections for multiple comparisons. EC_{50} (binding) and IC_{50} (neutralization) values will be reported only following at least 3 identically conducted experiments. All mAb screening will incorporate appropriate + and - controls. Positive signals in binding assays will be defined as >3 SD above background. ***<u>Protein quality</u>.*** We have a high capacity to purify proteins using a Protein Maker workstation that allows purification chromatography on 24 parallel columns. We perform QC on protein reagents using a Maurice instrument with capillary electrophoresis technology to automate our protein profiling either by size or charge, providing cIEF and CE-SDS data. Animal ***studies*** will be performed blinded with independent replicates and include negative (*e.g.*, placebo), and positive (when available) controls. We will use power calculations (**Data Management Core B**) to determine sample sizes. For virological studies, power analysis was performed using accepted values for type I error (0.05) and power (80%). The values for population variance (15×) are based on existing data sets and our experience with rodent challenge studies. We will perform experiments at least 2-3 independent times (n = 4-5 each) to attain n = 12-15 per arm. Smaller group sizes can be used if differences are larger than expected.

G. Relevant biological variables. The human mAbs are derived from immune human donors or Alloy mice. Humans. Human Abs will be isolated for biological, structural, and functional studies at a clonal level. The sample size is not powered for large scale epidemiologic or clinical study conclusions. There is no evidence that sex, age, body mass index, or underlying health conditions other than immunodeficiency or immunosuppressive treatments alters the activity of cloned Abs in structure/function studies. The samples are de-identified without patient specific identifiers to protect the health information of the donors; thus, research with these samples is considered *Not Human Subjects Research* category activity. Mice, hamsters, guinea pigs, NHP, and viruses are also biological systems used in this application. Conventional animal housing conditions will be used because there is no evidence that altered room temperatures and light/dark cycles influence paramyxovirus, nairovirus, or arenavirus pathogenesis. Mice, hamsters, guinea pigs, and NHPs of both sexes will be used, and phenotypes will be monitored for sex-based differences. Virus stocks will be either low passage seed stocks from natural isolates or generated from existing cDNA clones and sequence-confirmed prior to use for infection studies.

H. Milestones and quantitative Go/No-Go criteria. Through **Aims 1-3**, we have proposed experiments that will advance our knowledge of the mAb-mediated mechanisms of action against paramyxoviruses, nairoviruses, and arenaviruses. In each Aim, we will use down-selection criteria (as below) to advance mAb combinations or variants for additional studies. By year 3, we will have defined the principles that govern optimal mAb combinations for paramyxoviruses, nairoviruses, and arenaviruses and the rational approaches needed to select mAbs for potency and breadth. We will use the following metrics to advance mAbs: ***(a) Neutralizing activity.*** All mAbs will have neutralizing potency < 10 ng/mL, EC_{50} value; ***(b) Binding affinity***. MAbs will be of high affinity to surface proteins or virions ($K_D < 5$ nM). ***(c) Protein stability and production quality.*** MAbs must produce at high levels without optimization (> 100 mg/L) and show biochemical/functional stability at 4°C or -80°C (>90% retention of binding and neutralization activity at 30 d). ***(d) Synergy***. Combinations of 2 mAbs against a given virus ideally will show synergy of neutralization *in vitro* or at a minimum, additive inhibition (no antagonism); ***(e) Epitopes***. To avoid resistance, mAbs in combination will bind 2 epitopes (determined by competition binding (<20% reduction in binding), mapping, and structural studies. ***(f) Resistance*** against mAbs will be assessed for virus escape. Deep sequencing of viruses that emerge from cells or animals treated with mAbs will inform prioritization. Combinations of mAbs with high genetic barriers to resistance (<10× loss in EC_{50}) will be advanced. ***(g) Protection in mice, hamsters, guinea pigs, or NHPs.*** The following metrics can be used: (i) Protection against lethal challenge by homologous virus (>90% survival; (ii) Protection against clinical disease by homologous virus (>80%); (iii) Protection against infection by homologous virus (>100-fold reduction in viral titers in multiple organs). ***(h) pK measurements***. For lead protective mAbs with mutations that should confer extended half-life, we will perform pK studies in NHPs (with **Core D** and **E**) to assess levels over time with a goal of a human predicted serum half-life of >6 months.

Timeline for RP4	Year 1	Year 2	Year 3		Year 4	Year 5
Prototype mAb generation and testing: **LASV and MACV mAbs**	X	X	X		X	
Test case mAb generation and testing: **Lujo and Chapare mAbs**			X		X	X

A. BACKGROUND AND SIGNIFICANCE. Paramyxoviruses, nairoviruses, and arenaviruses are widely distributed RNA viruses that cause severe human syndromes. Because of their geographical distribution and expansion, changes in human demographics and increased exposures to wild animals including rodents and bats, and their capacity for human-to-human spread, these viruses have the potential to cause pandemics. Together with the other investigators in **PABVAX**, we have selected several important prototype paramyxoviruses, nairoviruses, and arenaviruses to study to learn the rules governing immunity to these pathogens. The work on the pathogens selected is justified based on their prevalence and severity alone, but also because of their ability to serve as prototypes for genetically related viruses. We chose the viruses for focus in this RP4 on human antibody development because of their clinical relevance and because several will be studied as prototypes for vaccine development in **RP1** (arenaviruses, nairoviruses) and **RP2** (paramyxoviruses). Among the arenaviruses, we will target Lassa virus (LASV) and Machupo virus (MACV), and among the nairoviruses, we will study Crimean–Congo hemorrhagic fever virus (CCHFV). In tandem with the vaccine projects in **RP2** focused on paramyxoviruses, we will study Nipah virus (NiV) and Hendra virus (HeV) as the prototypes. Information about the principles we discover about critical neutralizing epitopes identified here in **RP4** with prototype viruses can feed back into all other **Projects** that address the subsequent plug and play test cases in later years (Lujo, Chapare, Kasokero, Langya).

LASV is an Old World arenavirus (OWAV) with a single-stranded RNA virus belonging to the Arenaviridae family. Infection in humans is often the result of exposure to infected excreta from the rodent reservoir, *Mastomys natalensis* where up to 500,000 cases and an estimated 5,000 deaths occur annually in West Africa[2]. While rodent infection is largely benign, human infection can result in severe hemorrhagic disease with neurological complications and long-term hearing and vision sequelae[3,4]. There are no approved vaccines or treatments for LASV infection. ~~The virus possesses a bi-segmented genome comprising large (L) and small (S) segments, both of which are enclosed within a lipid envelope. The L segment (~7.2 kb) encodes the RNA-dependent RNA polymerase (RdRp) and a zinc-binding protein (Z), while the S segment (~3.4 kb) codes for the nucleoprotein (NP) and the glycoprotein precursor (GPC). The GPC is further cleaved into two surface glycoproteins, GP1 and GP2, which play critical roles in viral entry. The genetic diversity of LASV can be classified into six lineages (I-VI), with lineages III and IV being the most prevalent[5]. Genetic variation arises mainly due to the error-prone nature of the viral RNA polymerase, leading to the emergence of quasi-species. This diversity contributes to the virus's ability to evade host immune responses and pose challenges to vaccine development[6]. The surface glycoproteins GP1 and GP2, are responsible for receptor binding and membrane fusion, respectively. While GP1 is highly variable among strains, GP2 is more conserved. The nucleoprotein (NP) is another major antigen, and its immunodominant epitopes are targeted by the host's immune response. Its genetic diversity and antigenic properties complicate diagnosis and vaccine development, emphasizing the need for continued research on medical countermeasures.~~

MACV is a New World Arenavirus (NWAV) and the causative agent of Bolivian Hemorrhagic fever. Humans are infected after exposure to excreta from the reservoir, *Calomys callosus,* the large vesper mouse. Disease in humans has a slow onset, but can progress to severe hemorrhagic fever coupled to insidious neurological complications including tremors, seizures, and paralysis[7]. ~~MACV has a similar genomic organization and contains a GPC, NP, Z, and L polymerase proteins. Genetic diversity of MACV is delineated into 8 lineages (I-VIII) where there is growing concern of an expanding host range of *C. callosus* is responsible for outbreaks outside the known endemic region[8]. While the host entry receptor for NWAV is not shared with OWAV, the role for GP to drive immunity as a major antigen alongside NP. The better studied Junin has a regionally approved vaccine[9] and convalescent plasma program[10] available to prevent and treat disease, respectively.~~ There are no approved vaccines or therapies approved for MACV.~~any other NWAV, including MACV. Further, it is not well established whether these countermeasures have potential for cross protect other NWAV such as MACV, underscoring the value of continued efforts to develop broadly active countermeasures to safeguard against lethal disease.~~

CCHFV is a highly pathogenic tick-borne virus classified under the Nairovirus genus within the Bunyaviridae family[11]. CCHF outbreaks have a case fatality rate of up to 40% and there are no vaccines or treatments approved for human use.~~It has a negative-sense, single-stranded RNA genome comprising three segments: Small (S), Medium (M), and Large (L). These segments are enclosed within a lipid envelope and code for various structural and non-structural proteins. The S segment (~1.7 kb) encodes the nucleocapsid protein (N), which is essential for viral replication and assembly. The M segment (~5.3 kb) codes for the glycoprotein precursor (GPC), which is post-translationally cleaved into two surface glycoproteins, Gn and Gc. These glycoproteins are involved in viral entry and fusion. The L segment (~12.1 kb) encodes the RNA-dependent RNA polymerase (RdRp), responsible for viral RNA synthesis. CCHFV exhibits significant genetic diversity, with at least seven distinct clades (Europe 1, Europe 2, Africa 1-3, and Asia 1-2) based on the partial S segment sequences[12]. This diversity is attributed to the segmented genome, geographical distribution, and error-prone viral RNA polymerase, leading~~

Formatted: Font: 11 pt, Not Bold

~~to the emergence of various quasi-species. The major antigens of CCHFV include the surface glycoproteins Gn and Gc, as well as the nucleocapsid protein (N)[13,14]. These antigens are targeted by the host immune response. CCHFV is genetically diverse, so breadth of reactivity will be a focus of our discovery efforts.~~

NiV/HeV. Bat borne**,** NiV and HeV are enveloped, negative-sense, single-stranded RNA viruses belonging to the Henipavirus genus within the Paramyxoviridae family[15]. These emerging zoonotic viruses pose a significant threat to human and animal health due to their high fatality rates and broad host range. ~~The genomes of NiV and HeV are approximately 18.2 kb or 18.4 kb in length, respectively, and share a similar gene organization. They encode six major structural proteins: nucleocapsid (N), phosphoprotein (P), matrix (M), fusion (F), attachment glycoprotein (G), and large polymerase (L) proteins. The N, P, and L proteins form the viral RNA-dependent RNA polymerase (RdRp) complex necessary for transcription and replication, whereas the M, F, and G proteins are essential for virus assembly and entry. Genetic diversity in henipaviruses is relatively low compared to other RNA viruses, with NiV strains showing 91-100% nucleotide similarity and HeV strains displaying 83-100% similarity[16]. However, the error-prone nature of the RdRp can still generate genetic variability, leading to the emergence of distinct lineages. The major surface antigens of Nipah and Hendra viruses are the attachment glycoprotein (G) and fusion protein (F). The G protein facilitates receptor binding, while the F protein mediates viral membrane fusion. Both antigens are involved in host immune responses and are potential targets for vaccine development, and the neutralizing antibody approaches we propose here. NiV and HeV exhibit relatively low genetic diversity, and in preliminary studies, we have identified human mAbs that neutralize HeV, NiV Bangladesh and NiV Malaysia strains[17-19]. Antibodies to the major surface antigens, the G and F proteins, are therefore, promising candidates for development as prophylactic or therapeutic molecules.~~As with the other prototype virus in the **PABAX** Center there are no vaccines or treatments against henipaviruses licensed for human use.

Formatted: Font: Bold

Antibodies (Abs) are important correlates of protection for paramyxoviruses, nairoviruses, and arenaviruses. Immune sera against members of each of these groups of viruses has been shown to exhibit protective efficacy *in vivo*, which supports the use for Abs as treatment options. However, the specificity, functional properties, and other attributes of protective antibodies are poorly defined for most of these viruses. MAbs to the attachment and fusion surface proteins of paramyxoviruses (such as the G and F proteins of Hendra/Nipah[18,20] and the GP proteins of the arenaviruses like LASV[21,22]) can neutralize and protect against infection in rodent models. CCHFV is a bit of a conundrum in that ultrapotent human neutralizing antibodies to the related Rift Valley fever virus surface proteins are highly protective *in vivo*[23,24], but CCHFV neutralizing antibodies are not protective. In contrast, some non-neutralizing antibodies do protect partially for CCHFV[25]. Clearly, there is a lot to learn about the rules of immunity to these viruses, and the genetic, molecular, and structural basis of antibody-mediated protection for viruses like CCHFV. Based on these data, we propose the use of mAbs as treatment options to learn the rule of how to protect against emerging paramyxoviruses, nairoviruses, and arenaviruses and to develop candidate antibody countermeasures for translational development with **Core D**. To do so, we will further develop our technical methods for rapidly discovering mAbs, in the case of a future unexpected epidemic caused by viruses of these families. Most importantly, we will define the principles governing combination antibody therapy to prevent virus escape from treatment or prevention and to optimize the efficacy of the beneficial effects conferred by passive immunity.

B. SCIENTIFIC PREMISE. The work proposed here in **RP4** is based on the extensive basic, translational, and clinical trial data on the role of neutralizing Abs in protection against infection and disease caused by paramyxoviruses, nairoviruses, and arenaviruses. Although a significant amount of data supports the use of mAbs to prevent or control paramyxovirus, nairovirus, and arenavirus infection, many questions remain, such as the ideal epitopes to target with mAb combination therapy to improve upon neutralization potency, *in vivo* efficacy, and resistance to viral escape. Identifying these epitopes can help inform vaccine design to elicit optimal protective polyclonal responses (in **RP1** and **RP2**, especially with designs for test cases in years 4 and 5). Here we aim to refine our understanding of the correlates of mAb protection against paramyxoviruses, nairoviruses, and arenaviruses to enable the design of a modular "plug-and-play" workflow to rapidly respond to potential pandemics by generating optimized combinations of vaccine-like mAbs with an extended half-life that could be used for long-term prophylaxis (> 6 months) and therapy.

C. INNOVATION. RP4 has many innovative conceptual and technical features including: Conceptual. **(1)** determining the principles that govern optimal combinations of human mAbs against paramyxoviruses, nairoviruses, and arenaviruses for protection and resistance to viral escape; **(2)** the development of a clear workflow that generates therapeutic or preventative antibodies (long half-life mAbs that serve as vaccine surrogates) against emerging or new paramyxoviruses, nairoviruses, and arenaviruses with pandemic potential. Our goal is to define the principles and features, including epitope, combination ratios, and mechanisms of action, that result in optimal efficacy of mAbs against paramyxoviruses, nairoviruses, and arenaviruses in animal models and create a higher barrier for resistance. These studies will serve as paradigms for rapid antibody discovery in response to future paramyxovirus, nairovirus, and arenavirus pandemic threats. Technical. **(3)** large-scale B cell repertoire sequencing with customized methods and software; **(4**) use of humanized (Alloy) mice and novel immunogens from **RP1** and **RP2** and **Core D**; **(5)** single B cell functional (neutralization) assays performed on a Beacon instrument; **(6)** development of high-throughput real-time label-free virus neutralization assays (xCELLigence platform); and **(7)** use of *simultaneous* in parallel screening with several different high-throughput virus-specific B cell isolation approaches (Beacon, 10X Genomics, Rhapsody) to generate and validate best-in-class human mAbs as candidate medical countermeasures.

D. LINKAGE TO OTHER PABVAX PROJECTS AND CORES. The group will focus on developing a modular test case platform for rapid selection of highly neutralizing and/or protective mAbs against paramyxoviruses, nairoviruses, and arenaviruses. Members of our group have active collaborations with most members of the **PABVAX Center** as reflected in previous collaborations and publications (see **Overall** document). We will interact extensively with the Animal Model and Preclinical Evaluation Core (**Core E)** to study neutralization against authentic viruses and to test for protection in small and large animals as well as with **RP3** for testing paramyxovirus mAbs. The knowledge gained from our studies on the structure-function relationships of neutralizing mAb combinations can be applied to rational vaccine design for **RP 1** and **RP2** in later years of the effort when we pivot to apply the lessons learned to the same test case targets as **RP1** and **RP2.** Numerous antigens will be made available to our RP. Finally, long-half-life Fc mutations are now available based on engineering of human IgG1 for enhanced binding to the neonatal Fc receptor (FcRn) such as LS (M428L /N434S)[26], or YTE (M252Y/S254T/T256E)[27] mutations. With ≥ 90 days half-life in humans, our approach will generate mAbs with vaccine-like properties that remain effective for months during a virus epidemic and thus provides a platform for response to future paramyxovirus, nairovirus, and arenavirus pandemic threats, a key goal of our **PABVAX Center.** *Our laboratory previously validated this vaccine surrogate concept when we isolated the human mAbs that formed the basis for Evusheld with YTE long-half-life Fc mutations (used in 70 countries and millions of people) that exhibited > 6 months protective levels in humans after single IM injections*.

E. APPROACH

E.1. Specific Aim 1. Discover potently neutralizing arenavirus combination therapies. For the prototypes, we will focus on LASV, an Old World virus and MACV, a New World virus. We will investigate the principles underlying antibody-mediated arenavirus protection. Preliminary evidence suggests that potent virus neutralization is a mechanistic correlate of protection for arenaviruses[28,29]. **RP1/Core D** will provide optimized antigens for mAb selection for the Prototype LASV and MACV (or subsequent Test Cases). We will use a workflow for rapid identification of potently neutralizing mAb combinations for LASV and MACV. We will generate mAbs from individuals with prior natural infection or use transgenic mice with human antibody repertoires. A large panel of human anti-LASV and anti-MACV mAbs will be generated using multiple approaches (immune human B cells and immunized humanized mice), and highly neutralizing mAbs will be evaluated to identify optimal combinations. The best mAb combinations will be assessed to determine the minimal effective dose for protection, and the lead mAb combination therapy(ies) will be transferred to **Core E** for further evaluation and ultimately testing in an NHP model of LASV or MACV infection. Leads will be transferred to **Core D** for further translational development as medical countermeasures. The prototype LASV and MACV will be studied in years 1 to 3, followed by mAb discovery efforts for Test Cases Lujo and Chapare viruses based on the established principles in years 4-5.

Field Code Changed

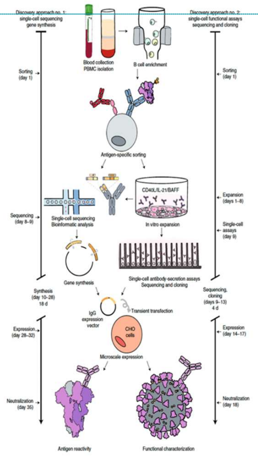

Figure 1. Single cell mAb discovery. PBMC samples are used to enrich for B cells, which can be sorted for antigen-specific B cells. Expansion allows us to further assess the functionality of the B cells or for antibody sequencing. Recombinant mAb expression validates the mAb sequence and functional activity. Figure is adapted from [1].

__Preliminary Data__. ***(a) Potently neutralizing human anti-LASV and anti-MACV mAbs.*** The Crowe laboratory has previously characterized panels of neutralizing human anti-viral human mAbs from virus-immune or vaccinated individuals for about 50 viruses, mostly RNA viruses. Isolated peripheral blood mononuclear cells (PBMCs) are used to generate hybridomas or alternatively antigen-sorted at single B cell level and antibody variable genes sequenced to generate mAbs recombinantly. Panels of human anti-viral mAbs are produced rapidly (we recently reported isolation of 15,000 mAb gene pairs from single Ebola-virus-specific human B cells from a single blood sample of an immune individual[30]. Previous studies by others clearly show that representative neutralizing and protective human antibodies can be isolated from LASV-immune subjects[31-35]. In this Aim, we will refine the approaches we have developed previously for other RNA viruses in a proof-of-concept study by identifying potently neutralizing combinations of anti-LASV and anti-MACV human mAbs. We will rapidly discover human anti-LASV mAbs from LASV-immune individuals and human anti-MACV mAbs by immunizing Alloy transgenic mice. Synergy studies will be performed to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify optimal anti-LASV and anti-MACV mAb combinations and further advance the discovery platform for rapid response against emerging arenaviruses.

(b) Advanced mAb technologies. The Crowe laboratory has developed some of the highest yield systems to isolate naturally occurring human mAbs using human hybridoma or advanced single-cell RNA-seq methods (**Fig 1**). We have used sorting of antigen-specific cells with recombinant viral surface protein antigens (like the GP1 and GP2 proteins we will use here), cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. One variation we will use is to capture Ab genes directly from viral glycoprotein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), as we have done for Ebola virus[30,36] and SARS-CoV-2[1,37-42]. These single-cell techniques enhance the capture of rare antigen-specific B cells.

E.1.1. Rapid isolation of human anti-LASV and anti-MACV mAbs. *(a) Immune cells.* We have obtained human PBMCs from one previously LASV-infected individual who was medically managed previously by Emory University in their infectious diseases containment unit. This person has a documented robust neutralizing serum antibody response, suggesting isolation of neutralizing human mAbs from these PBMC aliquots will be straightforward for us. Our colleagues in **RP1** have ongoing field operations for over a decade in Sierra Leone, Liberia, and Nigeria. This work is currently in association with the NIH-Centers for Research on Emerging Infectious Diseases (CREID) with a heavy focus on the study of LASV ecology, epidemiology, and host responses. **RP4** is currently working with **RP1** on obtaining PBMCs from ~10 individuals with prior laboratory-confirmed cases of LASV. The acquisition of these samples is being managed by the Vanderbilt Vaccine Center Biorepository with separate institutional funding to be de-identified prior to use in the studies proposed here. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies have been approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples will be deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded. For anti-MACV mAbs, as a human PBMC source is not readily available, we will immunize Alloy humanized mice. These animals yield PBMCs that secrete fully human mAbs. Alloy mice are used routinely in the Crowe lab workflow.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-LASV and anti-MACV mAbs in a rapid manner to mimic a pandemic response to an outbreak. We will single-cell sort antigen-specific B cells using recombinant LASV or MACV proteins (*e.g.*, **Table 1)** or non-infectious viral particles as bait. These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including LASV and MACV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe GP protein or virus-particle binding to single B cells. These cells are exported for sequencing of the variable gene regions and analysis using the PyIR software developed in the Crowe laboratory. We will select a panel of up to 500 neutralizing anti-LASV mAbs and a similar number of anti-MACV mAbs to express recombinantly and advance for further characterization. We can easily conduct multiple approaches simultaneously in parallel[1,43].

Lassa Josiah GPe
Machupo GPe
Machupo NP

(c) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using a custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors.

(d) Micro-scale mAb expression. The Crowe laboratory has the capacity for large-throughput micro-scale mAb expression and purification. The lower end of this range allows expression of thousands of mAbs, which will feed into automated mAb purification platforms. This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(e) A CPE-based LASV and MACV neutralization assay using RTCA. We have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of cytopathic effect (CPE). Here, we will apply this method to assess neutralization of LASV. Recently, we validated the inclusion of simultaneous live-cell fluorescence microscopy into this real-time CPE-based screening platform (xCelligence RTCA eSight). These capabilities expand the platform to screen viruses that may or may not induce CPE, allowing us to also use a replication-competent vesicular stomatitis virus (VSV) LASV surrogate that expresses LASV surface proteins and causes CPE[44]. Currently, we have a VSV-LASV-Josiah (lineage IV)[44] and a Sauerwald version (lineage II) of these recombinants. Making additional LASV VSV-LASVs is not difficult, and **RP1** will make the other missing lineages or needed arenaviruses based on the same approaches as previously published. **RP1** also can easily make versions of these VSVs that express the green fluorescent protein (GFP) reporter gene. Existing VSV-CCHFV, VSV-NiV, and VSV-HeV vectors[45-47] will be provided by Dr. Geisbert overall PI and Lead of **Core E**. We already have Vanderbilt IBC approval for use of these constructs. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression if used will identify mAbs with neutralizing activity against LASV. These mAbs will be moved forward for additional studies to identify an optimal anti-LASV mAb combination. Similar processes will be followed to determine neutralization capacity of MACV mAb candidates.

E.1.2. Identifying LASV and MACV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind LASV or MACV and validate their epitopes. We will perform competition-binding studies with GP or subunit proteins (as above) or virus-like particles (VLPs)[48] available from **Core E** at UTMB. **Core E** will also inactivate LASV and MACV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from previously reported antibodies for the identification of mAbs that can concurrently bind LASV or MACV with a goal of finding more potent clones at those sites or clones that complement these inhibitory mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-LASV or anti-MACV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations for each virus, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key residues binding residues of human anti-LASV and anti-MACV mAbs.*** To determine the key residues for binding of down-selected mAbs, we will perform deep mutational scanning[49]. Briefly, all amino acids of the GP proteins will be mutated to the other 19 amino acids with a unique barcode using PCR-based mutagenesis. The LASV or MACV GP protein library will be incubated with the appropriate mAbs to identify residues with loss-of-binding phenotypes. A sequence 'logo' showing the relative contributions of each amino acid mutation will identify residues critical for binding. Multiple amino acid substitutions can then be assessed by reverse genetics at UTMB to confirm the epitopes recognized by the down-selected mAbs. This method also serves as a surrogate for *in vitro* neutralization escape studies. ***(d) Neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-LASV or VSV-MACV constructs at BSL2 in the presence of saturating concentrations of mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Confirmatory reverse genetics studies will be performed by introducing mutations into an infectious cDNA clone of LASV or MACV by **RP1** to test neutralization. We hypothesize that escape will be less likely in the presence of mAb combinations than single mAbs. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of escape variants in the presence of mAbs.

E.1.3. Structural basis of neutralization by mAb combinations. The studies above should identify optimal anti-LASV and anti-MACV mAb combinations that simultaneously bind, neutralize, and increase the barrier for viral escape under mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for arenavirus by identifying key epitope targets (**RP1**).

E.1.4. Protective efficacy of human anti-arenavirus mAbs. ***(a) Studies in guinea pigs***. MAbs that satisfy the criteria stated above and that display stage-appropriate manufacturability characteristics will advance to *in vivo* testing. We will use established models of LASV[22,50] and MACV[51,52] infection in guinea pigs. PABVAX **Core E** has access to many strains from different LASV and MACV lineages, which will be tested. For prioritization, we will focus on LASV lineage II, III, and IV strains and MACV lineage I, II, and VIII strains for which uniformly lethal models are available. Groups of 6 outbred Hartley guinea pigs will be treated with low, medium, and high doses of single or combinations of anti-LASV or anti-MACVs mAb, or isotype controls at day +1 after inoculation with the LASVs or MACVs This approach allows us to determine whether combinations provide advantage over the best monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-LASV and anti-MACV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements (blood) at day 5 or 6 after LASV or MACV challenge and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal LASV and MACV mAb pairs that are comparable to or outperform previously reported mAbs for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-LASV and anti-MACV mAb combination against LASV or MACV in NHPs. As a final test of an optimal anti-LASV and anti-MACV mAb combinations, we will assess protective efficacy of the lead anti-LASV mAb pair in NHPs as well as the anti-MACV mAb pair in NHPs. These anti-LASV and anti-MACV mAb pairs will be selected based on the *in vitro* and guinea pig data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys will only be considered pending success in the guinea pig studies and consultation with the external Scientific Advisory Board (SAB) and NIAID program staff.

E.1.5. Applying lessons learned in LASV and MACV research with the selected test case pathogens for mAb generation: Lujo and Chapare mAbs. Once we have completed the LASV and MACV discovery campaigns, will turn to the test case pathogens to see if we can use the prototype pathogen approach to related viruses, Lujo (LUJV) and Chapare (CHAPV). We do not have access to human PBMCs from LUJV - or CHAPV-immune donors. As an alternative approach, we will use humanized mouse models as a source of B cells encoding fully human monoclonal antibodies. The Vanderbilt core investigators have an established fully executed agreement to use Alloy human antibody mice for this purpose (See Letter of Support). The Alloy ATX-Gx™ mouse is one of the most effective *in vivo* human antibody discovery platforms, with over 140 partners and counting. This mouse system was originally invented and validated inside a major pharma company and then further developed by Alloy. This foundational suite of highly immunocompetent transgenic mice is engineered to drive the greatest potential diversity of unique human antibodies binding to the viral target of interest, with broad epitopic coverage. The comprehensive functional human antibody repertoire in these mice is optimized for human Ab sequence developability and diversity. Alloy and Vanderbilt have already executed a simple licensing process for use of the ATX-Gx platform, and as an established partner the Vanderbilt core team will access the expanding portfolio of transgenic Alloy strains designed to address a range of discovery challenges (including diverse Ab isotypes). Mice will be immunized with conformationally correct recombinant protein antigens (**Table 2**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for the target of interest. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for LASV and MACV.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-LASV and anti-MACV mAb combinations with optimal neutralizing and protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging LASV, MACV, or related arenaviruses. Given our previous ability to generate human antiviral mAbs, we do not anticipate problems in isolating anti-LASV or anti-MACV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently neutralizing anti-LASV or anti-MACV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody$^{\text{TM}}$) on enriched B cells (*i.e.*, memory B cells) isolated from human LASV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in LASV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-LASV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-LASV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-LASV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-LASV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the high-throughput Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E2. Specific Aim 2. Discover a protective CCHF virus mAb combination therapy. Establishing the generality of protection approaches against nairoviruses, we will perform a mAb discovery proof-of-concept campaign for the Prototype CCHFV. Preliminary studies have identified human anti-CCHF mAbs with varying levels of protection in experimentally infected animals[25,53,54]. We will isolate a large panel of human anti-CCHFV mAbs and determine the rules governing optimal mAb combinations through competition-binding, epitope mapping, neutralization, and viral escape studies. Lead antibodies with acceptable manufacturability characteristics (**Core D**) and the highest capacity to overcome resistance while maintaining potency of protection will be selected. The structural basis of their activity will be established using structural biology techniques (electron microscopy and crystallography). Lead mAb cocktail therapies will be evaluated for *in vivo* protective efficacy in STAT1$^{-/-}$ mice (with **Core E).** As a final test of an optimal anti-CCHFV mAb combination, we will assess protective efficacy of the lead anti-CCHFV mAb pair in NHPs, to be selected based on the *in vitro* and mouse data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys studies would only be considered pending success in the mouse studies and consultation with the external Scientific Advisory Board and NIAID program staff. In years 4-5, we will apply the lessons learned to the plug and play test case Kasokero virus (KASV) in collaboration with **RP1**, **Core D**, and **Core E**.

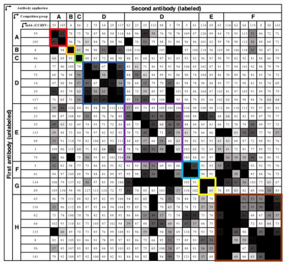

Figure 2. Competition assessment of human Abs to CCHFV using M-segment expressing cells. We tested 28 mAbs in competition assays. MAbs are displayed in 8 groups (A-H) based on their ability to compete for binding. Values shown are the % of binding that occurred during competition compared to non-competed binding of the mAb. This value was normalized to 100%. The values are also indicated by the box fill color; darker colors toward black indicate higher competition and lighter colors toward white indicate less competition, on a gradient scale.

__Preliminary Data__. ***__(a) Potently neutralizing and non-neutralizing human anti-CCHFV mAbs.__*** In this Aim, we will rapidly discover human anti-CCHFV mAbs from CCHFV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify an optimal anti-CCHFV mAb combination and further advance the discovery platform for rapid response against emerging nairoviruses. In preliminary experiments in collaboration with investigators in **RP1** and **Core E**, the Crowe laboratory has previously isolated and characterized panels of neutralizing human anti-CCHFV human mAbs from individuals who were convalescent after naturally-acquired laboratory-confirmed infection in Spain or Turkey. We isolated a panel of antibodies against CCHFV that recognize the M-segment in transfected cells, and they exhibit a diversity of recognition patterns in that they fall into multiple competition-binding groups (**Fig 2**). This panel contains cross-binding and cross-neutralizing antibodies for diverse strains. We observed a human mAb designated CCHF-82 competing with competition group 1 and group 2 antibodies from the previously isolated GP38-reactive murine antibodies. CCHF-82 showed some protection in a STAT1$^{-/-}$ mouse model of infection conducted by investigators in **RP1 (Fig 3)**. Further investigation with this antibody in the IbAr10200 prophylaxis and therapeutic models is warranted. In contrast, the CCHFV-neutralizing mAbs that we isolated and tested *in vivo* did not perform well in the Turkish strain STAT1$^{-/-}$ mouse model. We now know protection in this model is possible, given the work from Fels *et al*., 2021 who showed that potent antibodies against various sites on the Gc surface can afford protection in this model[53]. However, in their study they did not test GP38-reactive antibodies. To our knowledge, our preliminary data is the first indication that a human GP38-targeting antibody can provide some protection in this mouse model.

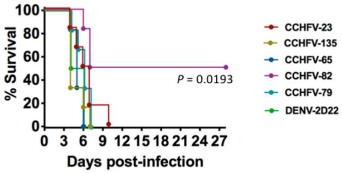

Figure 3. Human mAb CCHF-82 provides partial protection as a post-exposure prophylaxis against the Turkish strain of CCHFV in the STAT1$^{-/-}$ mouse model. A single dose of mAb was administered by the IP route to mice (n=6 per group (3 male, 3 female)) at 30 min post infections. A lethal dose of Turkish strain of CCHFV was administered. CCHF mAbs or DENV-2D22 (an isotype-matched negative control mAb) were tested in a single dose of 250 µg per mouse. Kaplan-Meier survival curves were statistically analyzed using a log-rank (Mantel-Cox) test where mAb-treated animals (*P* value shown in figure) were compared to animals treated with the DENV-2D22 negative control mAb. Unpublished data.

Non-neutralizing murine mAbs protect in mouse models of infection[25], but it is unknown if the human antibody response could provide similar levels of protection. Murine mAb 13G8 binds to GP38 and does not neutralize CCHFV. This mAb provides protection against lethal challenge as a prophylaxis and a therapeutic against CCHFV. In preliminary experiments we sought to understand if human survivors of CCHFV infection possess B cells encoding mAbs that bind a similar epitope as 13G8 and provide protection. CCHF-82 competes for binding with 13G8 to preGn-transfected cells containing GP38. This antibody offered some protection as a post-exposure prophylaxis against the Turkish strain of CCHFV (**Fig 3**). Human antibodies like this should be further studied and the frequency of these clones should be elucidated to understand if this is a feasible strategy for future vaccine efforts for humans. The epitope that 13G8 and CCHF-82 identifies could inform vaccine design if these antibodies offer protection in larger animal models. Understanding how non-neutralizing antibodies function is critical in efforts to validate the GP38-binding class of antibodies. Golden *et al.* undertook a study to understand the mechanisms 13G8 functioned and observed that complement activation contributes to the protective capacity of this antibody[25]. Here, in studies of CCHF-82, we also will assess complement activation in mouse models of infection to fully understand the function of this mAb *in vivo*. Furthermore, if this mAb protects in the CCHFV IbAr10200 strain challenge model, assessing its mechanism is warranted. Together with **Core D**, we will assess

IgG molecules with complement knockout (“KA”) and Fc gamma receptor knockout (LALA-PG) mutations in the Fc domain to study this matter. Human mAb CCHF-82 displayed limited cross-protection against experimental infection with the Turkish strain of CCHFV. Our antibody isolation here will aim to identify cross-protective non-neutralizing antibodies reactive with GP38. Recently, vaccinating with NP was shown to be another way to elicit non- neutralizing antibodies[55]. The NP of CCHFV is more conserved than the glycoproteins and might also be a non-canonical target for the identification of cross-protective non-neutralizing antibodies[55].

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant viral surface protein antigens, cloning of Ab variable genes, and then expression of mAbs as as described above in Specific Aim 1.

E.2.1. Rapid isolation of human anti-CCHFV mAbs. *(a) Immune cells.* We have obtained human PBMCs from a number of previously CCHFV-infected individuals. One was a health care survivor who was infected while caring for a patient in Spain[56]. We also collected a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Turkey, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples were only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies were approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples were deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-CCHFV mAbs rapidly, as if we had to respond to a nairovirus outbreak in real time. Our ability to respond rapidly in the setting of outbreaks is well-documented in the lay press (60 Minutes features and others) and the scientific literature, e.g., 78 days from sample to protection of NHPs for Zika virus[43], and 25 days from PBMC sample receipt to delivery of the antibody genes for the approved COVID-19 drug Evusheld to AstraZeneca[1]. Here, we will single-cell sort antigen-specific B cells using recombinant CCHFV proteins (GP38, Gc, Gn, Gc/Gn) or non-infectious particles as bait as described in Specific Aim 1. We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D**, (**Table 3**) or by **RP1 (Table 4)**.

CCHF NP

(c) Recombinant mAb cloning. As described in Specific Aim 1 above.

(d) Micro-scale mAb expression. As described in Specific Aim 1 above.

(e) A CPE-based CCHFV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of CCHFV. We will use a rVSV CCHFV surrogate that expresses CCHFV surface proteins and causes CPE[46]. Investigators in **RP1** have the VSV-CCHFV-GFP versions of clades 1 through 7 based on this publication. We will obtain these VSV constructs from investigators in **PABVAX**. Existing VSV vectors will be provided by investigators in **RP1 and Core E**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against CCHFV. These mAbs will be moved forward for additional studies to identify an optimal anti-CCHFV mAb combination. GP38-reactive clones will be advanced based on avidity ranking since they are not likely to be neutralizing but may be protective *in vivo*.

E.2.2. Identifying CCHFV mAb combinations. *(a) Epitope mapping through competition-binding studies.* Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind CCHFV surface proteins and validate their epitopes. We will perform competition-binding studies with CCHFV Gc/Gn or subunit proteins (as above) or CCHFV virus-like particles (VLPs) made from a replicon system in hand. **Core E** will inactivate CCHFV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site. Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from some of the mAbs shown in the unpublished preliminary data above for the identification of mAbs that can concurrently bind CCHFV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-CCHFV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. GP-38-reactive clones will be screened for synergistic binding as they are not expected to be neutralizing. ***(c) Identification of key binding residues of human anti-CCHFV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-CCHFV constructs at BSL2 in the presence of saturating concentrations of CCHFV mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of VSV-CCHFV escape variants in the presence of mAbs.

E.2.3. Structural basis of neutralization by anti-CCHFV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.2.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies in $STAT1^{-/-}$ mouse models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (Core D), will advance to *in vivo* testing. We will use an established $STAT1^{-/-}$ mouse model of CCHFV infection that the **RP1** and **Core E** investigators have deployed[46]. To benchmark our mAbs, a separate set of $STAT1^{-/-}$ mice will be treated with CCHF-82, which we showed in unpublished preliminary data above confers substantial but incomplete protection (**Fig 3**). The **Core E** laboratory has access to strains representing all 6 clades that can be tested. Groups of 6-8 $STAT1^{-/-}$ mice will be treated with low, medium, and high doses) of single or combinations of anti-CCHFV mAb, or isotype controls at day +1 after inoculation with CCHFVs. This approach allows us to determine whether combinations provide advantage over the best CCHFV monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after CCHFV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal CCHFV mAb pairs that are comparable to or outperform the mAbs we reported above. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-CCHFV mAb combination against CCHFV in NHPs. As a final test of an optimal anti-CCHFV mAb combination, we will assess efficacy of the lead anti-CCHFV mAb pair in NHPs (**Core E**), to be selected based on the *in vitro,* $STAT1^{-/-}$ mice, and manufacturability data (**Core D**). Down-selection for testing in cynomolgus monkeys would only be considered with success in the $STAT1^{-/-}$ mouse studies and in consultation with the external SAB and NIAID program staff.

E.2.5. Applying lessons learned in CCHFV research to Kasokero mAbs. Once we have completed the CCHFV discovery campaigns, will turn to the test case pathogen Kasokero virus to see if we can use the prototype pathogen approach for this virus. We do not have access to human PBMCs from Kasokero-immune donors. We will use Alloy humanized mouse models as a source of B cells encoding fully human mAbs, as described above. Mice will be immunized with conformationally correct recombinant protein antigens (**Table 5**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Kasokero. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for CCHFV.

~~**E.2.5. Applying lessons learned in CCHFV research to Kasokero mAbs.** Once we have completed the CCHFV discovery campaigns, will turn to the test case pathogen Kasokero virus to see if we can use the prototype pathogen approach for this virus. We do not have access to human PBMCs from Kasokero-immune donors. We will use Alloy humanized mouse models as a source of B cells encoding fully human mAbs, as described above. Mice will be immunized with conformationally correct recombinant protein antigens (**Table 5**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Kasokero. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for CCHFV.~~

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-CCHFV mAb combinations with optimal protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging CCHFV or related nairoviruses. Given our previous ability to generate human anti-CCHFV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-CCHFV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-

CCHFV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (i.e., memory B cells) isolated from human CCHFV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in CCHFV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-CCHFV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-CCHFV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-CCHFV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-CCHFV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E3. Specific Aim 3. Establish optimal mAb combination therapies against henipaviruses Hendra (HeV) and Nipah (NiV) viruses. We will use a large panel of potent anti-henipavirus mAbs that we previously made from the memory B cells of immune individuals and generate new antibodies targeting the fusion (F) protein. **RP2** will provide new antigens for mAb selection and BSL-2-compatible viruses for neutralization screens including Cedar virus constructs displaying HeV and NiV F and G proteins. We will identify optimal mAb combinations to enhance henipavirus therapy, minimize viral escape, and improve treatment efficacy through synergy. *In vitro* competition-binding, neutralization, and mechanistic studies will be conducted, including authentic virus neutralization with **PABVAX Core E**. We will refine the recognized epitopes and investigate the structural basis for optimal combination neutralization of henipaviruses using HeV and NiV as prototypes. *In vivo* assessment of mAb combinations will determine the minimal effective dose for protection and the ability to prevent *in vivo* escape. Protective efficacy of lead mAb combinations will be assessed in hamster models of NiV and HeV infection with **Core E**. Leads will be transferred to **Core D**. As a final test of optimal henipavirus mAb combinations, we will assess protective efficacy of the lead henipavirus mAb pairs in NHPs, to be selected based on the *in vitro* and hamster data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in African green monkey (AGM) henipavirus model studies would only be considered pending success in the hamster studies and consultation with the external SAB and NIAID program staff. The HeV and NiV studies will be conducted in years 1-3 and then applied to the plug-and-play test case Langya virus in years 2-5. If **RP2** and **Core E** cannot rescue recombinant Langya virus, the lessons learned in Years 1-3 will be applied to the alternate “plug and play” test viruses Angavokely or Sosuga (SOSV) virus. Preliminary data on SOSV mAbs are provided.

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-NIV/HeV mAbs.*** In this Aim, we will further adapt approaches we have developed in preliminary experiments with henipavirus mAb studies by identifying a potently protective combination of anti-NiV/HeV human mAbs. Through these studies, we aim to identify an optimal anti-NiV+HeV mAb combination and further advance the discovery platform for rapid response against emerging paramyxoviruses, especially henipaviruses. In previous experiments in collaboration with investigators in **RP2** and **Core E**, the Crowe laboratory has isolated characterized panels of neutralizing human anti-G NiV/HeV human mAbs from an individual with G-based immunity following occupational exposure to an equine HeV G subunit vaccine. Isolated peripheral blood mononuclear cells (PBMCs) were used to generate human B cell hybridomas secreting human mAbs to G, and antibody variable genes were sequenced to generate mAbs recombinantly. We isolated a panel of antibodies against the G protein that recognize the HeV G, NiV Bangladesh G, and NiV Malaysia G proteins. The mAbs exhibited a diversity of recognition patterns in that they fall into multiple competition-binding groups. This panel contains cross-binding and cross-neutralizing antibodies for diverse NiV and HeV strains. In the work proposed here, we will rapidly discover human NiV/HeV anti-F mAbs from NiV-immune individuals and outstanding potency anti-G antibodies with extensive characterization, including synergistic neutralization.

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant henipavirus F protein antigens, as described above in Specific Aim 1.

E.3.1. Rapid isolation of human anti-HeV/NiV mAbs. ***(a) Immune cells.*** We are obtaining human PBMCs from a number of previously NiV-infected individuals who acquired immunity following natural infection in collaboration with the **icddr,b**, an international health research institute based in Dhaka, Bangladesh. We are collecting a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Bangladesh, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies are approved by the icddr,b and Vanderbilt University Medical Center IRBs. PBMCs isolated from the blood samples are deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their use in this **RP4,** if funded. ***(b) Applying mAb technologies for new mAb isolation***. We will use sorting of antigen-specific B cells, cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), and this may be helpful for rarer antigen-specific B cells. We will sort soluble fusion (sF) or attachment (G) protein-specific cells with recombinant viral surface protein antigens from **Core D** (**Table 6**).

(c) Ab screening and sequence analysis. Our goal is to identify human anti-NiV/HeV mAbs rapidly, as if we had to respond to a paramyxovirus outbreak in real time. We will single-cell sort antigen-specific B cells using recombinant HeV and NiV proteins (sF or G) as bait as described in Specific Aim 1 above.

(d) Recombinant mAb cloning. As described in Specific Aim 1 above.

(e) Micro-scale mAb expression. As described in Specific Aim 1 above.

(f) CPE-based HeV/NiV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of HeV and NiV. We will use rVSV HeV and NiV surrogates that expresses henipaviurs surface proteins and cause CPE. Investigators in **RP2 and RP3** have VSV-NiV F and VSV-NiV G with GFP[45], VSV-NiV G without GFP[47] and VSV-HeVG (Geisbert and Cross, unpublished). We will obtain these all these VSV constructs from investigators in **PABVAX**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against HeV and NiV. We also can use Cedar virus constructs for neutralization assays as the have reduced pathogenicity[57] and can be used in high-throughput screening assays for henipavirus antiviral discovery[58]. Cedar viruses will be provided by Dr. Broder of **RP2**. The mAbs with most potent activity will be moved forward for additional studies to identify an optimal anti-HeV/NiV mAb combination.

E.3.2. Identifying HeV/NiV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind HeV/NiV surface proteins and validate their epitopes. We will perform competition-binding studies with HeV/NiV sF or G proteins (as above). We will include positive controls made recombinantly from some of the mAbs shown in the preliminary data above for the identification of mAbs that can concurrently bind HeV/NiV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti- HeV/NiV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key binding residues of human anti-HeV/NiV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-NiV F, VSV-NiV G and VSV-HeV G constructs at BSL-2 in the presence of saturating concentrations of HeV/NiV mAbs (single or combination) using RTCA to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test the level of infection of VSV-HeV/NiV escape variants in the presence of mAbs.

E.3.3. Structural basis of neutralization by anti-HeV/NiV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.3.4. Protective efficacy of human anti-henipavirus mAbs. ***(a) Studies in hamsters***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (**Core D**), will advance to *in vivo* testing. We will use an established hamster model of NiV or HeV infection that the **Core E** investigators have deployed. To benchmark our mAbs, a separate set of hamsters will be treated with G mAbs HENV-103+HENV-117, which we showed in previous data above confers substantial protection[18]. Groups of 6-8 hamsters will be treated with low, medium, or high IgG doses) of single or combinations of anti-HeV/NiV mAbs, or isotype controls at day +1 after inoculation with HeV or NiV. This approach allows us to determine whether combinations provide advantage over the best HeV or NiV mAb monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-HeV and anti-NiV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after HeV or NiV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal HeV/NiV mAb pairs that are comparable to or outperform the mAbs we reported previously. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-HeV/NiV mAb combination against HeV and NiV in NHPs. As a final test of an optimal anti-HeV/NiV mAb combination, we may assess efficacy of the lead anti-HeV/NiV mAb pair in NHPs (**Core E**), selected based on the *in vitro,* hamster data, and manufacturability data (**Core D**). Down-selection for testing in AGMs would only be considered with success in the hamster studies and in consultation with the external SAB and NIAID program staff.

E.3.5. Applying lessons learned in HeV/NiV research to Langya, Angavokely and Sosuga viruses. Once we have completed the HeV/NiV discovery campaigns, will turn to the test case pathogen Langya (or alternate Angavokely and Sosuga (SOSV) viruses) to see if we can use the prototype pathogen approach for this virus. We have plenty of human PBMCs from the sole identified SOSV-immune individual and have already shown that it is possible to obtain HN- and F-specific neutralizing antibodies from this individual's B cells[59]. We also have already prepared recombinant SOSV prefusion F and HN proteins[59]. We do not have access to human PBMCs from Langya- or Angavokely-immune donors. For those mAb discovery campaigns, we will use Alloy humanized mouse models as a source of B cells encoding human mAbs, as above. Mice will be immunized with recombinant protein antigens (**Table 7**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Langya or Angavokely. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for Hev/NiV described above.

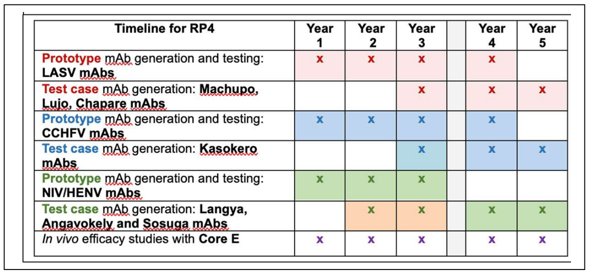
Table 7. Paramyxovirus antigens from Core D
Mojang sF
Angavokely sF
Langya sF

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-HeV/NiV mAb combinations with optimal protective activity. These mAb combinations will be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging HeV/NiV or related paramyxoviruses. Given our previous ability to generate human anti-HeV/NiV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-HeV/NiV mAbs. We may observe that new mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-HeV/NiV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells *(i.e., memory B cells) isolated from human NiV-immune PBMC samples. In addition, we can deep sequence the B* cell repertoires present in NiV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-HeV/NiV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-HeV/NiV mAb combinations that can inform vaccine design (**RP2**) for related viruses being used as test cases in years 2 through 5.

F. Scientific rigor. *Experimental design.* Experiments will include biological and technical replicates, and results will be analyzed by parametric or non-parametric analyses (depending on data distribution) and corrections for multiple comparisons. EC_{50} (binding) and IC_{50} (neutralization) values will be reported only following at least 3 identically conducted experiments. All mAb screening will incorporate appropriate + and - controls. Positive signals in binding assays will be defined as >3 SD above background. ***Protein quality.*** We have a high capacity to purify proteins using a Protein Maker workstation that allows purification chromatography on 24 parallel columns. We perform QC on protein reagents using a Maurice instrument with capillary electrophoresis technology to automate our protein profiling either by size or charge, providing cIEF and CE-SDS data. Animal ***studies*** will be performed blinded with independent replicates and include negative (*e.g.*, placebo), and positive (when available) controls. We will use power calculations (**Data Management Core B**) to determine sample sizes. For virological studies, power analysis was performed using accepted values for type I error (0.05) and power (80%). The values for population variance (15×) are based on existing data sets and our experience with rodent challenge studies. We will perform experiments at least 2-3 independent times (n = 4-5 each) to attain n = 12-15 per arm. Smaller group sizes can be used if differences are larger than expected.

G. Relevant biological variables. The human mAbs are derived from immune human donors or Alloy mice. Humans. Human Abs will be isolated for biological, structural, and functional studies at a clonal level. The sample size is not powered for large scale epidemiologic or clinical study conclusions. There is no evidence that sex, age, body mass index, or underlying health conditions other than immunodeficiency or immunosuppressive treatments alters the activity of cloned Abs in structure/function studies. The samples are de-identified without patient specific identifiers to protect the health information of the donors; thus, research with these samples is considered *Not Human Subjects Research* category activity. Mice, hamsters, guinea pigs, NHP, and viruses are also biological systems used in this application. Conventional animal housing conditions will be used because there is no evidence that altered room temperatures and light/dark cycles influence paramyxovirus, nairovirus, or arenavirus pathogenesis. Mice, hamsters, guinea pigs, and NHPs of both sexes will be used, and phenotypes will be monitored for sex-based differences. Virus stocks will be either low passage seed stocks from natural isolates or generated from existing cDNA clones and sequence-confirmed prior to use for infection studies.

H. Milestones and quantitative Go/No-Go criteria. Through **Aims 1-3**, we have proposed experiments that will advance our knowledge of the mAb-mediated mechanisms of action against paramyxoviruses, nairoviruses, and arenaviruses. In each Aim, we will use down-selection criteria (as below) to advance mAb combinations or variants for additional studies. By year 3, we will have defined the principles that govern optimal mAb combinations for paramyxoviruses, nairoviruses, and arenaviruses and the rational approaches needed to select mAbs for potency and breadth. We will use the following metrics to advance mAbs: ***(a) Neutralizing activity*.** All mAbs will have neutralizing potency < 10 ng/mL, EC_{50} value; ***(b) Binding affinity***. MAbs will be of high affinity to surface proteins or virions (K_D < 5 nM). ***(c) Protein stability and production quality*.** MAbs must produce at high levels without optimization (> 100 mg/L) and show biochemical/functional stability at 4°C or -80°C (>90% retention of binding and neutralization activity at 30 d). ***(d) Synergy***. Combinations of 2 mAbs against a given virus ideally will show synergy of neutralization *in vitro* or at a minimum, additive inhibition (no antagonism); ***(e) Epitopes***. To avoid resistance, mAbs in combination will bind 2 epitopes (determined by competition binding (<20% reduction in binding), mapping, and structural studies. ***(f) Resistance*** against mAbs will be assessed for virus escape. Deep sequencing of viruses that emerge from cells or animals treated with mAbs will inform prioritization. Combinations of mAbs with high genetic barriers to resistance (<10× loss in EC_{50}) will be advanced. ***(g) Protection in mice, hamsters, guinea pigs, or NHPs.*** The following metrics can be used: (i) Protection against lethal challenge by homologous virus (>90% survival; (ii) Protection against clinical disease by homologous virus (>80%); (iii) Protection against infection by homologous virus (>100-fold reduction in viral titers in multiple organs). ***(h) pK measurements***. For lead protective mAbs with mutations that should confer extended half-life, we will perform pK studies in NHPs (with **Core D** and **E**) to assess levels over time with a goal of a human predicted serum half-life of >6 months.



Timeline for RP4	**Year 1**	**Year 2**	**Year 3**		**Year 4**	**Year 5**
Prototype mAb generation and testing: **LASV mAbs**	x	x	x		x	
Test case mAb generation: **Machupo, Lujo, Chapare mAbs**			x		x	x
Prototype mAb generation and testing: **CCHFV mAbs**	x	x	x		x	
Test case mAb generation: **Kasokero mAbs**			x		x	x
Prototype mAb generation and testing: **NIV/HENV mAbs**	x	x	x			
Test case mAb generation: **Langya, Angavokely and Sosuga mAbs**		x	x		x	x
In vivo efficacy studies with **Core E**	x	x	x		x	x

A. BACKGROUND AND SIGNIFICANCE. Paramyxoviruses, nairoviruses, and arenaviruses are widely distributed RNA viruses that cause severe human syndromes. Because of their geographical distribution and expansion, changes in human demographics and increased exposures to wild animals including rodents and bats, and their capacity for human-to-human spread, these viruses have the potential to cause pandemics. Together with the other investigators in **PABVAX**, we have selected several important prototype paramyxoviruses, nairoviruses, and arenaviruses to study to learn the rules governing immunity to these pathogens. The work on the pathogens selected is justified based on their prevalence and severity alone, but also because of their ability to serve as prototypes for genetically related viruses. We chose the viruses for focus in this RP4 on human antibody development because of their clinical relevance and because several will be studied as prototypes for vaccine development in **RP1** (arenaviruses, nairoviruses) and **RP2** (paramyxoviruses). Among the arenaviruses, we will target Lassa virus (LASV) and Machupo virus (MACV), and among the nairoviruses, we will study Crimean–Congo hemorrhagic fever virus (CCHFV). In tandem with the vaccine projects in **RP2** focused on paramyxoviruses, we will study Nipah virus (NiV) and Hendra virus (HeV) as the prototypes. Information about the principles we discover about critical neutralizing epitopes identified here in **RP4** with prototype viruses can feed back into all other **Projects** that address the subsequent plug and play test cases in later years (Lujo, Chapare, Kasokero, Langya).

LASV is an Old World arenavirus (OWAV) with a single-stranded RNA virus belonging to the Arenaviridae family. Infection in humans is often the result of exposure to infected excreta from the rodent reservoir, *Mastomys natalensis* where up to 500,000 cases and an estimated 5,000 deaths occur annually in West Africa[2]. While rodent infection is largely benign, human infection can result in severe hemorrhagic disease with neurological complications and long-term hearing and vision sequelae[3,4]. There are no approved vaccines or treatments for LASV infection. ~~The virus possesses a bi-segmented genome comprising large (L) and small (S) segments, both of which are enclosed within a lipid envelope. The L segment (~7.2 kb) encodes the RNA-dependent RNA polymerase (RdRp) and a zinc-binding protein (Z), while the S segment (~3.4 kb) codes for the nucleoprotein (NP) and the glycoprotein precursor (GPC). The GPC is further cleaved into two surface glycoproteins, GP1 and GP2, which play critical roles in viral entry. The genetic diversity of LASV can be classified into six lineages (I-VI), with lineages III and IV being the most prevalent[5]. Genetic variation arises mainly due to the error-prone nature of the viral RNA polymerase, leading to the emergence of quasi-species. This diversity contributes to the virus's ability to evade host immune responses and pose challenges to vaccine development[6]. The surface glycoproteins GP1 and GP2, are responsible for receptor binding and membrane fusion, respectively. While GP1 is highly variable among strains, GP2 is more conserved. The nucleoprotein (NP) is another major antigen, and its immunodominant epitopes are targeted by the host's immune response. Its genetic diversity and antigenic properties complicate diagnosis and vaccine development, emphasizing the need for continued research on medical countermeasures.~~

MACV is a New World Arenavirus (NWAV) and the causative agent of Bolivian Hemorrhagic fever. Humans are infected after exposure to excreta from the reservoir, *Calomys callosus,* the large vesper mouse. Disease in humans has a slow onset, but can progress to severe hemorrhagic fever coupled to insidious neurological complications including tremors, seizures, and paralysis[7]. ~~MACV has a similar genomic organization and contains a GPC, NP, Z, and L polymerase proteins. Genetic diversity of MACV is delineated into 8 lineages (I-VIII) where there is growing concern of an expanding host range of *C. callosus* is responsible for outbreaks outside the known endemic region[8]. While the host entry receptor for NWAV is not shared with OWAV, the role for GP to drive immunity as a major antigen alongside NP. The better studied Junin has a regionally approved vaccine[9] and convalescent plasma program[10] available to prevent and treat disease, respectively.~~ There are no approved vaccines or therapies approved for MACV.~~any other NWAV, including MACV. Further, it is not well established whether these countermeasures have potential for cross protect other NWAV such as MACV, underscoring the value of continued efforts to develop broadly active countermeasures to safeguard against lethal disease.~~

CCHFV is a highly pathogenic tick-borne virus classified under the Nairovirus genus within the Bunyaviridae family[11]. CCHF outbreaks have a case fatality rate of up to 40% and there are no vaccines or treatments approved for human use.~~It has a negative-sense, single-stranded RNA genome comprising three segments: Small (S), Medium (M), and Large (L). These segments are enclosed within a lipid envelope and code for various structural and non-structural proteins. The S segment (~1.7 kb) encodes the nucleocapsid protein (N), which is essential for viral replication and assembly. The M segment (~5.3 kb) codes for the glycoprotein precursor (GPC), which is post-translationally cleaved into two surface glycoproteins, Gn and Gc. These glycoproteins are involved in viral entry and fusion. The L segment (~12.1 kb) encodes the RNA-dependent RNA polymerase (RdRp), responsible for viral RNA synthesis. CCHFV exhibits significant genetic diversity, with at least seven distinct clades (Europe 1, Europe 2, Africa 1-3, and Asia 1-2) based on the partial S segment sequences[12]. This diversity is attributed to the segmented genome, geographical distribution, and error-prone viral RNA polymerase, leading~~

Formatted: Font: 11 pt, Not Bold

~~to the emergence of various quasi-species. The major antigens of CCHFV include the surface glycoproteins Gn and Gc, as well as the nucleocapsid protein (N)[13,14]. These antigens are targeted by the host immune response. CCHFV is genetically diverse, so breadth of reactivity will be a focus of our discovery efforts.~~

NiV/HeV. Bat borne**,** NiV and HeV are enveloped, negative-sense, single-stranded RNA viruses belonging to the Henipavirus genus within the Paramyxoviridae family[15]. These emerging zoonotic viruses pose a significant threat to human and animal health due to their high fatality rates and broad host range. ~~The genomes of NiV and HeV are approximately 18.2 kb or 18.4 kb in length, respectively, and share a similar gene organization. They encode six major structural proteins: nucleocapsid (N), phosphoprotein (P), matrix (M), fusion (F), attachment glycoprotein (G), and large polymerase (L) proteins. The N, P, and L proteins form the viral RNA-dependent RNA polymerase (RdRp) complex necessary for transcription and replication, whereas the M, F, and G proteins are essential for virus assembly and entry. Genetic diversity in henipaviruses is relatively low compared to other RNA viruses, with NiV strains showing 91-100% nucleotide similarity and HeV strains displaying 83-100% similarity[16]. However, the error-prone nature of the RdRp can still generate genetic variability, leading to the emergence of distinct lineages. The major surface antigens of Nipah and Hendra viruses are the attachment glycoprotein (G) and fusion protein (F). The G protein facilitates receptor binding, while the F protein mediates viral membrane fusion. Both antigens are involved in host immune responses and are potential targets for vaccine development, and the neutralizing antibody approaches we propose here. NiV and HeV exhibit relatively low genetic diversity, and in preliminary studies, we have identified human mAbs that neutralize HeV, NiV Bangladesh and NiV Malaysia strains[17-19]. Antibodies to the major surface antigens, the G and F proteins, are therefore, promising candidates for development as prophylactic or therapeutic molecules.~~As with the other prototype virus in the **PABAX** Center there are no vaccines or treatments against henipaviruses licensed for human use.

Antibodies (Abs) are important correlates of protection for paramyxoviruses, nairoviruses, and arenaviruses. Immune sera against members of each of these groups of viruses has been shown to exhibit protective efficacy *in vivo*, which supports the use for Abs as treatment options. However, the specificity, functional properties, and other attributes of protective antibodies are poorly defined for most of these viruses. MAbs to the attachment and fusion surface proteins of paramyxoviruses (such as the G and F proteins of Hendra/Nipah[18,20] and the GP proteins of the arenaviruses like LASV[21,22]) can neutralize and protect against infection in rodent models. CCHFV is a bit of a conundrum in that ultrapotent human neutralizing antibodies to the related Rift Valley fever virus surface proteins are highly protective *in vivo*[23,24], but CCHFV neutralizing antibodies are not protective. In contrast, some non-neutralizing antibodies do protect partially for CCHFV[25]. Clearly, there is a lot to learn about the rules of immunity to these viruses, and the genetic, molecular, and structural basis of antibody-mediated protection for viruses like CCHFV. Based on these data, we propose the use of mAbs as treatment options to learn the rule of how to protect against emerging paramyxoviruses, nairoviruses, and arenaviruses and to develop candidate antibody countermeasures for translational development with **Core D**. To do so, we will further develop our technical methods for rapidly discovering mAbs, in the case of a future unexpected epidemic caused by viruses of these families. Most importantly, we will define the principles governing combination antibody therapy to prevent virus escape from treatment or prevention and to optimize the efficacy of the beneficial effects conferred by passive immunity.

B. SCIENTIFIC PREMISE. The work proposed here in **RP4** is based on the extensive basic, translational, and clinical trial data on the role of neutralizing Abs in protection against infection and disease caused by paramyxoviruses, nairoviruses, and arenaviruses. Although a significant amount of data supports the use of mAbs to prevent or control paramyxovirus, nairovirus, and arenavirus infection, many questions remain, such as the ideal epitopes to target with mAb combination therapy to improve upon neutralization potency, *in vivo* efficacy, and resistance to viral escape. Identifying these epitopes can help inform vaccine design to elicit optimal protective polyclonal responses (in **RP1** and **RP2**, especially with designs for test cases in years 4 and 5). Here we aim to refine our understanding of the correlates of mAb protection against paramyxoviruses, nairoviruses, and arenaviruses to enable the design of a modular "plug-and-play" workflow to rapidly respond to potential pandemics by generating optimized combinations of vaccine-like mAbs with an extended half-life that could be used for long-term prophylaxis (> 6 months) and therapy.

C. INNOVATION. RP4 has many innovative conceptual and technical features including: Conceptual. **(1)** determining the principles that govern optimal combinations of human mAbs against paramyxoviruses, nairoviruses, and arenaviruses for protection and resistance to viral escape; **(2)** the development of a clear workflow that generates therapeutic or preventative antibodies (long half-life mAbs that serve as vaccine surrogates) against emerging or new paramyxoviruses, nairoviruses, and arenaviruses with pandemic potential. Our goal is to define the principles and features, including epitope, combination ratios, and mechanisms of action, that result in optimal efficacy of mAbs against paramyxoviruses, nairoviruses, and arenaviruses in animal models and create a higher barrier for resistance. These studies will serve as paradigms for rapid antibody discovery in response to future paramyxovirus, nairovirus, and arenavirus pandemic threats. Technical. **(3)** large-scale B cell

Formatted: Font: Bold

repertoire sequencing with customized methods and software; **(4**) use of humanized (Alloy) mice and novel immunogens from **RP1** and **RP2** and **Core D**; **(5)** single B cell functional (neutralization) assays performed on a Beacon instrument; **(6)** development of high-throughput real-time label-free virus neutralization assays (xCELLigence platform); and **(7)** use of *simultaneous* in parallel screening with several different high-throughput virus-specific B cell isolation approaches (Beacon, 10X Genomics, Rhapsody) to generate and validate best-in-class human mAbs as candidate medical countermeasures.

D. LINKAGE TO OTHER PABVAX PROJECTS AND CORES. The group will focus on developing a modular test case platform for rapid selection of highly neutralizing and/or protective mAbs against paramyxoviruses, nairoviruses, and arenaviruses. Members of our group have active collaborations with most members of the **PABVAX Center** as reflected in previous collaborations and publications (see **Overall** document). We will interact extensively with the Animal Model and Preclinical Evaluation Core (**Core E)** to study neutralization against authentic viruses and to test for protection in small and large animals as well as with **RP3** for testing paramyxovirus mAbs. The knowledge gained from our studies on the structure-function relationships of neutralizing mAb combinations can be applied to rational vaccine design for **RP 1** and **RP2** in later years of the effort when we pivot to apply the lessons learned to the same test case targets as **RP1** and **RP2.** Numerous antigens will be made available to our RP. Finally, long-half-life Fc mutations are now available based on engineering of human IgG1 for enhanced binding to the neonatal Fc receptor (FcRn) such as LS (M428L /N434S)[26], or YTE (M252Y/S254T/T256E)[27] mutations. With ≥ 90 days half-life in humans, our approach will generate mAbs with vaccine-like properties that remain effective for months during a virus epidemic and thus provides a platform for response to future paramyxovirus, nairovirus, and arenavirus pandemic threats, a key goal of our **PABVAX Center.** *Our laboratory previously validated this vaccine surrogate concept when we isolated the human mAbs that formed the basis for Evusheld with YTE long-half-life Fc mutations (used in 70 countries and millions of people) that exhibited > 6 months protective levels in humans after single IM injections*.

E. APPROACH

E.1. Specific Aim 1. Discover potently neutralizing arenavirus combination therapies. For the prototypes, we will focus on LASV, an Old World virus and MACV, a New World virus. We will investigate the principles underlying antibody-mediated arenavirus protection. Preliminary evidence suggests that potent virus neutralization is a mechanistic correlate of protection for arenaviruses[28,29]. **RP1/Core D** will provide optimized antigens for mAb selection for the Prototype LASV and MACV (or subsequent Test Cases). We will use a workflow for rapid identification of potently neutralizing mAb combinations for LASV and MACV. We will generate mAbs from individuals with prior natural infection or use transgenic mice with human antibody repertoires. A large panel of human anti-LASV and anti-MACV mAbs will be generated using multiple approaches (immune human B cells and immunized humanized mice), and highly neutralizing mAbs will be evaluated to identify optimal combinations. The best mAb combinations will be assessed to determine the minimal effective dose for protection, and the lead mAb combination therapy(ies) will be transferred to **Core E** for further evaluation and ultimately testing in an NHP model of LASV or MACV infection. Leads will be transferred to **Core D** for further translational development as medical countermeasures. The prototype LASV and MACV will be studied in years 1 to 3, followed by mAb discovery efforts for Test Cases Lujo and Chapare viruses based on the established principles in years 4-5.

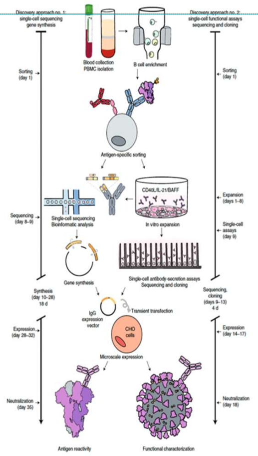

Figure 1. Single cell mAb discovery. PBMC samples are used to enrich for B cells, which can be sorted for antigen-specific B cells. Expansion allows us to further assess the functionality of the B cells or for antibody sequencing. Recombinant mAb expression validates the mAb sequence and functional activity. Figure is adapted from [1].

Field Code Changed

~~**E.1. Specific Aim 1. Discover potently neutralizing arenavirus combination therapies.** For the prototypes, we will focus on LASV, an Old World virus and MACV, a New World virus. We will investigate the principles underlying antibody-mediated arenavirus protection. Preliminary evidence suggests that potent virus neutralization is a mechanistic correlate of protection for arenaviruses[28,29]. **RP1/Core D** will provide optimized antigens for mAb selection for the Prototype LASV and MACV (or subsequent Test Cases). We will use a workflow for rapid identification of potently neutralizing mAb combinations for LASV and MACV. We will generate mAbs from individuals with prior natural infection or use transgenic mice with human antibody repertoires. A large panel of human anti-LASV and anti-MACV mAbs will be generated using multiple approaches (immune human B cells and immunized humanized mice), and highly neutralizing mAbs will be evaluated to identify optimal combinations. The best mAb combinations will be assessed to determine the minimal effective dose for protection, and the lead mAb combination therapy(ies) will be transferred to **Core E** for further evaluation and ultimately testing in an NHP model of LASV or MACV infection. Leads will be transferred to **Core D** for further translational development as medical countermeasures. The prototype LASV and MACV will be studied in years 1 to 3, followed by mAb discovery efforts for Test Cases Lujo and Chapare viruses based on the established principles in years 4-5.~~

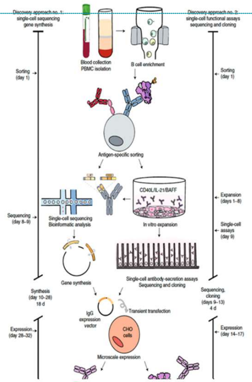

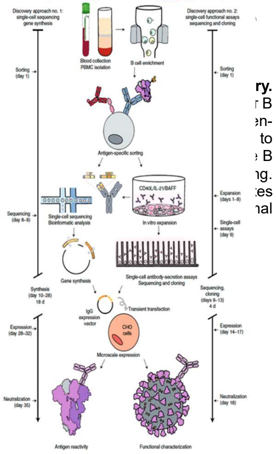

Figure 1. Single cell mAb discovery. PBMC samples are used to enrich for B cells, which can be sorted for antigen-specific B cells. Expansion allows us to further assess the functionality of the B cells or for antibody sequencing. Recombinant mAb expression validates the mAb sequence and functional activity. Figure is adapted from [1].

__Preliminary Data__. ***(a) Potently neutralizing human anti-LASV and anti-MACV mAbs.*** The Crowe laboratory has previously characterized panels of neutralizing human anti-viral human mAbs from virus-immune or vaccinated individuals for about 50 viruses, mostly RNA viruses. Isolated peripheral blood mononuclear cells (PBMCs) are used to generate hybridomas or alternatively antigen-sorted at single B cell level and antibody variable genes sequenced to generate mAbs recombinantly. Panels of human anti-viral mAbs are produced rapidly (we recently reported isolation of 15,000 mAb gene pairs from single Ebola-virus-specific human B cells from a single blood sample of an immune individual[30]. Previous studies by others clearly show that representative neutralizing and protective human antibodies can be isolated from LASV-immune subjects[31-35]. In this Aim, we will refine the approaches we have developed previously for other RNA viruses in a proof-of-concept study by identifying potently neutralizing combinations of anti-LASV and anti-MACV human mAbs. We will rapidly discover human anti-LASV mAbs from LASV-immune individuals and human anti-MACV mAbs by immunizing Alloy transgenic mice. Synergy studies will be performed to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify optimal anti-LASV and anti-MACV mAb combinations and further advance the discovery platform for rapid response against emerging arenaviruses.

(b) Advanced mAb technologies. The Crowe laboratory has developed some of the highest yield systems to isolate naturally occurring human mAbs using human hybridoma or advanced single-cell RNA-seq methods (**Fig 1**). We have used sorting of antigen-specific cells with recombinant viral surface protein antigens (like the GP1 and GP2 proteins we will use here), cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. One variation we will use is to capture Ab genes directly from viral glycoprotein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), as we have done for Ebola virus[30,36] and SARS-CoV-2[1,37-42]. These single-cell techniques enhance the capture of rare antigen-specific B cells.

E.1.1. Rapid isolation of human anti-LASV and anti-MACV mAbs. *(a) Immune cells.* We have obtained human PBMCs from one previously LASV-infected individual who was medically managed previously by Emory University in their infectious diseases containment unit. This person has a documented robust neutralizing serum antibody response, suggesting isolation of neutralizing human mAbs from these PBMC aliquots will be straightforward for us. Our colleagues in **RP1** have ongoing field operations for over a decade in Sierra Leone, Liberia, and Nigeria. This work is currently in association with the NIH-Centers for Research on Emerging Infectious Diseases (CREID) with a heavy focus on the study of LASV ecology, epidemiology, and host responses. **RP4** is currently working with **RP1** on obtaining PBMCs from ~10 individuals with prior laboratory-confirmed cases of LASV. The acquisition of these samples is being managed by the Vanderbilt Vaccine Center Biorepository with separate institutional funding to be de-identified prior to use in the studies proposed here. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies have been approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples will be deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded. For anti-MACV mAbs, as a human PBMC source is not readily available, we will immunize Alloy humanized mice. These animals yield PBMCs that secrete fully human mAbs. Alloy mice are used routinely in the Crowe lab workflow.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-LASV and anti-MACV mAbs in a rapid manner to mimic a pandemic response to an outbreak. We will single-cell sort antigen-specific B cells using recombinant LASV or MACV proteins (*e.g.*, **Table 1)** or non-infectious viral particles as bait. These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including LASV and MACV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe GP protein or virus-particle binding to single B cells. These cells are exported for sequencing of the variable gene regions and analysis using the PyIR software developed in the Crowe laboratory. We will select a panel of up to 500 neutralizing anti-LASV mAbs and a similar number of anti-MACV mAbs to express recombinantly and advance for further characterization. We can easily conduct multiple approaches simultaneously in parallel[1,43].

Table 1. Antigens from Core D
Lassa Josiah NP
Lassa Josiah GPe
Machupo GPe
Machupo NP

(c) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using a custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors.

(d) Micro-scale mAb expression. The Crowe laboratory has the capacity for large-throughput micro-scale mAb expression and purification. The lower end of this range allows expression of thousands of mAbs, which will feed into automated mAb purification platforms. This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(e) A CPE-based LASV and MACV neutralization assay using RTCA. We have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of cytopathic effect (CPE). Here, we will apply this method to assess neutralization of LASV. Recently, we validated the inclusion of simultaneous live-cell fluorescence microscopy into this real-time CPE-based screening platform (xCelligence RTCA eSight). These capabilities expand the platform to screen viruses that may or may not induce CPE, allowing us to also use a replication-competent vesicular stomatitis virus (VSV) LASV surrogate that expresses LASV surface proteins and causes CPE[44]. Currently, we have a VSV-LASV-Josiah (lineage IV)[44] and a Sauerwald version (lineage II) of these recombinants. Making additional LASV VSV-LASVs is not difficult, and **RP1** will make the other missing lineages or needed arenaviruses based on the same approaches as previously published. **RP1** also can easily make versions of these VSVs that express the green fluorescent protein (GFP) reporter gene. Existing VSV-CCHFV, VSV-NiV, and VSV-HeV vectors[45-47] will be provided by Dr. Geisbert overall PI and Lead of **Core E**. We already have Vanderbilt IBC approval for use of these constructs. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression if used will identify mAbs with neutralizing activity against LASV. These mAbs will be moved forward for additional studies to identify an optimal anti-LASV mAb combination. Similar processes will be followed to determine neutralization capacity of MACV mAb candidates.

E.1.2. Identifying LASV and MACV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind LASV or MACV and validate their epitopes. We will perform competition-binding studies with GP or subunit proteins (as above) or virus-like particles (VLPs)[48] available from **Core E** at UTMB. **Core E** will also inactivate LASV and MACV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from previously reported antibodies for the identification of mAbs that can concurrently bind LASV or MACV with a goal of finding more potent clones at those sites or clones that complement these inhibitory mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-LASV or anti-MACV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations for each virus, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key residues binding residues of human anti-LASV and anti-MACV mAbs.*** To determine the key residues for binding of down-selected mAbs, we will perform deep mutational scanning[49]. Briefly, all amino acids of the GP proteins will be mutated to the other 19 amino acids with a unique barcode using PCR-based mutagenesis. The LASV or MACV GP protein library will be incubated with the appropriate mAbs to identify residues with loss-of-binding phenotypes. A sequence 'logo' showing the relative contributions of each amino acid mutation will identify residues critical for binding. Multiple amino acid substitutions can then be assessed by reverse genetics at UTMB to confirm the epitopes recognized by the down-selected mAbs. This method also serves as a surrogate for *in vitro* neutralization escape studies. ***(d) Neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-LASV or VSV-MACV constructs at BSL2 in the presence of saturating concentrations of mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Confirmatory reverse genetics studies will be performed by introducing mutations into an infectious cDNA clone of LASV or MACV by **RP1** to test neutralization. We hypothesize that escape will be less likely in the presence of mAb combinations than single mAbs. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of escape variants in the presence of mAbs.

E.1.3. Structural basis of neutralization by mAb combinations. The studies above should identify optimal anti-LASV and anti-MACV mAb combinations that simultaneously bind, neutralize, and increase the barrier for viral escape under mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for arenavirus by identifying key epitope targets (**RP1**).

E.1.4. Protective efficacy of human anti-arenavirus mAbs. ***(a) Studies in guinea pigs***. MAbs that satisfy the criteria stated above and that display stage-appropriate manufacturability characteristics will advance to *in vivo* testing. We will use established models of LASV[22,50] and MACV[51,52] infection in guinea pigs. PABVAX **Core E** has access to many strains from different LASV and MACV lineages, which will be tested. For prioritization, we will focus on LASV lineage II, III, and IV strains and MACV lineage I, II, and VIII strains for which uniformly lethal models are available. Groups of 6 outbred Hartley guinea pigs will be treated with low, medium, and high doses of single or combinations of anti-LASV or anti-MACVs mAb, or isotype controls at day +1 after inoculation with the LASVs or MACVs This approach allows us to determine whether combinations provide advantage over the best monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-LASV and anti-MACV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements (blood) at day 5 or 6 after LASV or MACV challenge and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal LASV and MACV mAb pairs that are comparable to or outperform previously reported mAbs for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-LASV and anti-MACV mAb combination against LASV or MACV in NHPs. As a final test of an optimal anti-LASV and anti-MACV mAb combinations, we will assess protective efficacy of the lead anti-LASV mAb pair in NHPs as well as the anti-MACV mAb pair in NHPs. These anti-LASV and anti-MACV mAb pairs will be selected based on the *in vitro* and guinea pig data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys will only be considered pending success in the guinea pig studies and consultation with the external Scientific Advisory Board (SAB) and NIAID program staff.

E.1.5. Applying lessons learned in LASV and MACV research with the selected test case pathogens for mAb generation: Lujo and Chapare mAbs. Once we have completed the LASV and MACV discovery campaigns, will turn to the test case pathogens to see if we can use the prototype pathogen approach to related viruses, Lujo (LUJV) and Chapare (CHAPV). We do not have access to human PBMCs from LUJV - or CHAPV-immune donors. As an alternative approach, we will use humanized mouse models as a source of B cells encoding fully human monoclonal antibodies. The Vanderbilt core investigators have an established fully executed agreement to use Alloy human antibody mice for this purpose (See Letter of Support). The Alloy ATX-Gx™ mouse is one of the most effective *in vivo* human antibody discovery platforms, with over 140 partners and counting. This mouse system was originally invented and validated inside a major pharma company and then further developed by Alloy. This foundational suite of highly immunocompetent transgenic mice is engineered to drive the greatest potential diversity of unique human antibodies binding to the viral target of interest, with broad epitopic coverage. The comprehensive functional human antibody repertoire in these mice is optimized for human Ab sequence developability and diversity. Alloy and Vanderbilt have already executed a simple licensing process for use of the ATX-Gx platform, and as an established partner the Vanderbilt core team will access the expanding portfolio of transgenic Alloy strains designed to address a range of discovery challenges (including diverse Ab isotypes). Mice will be immunized with conformationally correct recombinant protein antigens (**Table 2**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for the target of interest. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for LASV and MACV.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-LASV and anti-MACV mAb combinations with optimal neutralizing and protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging LASV, MACV, or related arenaviruses. Given our previous ability to generate human antiviral mAbs, we do not anticipate problems in isolating anti-LASV or anti-MACV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently neutralizing anti-LASV or anti-MACV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody$^{\text{TM}}$) on enriched B cells (*i.e.*, memory B cells) isolated from human LASV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in LASV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-LASV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-LASV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-LASV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-LASV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the high-throughput Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E2. Specific Aim 2. Discover a protective CCHF virus mAb combination therapy. Establishing the generality of protection approaches against nairoviruses, we will perform a mAb discovery proof-of-concept campaign for the Prototype CCHFV. Preliminary studies have identified human anti-CCHF mAbs with varying levels of protection in experimentally infected animals[25,53,54]. We will isolate a large panel of human anti-CCHFV mAbs and determine the rules governing optimal mAb combinations through competition-binding, epitope mapping, neutralization, and viral escape studies. Lead antibodies with acceptable manufacturability characteristics (**Core D**) and the highest capacity to overcome resistance while maintaining potency of protection will be selected. The structural basis of their activity will be established using structural biology techniques (electron microscopy and crystallography). Lead mAb cocktail therapies will be evaluated for *in vivo* protective efficacy in STAT1$^{-/-}$ mice (with **Core E).** As a final test of an optimal anti-CCHFV mAb combination, we will assess protective efficacy of the lead anti-CCHFV mAb pair in NHPs, to be selected based on the *in vitro* and mouse data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys studies would only be considered pending success in the mouse studies and consultation with the external Scientific Advisory Board and NIAID program staff. In years 4-5, we will apply the lessons learned to the plug and play test case Kasokero virus (KASV) in collaboration with **RP1**, **Core D**, and **Core E**.

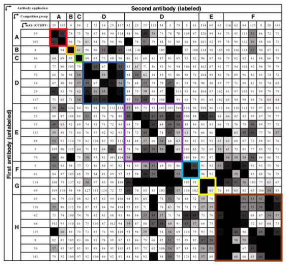

Figure 2. Competition assessment of human Abs to CCHFV using M-segment expressing cells. We tested 28 mAbs in competition assays. MAbs are displayed in 8 groups (A-H) based on their ability to compete for binding. Values shown are the % of binding that occurred during competition compared to non-competed binding of the mAb. This value was normalized to 100%. The values are also indicated by the box fill color; darker colors toward black indicate higher competition and lighter colors toward white indicate less competition, on a gradient scale.

<u>**Preliminary Data**</u>**.** ***<u>(a) Potently neutralizing and non-neutralizing human anti-CCHFV mAbs.</u>*** In this Aim, we will rapidly discover human anti-CCHFV mAbs from CCHFV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify an optimal anti-CCHFV mAb combination and further advance the discovery platform for rapid response against emerging nairoviruses. In preliminary experiments in collaboration with investigators in **RP1** and **Core E**, the Crowe laboratory has previously isolated and characterized panels of neutralizing human anti-CCHFV human mAbs from individuals who were convalescent after naturally-acquired laboratory-confirmed infection in Spain or Turkey. We isolated a panel of antibodies against CCHFV that recognize the M-segment in transfected cells, and they exhibit a diversity of recognition patterns in that they fall into multiple competition-binding groups (**Fig 2**). This panel contains cross-binding and cross-neutralizing antibodies for diverse strains. We observed a human mAb designated CCHF-82 competing with competition group 1 and group 2 antibodies from the previously isolated GP38-reactive murine antibodies. CCHF-82 showed some protection in a STAT1$^{-/-}$ mouse model of infection conducted by investigators in **RP1 (Fig 3)**. Further investigation with this antibody in the IbAr10200 prophylaxis and therapeutic models is warranted. In contrast, the CCHFV-neutralizing mAbs that we isolated and tested *in vivo* did not perform well in the Turkish strain STAT1$^{-/-}$ mouse model. We now know protection in this model is possible, given the work from Fels *et al*., 2021 who showed that potent antibodies against various sites on the Gc surface can afford protection in this model[53]. However, in their study they did not test GP38-reactive antibodies. To our knowledge, our preliminary data is the first indication that a human GP38-targeting antibody can provide some protection in this mouse model.

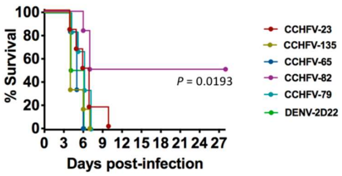

Figure 3. Human mAb CCHF-82 provides partial protection as a post-exposure prophylaxis against the Turkish strain of CCHFV in the STAT1$^{-/-}$ mouse model. A single dose of mAb was administered by the IP route to mice (n=6 per group (3 male, 3 female)) at 30 min post infections. A lethal dose of Turkish strain of CCHFV was administered. CCHF mAbs or DENV-2D22 (an isotype-matched negative control mAb) were tested in a single dose of 250 µg per mouse. Kaplan-Meier survival curves were statistically analyzed using a log-rank (Mantel-Cox) test where mAb-treated animals (*P* value shown in figure) were compared to animals treated with the DENV-2D22 negative control mAb. Unpublished data.

Non-neutralizing murine mAbs protect in mouse models of infection[25], but it is unknown if the human antibody response could provide similar levels of protection. Murine mAb 13G8 binds to GP38 and does not neutralize CCHFV. This mAb provides protection against lethal challenge as a prophylaxis and a therapeutic against CCHFV. In preliminary experiments we sought to understand if human survivors of CCHFV infection possess B cells encoding mAbs that bind a similar epitope as 13G8 and provide protection. CCHF-82 competes for binding with 13G8 to preGn-transfected cells containing GP38. This antibody offered some protection as a post-exposure prophylaxis against the Turkish strain of CCHFV (**Fig 3**). Human antibodies like this should be further studied and the frequency of these clones should be elucidated to understand if this is a feasible strategy for future vaccine efforts for humans. The epitope that 13G8 and CCHF-82 identifies could inform vaccine design if these antibodies offer protection in larger animal models. Understanding how non-neutralizing antibodies function is critical in efforts to validate the GP38-binding class of antibodies. Golden *et al.* undertook a study to understand the mechanisms 13G8 functioned and observed that complement activation contributes to the protective capacity of this antibody[25]. Here, in studies of CCHF-82, we also will assess complement activation in mouse models of infection to fully understand the function of this mAb *in vivo*. Furthermore, if this mAb protects in the CCHFV IbAr10200 strain challenge model, assessing its mechanism is warranted. Together with **Core D**, we will assess

IgG molecules with complement knockout (“KA”) and Fc gamma receptor knockout (LALA-PG) mutations in the Fc domain to study this matter. Human mAb CCHF-82 displayed limited cross-protection against experimental infection with the Turkish strain of CCHFV. Our antibody isolation here will aim to identify cross-protective non-neutralizing antibodies reactive with GP38. Recently, vaccinating with NP was shown to be another way to elicit non- neutralizing antibodies[55]. The NP of CCHFV is more conserved than the glycoproteins and might also be a non-canonical target for the identification of cross-protective non-neutralizing antibodies[55].

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant viral surface protein antigens, cloning of Ab variable genes, and then expression of mAbs as as described above in Specific Aim 1.

E.2.1. Rapid isolation of human anti-CCHFV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from a number of previously CCHFV-infected individuals. One was a health care survivor who was infected while caring for a patient in Spain[56]. We also collected a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Turkey, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples were only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies were approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples were deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-CCHFV mAbs rapidly, as if we had to respond to a nairovirus outbreak in real time. Our ability to respond rapidly in the setting of outbreaks is well-documented in the lay press (60 Minutes features and others) and the scientific literature, e.g., 78 days from sample to protection of NHPs for Zika virus[43], and 25 days from PBMC sample receipt to delivery of the antibody genes for the approved COVID-19 drug Evusheld to AstraZeneca[1]. Here, we will single-cell sort antigen-specific B cells using recombinant CCHFV proteins (GP38, Gc, Gn, Gc/Gn) or non-infectious particles as bait as described in Specific Aim 1. We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D**, (**Table 3**) or by **RP1 (Table 4)**.

(e) A CPE-based CCHFV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of CCHFV. We will use a rVSV CCHFV surrogate that expresses CCHFV surface proteins and causes CPE[46]. Investigators in **RP1** have the VSV-CCHFV-GFP versions of clades 1 through 7 based on this publication. We will obtain these VSV constructs from investigators in **PABVAX**. Existing VSV vectors will be provided by investigators in **RP1 and Core E**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against CCHFV. These mAbs will be moved forward for additional studies to identify an optimal anti-CCHFV mAb combination. GP38-reactive clones will be advanced based on avidity ranking since they are not likely to be neutralizing but may be protective *in vivo*.

E.2.2. Identifying CCHFV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind CCHFV surface proteins and validate their epitopes. We will perform competition-binding studies with CCHFV Gc/Gn or subunit proteins (as above) or CCHFV virus-like particles (VLPs) made from a replicon system in hand. **Core E** will inactivate CCHFV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site. Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from some of the mAbs shown in the unpublished preliminary data above for the identification of mAbs that can concurrently bind CCHFV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-CCHFV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. GP-38-reactive clones will be screened for synergistic binding as they are not expected to be neutralizing. ***(c) Identification of key binding residues of human anti-CCHFV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-CCHFV constructs at BSL2 in the presence of saturating concentrations of CCHFV mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of VSV-CCHFV escape variants in the presence of mAbs.

E.2.3. Structural basis of neutralization by anti-CCHFV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.2.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies in STAT1$^{-/-}$ mouse models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (Core D), will advance to *in vivo* testing. We will use an established STAT1$^{-/-}$ mouse model of CCHFV infection that the **RP1** and **Core E** investigators have deployed[46]. To benchmark our mAbs, a separate set of STAT1$^{-/-}$ mice will be treated with CCHF-82, which we showed in unpublished preliminary data above confers substantial but incomplete protection (**Fig 3**). The **Core E** laboratory has access to strains representing all 6 clades that can be tested. Groups of 6-8 STAT1$^{-/-}$ mice will be treated with low, medium, and high doses) of single or combinations of anti-CCHFV mAb, or isotype controls at day +1 after inoculation with CCHFVs. This approach allows us to determine whether combinations provide advantage over the best CCHFV monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after CCHFV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal CCHFV mAb pairs that are comparable to or outperform the mAbs we reported above. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-CCHFV mAb combination against CCHFV in NHPs. As a final test of an optimal anti-CCHFV mAb combination, we will assess efficacy of the lead anti-CCHFV mAb pair in NHPs (**Core E**), to be selected based on the *in vitro,* STAT1$^{-/-}$ mice, and manufacturability data (**Core D**). Down-selection for testing in cynomolgus monkeys would only be considered with success in the STAT1$^{-/-}$ mouse studies and in consultation with the external SAB and NIAID program staff.

E.2.5. Applying lessons learned in CCHFV research to Kasokero mAbs. Once we have completed the CCHFV discovery campaigns, will turn to the test case pathogen Kasokero virus to see if we can use the prototype pathogen approach for this virus. We do not have access to human PBMCs from Kasokero-immune donors. We will use Alloy humanized mouse models as a source of B cells encoding fully human mAbs, as described above. Mice will be immunized with conformationally correct recombinant protein antigens (**Table 5**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Kasokero. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for CCHFV.

~~**E.2.5. Applying lessons learned in CCHFV research to Kasokero mAbs.** Once we have completed the CCHFV discovery campaigns, will turn to the test case pathogen Kasokero virus to see if we can use the prototype pathogen approach for this virus. We do not have access to human PBMCs from Kasokero-immune donors. We will use Alloy humanized mouse models as a source of B cells encoding fully human mAbs, as described above. Mice will be immunized with conformationally correct recombinant protein antigens (**Table 5**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Kasokero. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for CCHFV.~~

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-CCHFV mAb combinations with optimal protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging CCHFV or related nairoviruses. Given our previous ability to generate human anti-CCHFV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-CCHFV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-

CCHFV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (i.e., memory B cells) isolated from human CCHFV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in CCHFV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-CCHFV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-CCHFV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-CCHFV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-CCHFV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E3. Specific Aim 3. Establish optimal mAb combination therapies against henipaviruses Hendra (HeV) and Nipah (NiV) viruses. We will use a large panel of potent anti-henipavirus mAbs that we previously made from the memory B cells of immune individuals and generate new antibodies targeting the fusion (F) protein. **RP2** will provide new antigens for mAb selection and BSL-2-compatible viruses for neutralization screens including Cedar virus constructs displaying HeV and NiV F and G proteins. We will identify optimal mAb combinations to enhance henipavirus therapy, minimize viral escape, and improve treatment efficacy through synergy. *In vitro* competition-binding, neutralization, and mechanistic studies will be conducted, including authentic virus neutralization with **PABVAX Core E**. We will refine the recognized epitopes and investigate the structural basis for optimal combination neutralization of henipaviruses using HeV and NiV as prototypes. *In vivo* assessment of mAb combinations will determine the minimal effective dose for protection and the ability to prevent *in vivo* escape. Protective efficacy of lead mAb combinations will be assessed in hamster models of NiV and HeV infection with **Core E**. Leads will be transferred to **Core D**. As a final test of optimal henipavirus mAb combinations, we will assess protective efficacy of the lead henipavirus mAb pairs in NHPs, to be selected based on the *in vitro* and hamster data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in African green monkey (AGM) henipavirus model studies would only be considered pending success in the hamster studies and consultation with the external SAB and NIAID program staff. The HeV and NiV studies will be conducted in years 1-3 and then applied to the plug-and-play test case Langya virus in years 2-5. If **RP2** and **Core E** cannot rescue recombinant Langya virus, the lessons learned in Years 1-3 will be applied to the alternate “plug and play” test viruses Angavokely or Sosuga (SOSV) virus. Preliminary data on SOSV mAbs are provided.

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-NIV/HeV mAbs.*** In this Aim, we will further adapt approaches we have developed in preliminary experiments with henipavirus mAb studies by identifying a potently protective combination of anti-NiV/HeV human mAbs. Through these studies, we aim to identify an optimal anti-NiV+HeV mAb combination and further advance the discovery platform for rapid response against emerging paramyxoviruses, especially henipaviruses. In previous experiments in collaboration with investigators in **RP2** and **Core E**, the Crowe laboratory has isolated characterized panels of neutralizing human anti-G NiV/HeV human mAbs from an individual with G-based immunity following occupational exposure to an equine HeV G subunit vaccine. Isolated peripheral blood mononuclear cells (PBMCs) were used to generate human B cell hybridomas secreting human mAbs to G, and antibody variable genes were sequenced to generate mAbs recombinantly. We isolated a panel of antibodies against the G protein that recognize the HeV G, NiV Bangladesh G, and NiV Malaysia G proteins. The mAbs exhibited a diversity of recognition patterns in that they fall into multiple competition-binding groups. This panel contains cross-binding and cross-neutralizing antibodies for diverse NiV and HeV strains. In the work proposed here, we will rapidly discover human NiV/HeV anti-F mAbs from NiV-immune individuals and outstanding potency anti-G antibodies with extensive characterization, including synergistic neutralization.

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant henipavirus F protein antigens, as described above in Specific Aim 1.

E.3.1. Rapid isolation of human anti-HeV/NiV mAbs. ***(a) Immune cells.*** We are obtaining human PBMCs from a number of previously NiV-infected individuals who acquired immunity following natural infection in collaboration with the **icddr,b**, an international health research institute based in Dhaka, Bangladesh. We are collecting a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Bangladesh, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies are approved by the icddr,b and Vanderbilt University Medical Center IRBs. PBMCs isolated from the blood samples are deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their use in this **RP4,** if funded. ***(b) Applying mAb technologies for new mAb isolation***. We will use sorting of antigen-specific B cells, cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), and this may be helpful for rarer antigen-specific B cells. We will sort soluble fusion (sF) or attachment (G) protein-specific cells with recombinant viral surface protein antigens from **Core D** (**Table 6**).

(c) Ab screening and sequence analysis. Our goal is to identify human anti-NiV/HeV mAbs rapidly, as if we had to respond to a paramyxovirus outbreak in real time. We will single-cell sort antigen-specific B cells using recombinant HeV and NiV proteins (sF or G) as bait as described in Specific Aim 1 above.

(d) Recombinant mAb cloning. As described in Specific Aim 1 above.

(e) Micro-scale mAb expression. As described in Specific Aim 1 above.

(f) CPE-based HeV/NiV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of HeV and NiV. We will use rVSV HeV and NiV surrogates that expresses henipaviurs surface proteins and cause CPE. Investigators in **RP2 and RP3** have VSV-NiV F and VSV-NiV G with GFP[45], VSV-NiV G without GFP[47] and VSV-HeVG (Geisbert and Cross, unpublished). We will obtain these all these VSV constructs from investigators in **PABVAX**. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against HeV and NiV. We also can use Cedar virus constructs for neutralization assays as the have reduced pathogenicity[57] and can be used in high-throughput screening assays for henipavirus antiviral discovery[58]. Cedar viruses will be provided by Dr. Broder of **RP2**. The mAbs with most potent activity will be moved forward for additional studies to identify an optimal anti-HeV/NiV mAb combination.

E.3.2. Identifying HeV/NiV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind HeV/NiV surface proteins and validate their epitopes. We will perform competition-binding studies with HeV/NiV sF or G proteins (as above). We will include positive controls made recombinantly from some of the mAbs shown in the preliminary data above for the identification of mAbs that can concurrently bind HeV/NiV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti- HeV/NiV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key binding residues of human anti-HeV/NiV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-NiV F, VSV-NiV G and VSV-HeV G constructs at BSL-2 in the presence of saturating concentrations of HeV/NiV mAbs (single or combination) using RTCA to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test the level of infection of VSV-HeV/NiV escape variants in the presence of mAbs.

E.3.3. Structural basis of neutralization by anti-HeV/NiV mAb combinations. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.

E.3.4. Protective efficacy of human anti-henipavirus mAbs. ***(a) Studies in hamsters***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (**Core D**), will advance to *in vivo* testing. We will use an established hamster model of NiV or HeV infection that the **Core E** investigators have deployed. To benchmark our mAbs, a separate set of hamsters will be treated with G mAbs HENV-103+HENV-117, which we showed in previous data above confers substantial protection[18]. Groups of 6-8 hamsters will be treated with low, medium, or high IgG doses) of single or combinations of anti-HeV/NiV mAbs, or isotype controls at day +1 after inoculation with HeV or NiV. This approach allows us to determine whether combinations provide advantage over the best HeV or NiV mAb monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-HeV and anti-NiV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after HeV or NiV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal HeV/NiV mAb pairs that are comparable to or outperform the mAbs we reported previously. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-HeV/NiV mAb combination against HeV and NiV in NHPs. As a final test of an optimal anti-HeV/NiV mAb combination, we may assess efficacy of the lead anti-HeV/NiV mAb pair in NHPs (**Core E**), selected based on the *in vitro,* hamster data, and manufacturability data (**Core D**). Down-selection for testing in AGMs would only be considered with success in the hamster studies and in consultation with the external SAB and NIAID program staff.

E.3.5. Applying lessons learned in HeV/NiV research to Langya, Angavokely and Sosuga viruses. Once we have completed the HeV/NiV discovery campaigns, will turn to the test case pathogen Langya (or alternate Angavokely and Sosuga (SOSV) viruses) to see if we can use the prototype pathogen approach for this virus. We have plenty of human PBMCs from the sole identified SOSV-immune individual and have already shown that it is possible to obtain HN- and F-specific neutralizing antibodies from this individual's B cells[59]. We also have already prepared recombinant SOSV prefusion F and HN proteins[59]. We do not have access to human PBMCs from Langya- or Angavokely-immune donors. For those mAb discovery campaigns, we will use Alloy humanized mouse models as a source of B cells encoding human mAbs, as above. Mice will be immunized with recombinant protein antigens (**Table 7**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Langya or Angavokely. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for Hev/NiV described above.

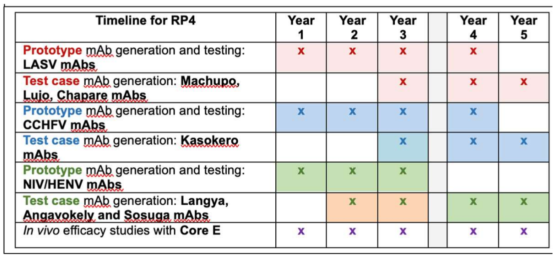
Table 7. Paramyxovirus antigens from Core D
Mojang sF
Angavokely sF
Langya sF

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-HeV/NiV mAb combinations with optimal protective activity. These mAb combinations will be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging HeV/NiV or related paramyxoviruses. Given our previous ability to generate human anti-HeV/NiV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-HeV/NiV mAbs. We may observe that new mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-HeV/NiV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells *(i.e., memory B cells) isolated from human NiV-immune PBMC samples. In addition, we can deep sequence the B* cell repertoires present in NiV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-HeV/NiV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-HeV/NiV mAb combinations that can inform vaccine design (**RP2**) for related viruses being used as test cases in years 2 through 5.

F. Scientific rigor. ***Experimental design.*** Experiments will include biological and technical replicates, and results will be analyzed by parametric or non-parametric analyses (depending on data distribution) and corrections for multiple comparisons. EC_{50} (binding) and IC_{50} (neutralization) values will be reported only following at least 3 identically conducted experiments. All mAb screening will incorporate appropriate + and - controls. Positive signals in binding assays will be defined as >3 SD above background. ***Protein quality.*** We have a high capacity to purify proteins using a Protein Maker workstation that allows purification chromatography on 24 parallel columns. We perform QC on protein reagents using a Maurice instrument with capillary electrophoresis technology to automate our protein profiling either by size or charge, providing cIEF and CE-SDS data. Animal ***studies*** will be performed blinded with independent replicates and include negative (*e.g.*, placebo), and positive (when available) controls. We will use power calculations (**Data Management Core B**) to determine sample sizes. For virological studies, power analysis was performed using accepted values for type I error (0.05) and power (80%). The values for population variance (15×) are based on existing data sets and our experience with rodent challenge studies. We will perform experiments at least 2-3 independent times (n = 4-5 each) to attain n = 12-15 per arm. Smaller group sizes can be used if differences are larger than expected.

G. Relevant biological variables. The human mAbs are derived from immune human donors or Alloy mice. Humans. Human Abs will be isolated for biological, structural, and functional studies at a clonal level. The sample size is not powered for large scale epidemiologic or clinical study conclusions. There is no evidence that sex, age, body mass index, or underlying health conditions other than immunodeficiency or immunosuppressive treatments alters the activity of cloned Abs in structure/function studies. The samples are de-identified without patient specific identifiers to protect the health information of the donors; thus, research with these samples is considered *Not Human Subjects Research* category activity. Mice, hamsters, guinea pigs, NHP, and viruses are also biological systems used in this application. Conventional animal housing conditions will be used because there is no evidence that altered room temperatures and light/dark cycles influence paramyxovirus, nairovirus, or arenavirus pathogenesis. Mice, hamsters, guinea pigs, and NHPs of both sexes will be used, and phenotypes will be monitored for sex-based differences. Virus stocks will be either low passage seed stocks from natural isolates or generated from existing cDNA clones and sequence-confirmed prior to use for infection studies.

H. Milestones and quantitative Go/No-Go criteria. Through **Aims 1-3**, we have proposed experiments that will advance our knowledge of the mAb-mediated mechanisms of action against paramyxoviruses, nairoviruses, and arenaviruses. In each Aim, we will use down-selection criteria (as below) to advance mAb combinations or variants for additional studies. By year 3, we will have defined the principles that govern optimal mAb combinations for paramyxoviruses, nairoviruses, and arenaviruses and the rational approaches needed to select mAbs for potency and breadth. We will use the following metrics to advance mAbs: ***(a) Neutralizing activity***. All mAbs will have neutralizing potency < 10 ng/mL, EC_{50} value; ***(b) Binding affinity***. MAbs will be of high affinity to surface proteins or virions (K_D < 5 nM). ***(c) Protein stability and production quality***. MAbs must produce at high levels without optimization (> 100 mg/L) and show biochemical/functional stability at 4°C or -80°C (>90% retention of binding and neutralization activity at 30 d). ***(d) Synergy***. Combinations of 2 mAbs against a given virus ideally will show synergy of neutralization *in vitro* or at a minimum, additive inhibition (no antagonism); ***(e) Epitopes***. To avoid resistance, mAbs in combination will bind 2 epitopes (determined by competition binding (<20% reduction in binding), mapping, and structural studies. ***(f) Resistance*** against mAbs will be assessed for virus escape. Deep sequencing of viruses that emerge from cells or animals treated with mAbs will inform prioritization. Combinations of mAbs with high genetic barriers to resistance (<10× loss in EC_{50}) will be advanced. ***(g) Protection in mice, hamsters, guinea pigs, or NHPs.*** The following metrics can be used: (i) Protection against lethal challenge by homologous virus (>90% survival; (ii) Protection against clinical disease by homologous virus (>80%); (iii) Protection against infection by homologous virus (>100-fold reduction in viral titers in multiple organs). ***(h) pK measurements***. For lead protective mAbs with mutations that should confer extended half-life, we will perform pK studies in NHPs (with **Core D** and **E**) to assess levels over time with a goal of a human predicted serum half-life of >6 months.



Timeline for RP4	**Year 1**	**Year 2**	**Year 3**		**Year 4**	**Year 5**

A. BACKGROUND AND SIGNIFICANCE. Paramyxoviruses, nairoviruses, and arenaviruses are widely distributed RNA viruses that cause severe human syndromes. Because of their geographical distribution and expansion, changes in human demographics and increased exposures to wild animals including rodents and bats, and their capacity for human-to-human spread, these viruses have the potential to cause pandemics. Together with the other investigators in **PABVAX**, we have selected several important prototype paramyxoviruses, nairoviruses, and arenaviruses to study to learn the rules governing immunity to these pathogens. The work on the pathogens selected is justified based on their prevalence and severity alone, but also because of their ability to serve as prototypes for genetically related viruses. We chose the viruses for focus in this RP4 on human antibody development because of their clinical relevance and because several will be studied as prototypes for vaccine development in **RP1** (arenavirus and nairovirus vaccines) and **RP2** (paramyxovirus vaccines). Among the arenaviruses, we will target *Lassa mammarenavirus* (LASV) and *Machupo mammarenavirus* (MACV)*, and* among the family Nairoviridae of RNA viruses, we will study Crimean–Congo hemorrhagic fever orthonairovirus (CCHFV). In tandem with the vaccine projects in **RP2** focused on paramyxoviruses, we study Nipah virus (NiV) and Hendra virus (HeV) as the prototypes, and already have preliminary data with Sosuga virus as a test case. Information about the principles we discover about critical neutralizing epitopes identified here in **RP4** with prototype viruses can feed back into all other **Projects** that address the subsequent test cases in later years (Lujo, Chapare, Kasokero, Langya, Sosuga).

LASV is an Old World arenavirus (OWAV) with a single-stranded RNA virus belonging to the Arenaviridae family. Infection in humans is often the result of exposure to infected excreta from the rodent reservoir, *Mastomys natalensis* where up to 500,000 cases and an estimated 5,000 deaths occur annually in West Africa[2]. While rodent infection is largely benign, human infection can result in severe hemorrhagic disease with neurological complications and long-term hearing and vision sequelae[3,4]. The virus possesses a bi-segmented genome comprising large (L) and small (S) segments, both of which are enclosed within a lipid envelope. The L segment (~7.2 kb) encodes the RNA-dependent RNA polymerase (RdRp) and a zinc-binding protein (Z), while the S segment (~3.4 kb) codes for the nucleoprotein (NP) and the glycoprotein precursor (GPC). The GPC is further cleaved into two surface glycoproteins, GP1 and GP2, which play critical roles in viral entry. The genetic diversity of LASV can be classified into six lineages (I-VI), with lineages III and IV being the most prevalent[5]. Genetic variation arises mainly due to the error-prone nature of the viral RNA polymerase, leading to the emergence of quasi-species. This diversity contributes to the virus's ability to evade host immune responses and pose challenges to vaccine development[6]. ~~LASV antigens include~~T~~ t~~he surface glycoproteins GP1 and GP2, are responsible for receptor binding and membrane fusion, respectively. While GP1 is highly variable among strains, GP2 is more conserved. The nucleoprotein (NP) is another major antigen, and its immunodominant epitopes are targeted by the host's immune response. Its genetic diversity and antigenic properties complicate diagnosis and vaccine development, emphasizing the need for continued research on medical countermeasures.

MACV is a New World Arenavirus (NWAV) and the causative agent of Bolivian Hemorrhagic fever. Humans are infected after exposure to excreta from the reservoir, *Calomys callosus,* the large vesper mouse. Disease in humans has a slow onset, but can progress to severe hemorrhagic fever coupled to insidious neurological complications including tremors, seizures, and paralysis[7]. MACV has a similar genomic organization and contains a GPC, NP, Z, and L polymerase proteins. Genetic diversity of MACV is delineated into 8 lineages (I-VIII) where there is growing concern of an expanding host range of *C. callosus* is responsible for outbreaks outside the known endemic region[8]. While the host entry receptor for NWAV is not shared with OWAV, the role for GP to drive immunity as a major antigen alongside NP. The better studied Junin has a regionally approved vaccine[9] and convalescent plasma program[10] available to prevent and treat disease, respectively. There are no approved vaccines or therapies approved for any other NWAV, including MACV. Further, itis not well established whether these countermeasures have potential for cross protect other NWAV such as MACV, underscoring the value of continued efforts to develop broadly active countermeasures to safeguard against lethal disease.

CCHFV is a highly pathogenic tick-borne virus classified under the Nairovirus genus within the Bunyaviridae family[11]. It has a negative-sense, single-stranded RNA genome comprising three segments: Small (S), Medium (M), and Large (L). These segments are enclosed within a lipid envelope and code for various structural and non-structural proteins. The S segment (~1.7 kb) encodes the nucleocapsid protein (N), which is essential for viral replication and assembly. The M segment (~5.3 kb) codes for the glycoprotein precursor (GPC), which is post-translationally cleaved into two surface glycoproteins, Gn and Gc. These glycoproteins are involved in viral entry and fusion. The L segment (~12.1 kb) encodes the RNA-dependent RNA polymerase (RdRp), responsible for viral RNA synthesis. CCHFV exhibits significant genetic diversity, with at least seven distinct clades (Europe 1, Europe 2, Africa 1-3, and Asia 1-2) based on the partial S segment sequences[12]. This diversity is attributed to the segmented genome, geographical distribution, and error-prone viral RNA polymerase, leading to the emergence of various quasi-species. The major antigens of CCHFV include the surface glycoproteins Gn and

Gc, as well as the nucleocapsid protein (N)[13,14]. These antigens are targeted by the host immune response. CCHFV is genetically diverse, so breadth of reactivity will be a focus of our discovery efforts.

NiV/HeV. Bat borne**,** NiV and HeV are enveloped, negative-sense, single-stranded RNA viruses belonging to the Henipavirus genus within the Paramyxoviridae family[15]. These emerging zoonotic viruses pose a significant threat to human and animal health due to their high fatality rates and broad host range. The genomes of NiV and HeV are approximately 18.2 kb or 18.4 kb in length, respectively, and share a similar gene organization. They encode six major structural proteins: nucleocapsid (N), phosphoprotein (P), matrix (M), fusion (F), attachment glycoprotein (G), and large polymerase (L) proteins. The N, P, and L proteins form the viral RNA-dependent RNA polymerase (RdRp) complex necessary for transcription and replication, whereas the M, F, and G proteins are essential for virus assembly and entry. Genetic diversity in Henipaviruses is relatively low compared to other RNA viruses, with NiV strains showing 91-100% nucleotide similarity and HeV strains displaying 83-100% similarity[16]. However, the error-prone nature of the RdRp can still generate genetic variability, leading to the emergence of distinct lineages. The major surface antigens of Nipah and Hendra viruses are the attachment glycoprotein (G) and fusion protein (F). The G protein facilitates receptor binding, while the F protein mediates viral membrane fusion. Both antigens are involved in host immune responses and are potential targets for vaccine development, and the neutralizing antibody approaches we propose here. NiV and HeV exhibit relatively low genetic diversity, and in preliminary studies, we have identified human mAbs that neutralize HeV, NiV Bangladesh and NiV Malaysia strains[17-19]. Antibodies to the major surface antigens, the G and F proteins, are therefore, promising candidates for development as prophylactic or therapeutic molecules.

Antibodies (Abs) are important correlates of protection for paramyxoviruses, nairoviruses, and arenaviruses. Immune sera against members of each of these groups of viruses has been shown to exhibit protective efficacy *in vivo*, which supports the use for Abs as treatment options. However, the specificity, functional properties, and other attributes of protective antibodies are poorly defined for most of these viruses. MAbs to the attachment and fusion surface proteins of paramyxoviruses (such as the G and F proteins of Hendra/Nipah[18,20] and the GP proteins of the arenaviruses like LASV[21,22] can neutralize and protect against infection in rodent models. CCHFV is a bit of a conundrum in that ultrapotent human neutralizing antibodies to the related Rift Valley fever virus surface proteins are highly protective *in vivo*[23,24], but CCHFV neutralizing antibodies are not protective. In contrast, some non-neutralizing antibodies do protect partially for CCHFV[25]. Clearly, there is a lot to learn about the rules of immunity to these viruses, and the genetic, molecular, and structural basis of antibody-mediated protection for viruses like CCHFV. Based on these data, we propose the use of mAbs as treatment options to learn the rule of how to protect against emerging paramyxoviruses, nairoviruses, and arenaviruses and to develop candidate antibody countermeasures for translational development with **Core D**. To do so, we will further develop our technical methods for rapidly discovering mAbs, in the case of a future unexpected epidemic caused by viruses of these families. Most importantly, we will define the principles governing combination antibody therapy to prevent virus escape from treatment or prevention and to optimize the efficacy of the beneficial effects conferred by passive immunity.

B. SCIENTIFIC PREMISE. The work proposed here in **RP4** is based on the extensive basic, translational, and clinical trial data on the role of neutralizing Abs in protection against infection and disease caused by paramyxoviruses, nairoviruses, and arenaviruses. Although a significant amount of data supports the use of mAbs to prevent or control paramyxovirus, nairovirus, and arenavirus infection, many questions remain, such as the ideal epitopes to target with mAb combination therapy to improve upon neutralization potency, *in vivo* efficacy, and resistance to viral escape. Identifying these epitopes can help inform vaccine design to elicit optimal protective polyclonal responses (in **RP1** and **RP2**, especially with designs for test cases in years 4 and 5). Here we aim to refine our understanding of the correlates of mAb protection against paramyxoviruses, nairoviruses, and arenaviruses to enable the design of a modular ‘plug-and-play’ workflow to rapidly respond to potential pandemics by generating optimized combinations of vaccine-like mAbs with an extended half-life that could be used for long-term prophylaxis (> 6 months) and therapy.

C. INNOVATION. RP4 has many innovative conceptual and technical features including: Conceptual. **(1)** determining the principles that govern optimal combinations of human mAbs against paramyxoviruses, nairoviruses, and arenaviruses for protection and resistance to viral escape; **(2)** the development of a clear workflow that generates therapeutic or preventative antibodies (long half-life mAbs that serve as vaccine surrogates) against emerging or new paramyxoviruses, nairoviruses, and arenaviruses with pandemic potential. Our goal is to define the principles and features, including epitope, combination ratios, and mechanisms of action, that result in optimal efficacy of mAbs against paramyxoviruses, nairoviruses, and arenaviruses in animal models and create a higher barrier for resistance. These studies will serve as paradigms for rapid antibody discovery in response to future paramyxovirus, nairovirus, and arenavirus pandemic threats. Technical. **(3)** large-scale B cell repertoire sequencing with customized methods and software; **(4**) use of humanized (Alloy) mice and novel immunogens from **RP1** and **RP2** and **Core D**; **(5)** single B cell functional (neutralization) assays performed on a

Beacon instrument; **(6)** development of high-throughput real-time label-free virus neutralization assays (xCELLigence platform); and **(7)** use of *simultaneous* in parallel screening with several different high-throughput virus-specific B cell isolation approaches (Beacon, 10X Genomics, Rhapsody) to generate and validate best-in-class human mAbs as candidate medical countermeasures.

D. LINKAGE TO OTHER PABVAX PROJECTS AND CORES. The group will focus on developing a modular test case platform for rapid selection of highly neutralizing and/or protective mAbs against paramyxoviruses, nairoviruses, and arenaviruses. Members of our group have active collaborations with most members of the **PABVAX Center** as reflected in previous collaborations and publications (see **Overall** document). We will interact extensively with the Animal Model and Preclinical Evaluation Core (**Core E)** to study neutralization against authentic viruses and to test for protection in small and large animals as well as with **RP3** for testing paramyxovirus mAbs. The knowledge gained from our studies on the structure-function relationships of neutralizing mAb combinations can be applied to rational vaccine design for **RP 1** and **RP2** in later years of the effort when we pivot to apply the lessons learned to the same test case targets as **RP1** and **RP2.** Numerous antigens will be made available to our RP. Finally, long-half-life Fc mutations are now available based on engineering of human IgG1 for enhanced binding to the neonatal Fc receptor (FcRn) such as LS (M428L /N434S)[26], or YTE (M252Y/S254T/T256E)[27] mutations. With ≥ 90 days half-life in humans, our approach will generate mAbs with vaccine-like properties that remain effective for months during a virus epidemic and thus provides a platform for response to future paramyxovirus, nairovirus, and arenavirus pandemic threats, a key goal of our **PABVAX Center.** *Our laboratory previously validated this vaccine surrogate concept when we isolated the human mAbs that formed the basis for Evusheld with YTE long-half-life Fc mutations (used in 70 countries and millions of people) that exhibited > 6 months protective levels in humans after single IM injections*.

E. APPROACH

E.1. Specific Aim 1. Discover potently neutralizing arenavirus combination therapies. For the prototypes, we will focus on Lassa virus (LASV), an Old World virus and Machupo virus (MACV), a New World virus. We will investigate the principles underlying antibody-mediated arenavirus protection. Preliminary evidence suggests that potent virus neutralization is a mechanistic correlate of protection for arenaviruses[28,29]. **RP1/Core D** will provide optimized antigens for mAb selection for the Prototype LASV and MACV (or subsequent Test Cases). We will use a workflow for rapid identification of potently neutralizing mAb combinations for LASV and MACV. We will generate mAbs from individuals with prior natural infection or use transgenic mice with human antibody repertoires. A large panel of human anti-LASV and anti-MACV mAbs will be generated using multiple approaches (immune human B cells and immunized humanized mice), and highly neutralizing mAbs will be evaluated to identify optimal combinations. The best mAb combinations will be assessed to determine the minimal effective dose for protection, and the lead mAb combination therapy(ies) will be transferred to **Core E** for further evaluation and ultimately testing in an NHP model of LASV infection. Leads will be transferred to **Core D** for further translational development as medical countermeasures. The prototype LASV and MACV will be studied in years 1 to 3, followed by mAb discovery efforts for Test Cases Lujo and Chapare viruses based on the established principles in years 4-5.

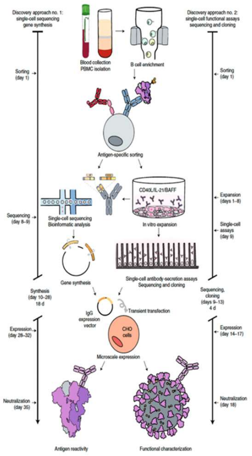

Figure 1. Single cell mAb discovery. PBMC samples are used to enrich for B cells, which can be sorted for antigen-specific B cells. Expansion allows us~~of these B cells is done~~ to further assess the functionality of the B cells or for antibody sequencing~~ to determine the variable genes contributing to antigen reactivity~~. Recombinant mAb

<u>Preliminary Data</u>. ***(a) Potently neutralizing human anti-LASV and anti-MACV mAbs.*** The Crowe laboratory has previously characterized panels of neutralizing human anti-viral human mAbs from virus-immune or vaccinated individuals for about 50 viruses, mostly RNA viruses. Isolated peripheral blood mononuclear cells (PBMCs) are used to generate hybridomas or alternatively antigen-sorted at single B cell level and antibody variable genes sequenced to generate mAbs recombinantly. Panels of human anti-viral mAbs are produced rapidly (we recently reported isolation of 15,000 mAb gene pairs from single Ebola-virus-specific human B cells from a single blood sample of an immune individual[30]. Previous studies by others clearly show that representative neutralizing and protective human antibodies can be isolated from LASV-immune subjects[31-35]. In this Aim, we will refine the approaches we have developed previously for other RNA viruses in a proof-of-concept study by identifying potently neutralizing combinations of anti-LASV and anti-MACV human mAbs. We will rapidly discover human anti-LASV mAbs from LASV-immune individuals and human anti-MACV mAbs by immunizing Alloy transgenic mice. Synergy studies will be performed to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify optimal anti-LASV and anti-MACV mAb combinations and further advance the discovery platform for rapid response against emerging arenaviruses.

(b) Advanced mAb technologies. The Crowe laboratory has developed some of the highest yield systems to isolate naturally occurring human mAbs using human hybridoma or advanced single-cell RNA-seq methods (**Fig 1**). We have used sorting of antigen-specific cells with recombinant viral surface protein antigens (like the GP1 and GP2 proteins we will use here), cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. One variation we will use is to capture Ab genes directly from viral glycoprotein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), as we have done for Ebola virus[30,36] and SARS-CoV-2[1,37-42]. These single-cell techniques enhance the capture of rare antigen-specific B cells.

E.1.1. Rapid isolation of human anti-LASV and anti-MACV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from one previously LASV-infected individual who was medically managed previously by Emory University in their infectious diseases containment unit. This person has a documented robust neutralizing serum antibody response, suggesting isolation of neutralizing human mAbs from these PBMC aliquots will be straightforward for us. Our colleagues in **RP1** have ongoing field operations for over a decade in Sierra Leone, Liberia, and Nigeria. This work is currently in association with the NIH-Centers for Research on Emerging Infectious Diseases (CREID) with a heavy focus on the study of LASV ecology, epidemiology, and host responses. **RP4** is currently working with **RP1** on obtaining PBMCs from ~10 individuals with prior laboratory-confirmed cases of LASV. The acquisition of these samples is being managed by the Vanderbilt Vaccine Center Biorepository with separate institutional funding to be de-identified prior to use in the studies proposed here. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies have been approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples will be deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded. For anti-MACV mAbs, as a human PBMC source is not readily available, we will immunize Alloy humanized mice. These animals yield PBMCs that secrete fully human mAbs. Alloy mice are used routinely in the Crowe lab workflow.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-LASV and anti-MACV mAbs in a rapid manner to mimic a pandemic response to an outbreak. We will single-cell sort antigen-specific B cells using recombinant LASV or MACV proteins (*e.g.* **Table 1**) or non-infectious viral particles as bait. These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including LASV and MACV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe GP protein or virus-particle binding to single B cells. These cells are exported for sequencing of the variable gene regions and analysis using the PyIR software developed in the Crowe laboratory. We will select a panel of up to 500 neutralizing anti-LASV mAbs and a similar number of anti-MACV mAbs to express recombinantly and advance for further characterization. We can easily conduct multiple approaches simultaneously in parallel[1,43].

Table 1. Antigens from Core D

Machupo GPe
Machupo NP

~~Table 1. Antigens from Core D~~
~~Lassa Josiah NP~~
~~Lassa Josiah GPe~~
~~Machupo GPe~~
~~Machupo NP~~

~~We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D** listed in **Table 1**.~~

(c) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using a custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors.

(d) Micro-scale mAb expression. The Crowe laboratory has the capacity for large-throughput micro-scale mAb expression and purification. The lower end of this range allows expression of thousands of mAbs, which will feed into automated mAb purification platforms. This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(e) A CPE-based LASV and MACV neutralization assay using RTCA. We have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of cytopathic effect (CPE). Here, we will apply this method to assess neutralization of LASV. Recently, we validated the inclusion of simultaneous live-cell fluorescence microscopy into this real-time CPE-based screening platform (xCelligence RTCA eSight). These capabilities expand the platform to screen viruses that may or may not induce CPE, allowing us to also use a replication-competent vesicular stomatitis virus (VSV) LASV surrogate that expresses LASV surface proteins and causes CPE[44]. Currently, we have a VSV-LASV-Josiah (lineage IV)[44] and a Sauerwald version (lineage II) of these recombinants. Making additional LASV VSV-LASVs is not difficult, and RP1 will make the other missing lineages or needed NWAV (MACV and CHAPV for test case evaluation) based on the same approaches as previously published. RP1 also can easily also make versions of these VSVs that express the

Formatted: Font: Italic

Formatted: Font color: Text 1

Formatted Table

green fluorescent protein (GFP) reporter gene. We will obtain these all these VSV constructs from investigators in **PABVAX**. Existing VSV-CCHFV, VSV-NiV, and VSV-HeV vectors[45-47] will be provided by Dr. Geisbert overall PI and Lead of **Core E**. We already have Vanderbilt Institutional Biosafety Committee approval for use of these constructs in this format and assay. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression if used will identify mAbs with neutralizing activity against LASV. These mAbs will be moved forward for additional studies to identify an optimal anti-LASV mAb combination. Similar processes will be followed to determine neutralization capacity of MACV mAb candidates.

E.1.2. Identifying LASV and MACV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind LASV or MACV and validate their epitopes. We will perform competition-binding studies with GP or subunit proteins (as above) or virus-like particles (VLPs)[48] available from **Core E** at UTMB. **Core E** will also inactivate LASV and MACV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from previously reported antibodies for the identification of mAbs that can concurrently bind LASV or MACV with a goal of finding more potent clones at those sites or clones that complement these inhibitory mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-LASV or anti-MACV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations for each virus, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key residues binding residues of human anti-LASV and anti-MACV mAbs.*** To determine the key residues for binding of down-selected mAbs, we will perform deep mutational scanning[49]. Briefly, all amino acids of the GP proteins will be mutated to the other 19 amino acids with a unique barcode using PCR-based mutagenesis. The LASV or MACV GP protein library will be incubated with the appropriate mAbs to identify residues with loss-of-binding phenotypes. A sequence 'logo' showing the relative contributions of each amino acid mutation will identify residues critical for binding. Multiple amino acid substitutions can then be assessed by reverse genetics at UTMB to confirm the epitopes recognized by the down-selected mAbs. This method also serves as a surrogate for *in vitro* neutralization escape studies. ***(d) Neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-LASV or VSV-MACV constructs at BSL2 in the presence of saturating concentrations of mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Confirmatory reverse genetics studies will be performed by introducing mutations into an infectious cDNA clone of LASV or MACV by **RP1** to test neutralization. We hypothesize that escape will be less likely in the presence of mAb combinations than single mAbs. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of escape variants in the presence of mAbs.

E.1.3. Structural basis of neutralization by mAb combinations. The studies above should identify optimal anti-LASV and anti-MACV mAb combinations that simultaneously bind, neutralize, and increase the barrier for viral escape under mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for arenavirus by identifying key epitope targets (**RP1**).

E.1.4. Protective efficacy of human anti-arenavirus mAbs. ***(a) Studies in guinea pigs***. MAbs that satisfy the criteria stated above and that display stage-appropriate manufacturability characteristics will advance to in vivo testing. We will use established models of LASV[22,50] and MACV[51,52] infection in guinea pigs. PABVAX **Core E** has access to many strains from different LASV and MACV lineages, which will be tested. For prioritization, we will focus on LASV lineage II, III, and IV strains and MACV lineage I, II, and VIII strainsfor which uniformly lethal models are available. Groups of 6 outbred Hartley guinea pigs will be treated with low, medium, and high doses) of single or combinations of anti-LASV or anti-MACVs mAb, or isotype controls at day +1 after inoculation with the LASVs or MACVs This approach allows us to determine whether combinations provide advantage over the best monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-LASV mAbs and 10 single mAbs and 5 pairs of anti-MACV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements (blood) at day 5 or 6 after LASV or MACV challenge and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal LASV mAb pairs and two additional MACV mAb pairs that are comparable to or outperform previously reported mAbs for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-LASV and anti-MACV mAb combination against LASV or MACV in NHPs. As a final test of an optimal anti-LASV and anti-MACV mAb combinations, we will assess protective efficacy of the lead anti-LASV mAb pair in NHPs as well as the anti-MACV mAb pair in NHPs. These anti-LASV and anti-MACV mAb pairs will be selected based on the *in vitro* and guinea pig data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys will only be considered pending success in the guinea pig studies and consultation with the external Scientific Advisory Board (SAB) and NIAID program staff.

E.1.5. Applying lessons learned in LASV and MACV research with the selected test case pathogens for mAb generation: Lujo and Chapare mAbs. Once we have completed the LASV and MACV discovery campaigns, will turn to the test case pathogens to see if we can use the prototype pathogen approach to related viruses, Lujo (LUJV) and Chapare (CHAPV). We do not have access to human PBMCs from LUJV - or CHAPV-immune donors. As an alternative approach, we will use humanized mouse models as a source of B cells encoding fully human monoclonal antibodies. The Vanderbilt core investigators have an established fully executed agreement to use Alloy human antibody mice for this purpose (See Letter of Support). The Alloy ATX-Gx™ mouse is one of the most effective *in vivo* human antibody discovery platforms, with over 140 partners and counting. This mouse system was originally invented and validated inside a major pharma company and then further developed by Alloy. This foundational suite of highly immunocompetent transgenic mice is engineered to drive the greatest potential diversity of unique human antibodies binding to the viral target of interest, with broad epitopic coverage. The comprehensive functional human antibody repertoire in these mice is optimized for human Ab sequence developability and diversity. Alloy and Vanderbilt have already executed a simple licensing process for use of the ATX-Gx platform, and as an established partner the Vanderbilt core team will access the expanding portfolio of transgenic Alloy strains designed to address a range of discovery challenges (including diverse Ab isotypes). Mice will be immunized with conformationally correct recombinant protein antigens (**Table 2**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for the target of interest. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for LASV and MACV.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-LASV and anti-MACV mAb combinations with optimal neutralizing and protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging LASV, MACV, or related arenaviruses. Given our previous ability to generate human antiviral mAbs, we do not anticipate problems in isolating anti-LASV or anti-MACV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently neutralizing anti-LASV or anti-MACV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (*i.e.*, memory B cells) isolated from human LASV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in LASV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-LASV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-LASV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-LASV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-LASV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the high-throughput Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E2. Specific Aim 2. Discover a protective CCHF virus mAb combination therapy. Establishing the generality of protection approaches against nairoviruses, we will perform a mAb discovery proof-of-concept campaign for the Prototype CCHFV. Preliminary studies have identified human anti-CCHF mAbs with varying levels of protection in experimentally infected animals[25,53,54]. We will isolate a large panel of human anti-CCHFV mAbs and determine the rules governing optimal mAb combinations through competition-binding, epitope mapping, neutralization, and viral escape studies. Lead antibodies with acceptable manufacturability characteristics (**Core D**) and the highest capacity to overcome resistance while maintaining potency of protection will be selected. The structural basis of their activity will be established using structural biology techniques (electron microscopy and crystallography). Lead mAb cocktail therapies will be evaluated for *in vivo* protective efficacy in STAT1$^{-/-}$ mice (with **Core E**). As a final test of an optimal anti-CCHFV mAb combination, we will assess protective efficacy of the lead anti-CCHFV mAb pair in NHPs, to be selected based on the *in vitro* and mouse data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys studies would only be considered pending success in the mouse studies and consultation with the external Scientific Advisory Board and NIAID program staff. In years 4-5, we will apply the lessons learned to the plug and play test case Kasokero virus (KASV) in collaboration with **RP1**, **Core D**, and **Core E**.

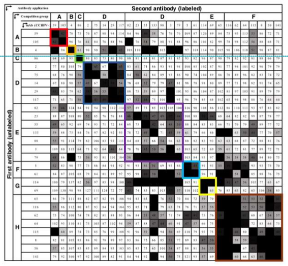

Figure 2. Competition assessment of human Abs to CCHFV using M-segment expressing cells. We tested 28 mAbs in competition assays. MAbs are displayed in 8 groups (A-H) based on their ability to compete for binding. Values shown are the % of binding that occurred during competition compared to non-competed binding of the mAb. This value was normalized to 100%. The values are also indicated by the box fill color; darker colors toward black indicate higher competition and lighter colors toward white indicate less competition, on a gradient scale.

~~**E2. Specific Aim 2. Discover a protective Crimean-Congo hemorrhagic fever (CCHF) virus mAb combination therapy.** Establishing the generality of protection approaches against nairoviruses, we will perform a mAb discovery proof-of-concept campaign for the Prototype CCHFV. Preliminary studies have identified human anti-CCHF mAbs with varying levels of protection in experimentally infected animals[25,53,54]. We will isolate a large panel of human anti-CCHFV mAbs and determine the rules governing optimal mAb combinations through competition-binding, epitope mapping, neutralization, and viral escape studies. Lead antibodies with acceptable manufacturability characteristics (**Core D**) and the highest capacity to overcome resistance while maintaining potency of protection will be selected. The structural basis of their activity will be established using structural biology techniques (electron microscopy and crystallography). Lead mAb cocktail therapies will be evaluated for *in vivo* protective efficacy in STAT1$^{-/-}$ mice (with **Core E**). As a final test of an optimal anti-CCHFV mAb combination, we will assess protective efficacy of the lead anti-CCHFV mAb pair in NHPs, to be selected based on the *in vitro* and mouse data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys studies would only be considered pending success in the mouse studies and consultation with the external Scientific Advisory Board and NIAID program staff. In years 4-5, we will apply the lessons learned to the plug and play test case Kasokero virus (KASV) in collaboration with **RP1**, **Core D**, and **Core E**.~~

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-CCHFV mAbs.*** In this Aim, we will rapidly discover human anti-CCHFV mAbs from CCHFV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify an optimal anti-CCHFV mAb combination and further advance the discovery platform for rapid response against emerging nairoviruses. In preliminary experiments in collaboration with investigators in **RP1** and **Core E**, the Crowe laboratory has previously isolated and characterized panels of neutralizing human anti-CCHFV human mAbs from individuals who were convalescent after naturally-acquired laboratory-confirmed infection in Spain or Turkey. ~~PBMCs were used to generate hybridomas and antibody variable genes sequenced to generate mAbs recombinantly.~~ We isolated a panel of antibodies against CCHFV that recognize the M-segment in transfected cells, and they exhibit a diversity of recognition patterns in that they fall into multiple competition-binding groups (**Fig 2**). This panel contains cross-binding and cross-neutralizing antibodies for diverse strains. We observed a human mAb designated CCHF-82 competing with competition group 1 and group 2 antibodies from the previously isolated GP38-reactive murine antibodies. CCHF-82 showed some protection in a STAT1$^{-/-}$ mouse model of infection conducted by investigators in **RP1 (Fig 3)**. Further investigation with this antibody in the IbAr10200 prophylaxis and therapeutic models is warranted. In contrast, the CCHFV-neutralizing mAbs that we isolated and tested *in vivo* did not perform well in the Turkish strain STAT1$^{-/-}$ mouse model. We now know protection in this model is possible, given the work from Fels *et al*., 2021 who showed that potent antibodies against various sites on the Gc surface can afford protection in this model[53]. However, in their study they did not test GP38-reactive antibodies. To our knowledge, our preliminary data is the first indication that a human GP38-targeting antibody can provide some protection in this mouse model of infection.

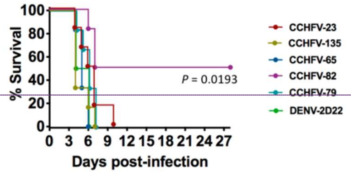

Figure 3. Human mAb CCHF-82 provides partial protection as a post-exposure prophylaxis against the Turkish strain of CCHFV in the STAT1$^{-/-}$ mouse model. A single dose of mAb was administered by the IP route to mice (n=6 per group (3 male, 3 female)) at 30 min post infections. A lethal dose of Turkish strain of CCHFV~~virus~~ was administered. CCHF mAbs~~-23, CCHF-135, CCHF-65, CCHF-82, CCHF-79,~~ or DENV-2D22 (an isotype-matched negative control mAb) were tested in a single dose of 250 µg per mouse ~~except for CCHFV-135 at 125 µg per mouse~~. Kaplan-Meier survival curves were statistically analyzed using a log-rank (Mantel-Cox) test where mAb-treated animals (*P* value shown in

Non-neutralizing murine mAbs protect in mouse models of infection[25], but it ~~has not been shown~~is unknown if the human antibody response could provide similar levels of protection. Murine mAb 13G8 binds to GP38 and does not neutralize CCHFV. This mAb provides protection against lethal challenge as a prophylaxis and a therapeutic against CCHFV. In preliminary experiments we sought to understand if human survivors of CCHFV infection possess B cells encoding mAbs that bind a similar epitope as 13G8 and provide protection. CCHF-82 competes for binding with 13G8 to preGn-transfected cells containing GP38. This antibody offered some protection as a post-exposure prophylaxis against the Turkish strain of CCHFV (**Fig 3**). Human antibodies like this should be further studied and the frequency of these clones should be elucidated to understand if this is a feasible strategy for future vaccine efforts for humans. The epitope that 13G8 and CCHF-82 identifies could inform vaccine design if these antibodies offer protection in larger animal models.

Understanding how non-neutralizing antibodies function is critical in efforts to validate the GP38-binding class of antibodies. Golden *et al.* undertook a study to understand the mechanisms 13G8 functioned and observed that complement activation contributes to the protective capacity of this antibody[25]. Here, in studies of CCHF-82, we also will assess complement activation in mouse models of infection to fully understand the function of this mAb *in vivo*. Furthermore, if this mAb protects in the CCHFV IbAr10200 strain challenge model, assessing its mechanism is warranted. Together with **Core D**, we will assess IgG molecules with complement knockout (“KA”) and Fc gamma receptor knockout (LALA-PG) mutations in the Fc domain to study this matter. Human mAb CCHF-82 displayed limited cross-protection against experimental infection with the Turkish strain of CCHFV. Our antibody isolation here will aim to identify cross-protective non-neutralizing antibodies reactive with GP38. Recently, vaccinating with NP was shown to be another way to elicit non- neutralizing antibodies[55]. The NP of CCHFV is more conserved than the glycoproteins and might also be a non-canonical target for the identification of cross-protective non-neutralizing antibodies[55].

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant viral surface protein antigens, cloning of Ab variable genes, and then expression of mAbs as ~~recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), and this may be helpful for rarer GP-38-specific B cells~~as described above in Specific Aim 1.

Formatted: Font: 8.5 pt

Formatted: Font: 8.5 pt

E.2.1. Rapid isolation of human anti-CCHFV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from a number of previously CCHFV-infected individuals. One was a health care survivor who was infected while caring for a patient in Spain[56]. We also collected a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Turkey, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples were only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies were approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples were deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-CCHFV mAbs rapidly, as if we had to respond to a nairovirus outbreak in real time. Our ability to respond rapidly in the setting of outbreaks is well-documented in the lay press (60 Minutes features and others) and the scientific literature, for ex., 78 days from sample to protection of NHPs for Zika virus[43], and 25 days from PBMC sample receipt to delivery of the antibody genes for the approved COVID-19 drug Evusheld to AstraZeneca[1]. Here, we will single-cell sort antigen-specific B cells using recombinant CCHFV proteins (GP38, Gc, Gn, Gc/Gn) or non-infectious viral particles as bait as described above in Specific Aim 1.~~.~~ ~~These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including VSV-CCHFV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe CCHFV protein or virus-particle binding to single B cells. These cells will be exported for sequencing of the variable gene regions and analysis using the PyIR software. We will select a panel of up to 500 neutralizing anti-CCHFV mAbs to express as recombinant mAbs and advance for further characterization. We have demonstrated the capacity to execute multiple approaches simultaneously in parallel[1,43], which enhances the diversity of clones obtained.~~ We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D**, listed in **Table 3** or by **RP1** **(Table 4)**.

Formatted: Font: 8.5 pt

(c) Recombinant mAb cloning. ~~We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using the custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson assembly-cloned on instrument into our custom full-length Ig expression vectors. We will design human anti-LASV mAbs as IgG1 with the Fc mutation, LALA-PG, to abrogate Fc effector functions to assess role of Fc-mediated effector functions to protection in animal models. We also will engineer IgG1 molecules with extended-half-life Fc mutations based on enhanced binding to FcRn including LS (M428L +N434S)[26] and YTE (M252Y +S254T +T256E)[27] mutations. These Fc engineering approaches will generate mAbs with vaccine-like properties. The LS and YTE mutations were developed in commercial settings (and have been used safely in the clinic), but the patent life of these mutations will expire prior to approval of antibodies developed here.~~As described in Specific Aim 1 above.

(d) Micro-scale mAb expression. ~~The Crowe laboratory will perform large-throughput micro-scale mAb expression and purification that, with our integrated approach allows, screening assays to identify candidate mAbs This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with diverse Fc mutants to assess the role of Fc-mediated effector functions *in vivo*~~ (~~**Core E**).~~As described in Specific Aim 1 above.

(e) A CPE-based CCHFV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of CCHFV. We will use a replication-competent vesicular stomatitis virus (VSV) CCHFV surrogate that expresses CCHFV surface proteins and causes CPE[46]. Investigators in **RP1** have the VSV-CCHFV-GFP versions of clades 1 through 7 based on this publication. We will obtain these all these VSV constructs from investigators in **PABVAX**. Existing VSV vectors will be provided by investigators in **RP1 and Core E**. We already have Vanderbilt Institutional Biosafety Committee approval for use of these constructs in this format and assay. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against CCHFV. These mAbs will be moved forward for additional studies to identify an optimal anti-CCHFV mAb combination. GP38-reactive clones will be advanced based on avidity ranking since they are not likely to be neutralizing but may be protective *in vivo*.

E.2.2. Identifying CCHFV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind CCHFV surface proteins and validate their epitopes. We will perform competition-binding studies with CCHFV Gc/Gn or subunit proteins (as above) or CCHFV virus-like particles (VLPs) made from a replicon system in hand. **Core E** will inactivate CCHFV virus particles that they have in the UTMB center by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from some of the mAbs shown in the unpublished preliminary data above for the identification of mAbs that can concurrently bind CCHFV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-CCHFV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. GP-38-reactive clones will be screened for synergistic binding as they are not expected to be neutralizing. ***(c) Identification of key binding residues of human anti-CCHFV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-CCHFV constructs at BSL2 in the presence of saturating concentrations of CCHFV mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of VSV-CCHFV escape variants in the presence of mAbs.

E.2.3. Structural basis of neutralization by anti-CCHFV mAb combinations. ~~The studies above should identify optimal anti-CCHFV mAb combinations that simultaneously bind, neutralize, and increase the barrier for CCHFV to escape mAb selective pressure.~~ For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above~~for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for nairoviruses by identifying key epitope targets (**RP1**)~~.

E.2.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies in STAT1$^{-/-}$ mouse models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (Core D), will advance to *in vivo* testing. We will use an established STAT1$^{-/-}$ mouse model of CCHFV infection that the **RP1** and **Core E** investigators have deployed[46]. To benchmark our mAbs, a separate set of STAT1$^{-/-}$ mice will be treated with CCHF-82, which we showed in unpublished preliminary data above confers substantial but incomplete protection (**Fig 3**). The **Core E** laboratory has access to strains representing all 6 clades that can be tested. Groups of 10 STAT1$^{-/-}$ mice will be treated with low, medium, and high doses) of single or combinations of anti-CCHFV mAb, or isotype controls at day +1 after inoculation with CCHFVs. This approach allows us to determine whether combinations provide advantage over the best CCHFV monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after CCHFV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal CCHFV mAb pairs that are comparable to or outperform the mAbs we reported above. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-CCHFV mAb combination against CCHFV in NHPs. As a final test of an optimal anti-CCHFV mAb combination, we will assess efficacy of the lead anti-CCHFV mAb pair in NHPs (**Core E**), to be selected based on the *in vitro,* STAT1$^{-/-}$ mice, and manufacturability data (**Core D**). Down-selection for testing in cynomolgus monkeys would only be considered with success in the STAT1$^{-/-}$ mouse studies and in consultation with the external SAB and NIAID program staff.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-CCHFV mAb combinations with optimal protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging CCHFV or related nairoviruses. Given our previous ability to generate human anti-CCHFV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-CCHFV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-CCHFV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (*i.e.*, memory B cells) isolated from human CCHFV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in CCHFV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-CCHFV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-CCHFV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-CCHFV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-CCHFV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E3. Specific Aim 3. Establish optimal mAb combination therapies against henipaviruses Hendra (HeV) and Nipah (NiV) viruses. We will use a large panel of potent anti-henipavirus mAbs that we previously made from the memory B cells of immune individuals and generate new antibodies targeting the fusion (F) protein. **RP2** will provide new antigens for mAb selection and BSL-2-compatible viruses for neutralization screens including Cedar virus constructs displaying HeV and NiV F and G proteins. We will identify optimal mAb combinations to enhance henipavirus therapy, minimize viral escape, and improve treatment efficacy through synergy. *In vitro* competition-binding, neutralization, and mechanistic studies will be conducted, including authentic virus neutralization with **PABVAX Core E**. We will refine the recognized epitopes and investigate the structural basis for optimal combination neutralization of henipaviruses using HeV and NiV as prototypes. *In vivo* assessment of mAb combinations will determine the minimal effective dose for protection and the ability to prevent *in vivo* escape. Protective efficacy of lead mAb combinations will be assessed in hamster models of NiV and HeV infection with **Core E**. Leads will be transferred to **Core D**. As a final test of optimal henipavirus mAb combinations, we will assess protective efficacy of the lead henipavirus mAb pairs in NHPs, to be selected based on the *in vitro* and hamster data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in African green monkey (AGM) henipavirus model studies would only be considered pending success in the hamster studies and consultation with the external SAB and NIAID program staff. The HeV+NiV studies will be conducted in years 1-3 and then applied to the plug-and-play test case Langya virus in years 2-5. If **RP2** and **Core E** cannot rescue recombinant Langya virus, the lessons learned in Years 1-3 will be applied to the alternate plug-and-play test viruses Angavokely or Sosuga (SOSV) virus. Preliminary data on SOSV mAbs are provided.

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-NIV/HeV mAbs.*** In this Aim, we will further adapt approaches we have developed in preliminary experiments with henipavirus mAb studies by identifying a potently protective combination of anti-NiV/HeV human mAbs. ~~We already have in hand some~~~~perform synergy studies to identify optimal mAb combinations by pairing them with each other and with anti-G antibodies.~~ Through these studies, we aim to identify an optimal anti-NiV+HeV mAb combination and further advance the discovery platform for rapid response against emerging paramyxoviruses, especially henipaviruses. In previous experiments in collaboration with investigators in **RP2** and **Core E**, the Crowe laboratory has isolated characterized panels of neutralizing human anti-G NiV/HeV human mAbs from an individual with G-based immunity following occupational exposure to an equine HeV G subunit vaccine. Isolated peripheral blood mononuclear cells (PBMCs) were used to generate human B cell hybridomas secreting human mAbs to G, and antibody variable genes were sequenced to generate mAbs recombinantly. We isolated a panel of antibodies against the G protein that recognize the HeV G, NiV Bangladesh G, and NiV Malaysia G proteins. The mAbs exhibited a diversity of recognition patterns in that they fall into multiple competition-binding groups ~~(**Fig 4**~~). This panel contains cross-binding and cross-neutralizing antibodies for diverse NiV and HeV strains. In the work proposed here, we will rapidly discover human NiV/HeV anti-F mAbs from NiV-immune individuals and outstanding potency anti-G antibodies with extensive characterization, including synergistic neutralization. ~~In the work proposed here, we will rapidly discover human NiV/HeV anti-F mAbs from NiV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them with each other and with anti-G antibodies. Through these studies, we aim to identify an optimal anti-NiV+HeV mAb combination and further advance the discovery platform for rapid response against emerging paramyxoviruses, especially henipaviruses. This panel contains cross-binding and cross-neutralizing antibodies for diverse NiV and HeV strains.~~

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant henipavirus F protein antigens, ~~perform cloning of Ab variable genes, and then express mAbs as recombinant IgGs. Alternatively, F-specific B cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through 2 different single-cell RNA-seq approaches (10X Genomics & Rhapsody)~~as described above in Specific Aim 1.

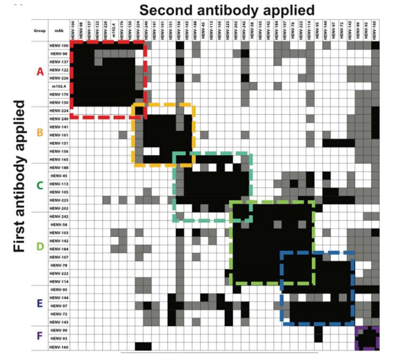

Figure 4. Identification of major antigenic sites for recognition of HeV RBP by human mAbs. SPR competition binding of human Abs against HeV-RBP. A first Ab was applied to a gold-coated sensor chip, and recombinant HeV-RBP head domain was associated to the coupled Ab. A second Ab was applied to the sensor chip to determine binding to RBP. Black boxes - a pairwise interaction in which the binding of the second Ab is blocked by the first. White - both Abs could bind simultaneously. Gray - intermediate competition phenotype.

E.3.1. Rapid isolation of human anti-HeV/NiV mAbs. *(a) Immune cells.* We are obtaining human PBMCs from a number of previously NiV-infected individuals who acquired immunity following natural infection in collaboration with the **icddr,b**, an international health research institute based in Dhaka, Bangladesh. We are collecting a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Bangladesh, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies are approved by the icddr,b and Vanderbilt University Medical Center IRBs. PBMCs isolated from the blood samples are deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their use in this **RP4,** if funded.

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific B cells, cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody^{TM}), and this may be helpful for rarer antigen-specific B cells. We will sort soluble fusion (sF) or attachment (G) protein-specific cells with recombinant viral surface protein antigens from **Core D** (**Table 6**).

Formatted Table

(c) Ab screening and sequence analysis. Our goal is to identify human anti-NiV/HeV mAbs rapidly, as if we had to respond to a paramyxovirus outbreak in real time. We will single-cell sort antigen-specific B cells using recombinant HeV and NiV proteins (sF or G) as bait as described in Specific Aim 1 above. ~~. These cells will be expanded on feeder layers expressing CD40L, IL-21, and BAFF for downstream applications, including VSV-CCHFV neutralization assays. We also can use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe CCHFV protein or virus-particle binding to single B cells. These cells will be exported for sequencing of the variable gene regions and analysis using the PyIR software. We will select a panel of up to 500 neutralizing anti-HeV/NiV mAbs to express as recombinant mAbs and advance for further characterization.~~

(d) Recombinant mAb cloning. As described in Specific Aim 1 above~~We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using the custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors. We will design human anti-LASV mAbs as IgG1 with the Fc mutation, LALA-PG, to abrogate Fc effector functions to assess role of Fc-mediated effector functions to protection in animal models. We also will engineer IgG1 molecules with extended half-life Fc mutations based on enhanced binding to FcRn including LS (M428L +N434S)[26] and YTE (M252Y +S254T +T256E)[27] mutations. These approaches will generate mAbs with vaccine-like properties~~.

(e) Micro-scale mAb expression. As described in Specific Aim 1 above~~The Crowe laboratory will perform large-throughput micro-scale mAb expression and purification that, with our integrated approach allows, screening assays to identify candidate mAbs. Early-stage assays will identify candidate mAbs that will then be produced at~~

~~larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**)~~.

(f) CPE-based HeV/NiV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of HeV and NiV. We will use replication-competent vesicular stomatitis virus (VSV) HeV and NiV surrogates that expresses henipaviurs surface proteins and cause CPE. Investigators in **RP2 and RP3** have VSV-NiV F and VSV-NiV G with GFP[45], VSV-NiV G without GFP[47] and VSV-HeVG (Geisbert and Cross, unpublished). We will obtain these all these VSV constructs from investigators in **PABVAX**. We already have Vanderbilt Institutional Biosafety Committee approval for use of these constructs in this format and assay. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against HeV and NiV. We also can use Cedar virus constructs for neutralization assays as the have reduced pathogenicity[57] and can be used in high-throughput screening assays for henipavirus antiviral discovery[58]. Cedar viruses will be provided by Dr. Broder of **RP3**. The mAbs with most potent activity will be moved forward for additional studies to identify an optimal anti-HeV/NiV mAb combination.

E.3.2. Identifying HeV/NiV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig** ~~2~~4) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind HeV/NiV surface proteins and validate their epitopes. We will perform competition-binding studies with HeV/NiV sF or G proteins (as above). We will include positive controls made recombinantly from some of the mAbs shown in the preliminary data above for the identification of mAbs that can concurrently bind HeV/NiV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti- HeV/NiV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key binding residues of human anti-HeV/NiV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-NiV F, VSV-NiV G and VSV-HeV G constructs at BSL2 in the presence of saturating concentrations of HeV/NiV mAbs (single or combination) using RTCA to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test the level of infection of VSV-HeV/NiV escape variants in the presence of mAbs.

E.3.3. Structural basis of neutralization by anti-HeV/NiV mAb combinations. ~~The studies above should identify optimal anti-HeV/NiV mAb combinations that simultaneously bind, neutralize, and increase the barrier for CCHFV to escape mAb selective pressure.~~ For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, as described in Specific Aim 1 above.~~for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for henipaviruses by identifying key epitope targets.~~

E.3.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies hamster models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (**Core D**), will advance to *in vivo* testing. We will use an established hamster model of NiV or HeV infection that the **Core E** investigators have deployed. To benchmark our mAbs, a separate set of hamsters will be treated with G mAbs HENV-103+HENV-117, which we showed in previous data above confers substantial protection[18]. Groups of 10 hamsters will be treated with low, medium, or high IgG doses) of single or combinations of anti-HeV/NiV mAbs, or isotype controls at day +1 after inoculation with HeV or NiV. This approach allows us to determine whether combinations provide advantage over the best HeV or NiV mAb monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after HeV or NiV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal HeV/NiV mAb pairs that are comparable to or outperform the mAbs we reported previously. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-HeV/NiV mAb combination against HeV and NiV in NHPs. As a final test of an optimal anti-HeV/NiV mAb combination, we may assess efficacy of the lead anti-HeV/NiV mAb pair in NHPs (**Core E**), selected based on the *in vitro,* hamster data, and manufacturability data (**Core D**). Down-selection for testing in African green monkeys would only be considered with success in the hamster studies and in consultation with the external SAB and NIAID program staff.

E.3.5. Applying lessons learned in HeV/NiV research to Langya, Angavokely and Sosuga viruses. Once we have completed the HeV/NiV discovery campaigns, will turn to the test case pathogen Langya, Angavokely and Sosuga (SOSV) viruses to see if we can use the prototype pathogen approach for this virus. We have plenty of human PBMCs from the sole identified SOSV-immune individual and have already shown that it is possible to obtain HN- and F-specific neutralizing antibodies from this individual's B cells[59]. We also have already prepared recombinant SOSV prefusion F and HN proteins[59]. We do not have access to human PBMCs from Langya- or Angavokely-immune donors. For those mAb discovery campaigns, we will use Alloy humanized mouse models as a source of B cells encoding human mAbs, as above. Mice will be immunized with recombinant protein antigens (**Table 7**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Langya or Angavokely. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for Hev/NiV described above.

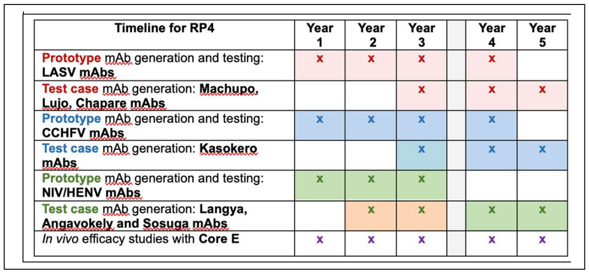
Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-HeV/NiV mAb combinations with optimal protective activity. These mAb combinations will be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging HeV/NiV or related paramyxoviruses. Given our previous ability to generate human anti-HeV/NiV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-HeV/NiV mAbs. We may observe that new mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-HeV/NiV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (*i.e.*, memory B cells) isolated from human NiV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in NiV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-HeV/NiV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-HeV/NiV mAb combinations that can inform vaccine design (**RP2**) for related viruses being used as test cases in years 2 through 5.

F. Scientific rigor. *Experimental design.* Experiments will include biological and technical replicates, and results will be analyzed by parametric or non-parametric analyses (depending on data distribution) and corrections for multiple comparisons. EC_{50} (binding) and IC_{50} (neutralization) values will be reported only following at least 3 identically conducted experiments. All mAb screening will incorporate appropriate + and - controls. Positive signals in binding assays will be defined as >3 SD above background. ***Protein quality.*** We have a high capacity to purify proteins using a Protein Maker workstation that allows purification chromatography on 24 parallel columns. We perform QC on protein reagents using a Maurice instrument with capillary electrophoresis technology to automate our protein profiling either by size or charge, providing cIEF and CE-SDS data. Animal ***studies*** will be performed blinded with independent replicates and include negative (*e.g.*, placebo), and positive (when available) controls. We will use power calculations (**Data Management Core B**) to determine sample sizes. For virological studies, power analysis was performed using accepted values for type I error (0.05) and power (80%). The values for population variance (15×) are based on existing data sets and our experience with rodent challenge studies. We will perform experiments at least 2-3 independent times (n = 4-5 each) to attain n = 12-15 per arm. Smaller group sizes can be used if differences are larger than expected.

G. Relevant biological variables. The human mAbs are derived from immune human donors or Alloy mice. Humans. Human Abs will be isolated for biological, structural, and functional studies at a clonal level. The sample size is not powered for large scale epidemiologic or clinical study conclusions. There is no evidence that sex, age, body mass index, or underlying health conditions other than immunodeficiency or immunosuppressive treatments alters the activity of cloned Abs in structure/function studies. The samples are de-identified without patient specific identifiers to protect the health information of the donors; thus, research with these samples is considered *Not Human Subjects Research* category activity. Mice, hamsters, guinea pigs, NHP, and viruses are also biological systems used in this application. Conventional animal housing conditions will be used because there is no evidence that altered room temperatures and light/dark cycles influence paramyxovirus, nairovirus, or arenavirus pathogenesis. Mice, hamsters, guinea pigs, and NHPs of both sexes will be used, and phenotypes will be monitored for sex-based differences. Virus stocks will be either low passage seed stocks from natural isolates or generated from existing cDNA clones and sequence-confirmed prior to use for infection studies.

H. Milestones and quantitative Go/No-Go criteria. Through **Aims 1-3**, we have proposed experiments that will advance our knowledge of the mAb-mediated mechanisms of action against paramyxoviruses, nairoviruses, and arenaviruses. In each Aim, we will use down-selection criteria (as below) to advance mAb combinations or variants for additional studies. By year 3, we will have defined the principles that govern optimal mAb combinations for paramyxoviruses, nairoviruses, and arenaviruses and the rational approaches needed to select mAbs for potency and breadth. We will use the following metrics to advance mAbs: ***(a) Neutralizing activity*.** All mAbs will have neutralizing potency < 10 ng/mL, EC_{50} value; ***(b) Binding affinity***. MAbs will be of high affinity to surface proteins or virions (K_D < 5 nM). ***(c) Protein stability and production quality*.** MAbs must produce at high levels without optimization (> 100 mg/L) and show biochemical/functional stability at 4°C or -80°C (>90% retention of binding and neutralization activity at 30 d). ***(d) Synergy***. Combinations of 2 mAbs against a given virus ideally will show synergy of neutralization *in vitro* or at a minimum, additive inhibition (no antagonism); ***(e) Epitopes***. To avoid resistance, mAbs in combination will bind 2 epitopes (determined by competition binding (<20% reduction in binding), mapping, and structural studies. ***(f) Resistance*** against mAbs will be assessed for virus escape. Deep sequencing of viruses that emerge from cells or animals treated with mAbs will inform prioritization. Combinations of mAbs with high genetic barriers to resistance (<10× loss in EC_{50}) will be advanced. ***(g) Protection in mice, hamsters, guinea pigs, or NHPs.*** The following metrics can be used: (i) Protection against lethal challenge by homologous virus (>90% survival; (ii) Protection against clinical disease by homologous virus (>80%); (iii) Protection against infection by homologous virus (>100-fold reduction in viral titers in multiple organs). ***(h) pK measurements***. For lead protective mAbs with mutations that should confer extended half-life, we will perform pK studies in NHPs (with **Core D** and **E**) to assess levels over time with a goal of a human predicted serum half-life of >6 months.



Timeline for RP4	**Year 1**	**Year 2**	**Year 3**		**Year 4**	**Year 5**
Prototype mAb generation and testing: **LASV mAbs**	x	x	x		x	
Test case mAb generation: **Machupo, Lujo, Chapare mAbs**			x		x	x
Prototype mAb generation and testing: **CCHFV mAbs**	x	x	x		x	
Test case mAb generation: **Kasokero mAbs**			x		x	x
Prototype mAb generation and testing: **NIV/HENV mAbs**	x	x	x			
Test case mAb generation: **Langya, Angavokely and Sosuga mAbs**		x	x		x	x
In vivo efficacy studies with **Core E**	x	x	x		x	x

A. BACKGROUND AND SIGNIFICANCE. Paramyxoviruses, nairoviruses, and arenaviruses are widely distributed RNA viruses that cause severe human syndromes. Because of their geographical distribution and expansion, changes in human demographics and increased exposures to wild animals including rodents and bats, and their capacity for human-to-human spread, these viruses have the potential to cause pandemics. Together with the other investigators in **PABVAX**, we have selected several important prototype paramyxoviruses, nairoviruses, and arenaviruses to study to learn the rules governing immunity to these pathogens. The work on the pathogens selected is justified based on their prevalence and severity alone, but also because of their ability to serve as prototypes for genetically related viruses. We chose the viruses for focus in this RP4 on human antibody development because of their clinical relevance and because several will be studied as prototypes for vaccine development in **RP1** (arenavirus and nairovirus vaccines) and **RP2** (paramyxovirus vaccines). Among the arenaviruses, we will target *Lassa mammarenavirus* (LASV) and *Machupo mammarenavirus* (MACV)*, and* among the family Nairoviridae of RNA viruses, we will study Crimean–Congo hemorrhagic fever orthonairovirus (CCHFV). In tandem with the vaccine projects in **RP2** focused on paramyxoviruses, we study Nipah virus (NiV) and Hendra virus (HeV) as the prototypes, and already have preliminary data with Sosuga virus as a test case. Information about the principles we discover about critical neutralizing epitopes identified here in **RP4** with prototype viruses can feed back into all other **Projects** that address the subsequent test cases in later years (Lujo, Chapare, Kasokero, Langya, Sosuga).

LASV is an Old World arenavirus (OWAV) with a single-stranded RNA virus belonging to the Arenaviridae family. Infection in humans is often the result of exposure to infected excreta from the rodent reservoir, *Mastomys natalensis* where up to 500,000 cases and an estimated 5,000 deaths occur annually in West Africa[2]. While rodent infection is largely benign, human infection can result in severe hemorrhagic disease with neurological complications and long-term hearing and vision sequelae[3,4]. The virus possesses a bi-segmented genome comprising large (L) and small (S) segments, both of which are enclosed within a lipid envelope. The L segment (~7.2 kb) encodes the RNA-dependent RNA polymerase (RdRp) and a zinc-binding protein (Z), while the S segment (~3.4 kb) codes for the nucleoprotein (NP) and the glycoprotein precursor (GPC). The GPC is further cleaved into two surface glycoproteins, GP1 and GP2, which play critical roles in viral entry. The genetic diversity of LASV can be classified into six lineages (I-VI), with lineages III and IV being the most prevalent[5]. Genetic variation arises mainly due to the error-prone nature of the viral RNA polymerase, leading to the emergence of quasi-species. This diversity contributes to the virus's ability to evade host immune responses and pose challenges to vaccine development[6]. LASV antigens include the surface glycoproteins GP1 and GP2, responsible for receptor binding and membrane fusion, respectively. While GP1 is highly variable among strains, GP2 is more conserved. The nucleoprotein (NP) is another major antigen, and its immunodominant epitopes are targeted by the host's immune response. Its genetic diversity and antigenic properties complicate diagnosis and vaccine development, emphasizing the need for continued research on medical countermeasures.

MACV is a New World Arenavirus (NWAV) and the causative agent of Bolivian Hemorrhagic fever. Humans are infected after exposure to excreta from the reservoir, *Calomys callosus,* the large vesper mouse. Disease in humans has a slow onset, but can progress to severe hemorrhagic fever coupled to insidious neurological complications including tremors, seizures, and paralysis[7]. MACV has a similar genomic organization and contains a GPC, NP, Z, and L polymerase proteins. Genetic diversity of MACV is delineated into 8 lineages (I-VIII) where there is growing concern of an expanding host range of *C. callosus* is responsible for outbreaks outside the known endemic region[8]. While the host entry receptor for NWAV is not shared with OWAV, the role for GP to drive immunity as a major antigen alongside NP. The better studied Junin has a regionally approved vaccine[9] and convalescent plasma program[10] available to prevent and treat disease, respectively. There are no approved vaccines or therapies approved for any other NWAV, including MACV. Further, itis not well established whether these countermeasures have potential for cross protect other NWAV such as MACV, underscoring the value of continued efforts to develop broadly active countermeasures to safeguard against lethal disease.

CCHFV is a highly pathogenic tick-borne virus classified under the Nairovirus genus within the Bunyaviridae family[11]. It has a negative-sense, single-stranded RNA genome comprising three segments: Small (S), Medium (M), and Large (L). These segments are enclosed within a lipid envelope and code for various structural and non-structural proteins. The S segment (~1.7 kb) encodes the nucleocapsid protein (N), which is essential for viral replication and assembly. The M segment (~5.3 kb) codes for the glycoprotein precursor (GPC), which is post-translationally cleaved into two surface glycoproteins, Gn and Gc. These glycoproteins are involved in viral entry and fusion. The L segment (~12.1 kb) encodes the RNA-dependent RNA polymerase (RdRp), responsible for viral RNA synthesis. CCHFV exhibits significant genetic diversity, with at least seven distinct clades (Europe 1, Europe 2, Africa 1-3, and Asia 1-2) based on the partial S segment sequences[12]. This diversity is attributed to the segmented genome, geographical distribution, and error-prone viral RNA polymerase, leading to the emergence of various quasi-species. The major antigens of CCHFV include the surface glycoproteins Gn and

Gc, as well as the nucleocapsid protein (N)[13,14]. These antigens are targeted by the host immune response. CCHFV is genetically diverse, so breadth of reactivity will be a focus of our discovery efforts.

NiV/HeV. Bat borne, NiV) and HeV are enveloped, negative-sense, single-stranded RNA viruses belonging to the Henipavirus genus within the Paramyxoviridae family[15]. These emerging zoonotic viruses pose a significant threat to human and animal health due to their high fatality rates and broad host range. The genomes of NiV and HeV are approximately 18.2 kb or 18.4 kb in length, respectively, and share a similar gene organization. They encode six major structural proteins: nucleocapsid (N), phosphoprotein (P), matrix (M), fusion (F), attachment glycoprotein (G), and large polymerase (L) proteins. The N, P, and L proteins form the viral RNA-dependent RNA polymerase (RdRp) complex necessary for transcription and replication, whereas the M, F, and G proteins are essential for virus assembly and entry. Genetic diversity in Henipaviruses is relatively low compared to other RNA viruses, with NiV strains showing 91-100% nucleotide similarity and HeV strains displaying 83-100% similarity[16]. However, the error-prone nature of the RdRp can still generate genetic variability, leading to the emergence of distinct lineages. The major surface antigens of Nipah and Hendra viruses are the attachment glycoprotein (G) and fusion protein (F). The G protein facilitates receptor binding, while the F protein mediates viral membrane fusion. Both antigens are involved in host immune responses and are potential targets for vaccine development, and the neutralizing antibody approaches we propose here. NiV and HeV exhibit relatively low genetic diversity, and in preliminary studies, we have identified human mAbs that neutralize HeV, NiV Bangladesh and NiV Malaysia strains[17-19]. Antibodies to the major surface antigens, the G and F proteins, are therefore, promising candidates for development as prophylactic or therapeutic molecules.

Antibodies (Abs) are important correlates of protection for paramyxoviruses, nairoviruses, and arenaviruses. Immune sera against members of each of these groups of viruses has been shown to exhibit protective efficacy *in vivo*, which supports the use for Abs as treatment options. However, the specificity, functional properties, and other attributes of protective antibodies are poorly defined for most of these viruses. MAbs to the attachment and fusion surface proteins of paramyxoviruses (such as the G and F proteins of Hendra/Nipah[18,20] and the GP proteins of the arenaviruses like LASV[21,22] can neutralize and protect against infection in rodent models. CCHFV is a bit of a conundrum in that ultrapotent human neutralizing antibodies to the related Rift Valley fever virus surface proteins are highly protective *in vivo*[23,24], but CCHFV neutralizing antibodies are not protective. In contrast, some non-neutralizing antibodies do protect partially for CCHFV[25]. Clearly, there is a lot to learn about the rules of immunity to these viruses, and the genetic, molecular, and structural basis of antibody-mediated protection for viruses like CCHFV. Based on these data, we propose the use of mAbs as treatment options to learn the rule of how to protect against emerging paramyxoviruses, nairoviruses, and arenaviruses and to develop candidate antibody countermeasures for translational development with **Core D**. To do so, we will further develop our technical methods for rapidly discovering mAbs, in the case of a future unexpected epidemic caused by viruses of these families. Most importantly, we will define the principles governing combination antibody therapy to prevent virus escape from treatment or prevention and to optimize the efficacy of the beneficial effects conferred by passive immunity.

B. SCIENTIFIC PREMISE. The work proposed here in **RP4** is based on the extensive basic, translational, and clinical trial data on the role of neutralizing Abs in protection against infection and disease caused by paramyxoviruses, nairoviruses, and arenaviruses. Although a significant amount of data supports the use of mAbs to prevent or control paramyxovirus, nairovirus, and arenavirus infection, many questions remain, such as the ideal epitopes to target with mAb combination therapy to improve upon neutralization potency, *in vivo* efficacy, and resistance to viral escape. Identifying these epitopes can help inform vaccine design to elicit optimal protective polyclonal responses (in **RP1** and **RP2**, especially with designs for test cases in years 4 and 5). Here we aim to refine our understanding of the correlates of mAb protection against paramyxoviruses, nairoviruses, and arenaviruses to enable the design of a modular 'plug-and-play' workflow to rapidly respond to potential pandemics by generating optimized combinations of vaccine-like mAbs with an extended half-life that could be used for long-term prophylaxis (> 6 months) and therapy.

C. INNOVATION. RP4 has many innovative conceptual and technical features including: Conceptual. **(1)** determining the principles that govern optimal combinations of human mAbs against paramyxoviruses, nairoviruses, and arenaviruses for protection and resistance to viral escape; **(2)** the development of a clear workflow that generates therapeutic or preventative antibodies (long half-life mAbs that serve as vaccine surrogates) against emerging or new paramyxoviruses, nairoviruses, and arenaviruses with pandemic potential. Our goal is to define the principles and features, including epitope, combination ratios, and mechanisms of action, that result in optimal efficacy of mAbs against paramyxoviruses, nairoviruses, and arenaviruses in animal models and create a higher barrier for resistance. These studies will serve as paradigms for rapid antibody discovery in response to future paramyxovirus, nairovirus, and arenavirus pandemic threats. Technical. **(3)** large-scale B cell repertoire sequencing with customized methods and software; **(4)** use of humanized (Alloy) mice and novel immunogens from **RP1** and **RP2** and **Core D**; **(5)** single B cell functional (neutralization) assays performed on a

Beacon instrument; **(6)** development of high-throughput real-time label-free virus neutralization assays (xCELLigence platform); and **(7)** use of *simultaneous* in parallel screening with several different high-throughput virus-specific B cell isolation approaches (Beacon, 10X Genomics, Rhapsody) to generate and validate best-in-class human mAbs as candidate medical countermeasures.

D. LINKAGE TO OTHER PABVAX PROJECTS AND CORES. The group will focus on developing a modular test case platform for rapid selection of highly neutralizing and/or protective mAbs against paramyxoviruses, nairoviruses, and arenaviruses. Members of our group have active collaborations with most members of the **PABVAX Center** as reflected in previous collaborations and publications (see **Overall** document). We will interact extensively with the Animal Model and Preclinical Evaluation Core (**Core E)** to study neutralization against authentic viruses and to test for protection in small and large animals as well as with **RP3** for testing paramyxovirus mAbs. The knowledge gained from our studies on the structure-function relationships of neutralizing mAb combinations can be applied to rational vaccine design for **RP 1** and **RP2** in later years of the effort when we pivot to apply the lessons learned to the same test case targets as **RP1** and **RP2.** Numerous antigens will be made available to our RP. Finally, long-half-life Fc mutations are now available based on engineering of human IgG1 for enhanced binding to the neonatal Fc receptor (FcRn) such as LS (M428L /N434S)[26], or YTE (M252Y/S254T/T256E)[27] mutations. With ≥ 90 days half-life in humans, our approach will generate mAbs with vaccine-like properties that remain effective for months during a virus epidemic and thus provides a platform for response to future paramyxovirus, nairovirus, and arenavirus pandemic threats, a key goal of our **PABVAX Center.** *Our laboratory previously validated this vaccine surrogate concept when we isolated the human mAbs that formed the basis for Evusheld with YTE long-half-life Fc mutations (used in 70 countries and millions of people) that exhibited > 6 months protective levels in humans after single IM injections*.

E. APPROACH

E.1. Specific Aim 1. Discover potently neutralizing arenavirus combination therapies. For the prototypes, we will focus on Lassa virus (LASV), an Old World virus and Machupo virus (MACV), a New World virus. We will investigate the principles underlying antibody-mediated arenavirus protection. Preliminary evidence suggests that potent virus neutralization is a mechanistic correlate of protection for arenaviruses[28,29]. **RP1/Core D** will provide optimized antigens for mAb selection for the Prototype LASV and MACV (or subsequent Test Cases). We will use a workflow for rapid identification of potently neutralizing mAb combinations for LASV and MACV. We will generate mAbs from individuals with prior natural infection or use transgenic mice with human antibody repertoires. A large panel of human anti-LASV and anti-MACV mAbs will be generated using multiple approaches (immune human B cells and immunized humanized mice), and highly neutralizing mAbs will be evaluated to identify optimal combinations. The best mAb combinations will be assessed to determine the minimal effective dose for protection, and the lead mAb combination therapy(ies) will be transferred to **Core E** for further evaluation and ultimately testing in an NHP model of LASV infection. Leads will be transferred to **Core D** for further translational development as medical countermeasures. The prototype LASV and MACV will be studied in years 1 to 3, followed by mAb discovery efforts for Test Cases Lujo and Chapare viruses based on the established principles in years 4-5.

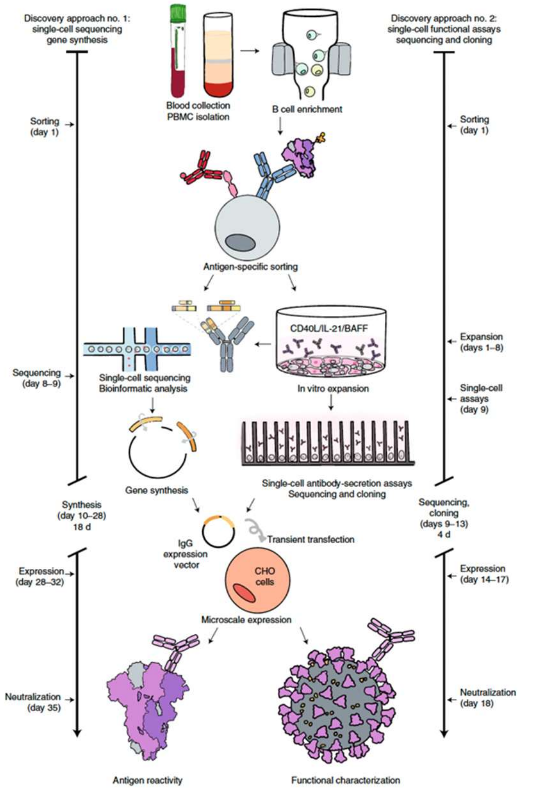

Figure 1. Single cell mAb discovery. PBMC samples are used to enrich for B cells, which can be sorted for antigen-specific B cells. Expansion of these B cells is done to further assess the functionality of the B cells or for antibody sequencing to determine the variable genes contributing to antigen reactivity. Recombinant mAb expression validates the mAb sequence and functional activity. Figure is adapted from [1].

<u>Preliminary Data</u>. ***(a) Potently neutralizing human anti-LASV and anti-MACV mAbs.*** The Crowe laboratory has previously characterized panels of neutralizing human anti-viral human mAbs from virus-immune or vaccinated individuals for about 50 viruses, mostly RNA viruses. Isolated peripheral blood mononuclear cells (PBMCs) are used to generate hybridomas or alternatively antigen-sorted at single B cell level and antibody variable genes sequenced to generate mAbs recombinantly. Panels of human anti-viral mAbs are produced rapidly (we recently reported isolation of 15,000 mAb gene pairs from single Ebola-virus-specific human B cells from a single blood sample of an immune individual[30]. Previous studies by others clearly show

that representative neutralizing and protective human antibodies can be isolated from LASV-immune subjects[31-35]. In this Aim, we will refine the approaches we have developed previously for other RNA viruses in a proof-of-concept study by identifying potently neutralizing combinations of anti-LASV and anti-MACV human mAbs. We will rapidly discover human anti-LASV mAbs from LASV-immune individuals and human anti-MACV mAbs by immunizing Alloy transgenic mice. Synergy studies will be performed to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify optimal anti-LASV and anti-MACV mAb combinations and further advance the discovery platform for rapid response against emerging arenaviruses.

(b) Advanced mAb technologies. The Crowe laboratory has developed some of the highest yield systems to isolate naturally occurring human mAbs using human hybridoma or advanced single-cell RNA-seq methods (**Fig 1**). We have used sorting of antigen-specific cells with recombinant viral surface protein antigens (like the GP1 and GP2 proteins we will use here), cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. One variation we will use is to capture Ab genes directly from viral glycoprotein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), as we have done for Ebola virus[30,36] and SARS-CoV-2[1,37-42]. These single-cell techniques enhance the capture of rare antigen-specific B cells.

E.1.1. Rapid isolation of human anti-LASV and anti-MACV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from one previously LASV-infected individual who was medically managed previously by Emory University in their infectious diseases containment unit. This person has a documented robust neutralizing serum antibody response, suggesting isolation of neutralizing human mAbs from these PBMC aliquots will be straightforward for us. Our colleagues in **RP1** have ongoing field operations for over a decade in Sierra Leone, Liberia, and Nigeria. This work is currently in association with the NIH-Centers for Research on Emerging Infectious Diseases (CREID) with a heavy focus on the study of LASV ecology, epidemiology, and host responses. **RP4** is currently working with **RP1** on obtaining PBMCs from ~10 individuals with prior laboratory-confirmed cases of LASV. The acquisition of these samples is being managed by the Vanderbilt Vaccine Center Biorepository with separate institutional funding to be de-identified prior to use in the studies proposed here. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies have been approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples will be deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded. For anti-MACV mAbs, as a human source is not readily available, we will immunize Alloy humanized mice. These animals yield PBMCs that secrete fully human mAbs. Alloy mice are used routinely in the Crowe lab workflow.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-LASV and anti-MACV mAbs in a rapid manner to mimic a pandemic response to an outbreak. We will single-cell sort antigen-specific B cells using recombinant LASV or MACV proteins or non-infectious viral particles as bait. These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including LASV and MACV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe GP protein or virus-particle binding to single B cells. These cells are exported for sequencing of the variable gene regions and analysis using the PyIR software developed in the Crowe laboratory. We will select a panel of up to 500 neutralizing anti-LASV mAbs and a similar number of anti-MACV mAbs to express recombinantly and advance for further characterization. We can easily conduct multiple approaches simultaneously in parallel[1,43].

We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D** listed in **Table 1**.

Table 1. Antigens from Core D

Antigen	Manufacturer (expression system)
Lassa Josiah NP	Mapp (bacteria)
Lassa Josiah GPe	Genovac (mammalian)
Machupo GPe	Genovac (mammalian)
Machupo NP	Mapp (bacteria)

(c) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using a custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors.

(d) Micro-scale mAb expression. The Crowe laboratory has the capacity for large-throughput micro-scale mAb expression and purification. The lower end of this range allows expression of thousands of mAbs, which will feed into automated mAb purification platforms. This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(e) A CPE-based LASV and MACV neutralization assay using RTCA. We have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of cytopathic effect (CPE). Here, we will apply this method to assess neutralization of LASV. Recently, we validated the inclusion of simultaneous live-cell fluorescence microscopy into this real-time CPE-based screening platform (xCelligence RTCA eSight). These capabilities expand the platform to screen viruses that may or may not induce CPE, allowing us to also use a replication-competent vesicular stomatitis virus (VSV) LASV surrogate that expresses LASV surface proteins and causes CPE[44]. Currently, we have a VSV-LASV-Josiah (lineage IV)[44] and a Sauerwald version (lineage II) of these recombinants. Making additional LASV VSV-LASVs is not difficult, and RP1 will make the other missing lineages or needed NWAV (MACV and CHAPV for test case evaluation) based on the same approaches as previously published. RP1 also can easily also make versions of these VSVs that express the green fluorescent protein (GFP) reporter gene. We will obtain these all these VSV constructs from investigators in **PABVAX**. Existing VSV-CCHFV, VSV-NiV, and VSV-HeV vectors[45-47] will be provided by Dr. Geisbert overall PI and Lead of **Core E**. We already have Vanderbilt Institutional Biosafety Committee approval for use of these constructs in this format and assay. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression if used will identify mAbs with neutralizing activity against LASV. These mAbs will be moved forward for additional studies to identify an optimal anti-LASV mAb combination. Similar processes will be followed to determine neutralization capacity of MACV mAb candidates.

E.1.2. Identifying LASV and MACV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind LASV or MACV and validate their epitopes. We will perform competition-binding studies with GP or subunit proteins (as above) or virus-like particles (VLPs)[48] available from **Core E** at UTMB. **Core E** will also inactivate LASV and MACV virus particles that they have at UTMB by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from previously reported antibodies for the identification of mAbs that can concurrently bind LASV or MACV with a goal of finding more potent clones at those sites or clones that complement these inhibitory mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-LASV or anti-MACV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations for each virus, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key residues binding residues of human anti-LASV and anti-MACV mAbs.*** To determine the key residues for binding of down-selected mAbs, we will perform deep mutational scanning[49]. Briefly, all amino acids of the GP proteins will be mutated to the other 19 amino acids with a unique barcode using PCR-based mutagenesis. The LASV or MACV GP protein library will be incubated with the appropriate mAbs to identify residues with loss-of-binding phenotypes. A sequence 'logo' showing the relative contributions of each amino acid mutation will identify residues critical for binding. Multiple amino acid substitutions can then be assessed by reverse genetics at UTMB to confirm the epitopes recognized by the down-selected mAbs. This method also serves as a surrogate for *in vitro* neutralization escape studies. ***(d) Neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-LASV or VSV-MACV constructs at BSL2 in the presence of saturating concentrations of mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Confirmatory reverse genetics studies will be performed by introducing mutations into an infectious cDNA clone of LASV or MACV by **RP1** to test neutralization. We hypothesize that escape will be less likely in the presence of mAb combinations than single mAbs. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of escape variants in the presence of mAbs.

E.1.3. Structural basis of neutralization by mAb combinations. The studies above should identify optimal anti-LASV and anti-MACV mAb combinations that simultaneously bind, neutralize, and increase the barrier for viral escape under mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for arenavirus by identifying key epitope targets (**RP1**).

E.1.4. Protective efficacy of human anti-arenavirus mAbs. ***(a) Studies in guinea pigs***. MAbs that satisfy the criteria stated above and that display stage-appropriate manufacturability characteristics will advance to in vivo testing. We will use established models of LASV[22,50] and MACV[51,52] infection in guinea pigs. PABVAX **Core E**

has access to many strains from different LASV and MACV lineages, which will be tested. For prioritization, we will focus on LASV lineage II, III, and IV strains and MACV lineage I, II, and VIII strainsfor which uniformly lethal models are available. Groups of 6 outbred Hartley guinea pigs will be treated with low, medium, and high doses) of single or combinations of anti-LASV or anti-MACVs mAb, or isotype controls at day +1 after inoculation with the LASVs or MACVs This approach allows us to determine whether combinations provide advantage over the best monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-LASV mAbs and 10 single mAbs and 5 pairs of anti-MACV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements (blood) at day 5 or 6 after LASV or MACV challenge and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal LASV mAb pairs and two additional MACV mAb pairs that are comparable to or outperform previously reported mAbs for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-LASV and anti-MACV mAb combination against LASV or MACV in NHPs. As a final test of an optimal anti-LASV and anti-MACV mAb combinations, we will assess protective efficacy of the lead anti-LASV mAb pair in NHPs as well as the anti-MACV mAb pair in NHPs. These anti-LASV and anti-MACV mAb pairs will be selected based on the *in vitro* and guinea pig data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys will only be considered pending success in the guinea pig studies and consultation with the external Scientific Advisory Board (SAB) and NIAID program staff.

E.1.5. Applying lessons learned in LASV and MACV research with the selected test case pathogens for mAb generation: Lujo and Chapare mAbs. Once we have completed the LASV and MACV discovery campaigns, will turn to the test case pathogens to see if we can use the prototype pathogen approach to related viruses, Lujo (LUJV) and Chapare (CHAPV). We do not have access to human PBMCs from LUJV - or CHAPV-immune donors. As an alternative approach, we will use humanized mouse models as a source of B cells encoding fully human monoclonal antibodies. The Vanderbilt core investigators have an established fully executed agreement to use Alloy human antibody mice for this purpose (See Letter of Support). The Alloy ATX-Gx™ mouse is one of the most effective *in vivo* human antibody discovery platforms, with over 140 partners and counting. This mouse system was originally invented and validated inside a major pharma company and then further developed by Alloy. This foundational suite of highly immunocompetent transgenic mice is engineered to drive the greatest potential diversity of unique human antibodies binding to the viral target of interest, with broad epitopic coverage. The comprehensive functional human antibody repertoire in these mice is optimized for human Ab sequence developability and diversity. Alloy and Vanderbilt have already executed a simple licensing process for use of the ATX-Gx platform, and as an established partner the Vanderbilt core team will access the expanding portfolio of transgenic Alloy strains designed to address a range of discovery challenges (including diverse Ab isotypes). Mice will be immunized with conformationally correct recombinant protein antigens (**Table 2**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for the target of interest. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for LASV and MACV.

Anticipated results, potential problems, and alternative approaches. In this Aim, we will identify human anti-LASV and anti-MACV mAb combinations with optimal neutralizing and protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging LASV, MACV, or related arenaviruses. Given our previous ability to generate human antiviral mAbs, we do not anticipate problems in isolating anti-LASV or anti-MACV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently neutralizing anti-LASV or anti-MACV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody$^{\text{TM}}$) on enriched B cells (*i.e.*, memory B cells) isolated from human LASV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in LASV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-LASV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-LASV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-LASV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-LASV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the high-throughput Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E2. Specific Aim 2. Discover a protective Crimean-Congo hemorrhagic fever (CCHF) virus mAb combination therapy. Establishing the generality of protection approaches against nairoviruses, we will perform a mAb discovery proof-of-concept campaign for the Prototype CCHFV. Preliminary studies have identified human anti-CCHF mAbs with varying levels of protection in experimentally infected animals[25,53,54]. We will isolate a large panel of human anti-CCHFV mAbs and determine the rules governing optimal mAb combinations through competition-binding, epitope mapping, neutralization, and viral escape studies. Lead antibodies with acceptable manufacturability characteristics (**Core D**) and the highest capacity to overcome resistance while maintaining potency of protection will be selected. The structural basis of their activity will be established using structural biology techniques (electron microscopy and crystallography). Lead mAb cocktail therapies will be evaluated for *in vivo* protective efficacy in STAT1$^{-/-}$ mice (with **Core E).** As a final test of an optimal anti-CCHFV mAb combination, we will assess protective efficacy of the lead anti-CCHFV mAb pair in NHPs, to be selected based on the *in vitro* and mouse data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in cynomolgus monkeys studies would only be considered pending success in the mouse studies and consultation with the external Scientific Advisory Board and NIAID program staff. In years 4-5, we will apply the lessons learned to the plug and play test case Kasokero virus (KASV) in collaboration with **RP1**, **Core D**, and **Core E**.

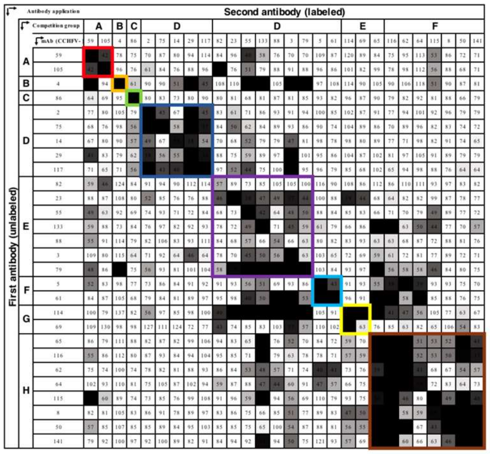

Figure 2. Competition assessment of human Abs to CCHFV using M-segment expressing cells. We tested 28 mAbs in competition assays. MAbs are displayed in 8 groups (A-H) based on their ability to compete for binding. Values shown are the % of binding that occurred during competition compared to non-competed binding of the mAb. This value was normalized to 100%. The values are also indicated by the box fill color; darker colors toward black indicate higher competition and lighter colors toward white indicate less competition, on a gradient scale. Unpublished data.

<u>Preliminary Data</u>. ***(a) Potently neutralizing and non-neutralizing human anti-CCHFV mAbs.*** In this Aim, we will rapidly discover human anti-CCHFV mAbs from CCHFV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them. Through these studies, we aim to identify an optimal anti-CCHFV mAb combination and further advance the discovery platform for rapid response against emerging nairoviruses. In preliminary experiments in collaboration with investigators in **RP1** and **Core E**, the Crowe laboratory has previously isolated and characterized panels of neutralizing human anti-CCHFV human mAbs from individuals who were convalescent after naturally-acquired laboratory-confirmed infection in Spain or Turkey. PBMCs were used to generate hybridomas and antibody variable genes sequenced to generate mAbs recombinantly. We isolated a panel of antibodies against CCHFV that recognize the M-segment in transfected cells, and they exhibit a diversity of recognition patterns in that they fall into multiple competition-binding groups (**Fig 2**). This panel contains cross-binding and cross-neutralizing antibodies for diverse strains. We observed a human mAb designated CCHF-82 competing with competition group 1 and group 2 antibodies from the previously isolated GP38-reactive murine antibodies. CCHF-82 showed some protection in a STAT1$^{-/-}$ mouse model of infection conducted by investigators in **RP1 (Fig 3)**. Further investigation with this antibody in the IbAr10200 prophylaxis and therapeutic models is warranted. In contrast, the CCHFV-neutralizing mAbs that we isolated and tested *in vivo* did not perform well in the Turkish strain STAT1$^{-/-}$ mouse model. We now know protection in this model is possible, given the work from Fels et al., 2021 who showed that potent antibodies against various sites on the Gc surface can afford protection in this model[53]. However, in their study they did not test

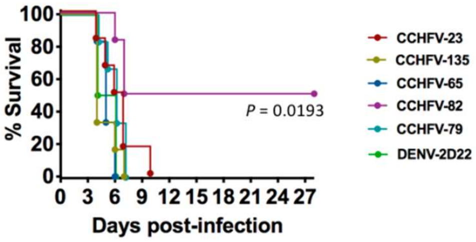

Figure 3. Human mAb CCHF-82 provides partial protection as a post-exposure prophylaxis against the Turkish strain of CCHFV in the STAT1$^{-/-}$ mouse model. A single dose of mAb was administered by the IP route to mice (n=6 per group (3 male, 3 female)) at 30 min post infections. A lethal dose of Turkish strain of CCHFVvirus was administered. CCHF-23, CCHF-135, CCHF-65, CCHF-82, CCHF-79, or DENV-2D22 (an isotype-matched negative control mAb) were tested in a single dose of 250 µg per mouse except for CCHFV-135 at 125 µg per mouse. Kaplan-Meier survival curves were statistically analyzed using a log-rank (Mantel-Cox) test where mAb-treated animals (*P* value shown in figure) were compared to animals treated with the DENV-2D22 negative control mAb. Unpublished data.

GP38-reactive antibodies. To our knowledge, our preliminary data is the first indication that a human GP38-targeting antibody can provide some protection in this mouse model of infection.

Non-neutralizing murine mAbs protect in mouse models of infection[25], but it has not been shown if the human antibody response could provide similar levels of protection. Murine mAb 13G8 binds to GP38 and does not neutralize CCHFV. This mAb provides protection against lethal challenge as a prophylaxis and a therapeutic against CCHFV. In preliminary experiments we sought to understand if human survivors of CCHFV infection possess B cells encoding mAbs that bind a similar epitope as 13G8 and provide protection. CCHF-82 competes for binding with 13G8 to preGn-transfected cells containing GP38. This antibody offered some protection as a post-exposure prophylaxis against the Turkish strain of CCHFV (**Fig 3**). Human antibodies like this should be further studied and the frequency of these clones should be elucidated to understand if this is a feasible strategy for future vaccine efforts for humans. The epitope that 13G8 and CCHF-82 identifies could inform vaccine design if these antibodies offer protection in larger animal models.

Understanding how non-neutralizing antibodies function is critical in efforts to validate the GP38-binding class of antibodies. Golden *et al.* undertook a study to understand the mechanisms 13G8 functioned and observed that complement activation contributes to the protective capacity of this antibody[25]. Here, in studies of CCHF-82, we also will assess complement activation in mouse models of infection to fully understand the function of this mAb *in vivo*. Furthermore, if this mAb protects in the CCHFV IbAr10200 strain challenge model, assessing its mechanism is warranted. Together with **Core D**, we will assess IgG molecules with complement knockout (“KA”) and Fc gamma receptor knockout (LALA-PG) mutations in the Fc domain to study this matter. Human mAb CCHF-82 displayed limited cross-protection against experimental infection with the Turkish strain of CCHFV. Our antibody isolation here will aim to identify cross-protective non-neutralizing antibodies reactive with GP38. Recently, vaccinating with NP was shown to be another way to elicit non- neutralizing antibodies[55]. The NP of CCHFV is more conserved than the glycoproteins and might also be a non-canonical target for the identification of cross-protective non-neutralizing antibodies[55].

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant viral surface protein antigens, cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), and this may be helpful for rarer GP-38-specific B cells.

E.2.1. Rapid isolation of human anti-CCHFV mAbs. ***(a) Immune cells.*** We have obtained human PBMCs from a number of previously CCHFV-infected individuals. One was a health care survivor who was infected while caring for a patient in Spain[56]. We also collected a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Turkey, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples were only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies were approved by the Vanderbilt University Medical Center IRB. PBMCs isolated from the blood samples were deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their used for mAb generation in this **RP4,** if funded.

(b) Ab screening and sequence analysis. Our goal is to identify human anti-CCHFV mAbs rapidly, as if we had to respond to a nairovirus outbreak in real time. Our ability to respond rapidly in the setting of outbreaks is well-documented in the lay press (60 Minutes features and others) and the scientific literature, for ex., 78 days from sample to protection of NHPs for Zika virus[43], and 25 days from PBMC sample receipt to delivery of the antibody genes for the approved COVID-19 drug Evusheld to AstraZeneca[1]. Here, we will single-cell sort antigen-specific B cells using recombinant CCHFV proteins (GP38, Gc, Gn, Gc/Gn) or non-infectious viral particles as bait. These cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF for downstream applications, including VSV-CCHFV neutralization assays. Alternatively, we will use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe CCHFV protein or virus-particle binding to single B cells. These cells will be exported for sequencing of the variable gene regions and analysis using the PyIR software. We will select a panel of up to 500 neutralizing anti-CCHFV mAbs to express as recombinant mAbs and advance for further characterization. We have demonstrated the capacity to execute multiple approaches simultaneously in parallel[1,43], which enhances the diversity of clones obtained. We will generate recombinant GP antigens for selecting GP-specific B cells, based on prior validated designs in the field, and use the antigens produced by **Core D**, listed in Table 3 or by **RP1** (Table 4).

(c) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using the custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors. We will design human anti-LASV mAbs as IgG1 with the Fc mutation, LALA-PG, to abrogate Fc effector functions to assess role of Fc-mediated effector functions to protection in animal models. We also will engineer IgG1 molecules with extended-half-life Fc mutations based on enhanced binding to FcRn including LS (M428L +N434S)[26] and YTE (M252Y +S254T +T256E)[27] mutations. These Fc engineering approaches will generate mAbs with vaccine-like properties. The LS and YTE mutations were developed in commercial settings (and have been used safely in the clinic), but the patent life of these mutations will expire prior to approval of antibodies developed here.

(d) Micro-scale mAb expression. The Crowe laboratory will perform large-throughput micro-scale mAb expression and purification that, with our integrated approach allows, screening assays to identify candidate mAbs This approach allows early-stage assays to identify candidate mAbs that will then be produced at larger scale by **Core D** with diverse Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(e) A CPE-based CCHFV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of CCHFV. We will use a replication-competent vesicular stomatitis virus (VSV) CCHFV surrogate that expresses CCHFV surface proteins and causes CPE[46]. Investigators in **RP1** have the VSV-CCHFV-GFP versions of clades 1 through 7 based on this publication. We will obtain these all these VSV constructs from investigators in **PABVAX**. Existing VSV vectors will be provided by investigators in **RP1 and Core E**. We already have Vanderbilt Institutional Biosafety Committee approval for use of these constructs in this format and assay. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against CCHFV. These mAbs will be moved forward for additional studies to identify an optimal anti-CCHFV mAb combination. GP38-reactive clones will be advanced based on avidity ranking since they are not likely to be neutralizing but may be protective *in vivo*.

E.2.2. Identifying CCHFV mAb combinations. *(a) Epitope mapping through competition-binding studies.* Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 2**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind CCHFV surface proteins and validate their epitopes. We will perform competition-binding studies with CCHFV Gc/Gn or subunit proteins (as above) or CCHFV virus-like particles (VLPs) made from a replicon system in hand. **Core E** will inactivate CCHFV virus particles that they have in the UTMB center by gamma irradiation and safety test and send those to our Vanderbilt site (we have previously accomplished this transfer with Ebola and Marburg particles). Inactivated virus particles will be used in ELISA. We will include positive controls made recombinantly from some of the mAbs shown in the unpublished preliminary data above for the identification of mAbs that can concurrently bind CCHFV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti-CCHFV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. GP-38-reactive clones will be screened for synergistic binding as they are not expected to be neutralizing. ***(c) Identification of key binding residues of human anti-CCHFV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-CCHFV constructs at BSL2 in the presence of saturating concentrations of CCHFV mAbs (single or combination) using the RTCA platform to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test this concept *in vivo* by determining the level of infection of VSV-CCHFV escape variants in the presence of mAbs.

E.2.3. Structural basis of neutralization by anti-CCHFV mAb combinations. The studies above should identify optimal anti-CCHFV mAb combinations that simultaneously bind, neutralize, and increase the barrier for CCHFV to escape mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for nairoviruses by identifying key epitope targets (**RP1**).

E.2.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies in STAT1$^{-/-}$ mouse models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (Core D), will advance to *in vivo* testing. We will use an established STAT1$^{-/-}$ mouse model of CCHFV infection that the **RP1** and **Core E** investigators have deployed[46]. To benchmark our mAbs, a separate set of STAT1$^{-/-}$ mice will be treated with CCHF-82, which we showed in unpublished preliminary data above confers substantial but incomplete protection (**Fig 3**). The **Core E** laboratory has access to strains representing all 6 clades that can be tested. Groups of 10 STAT1$^{-/-}$ mice will be treated with low, medium, and high doses) of single or combinations of anti-CCHFV mAb, or isotype controls at day +1 after inoculation with CCHFVs. This approach allows us to determine whether combinations provide advantage over the best CCHFV monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after CCHFV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal CCHFV mAb pairs that are comparable to or outperform the mAbs we reported above. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-CCHFV mAb combination against CCHFV in NHPs. As a final test of an optimal anti-CCHFV mAb combination, we will assess efficacy of the lead anti-CCHFV mAb pair in NHPs (**Core E**), to be selected based on the *in vitro,* STAT1$^{-/-}$ mice, and manufacturability data (**Core D**). Down-selection for testing in cynomolgus monkeys would only be considered with success in the STAT1$^{-/-}$ mouse studies and in consultation with the external SAB and NIAID program staff.

E.2.5. Applying lessons learned in CCHFV research to Kasokero mAbs. Once we have completed the CCHFV discovery campaigns, will turn to the test case pathogen Kasokero virus to see if we can use the prototype pathogen approach for this virus. We do not have access to human PBMCs from Kasokero-immune donors. We will use Alloy humanized mouse models as a source of B cells encoding fully human monoclonal antibodies, as described above. Mice will be immunized with conformationally correct recombinant protein antigens (**Table 5**), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Kasokero. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for CCHFV.

__Anticipated results, potential problems, and alternative approaches__**.** In this Aim, we will identify human anti-CCHFV mAb combinations with optimal protective activity. These mAb combinations can be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging CCHFV or related nairoviruses. Given our previous ability to generate human anti-CCHFV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-CCHFV mAbs. We may observe that mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-CCHFV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (*i.e.*, memory B cells) isolated from human CCHFV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in CCHFV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-CCHFV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-CCHFV mAb combinations that can inform vaccine design (**RP1**) for related viruses being used as test cases in years 4 and 5. In the case that VSV-CCHFV does not cause sufficient CPE via the RTCA platform (highly unlikely), established focus reduction neutralization assays that detect VSV-CCHFV-infected foci will be used to identify mAbs with synergistic properties. Furthermore, for competitive binding assays, biolayer interferometry using the Octet HTX instrumentation also can be used to assess binding of mAbs in solution.

E3. Specific Aim 3. Establish optimal mAb combination therapies against henipaviruses Hendra (HeV) and Nipah (NiV) viruses. We will use a large panel of potent anti-henipavirus mAbs that we previously made from the memory B cells of immune individuals and generate new antibodies targeting the fusion (F) protein. **RP2** will provide new antigens for mAb selection and BSL-2-compatible viruses for neutralization screens including Cedar virus constructs displaying HeV and NiV F and G proteins. We will identify optimal mAb combinations to enhance henipavirus therapy, minimize viral escape, and improve treatment efficacy through synergy. *In vitro* competition-binding, neutralization, and mechanistic studies will be conducted, including authentic virus neutralization with **PABVAX Core E**. We will refine the recognized epitopes and investigate the structural basis for optimal combination neutralization of henipaviruses using HeV and NiV as prototypes. *In vivo* assessment of mAb combinations will determine the minimal effective dose for protection and the ability to prevent *in vivo* escape. Protective efficacy of lead mAb combinations will be assessed in hamster models of NiV and HeV infection with **Core E**. Leads will be transferred to **Core D**. As a final test of optimal henipavirus mAb combinations, we will assess protective efficacy of the lead henipavirus mAb pairs in NHPs, to be selected based on the *in vitro* and hamster data from **Core E** and manufacturability data from **Core D**. Down-selection for testing in African green monkey (AGM) henipavirus model studies would only be considered pending success in the hamster studies and consultation with the external SAB and NIAID program staff. The HeV+NiV studies will be conducted in years 1-3 and then applied to the plug-and-play test case Langya virus in years 2-5. If **RP2** and **Core E** cannot rescue recombinant Langya virus, the lessons learned in Years 1-3 will be applied to the alternate plug-and-play test viruses Angavokely or Sosuga (SOSV) virus. Preliminary data on SOSV mAbs are provided.

Preliminary Data. ***(a) Potently neutralizing and non-neutralizing human anti-NIV/HeV mAbs.*** In this Aim, we will further adapt approaches we have developed in preliminary experiments with henipavirus mAb studies by identifying a potently protective combination of anti-NiV/HeV human mAbs. We already have in hand some outstanding potency anti-G antibodies with extensive characterization, including synergistic neutralization. In the work proposed here, we will rapidly discover human NiV/HeV anti-F mAbs from NiV-immune individuals and perform synergy studies to identify optimal mAb combinations by pairing them with each other and with anti-G antibodies. Through these studies, we aim to identify an optimal anti-NiV+HeV mAb combination and further advance the discovery platform for rapid response against emerging paramyxoviruses, especially henipaviruses. In previous experiments in collaboration with investigators in **RP2** and **Core E**, the Crowe laboratory has isolated characterized panels of neutralizing human anti-G NiV/HeV human mAbs from an individual with G-based immunity following occupational exposure to an equine HeV G subunit vaccine. Isolated peripheral blood mononuclear cells (PBMCs) were used to generate human B cell hybridomas secreting human mAbs to G, and antibody variable genes were sequenced to generate mAbs recombinantly. We isolated a panel of antibodies against the G protein that recognize the HeV G, NiV Bangladesh G, and NiV Malaysia G proteins. The mAbs exhibited a diversity of recognition patterns in that they fall into multiple competition-binding groups (**Fig 4**). This panel contains cross-binding and cross-neutralizing antibodies for diverse NiV and HeV strains.

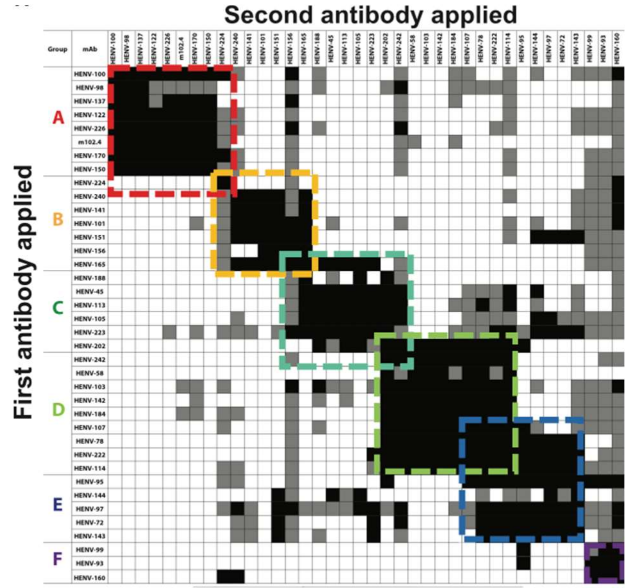

Figure 4. Identification of major antigenic sites for recognition of HeV RBP by human mAbs. SPR competition binding of human Abs against HeV-RBP. A first Ab was applied to a gold-coated sensor chip, and recombinant HeV-RBP head domain was associated to the coupled Ab. A second Ab was applied to the sensor chip to determine binding to RBP. Black boxes - a pairwise interaction in which the binding of the second Ab is blocked by the first. White - both Abs could bind simultaneously. Gray - intermediate competition phenotype.

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific cells with recombinant henipavirus F protein antigens, perform cloning of Ab variable genes, and then express mAbs as recombinant IgGs. Alternatively, F-specific B cells will be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through 2 different single-cell RNA-seq approaches (10X Genomics & Rhapsody).

E.3.1. Rapid isolation of human anti-HeV/NiV mAbs. ***(a) Immune cells.*** We are obtaining human PBMCs from a number of previously NiV-infected individuals who acquired immunity following natural infection in collaboration with the **icddr,b**, an international health research institute based in Dhaka, Bangladesh. We are collecting a panel of 10 fully de-identified PBMC samples from individuals naturally infected in Bangladesh, in sample acquisition work supervised by the Vanderbilt Vaccine Center Biorepository with separate institutional funding. Blood samples are only obtained after informed consent, de-identified, and assigned random specimen numbers. The studies are approved by the icddr,b and Vanderbilt University Medical Center IRBs. PBMCs isolated from the blood samples are deposited into the Vanderbilt Vaccine Center Biorepository, but we can designate their use in this **RP4,** if funded.

(b) Applying mAb technologies for new mAb isolation. We will use sorting of antigen-specific B cells, cloning of Ab variable genes, and then expression of mAbs as recombinant IgG. Alternatively, cells can be expanded on feeder layers expressing CD40 ligand, IL-21, and BAFF. As above, we can use high-throughput systems to capture Ab genes directly from viral protein-specific Ab-secreting B cells on the Berkeley Lights Beacon® optofluidic platform or through single-cell RNA-seq approaches (10X Genomics and BD Rhapsody™), and this may be helpful for rarer antigen-specific B cells. We will sort soluble fusion (sF) or attachment (G) protein-specific cells with recombinant viral surface protein antigens from **Core D** (Table 6).

Table 6. Henipavirus antigens from Core D

Antigen	Manufacturer (expression system)
Nipah sF	Genovac (mammalian)
Hendra sF	Genovac (mammalian)
NiV G	Geneovac (mammalian)

(c) Ab screening and sequence analysis. Our goal is to identify human anti-NiV/HeV mAbs rapidly, as if we had to respond to a paramyxovirus outbreak in real time. We will single-cell sort antigen-specific B cells using recombinant HeV and NiV proteins (sF or G) as bait. These cells will be expanded on feeder layers expressing CD40L, IL-21, and BAFF for downstream applications, including VSV-CCHFV neutralization assays. We also can use the Berkeley Lights Beacon® optofluidic platform, which can functionally ascribe CCHFV protein or virus-particle binding to single B cells. These cells will be exported for sequencing of the variable gene regions and analysis using the PyIR software. We will select a panel of up to 500 neutralizing anti-HeV/NiV mAbs to express as recombinant mAbs and advance for further characterization.

(d) Recombinant mAb cloning. We will synthesize heavy and light chain variable regions for cloning, expression, and downstream functional assays to validate the mAb sequence. We will perform high-throughput synthesis of mAb genes using the custom, commercial synthesis platform (Twist Bioscience). MAb genes are Gibson-assembly-cloned on-instrument into our custom full-length Ig expression vectors. We will design human anti-LASV mAbs as IgG1 with the Fc mutation, LALA-PG, to abrogate Fc effector functions to assess role of Fc-mediated effector functions to protection in animal models. We also will engineer IgG1 molecules with extended-half-life Fc mutations based on enhanced binding to FcRn including LS (M428L +N434S)[26] and YTE (M252Y +S254T +T256E)[27] mutations. These approaches will generate mAbs with vaccine-like properties.

(e) Micro-scale mAb expression. The Crowe laboratory will perform large-throughput micro-scale mAb expression and purification that, with our integrated approach allows, screening assays to identify candidate mAbs. Early-stage assays will identify candidate mAbs that will then be produced at larger scale by **Core D** with a variety of Fc mutants to assess the role of Fc-mediated effector functions *in vivo* (**Core E**).

(f) CPE-based HeV/NiV neutralization assay using RTCA. As above, we have established a high-throughput assay to assess mAb-mediated neutralization of viruses through the detection of CPE. In this aim, we will apply this method to assess neutralization of HeV and NiV. We will use replication-competent vesicular stomatitis virus (VSV) HeV and NiV surrogates that expresses henipaviurs surface proteins and cause CPE. Investigators in **RP2 and RP3** have VSV-NiV F and VSV-NiV G with GFP[45], VSV-NiV G without GFP[47] and VSV-HeVG (Geisbert and Cross, unpublished). We will obtain these all these VSV constructs from investigators in **PABVAX**. We already have Vanderbilt Institutional Biosafety Committee approval for use of these constructs in this format and assay. A decrease in cell impedance due to CPE and a corresponding decrease in GFP expression will identify mAbs with neutralizing activity against HeV and NiV. We also can use Cedar virus constructs for neutralization assays as the have reduced pathogenicity[57] and can be used in high-throughput screening assays for henipavirus antiviral discovery[58]. Cedar viruses will be provided by Dr. Broder of **RP3**. The mAbs with most potent activity will be moved forward for additional studies to identify an optimal anti-HeV/NiV mAb combination.

E.3.2. Identifying HeV/NiV mAb combinations. ***(a) Epitope mapping through competition-binding studies.*** Using previously established methods for competition-binding assays in Octet HTX biosensor (biolayer interferometry) (as above, **Fig 4**) or high-throughput analytical flow cytometry (using an iQue Plus screener), we will identify mAb pairs that can simultaneously bind HeV/NiV surface proteins and validate their epitopes. We will perform competition-binding studies with HeV/NiV sF or G proteins (as above). We will include positive controls made recombinantly from some of the mAbs shown in the preliminary data above for the identification of mAbs that can concurrently bind HeV/NiV proteins with a goal of finding more potent clones at those sites or clones that complement these mAbs. ***(b) Synergy studies using RTCA.*** To assess functional compatibility of the anti- HeV/NiV mAb pairs, we will assess neutralization potency using the RTCA platform. We anticipate testing up to 15 mAb combinations, using rational selection based on preliminary epitope mapping data. We can assess for synergy, additivity, or antagonism of neutralization. Based on these results, we will down-select neutralizing mAb pairs, with our priority on combinations with synergistic effects. ***(c) Identification of key binding residues of human anti-HeV/NiV mAbs by neutralization escape analysis***. The generation of mAb combinations should increase the barrier to viral escape. To assess whether combination mAb pairs reduce the incidence of viral escape, we will perform *in vitro* neutralization escape mutant analyses. For these analyses, we will passage VSV-NiV F, VSV-NiV G and VSV-HeV G constructs at BSL2 in the presence of saturating concentrations of HeV/NiV mAbs (single or combination) using RTCA to detect virus-induced CPE. Resistant virus will induce CPE, and supernatants will be extracted for sequencing. Even if partial escape occurs, virus fitness may suffer. We can test the level of infection of VSV-HeV/NiV escape variants in the presence of mAbs.

E.3.3. Structural basis of neutralization by anti-HeV/NiV mAb combinations. The studies above should identify optimal anti-HeV/NiV mAb combinations that simultaneously bind, neutralize, and increase the barrier for CCHFV to escape mAb selective pressure. For a limited number of mAb pairs (n = 3), we will determine the structural basis of this synergy with cryo-EM and crystallography, for which we have all capabilities and equipment in our laboratory in the Vanderbilt Vaccine Center, Vanderbilt Structural Biology Core, and external synchrotron sources. An understanding of the structural basis and rules governing an optimal neutralizing mAb combination can be applied to mAb therapy development against arenavirus pandemic threats and inform vaccine design for henipaviruses by identifying key epitope targets.

E.3.4. Protective efficacy of human anti-CCHF mAbs. ***(a) Studies hamster models***. MAbs that meet the above criteria and demonstrate acceptable manufacturability (**Core D**), will advance to *in vivo* testing. We will use an established hamster model of NiV or HeV infection that the **Core E** investigators have deployed. To benchmark our mAbs, a separate set of hamsters will be treated with G mAbs HENV-103+HENV-117, which we showed in previous data above confers substantial protection[18]. Groups of 10 hamsters will be treated with low, medium, or high IgG doses) of single or combinations of anti-HeV/NiV mAbs, or isotype controls at day +1 after inoculation with HeV or NiV. This approach allows us to determine whether combinations provide advantage over the best HeV or NiV mAb monotherapy treatments. These experiments will be repeated at least two independent times. We expect to test 10 single mAbs and 5 pairs of anti-CCHFV mAbs in these studies. Protection will be assessed using the following metrics: (i) survival; (ii) weight loss; (iii) clinical scores; (iv) viral burden measurements at day 3 after HeV or NiV exposure and the day 35 study endpoint by plaque and qRT-PCR assays. For any animals that show virological breakthrough of infection, deep sequencing will be performed from recovered viruses to assess for possible emergence of *in vivo* resistance. From these studies, we expect to down-select further to 2 optimal HeV/NiV mAb pairs that are comparable to or outperform the mAbs we reported previously. The lead mAbs will be advanced for further testing in **Core E** for additional dose-down studies.

(b) Validation of the protective efficacy of a down-selected human anti-HeV/NiV mAb combination against HeV and NiV in NHPs. As a final test of an optimal anti-HeV/NiV mAb combination, we may assess efficacy of the lead anti-HeV/NiV mAb pair in NHPs (**Core E**), selected based on the *in vitro,* hamster data, and manufacturability data (**Core D**). Down-selection for testing in African green monkeys would only be considered with success in the hamster studies and in consultation with the external SAB and NIAID program staff.

E.3.5. Applying lessons learned in HeV/NiV research to Langya, Angavokely and Sosuga viruses. Once we have completed the HeV/NiV discovery campaigns, will turn to the test case pathogen Langya, Angavokely and Sosuga (SOSV) viruses to see if we can use the prototype pathogen approach for this virus. We have plenty of human PBMCs from the sole identified SOSV-immune individual and have already shown that it is possible to obtain HN- and F-specific neutralizing antibodies from this individual's B cells[59]. We also have already prepared recombinant SOSV prefusion F and HN proteins[59]. We do not have access to human PBMCs from Langya- or Angavokely-immune donors. For those mAb discovery campaigns, we will use Alloy humanized mouse models as a source of B cells encoding human mAbs, as above. Mice will be immunized with recombinant protein antigens (Table 7), cDNAs encoding protective antigens, or replication-competent VSV strains encoding protective antigens for Langya or Angavokely. After the immunization protocol is completed, animals will be sacrificed humanely, spleens collected, and suspensions of splenocytes (enriched in B cells) will be purified by density gradient selection. Downstream, the generation of human mAbs follows our well-established methods as above for making human mAbs from B cells using single-cell RNAseq or human hybridoma methods. The development will follow as for Hev/NiV described above.

Table 7. Paramyxovirus antigens from Core D

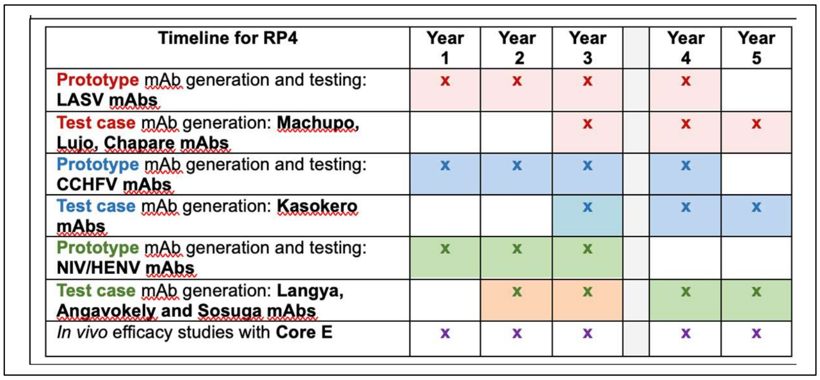
Antigen	Manufacturer (expression system)
Mojang sF	Genovac (mammalian)
Angavokely sF	Genovac (mammalian)
Langya sF	Genovac (mammalian)

<u>Anticipated results, potential problems, and alternative approaches</u>. In this Aim, we will identify human anti-HeV/NiV mAb combinations with optimal protective activity. These mAb combinations will be endowed genetically with half-life-extended Fc modifications to produce vaccine-like therapy options (for humans) for rapid response to emerging HeV/NiV or related paramyxoviruses. Given our previous ability to generate human anti-HeV/NiV mAbs, as shown in preliminary data, we do not anticipate problems in isolating anti-HeV/NiV mAbs. We may observe that new mAb combinations do not add any benefit over individual mAbs. If we do not identify potently protective anti-HeV/NiV mAbs via the planned approaches, we can also take a target-agnostic approach and perform single-cell RNA-seq (10X Genomics and BD Rhapsody^{TM}) on enriched B cells (*i.e.*, memory B cells) isolated from human NiV-immune PBMC samples. In addition, we can deep sequence the B cell repertoires present in NiV-immune PBMC samples and identify clonal lineages, including siblings. Often, additional Abs in the lineages may be more potently neutralizing than the ones obtained directly from human B cells. Together, through these complementary approaches (antigen-specific mAb isolation + single-cell RNA-seq + bulk NGS), we likely can select a diverse panel of human anti-HeV/NiV mAbs. We also anticipate defining key epitopes targeted by potently neutralizing anti-HeV/NiV mAb combinations that can inform vaccine design (**RP2**) for related viruses being used as test cases in years 2 through 5.

F. Scientific rigor. ***Experimental design.*** Experiments will include biological and technical replicates, and results will be analyzed by parametric or non-parametric analyses (depending on data distribution) and corrections for multiple comparisons. EC_{50} (binding) and IC_{50} (neutralization) values will be reported only following at least 3 identically conducted experiments. All mAb screening will incorporate appropriate + and - controls. Positive signals in binding assays will be defined as >3 SD above background. ***Protein quality.*** We have a high capacity to purify proteins using a Protein Maker workstation that allows purification chromatography on 24 parallel columns. We perform QC on protein reagents using a Maurice instrument with capillary electrophoresis technology to automate our protein profiling either by size or charge, providing cIEF and CE-SDS data. Animal ***studies*** will be performed blinded with independent replicates and include negative (*e.g.*, placebo), and positive (when available) controls. We will use power calculations (**Data Management Core B**) to determine sample sizes. For virological studies, power analysis was performed using accepted values for type I error (0.05) and power (80%). The values for population variance (15×) are based on existing data sets and our experience with rodent challenge studies. We will perform experiments at least 2-3 independent times (n = 4-5 each) to attain n = 12-15 per arm. Smaller group sizes can be used if differences are larger than expected.

G. Relevant biological variables. The human mAbs are derived from immune human donors or Alloy mice. Humans. Human Abs will be isolated for biological, structural, and functional studies at a clonal level. The sample size is not powered for large scale epidemiologic or clinical study conclusions. There is no evidence that sex, age, body mass index, or underlying health conditions other than immunodeficiency or immunosuppressive treatments alters the activity of cloned Abs in structure/function studies. The samples are de-identified without patient specific identifiers to protect the health information of the donors; thus, research with these samples is considered *Not Human Subjects Research* category activity. Mice, hamsters, guinea pigs, NHP, and viruses are also biological systems used in this application. Conventional animal housing conditions will be used because there is no evidence that altered room temperatures and light/dark cycles influence paramyxovirus, nairovirus, or arenavirus pathogenesis. Mice, hamsters, guinea pigs, and NHPs of both sexes will be used, and phenotypes will be monitored for sex-based differences. Virus stocks will be either low passage seed stocks from natural isolates or generated from existing cDNA clones and sequence-confirmed prior to use for infection studies.

H. Milestones and quantitative Go/No-Go criteria. Through **Aims 1-3**, we have proposed experiments that will advance our knowledge of the mAb-mediated mechanisms of action against paramyxoviruses, nairoviruses, and arenaviruses. In each Aim, we will use down-selection criteria (as below) to advance mAb combinations or variants for additional studies. By year 3, we will have defined the principles that govern optimal mAb combinations for paramyxoviruses, nairoviruses, and arenaviruses and the rational approaches needed to select mAbs for potency and breadth. We will use the following metrics to advance mAbs: ***(a) Neutralizing activity*.** All mAbs will have neutralizing potency < 10 ng/mL, EC_{50} value; ***(b) Binding affinity***. MAbs will be of high affinity to surface proteins or virions (K_D < 5 nM). ***(c) Protein stability and production quality*.** MAbs must produce at high levels without optimization (> 100 mg/L) and show biochemical/functional stability at 4°C or -80°C (>90% retention of binding and neutralization activity at 30 d). ***(d) Synergy***. Combinations of 2 mAbs against a given virus ideally will show synergy of neutralization *in vitro* or at a minimum, additive inhibition (no antagonism); ***(e) Epitopes***. To avoid resistance, mAbs in combination will bind 2 epitopes (determined by competition binding (<20% reduction in binding), mapping, and structural studies. ***(f) Resistance*** against mAbs will be assessed for virus escape. Deep sequencing of viruses that emerge from cells or animals treated with mAbs will inform prioritization. Combinations of mAbs with high genetic barriers to resistance (<10× loss in EC_{50}) will be advanced. ***(g) Protection in mice, hamsters, guinea pigs, or NHPs.*** The following metrics can be used: (i) Protection against lethal challenge by homologous virus (>90% survival; (ii) Protection against clinical



Timeline for RP4	**Year 1**	**Year 2**	**Year 3**		**Year 4**	**Year 5**
Prototype mAb generation and testing: **LASV mAbs**	x	x	x		x	
Test case mAb generation: **Machupo, Lujo, Chapare mAbs**			x		x	x
Prototype mAb generation and testing: **CCHFV mAbs**	x	x	x		x	
Test case mAb generation: **Kasokero mAbs**			x		x	x
Prototype mAb generation and testing: **NIV/HENV mAbs**	x	x	x

OK I accepted all of Larry's changes and then some of my own and we were still about half a page over. The only way I could really make this work without ripping the guts out of the approach was to cut back the Background section. This made it work. Larry, you will need to fix the references. If anyone is inclined to add some text back to the Background we do have a little space left now. We have about a hour or so before I have to send this to Sponsored Programs. Many thanks!

Subject: RP4

Ok, I got all of the important pieces into this draft and cleaned it up

I need to give it a little rest.

Its 2 pages too long now

Tom, if you really reengage at ~5 am (3 hrs from now) I wont likely be up yet. So you could review it, and if you wanted to start cutting the length, that is good. There is methodologic redundancy in SA2 and SA3 that can be cut and converted to “as in SA1 above”

I can do that in the morning if no one gets to it before I get up. But is someone is in process of cutting it, let me know!

Cheers

Jim

RESEARCH STRATEGY – RP1 (Antigen Design and Testing of Arenavirus and Nairovirus Vaccines)

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) – are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness[3] . Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocompromised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success[4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability[5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other arenaviruses and nairoviruses.

The Arenaviridae: All mammarenaviruses (Arenaviridae genus of viruses infecting mammals) share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge[7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible.[9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

The *Nairoviridae*: Unique from other Bunyaviruses, orthonairoviruses (Nairoviridae genus of human pathogens) are transmitted primarily by ticks in nature. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever

which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC[20]. Like arenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 7 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens: The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the virion), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine[9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens: CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation[20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface[20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge[33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control arenaviruses: For situations where a vaccine does not exist or is not appropriate (*e.g.*, immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE[34, 35] and LA[36, 37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral

families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families. These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for select mammarenaviruses and orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop BSL4 research tools and animal models for viruses that are otherwise not available to the research community.

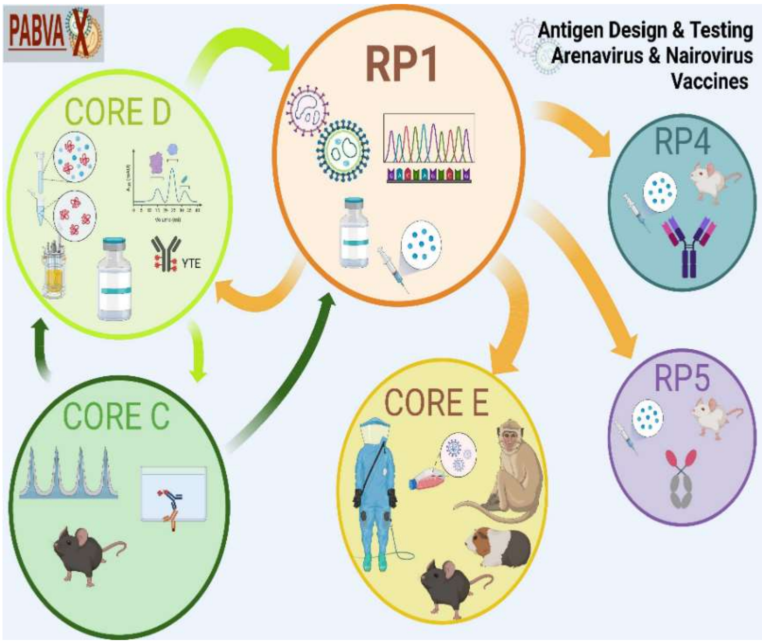

Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

Preliminary Results

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant,

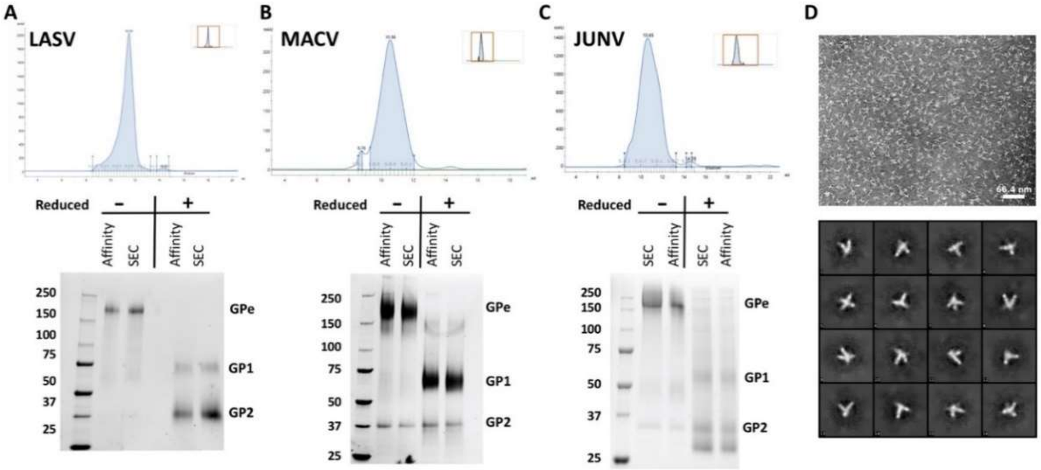

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

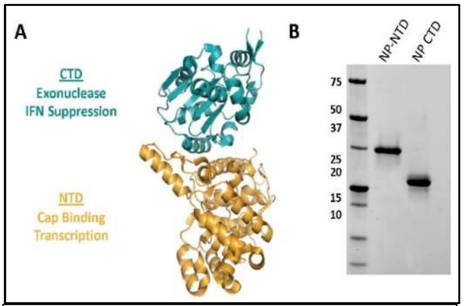

Figure 3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

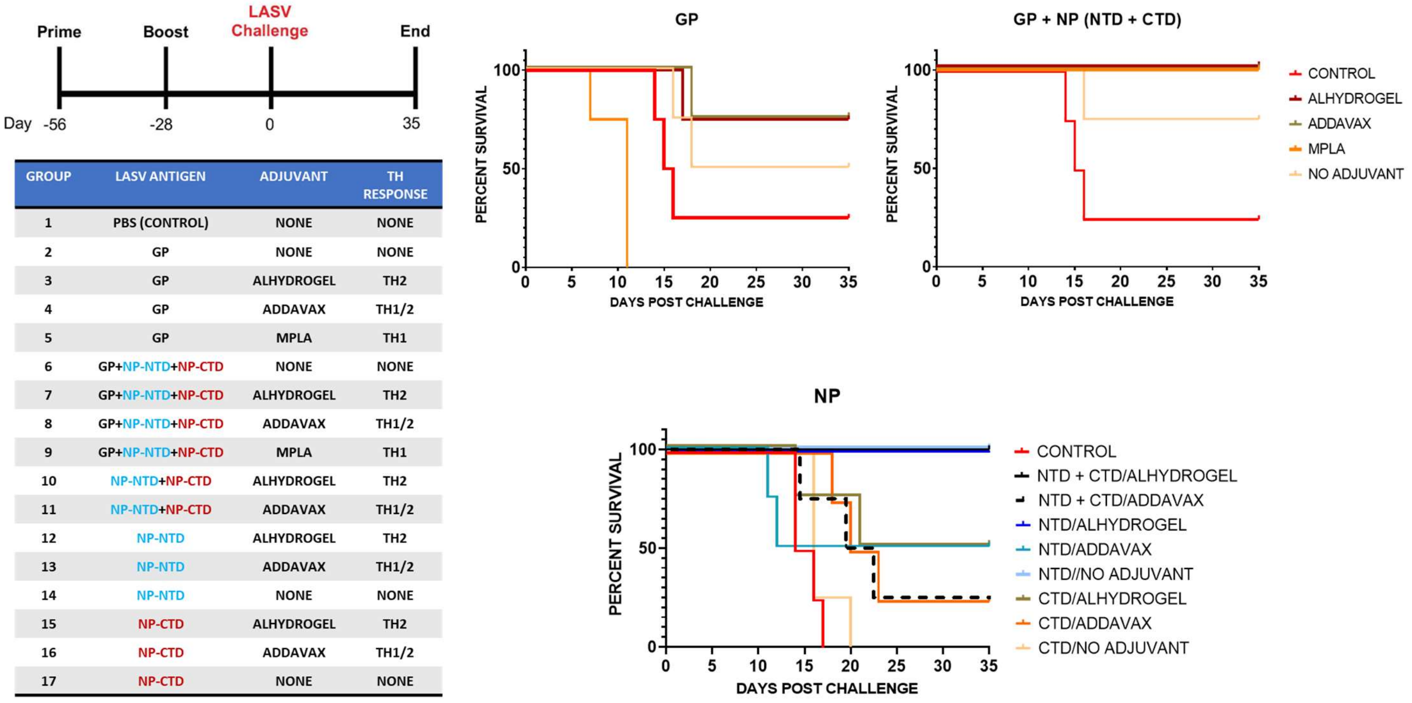
LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were



GROUP	LASV ANTIGEN	ADJUVANT	TH RESPONSE

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival whereas Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

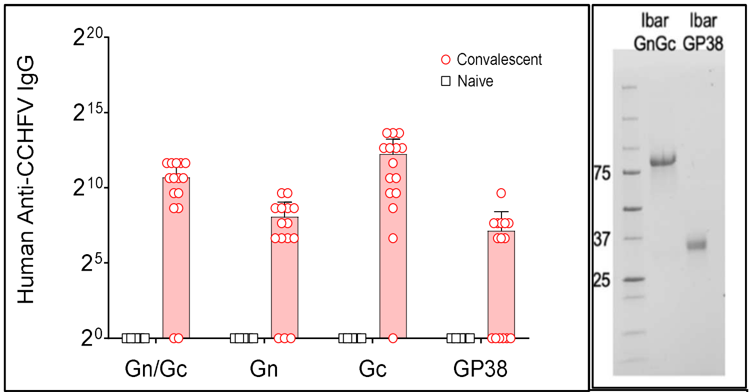

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

<u>*Engineering glycoproteins antigens for CCHFV:*</u> The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

<u>***Scientific Approach:***</u> The choice of Bunyavirales Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Arenaviridae and the Nairoviridae. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- <u>*Old Word Arenaviruses (OWAV):*</u> In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae [42-44] . There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- <u>*New World Arenaviruses (NWAV):*</u> A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[45], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[46, 47]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[48]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- <u>*Nairoviruses:*</u> In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the Nairoviridae family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[49]. A

suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[50]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[50]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[51]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[52]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model[53] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38. Once a candidate subunit-patch vaccine approach is selected, **RP1** will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative "test case" pathogen from each prototype virus group for which no vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa[54]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[55] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[56, 57]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[57]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV in the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat associated orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats[58]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[59]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[58]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[60]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant

viruses for research and vaccine design for several different virus families[46, 61, 62] . An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Table 1: Outline of LASV Vaccination Schedule for Milestone 1.1.1.A

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[63]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[64]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[46, 47].

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

Table 10: Outline of efficacy studies for LUJV, CHAPV, & KASV Milestone 1.1.1.D

Milestone 1.1.2.D: Determination of protective efficacy against novel, emerging arenaviruses and nairovirus "test case" viruses using optimized subunit-patch vaccination in STAT-1/KO mice, guinea pigs and NHP: **RP1 and Core D** will produce optimized GPe and NP-NTD antigens to formulate vaccines for LUJV and CHAPV based off lessons learned from 1.1.1A-C. Protective efficacy studies then be carried out where **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10). RP1 and Core D** will also produce optimized KASV GP and NP-NTD antigens to formulate subunit/MNP vaccines based off lessons learned from 1.1.1A-C. Protective efficacy studies will then be carried **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10).**

***Milestone* 1.1.3: Determination of cellular and humoral immune correlates associated with protection.**

Milestone 1.1.3.A: Define the phenotype and function of arenavirus or nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: PBMC stimulations will be set up according to modifications of well established, previously published protocols[67, 68]. PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

Data Analysis: We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone 1.1.3.B: Systems serology characterization of arenavirus and nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups*:* We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[69-71] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument[70, 72]. Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

Milestone 1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates: We will use existing mammarenaviruses[62, 73] and orthonairovirus[61] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog[74] but is still pathogenic in mice and humans. There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Specific Aim 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

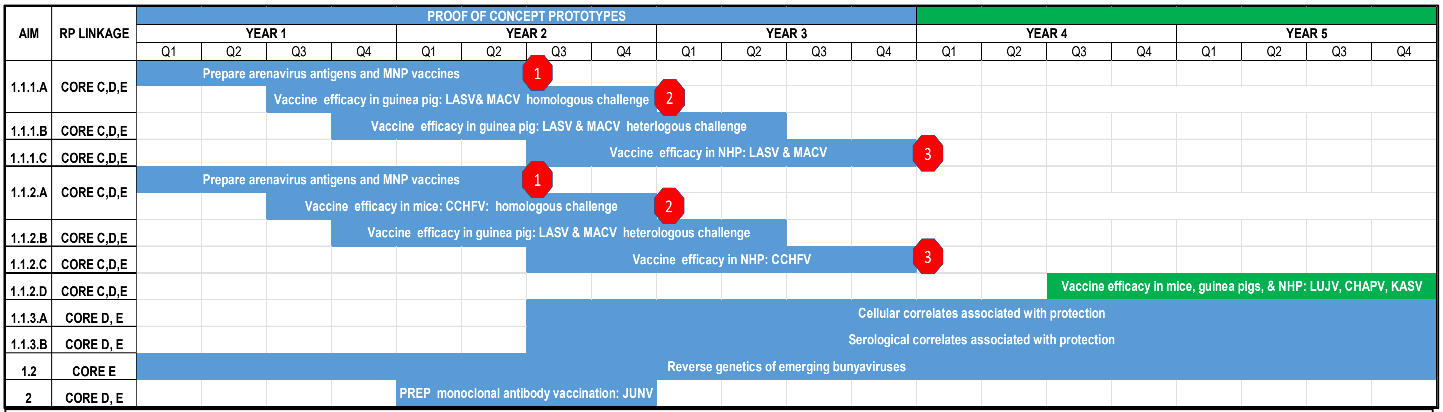
Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months[34-37].

PREP	JUNV NHP CHALLENGE
5 mg/kg	**5**
15mg/kg	**5**
Control animals (NO PREP)	**5**
TOTALS	**15**

Table 11: PREP schedule outline in Milestone 2

***Scientific Approach**: A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine:* In conjunction with **Cores D** and **E**, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[75, 76] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11) Further** details are described in **Core E**. These data will be reviewed by Scientific Advisory Board (SAB) to aid decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three "test case" viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the "go" criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and **SAB**. *Please note: Discussion of expected results, other alternative approaches, and criteria for "go" or "no go" decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*



RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

RESEARCH STRATEGY – RP1 (Antigen Design and Testing of Arenavirus and Nairovirus Vaccines)

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) – are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness[3] . Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocompromised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success[4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability[5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other arenaviruses and nairoviruses.

<u>The Arenaviridae</u>**:** All mammarenaviruses (Arenaviridae genus of viruses infecting mammals) share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge[7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible.[9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

<u>The *Nairoviridae*</u>: Unique from other Bunyaviruses, orthonairoviruses (Nairoviridae genus of human pathogens) are transmitted primarily by ticks in nature. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever

which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC[20]. Like arenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 7 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens: The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the virion), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine[9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens: CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation[20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface[20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge[33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control arenaviruses: For situations where a vaccine does not exist or is not appropriate (*e.g.*, immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE[34, 35] and LA[36, 37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral

families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families. These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for select mammarenaviruses and orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop BSL4 research tools and animal models for viruses that are otherwise not available to the research community.

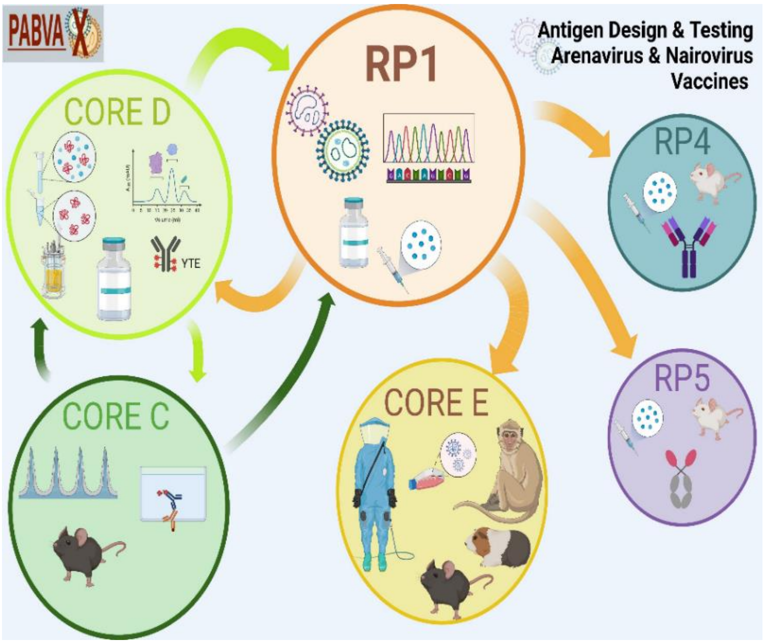


Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

Preliminary Results

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant,

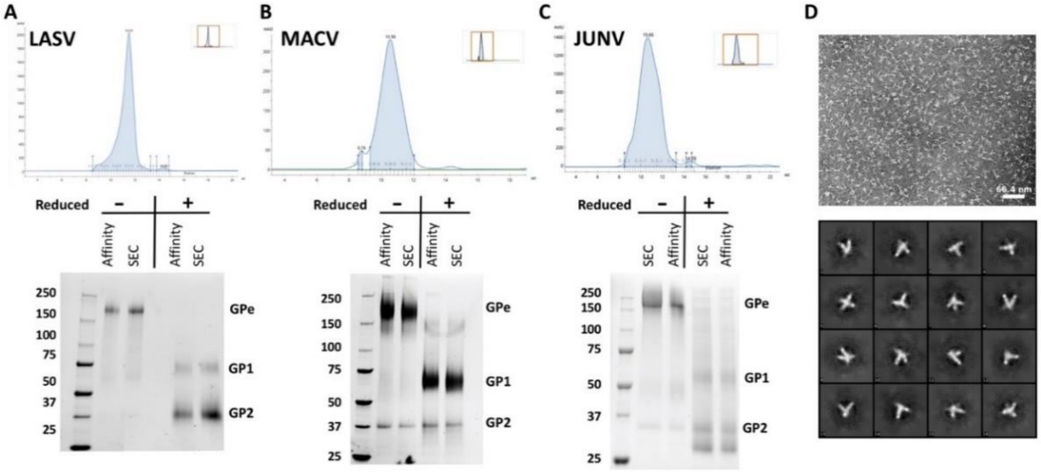

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

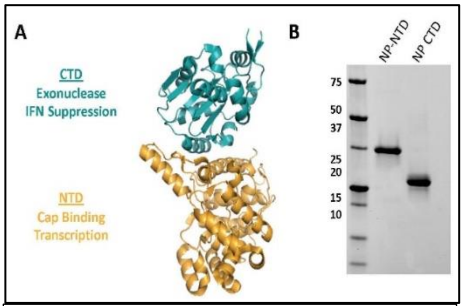

Figure 3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were

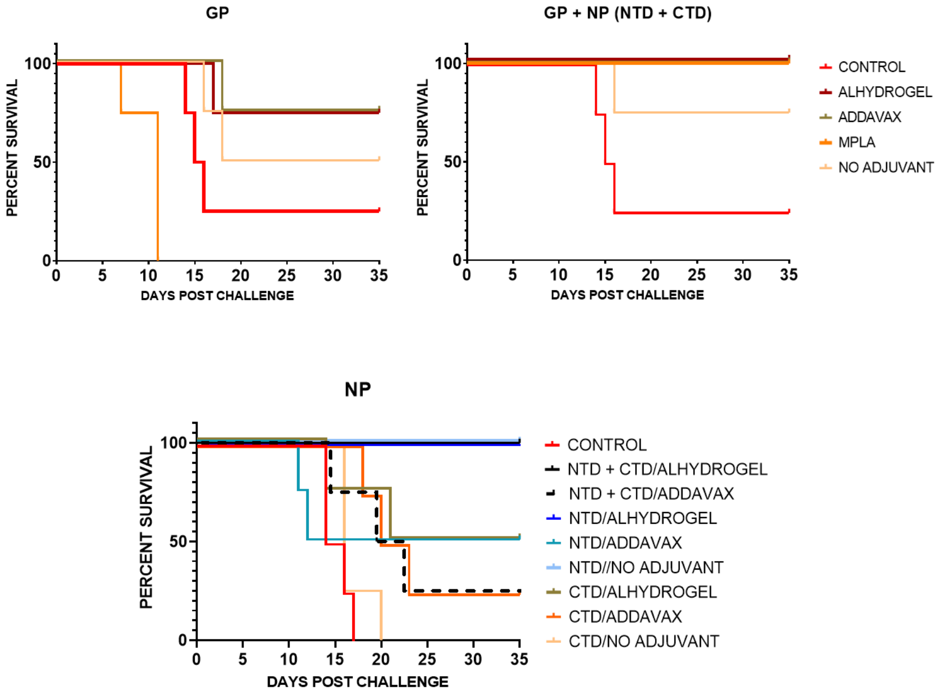

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival whereas Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

<u>*Engineering glycoproteins antigens for CCHFV:*</u> The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

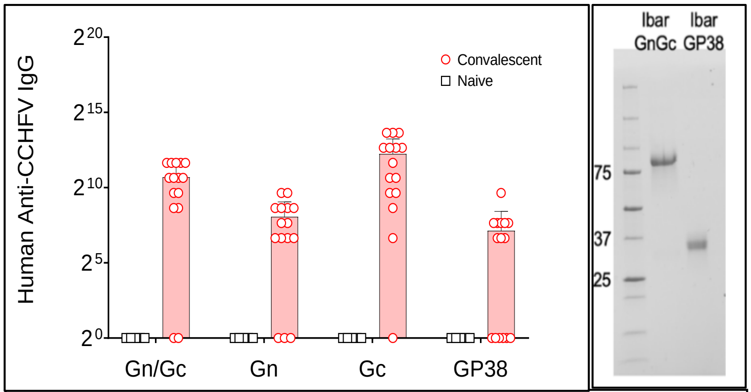

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

<u>***Scientific Approach:***</u> The choice of Bunyavirales Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Arenaviridae and the Nairoviridae. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- <u>*Old Word Arenaviruses (OWAV):*</u> In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae [42-44] . There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- <u>*New World Arenaviruses (NWAV):*</u> A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[45], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[46, 47]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[48]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- <u>*Nairoviruses:*</u> In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the Nairoviridae family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[49]. A

suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[50]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[50]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[51]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[52]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model[53] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38. Once a candidate subunit-patch vaccine approach is selected, **RP1** will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative "test case" pathogen from each prototype virus group for which no vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa[54]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[55] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[56, 57]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[57]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV in the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat associated orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats[58]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[59]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[58]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[60]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant

viruses for research and vaccine design for several different virus families[46, 61, 62]. An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Table 1: Outline of LASV Vaccination Schedule for Milestone 1.1.1.A

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[63]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[64]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[46, 47].

Table 2: Outline of MACV Vaccination Schedule for Milestone 1.1.1.A

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 4: Outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

For our MACV subunit vaccines, we will assess the potential to confer heterologous protection against three lineages of MACV genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core E** as outlined in **Table 4.** We will also utilize JUNV (Romero strain)[65] challenge to assess heterologous protection against a related but

distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

Table 6: Outline of NHP efficacy studes for MACV Milestone 1.1.1.C

Similarly, we will also determine the protective efficacy of MACV following the grouping described in **Table 6** using the identical experimental approach as outlined above for LASV challenge. The challenge virus will be the established MACV Chicava strain[66]**.** If Candid-1 confers protection in guinea pigs outlined in 1.1.1.A we will confirm protection in NHPs if demonstrated in guinea pigs[46, 47]

***Milestone* 1.1.2.A: Development and optimization of patch vaccination approach employing nairovirus subunits:** Here we will determine if our GPe + NP-NTD subunit vaccine approach can be deployed against CCHFV. We will compare the protective efficacy of two adjuvants coupled to our CCHFV GP and NP-NTD proteins developed and manufactured in collaboration with **Core D** either as individual subunit vaccines or combinations as outlined in **Table 7** using an intramuscular (IM) vaccination approach. Eight 6-8 week STAT-1/KO mice (balanced sex) will be randomly assigned to groups as outlined in **Table 7.** Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core E** and challenged with 100 pfu of a low passage CCHF-Hoti[52]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Table 8: Outline of efficacy studies for CCHF Milestone 1.1.2.B

Milestone 1.1.2.B: Determination of pan-CCHF protective efficacy using optimized subunit-patch vaccination in STAT-1KO mice: Using the adjuvant and vaccination route down selected in 1.1.2.A, we will assess the potential for our CCHFV subunit vaccines to confer heterologous protection against four lineages of CCHFV endemic to geographically distinct areas from the prototype strain (CCHF-Hoti). Employing STAT-1KO mice for Clade 1(Uganda), 3 (Nigeria), 4 (Afghanistan) and 6(Greece) established in the **BSL4 evaluation Core C** as outlined in **Table 8.** The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.2.A above.

Milestone 1.1.2.C: Determination of protective efficacy using optimized subunit-patch vaccination in NHP: In collaboration with **Core E**, 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-CCHFV-GPC, demonstrated effective in mice[23] and NHP (Unpublished, Cross and Geisbert) with 5 animals, and a control group of five unvaccinated animals **(Table 9).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected CCHFV antigens, adjuvants, and vaccination route identified in 1.1.2.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post-boost for boosted animals), all animals will be challenged with 5000 PFU of CCHFV-Hoti. The disease of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after CCHFV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. PBMCs will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Table 10: Outline of efficacy studies for LUJV, CHAPV, & KASV Milestone 1.1.1.D

***Milestone 1.1.2.D: Determination of protective efficacy against novel, emerging arenaviruses and nairovirus "test case" viruses using optimized subunit-patch vaccination in STAT-1/KO mice, guinea pigs and NHP:* RP1 and Core D** will produce optimized GPe and NP-NTD antigens to formulate vaccines for LUJV and CHAPV based off lessons learned from 1.1.1A-C. Protective efficacy studies then be carried out where **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10). RP1 and Core D** will also produce optimized KASV GP and NP-NTD antigens to formulate subunit/MNP vaccines based off lessons learned from 1.1.1A-C. Protective efficacy studies will then be carried **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10).**

***Milestone* 1.1.3: Determination of cellular and humoral immune correlates associated with protection.**

Milestone 1.1.3.A: Define the phenotype and function of arenavirus or nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: PBMC stimulations will be set up according to modifications of well established, previously published protocols[67, 68]. PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

Data Analysis: We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone 1.1.3.B: Systems serology characterization of arenavirus and nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[69-71] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument[70, 72]. Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

Milestone 1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates: We will use existing mammarenaviruses[62, 73] and orthonairovirus[61] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog[74] but is still pathogenic in mice and humans. There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Specific Aim 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

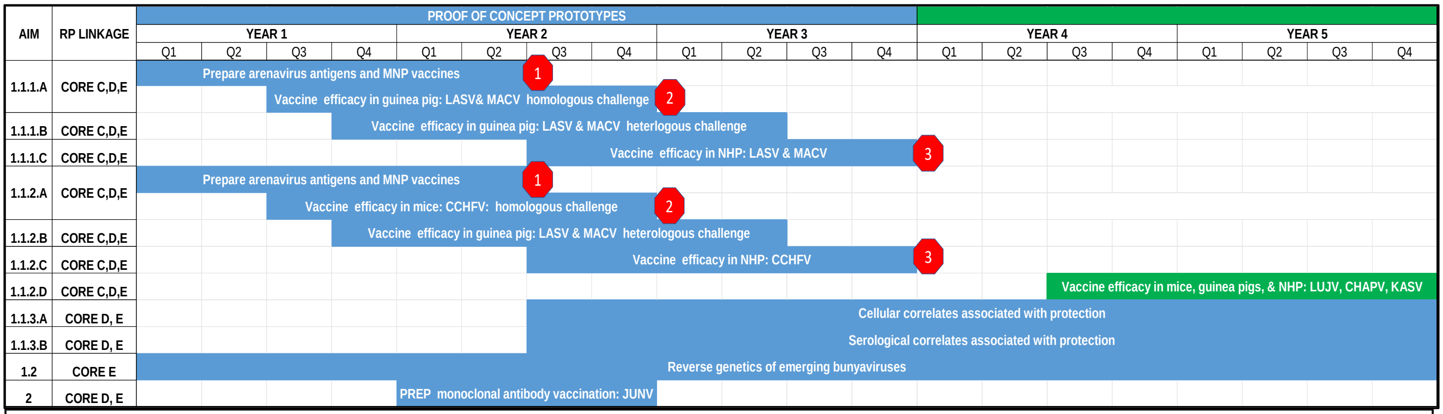
Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months[34-37].

PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

Table 11: PREP schedule outline in Milestone 2

Scientific Approach: *A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine:* In conjunction with **Cores D** and **E**, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[75, 76] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11) Further** details are described in **Core E**. These data will be reviewed by Scientific Advisory Board (SAB) to aid decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three "test case" viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the "go" criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and **SAB**. *Please note: Discussion of expected results, other alternative approaches, and criteria for "go" or "no go" decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*



RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

RESEARCH STRATEGY – RP1 (Antigen Design and Testing o~~O~~f Arenavirus ~~A~~and Nairovirus Vaccines)

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) – are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness[3] . Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocompromised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success[4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability[5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other arenaviruses and nairoviruses.

<u>The Arenaviridae</u>**:** All mammarenaviruses (Arenaviridae genus of viruses infecting mammals) share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge[7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible.[9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

<u>The *Nairoviridae*</u><u>:</u> Unique from other Bunyaviruses, orthonairoviruses (Nairoviridae genus of human pathogens) are transmitted primarily by ticks in nature. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever

which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC[20]. Like arenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens: The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the virion), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine[9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens: CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation[20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface[20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge[33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP “vaccination” as a measure to control arenaviruses: For situations where a vaccine does not exist or is not appropriate (*e.g*., immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE[34, 35] and LA[36, 37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral

families within **Bunyavirales** **(Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families. These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for select mammarenaviruses and orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop BSL4 research tools and animal models for viruses that are otherwise not available to the research community.

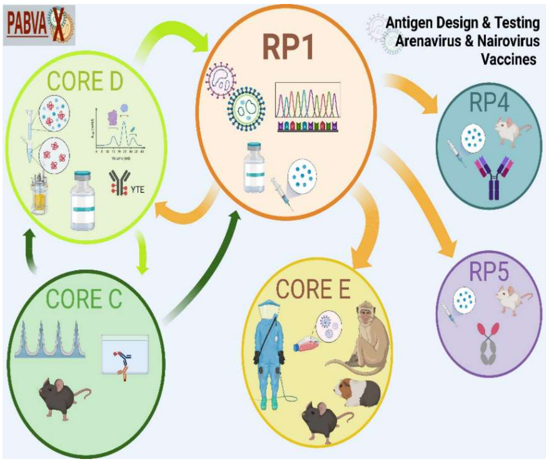


Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

Preliminary Results

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the

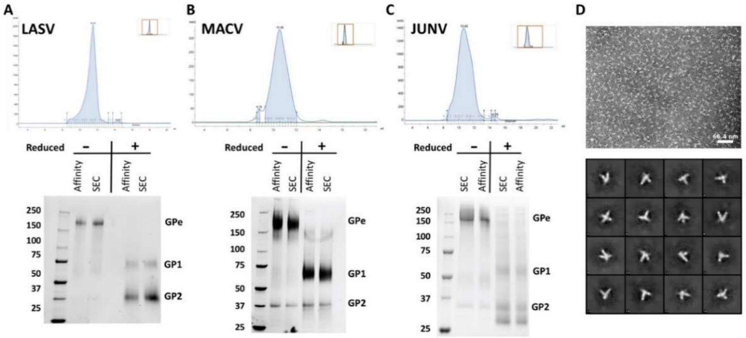

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

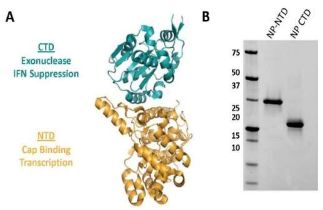

Figure 3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

<u>LASV subunit vaccine protects guinea pigs against lethal challenge</u>

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival whereas Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

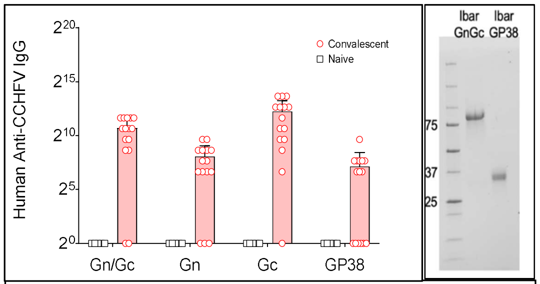

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

Engineering glycoproteins antigens for CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

Scientific Approach: The choice of Bunyavirales Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Arenaviridae and the Nairoviridae. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *Old Word Arenaviruses (OWAV):* In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae [42-44] . There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *New World Arenaviruses (NWAV):* A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[45], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[46, 47]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[48]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *Nairoviruses:* In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the Nairoviridae family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[49]. A

suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[50]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[50]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[51]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[52]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model[53] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38. Once a candidate subunit-patch vaccine approach is selected, **RP1** will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative "test case" pathogen from each prototype virus group for which no vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa[54]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[55] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[56, 57]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[57]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV in the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat associated orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats[58]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[59]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[58]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[60]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant

viruses for research and vaccine design for several different virus families[46, 61, 62] . An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Table 1: Outline of LASV Vaccination Schedule for Milestone 1.1.1.A

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[63]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[64]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[46, 47].

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 4: Outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

For our MACV subunit vaccines, we will assess the potential to confer heterologous protection against three lineages of MACV genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core E** as outlined in **Table 4.** We will also utilize JUNV (Romero strain)[65] challenge to assess heterologous protection against a related but

distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

***Milestone* 1.1.2.A: Development and optimization of patch vaccination approach employing nairovirus subunits:** Here we will determine if our GPe + NP-NTD subunit vaccine approach can be deployed against CCHFV. We will compare the protective efficacy of two adjuvants coupled to our CCHFV GP and NP-NTD proteins developed and manufactured in collaboration with **Core D** either as individual subunit vaccines or combinations as outlined in **Table 7** using an intramuscular (IM) vaccination approach. Eight 6-8 week STAT-1/KO mice (balanced sex) will be randomly assigned to groups as outlined in **Table 7.** Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core E** and challenged with 100 pfu of a low passage CCHF-Hoti[52]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

1KO mice: Using the adjuvant and vaccination route down selected in 1.1.2.A, we will assess the potential for our CCHFV subunit vaccines to confer heterologous protection against four lineages of CCHFV endemic to geographically distinct areas from the prototype strain (CCHF-Hoti). Employing ~~optimized strain 13 or outbred, Hartley guinea pig models~~STAT-1KO mice for Clade 1(Uganda), 3 (Nigeria), 4 (Afghanistan) and 6(Greece) established in the **BSL4 evaluation Core C** as outlined in **Table 8.** The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.2.A above.

Milestone ~~2~~1.1.2.C: Determination of protective efficacy using optimized subunit-patch vaccination in NHP: In collaboration with **Core E**, 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-CCHFV-GPC, demonstrated effective in mice[23] and NHP (Unpublished, Cross and Geisbert) with 5 animals, and a control group of five unvaccinated animals **(Table 9).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected CCHFV antigens, adjuvants, and vaccination route identified in 1.1.2.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post-boost for boosted animals), all animals will be challenged with 5000 PFU of CCHFV-Hoti. The disease of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after CCHFV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. PBMCs will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Milestone 1.1.3: Determination of cellular and humoral immune correlates associated with protection.

Milestone 1.1.3.A: Define the phenotype and function of arenavirus or nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Commented [SSJ6]: Table 10 for mice/GP/NHP; Milestone 1.1.2.D-legend for NHP 1.1.1.B

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: PBMC stimulations will be set up according to modifications of well established, previously published protocols[67, 68]. PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37ºC for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37ºC. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37ºC. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4ºC or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37ºC), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

Data Analysis: We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone 1.1.3.~~A~~B:~~:~~ Systems serology characterization of arenavirus and nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups*:* We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[69-71] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument[70, 72]. Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

Milestone 1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates: We will use existing mammarenaviruses[62, 73] and orthonairovirus[61] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog[74] but is still pathogenic in mice and humans. There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Formatted: Space After: 0 pt

Formatted: Font: Italic

~~Milestone~~ Specific Aim 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

Commented [SSJ7]: No reference/subheading for Specific Aim 2

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months[34-37].

PREP	JUNV NHP CHALLENGE

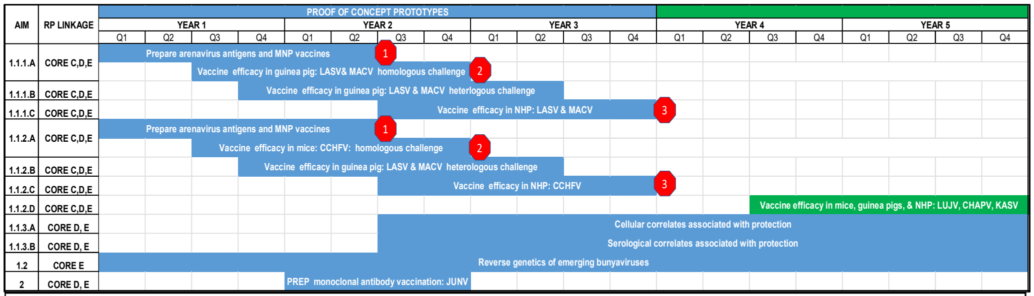
Table 11: PREP schedule outline in Milestone 2

Scientific Approach:

Formatted: Font: 11 pt

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine: In conjunction with **Cores D** and **E**, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[75, 76] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11) Further** details are described in **Core E**. These data will be reviewed by Scientific Advisory Board (SAB) to aid decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three “test case” viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the “go” criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and **SAB**. *Please note: Discussion of expected results, other alternative approaches, and criteria for “go” or “no go” decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*



RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future “plug and play” pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

RESEARCH STRATEGY:

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) – are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness[3] . Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocompromised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success[4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability[5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other arenaviruses and nairoviruses.

<u>The Arenaviridae</u>: All mammarenaviruses (Arenaviridae genus of viruses infecting mammals) share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge[7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible.[9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

<u>The *Nairoviridae*</u>: Unique from other Bunyaviruses, orthonairoviruses (Nairoviridae genus of human pathogens) are transmitted primarily by ticks in nature. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited

efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC[20]. Like arenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens: The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the virion), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine[9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens: CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation[20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface[20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge[33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control arenaviruses: For situations where a vaccine does not exist or is not appropriate (*e.g.*, immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE[34, 35] and LA[36, 37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families.

These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for select mammarenaviruses and orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop BSL4 research tools and animal models for viruses that are otherwise not available to the research community.

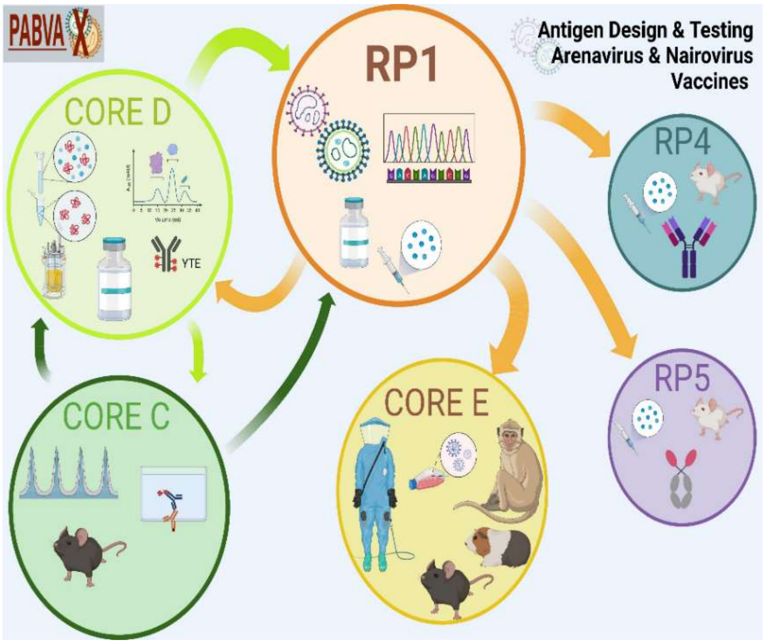


Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

<u>Preliminary Results</u>

<u>Engineering trimeric glycoprotein antigens for the arenaviruses</u>

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE

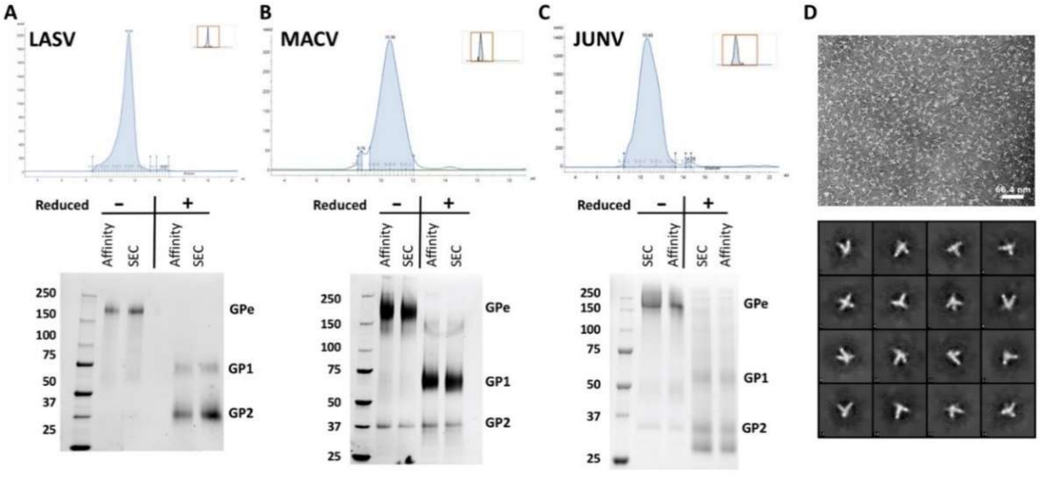

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

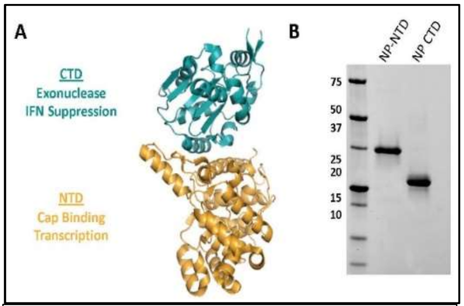

Figure 3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were**

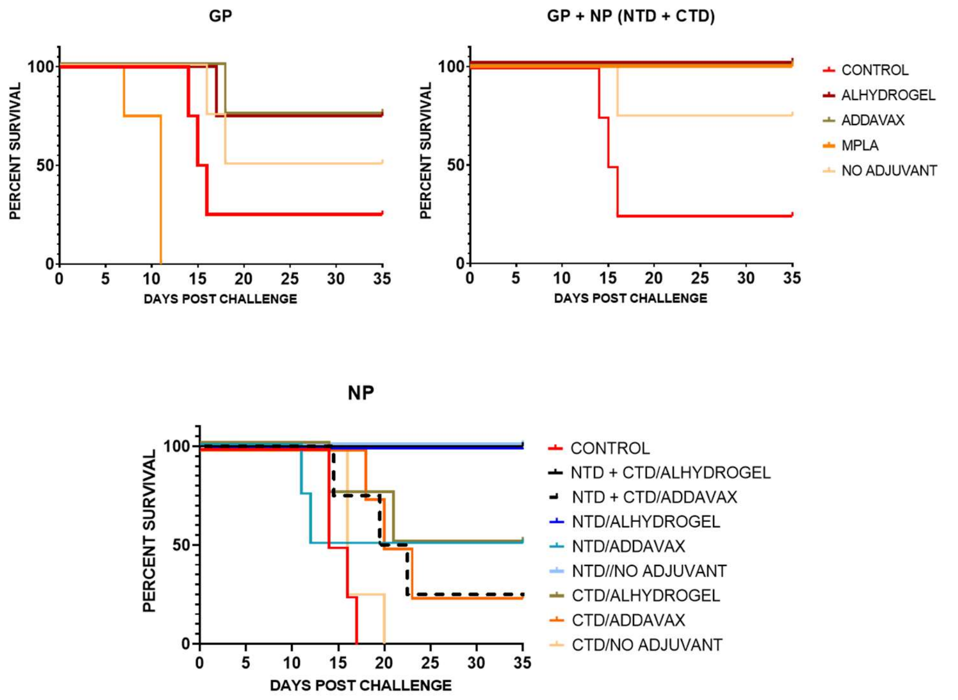

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV. Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival whereas Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

Engineering glycoproteins antigens for CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

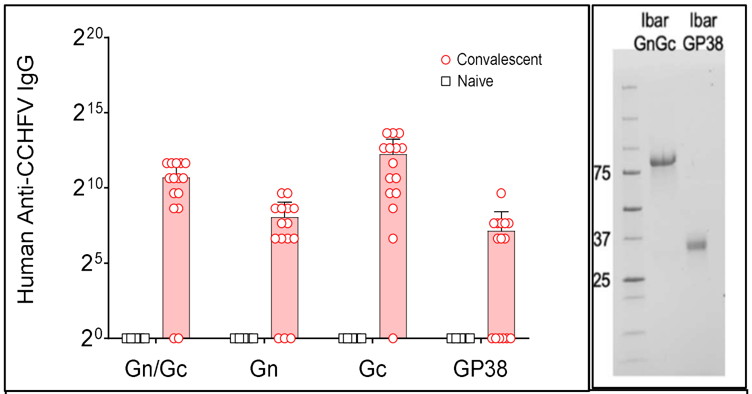

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

Scientific Approach: The choice of Bunyavirales Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Arenaviridae and the Nairoviridae. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *Old Word Arenaviruses (OWAV):* In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae [42-44] . There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *New World Arenaviruses (NWAV):* A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[45], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[46, 47]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[48]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *Nairoviruses:* In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the Nairoviridae family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[49]. A suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[50]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying

efficacy, advantages, and disadvantages[50]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[51]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[52]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model[53] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38. Once a candidate subunit-patch vaccine approach is selected, **RP1** will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative "test case" pathogen from each prototype virus group for which no vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa[54]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[55] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[56, 57]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[57]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV in the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat associated orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats[58]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[59]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[58]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[60]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families[46, 61, 62] . An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared

with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[63]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve. Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[64]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[46, 47].

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

For our MACV subunit vaccines, we will assess the potential to confer heterologous protection against three lineages of MACV genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core E** as outlined in **Table 4.** We will also utilize JUNV (Romero strain)[65] challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

Similarly, we will also determine the protective efficacy of MACV following the grouping described in **Table 6** using the identical experimental approach as outlined above for LASV challenge. The challenge virus will be the established MACV Chicava strain[66]**.** If Candid-1 confers protection in guinea pigs outlined in 1.1.1.A we will confirm protection in NHPs if demonstrated in guinea pigs[46, 47]

***Milestone* 1.1.2.A: Development and optimization of patch vaccination approach employing nairovirus subunits:** Here we will determine if our GPe + NP-NTD subunit vaccine approach can be deployed against CCHFV.We will compare the protective efficacy of two adjuvants coupled to our CCHFV GP and NP-NTD proteins developed and manufactured in collaboration with **Core D** either as individual subunit vaccines or combinations as outlined in **Table 7** using an intramuscular (IM) vaccination approach. Eight 6-8 week STAT-1/KO mice (balanced sex) will be randomly assigned to groups as outlined in **Table 7.** Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core E** and challenged with 100 pfu of a low passage CCHF-Hoti[52]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Table 10: Outline of NHP efficacy studies for MACV Milestone 1.1.1.B

Milestone 1.1.2.D: Determination of protective efficacy against novel, emerging arenaviruses and nairovirus "test case" viruses using optimized subunit-patch vaccination in STAT-1/KO mice, guinea pigs and NHP: **RP1 and Core D** will produce optimized GPe and NP-NTD antigens to formulate vaccines for LUJV and CHAPV based off lessons learned from 1.1.1A-C. Protective efficacy studies then be carried out where **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10). RP1 and Core D** will also produce optimized KASV GP and NP-NTD antigens to formulate subunit/MNP vaccines based off lessons learned from 1.1.1A-C. Protective efficacy studies will then be carried **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10).**

Milestone **1.1.3: Determination of cellular and humoral immune correlates associated with protection.**

Milestone 1.1.3.A: Define the phenotype and function of arenavirus or nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

<u>*Immune subset phenotyping*</u>**:** We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell

phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: PBMC stimulations will be set up according to modifications of well established, previously published protocols[67, 68]. PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

Data Analysis: We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone 1.1.3.A:: Systems serology characterization of arenavirus and nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups*:* We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[69-71] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the

GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument[70, 72]. Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

Milestone **1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:** We will use existing mammarenaviruses[62, 73] and orthonairovirus[61] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog[74] but is still pathogenic in mice and humans. There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months[34-37].

PREP	JUNV NHP CHALLENGE

TOTALS	15

Table 11: PREP schedule outline in Milestone 2

Scientific Approach:

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine: In conjunction with **Cores D** and **E**, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[75, 76] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11) Further** details are described in **Core E**. These data will be reviewed by Scientific Advisory Board (SAB) to aid decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three "test case" viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the "go" criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and **SAB**. *Please note: Discussion of expected results, other alternative approaches, and criteria for "go" or "no go" decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*

RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

RESEARCH STRATEGY:

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) – are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness[3] . Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocompromised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success[4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability[5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other arenaviruses and nairoviruses.

***The Arenaviridae*:** All mammarenaviruses (Arenaviridae genus of viruses infecting mammals) share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge[7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible.[9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

The *Nairoviridae*: Unique from other Bunyaviruses, orthonairoviruses (Nairoviridae genus of human pathogens) are transmitted primarily by ticks in nature. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited

efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC[20]. Like arenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens: The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the virion), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine[9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens: CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation[20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface[20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge[33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control arenaviruses: For situations where a vaccine does not exist or is not appropriate (*e.g.*, immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE[34, 35] and LA[36, 37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families.

These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for select mammarenaviruses and orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop BSL4 research tools and animal models for viruses that are otherwise not available to the research community.

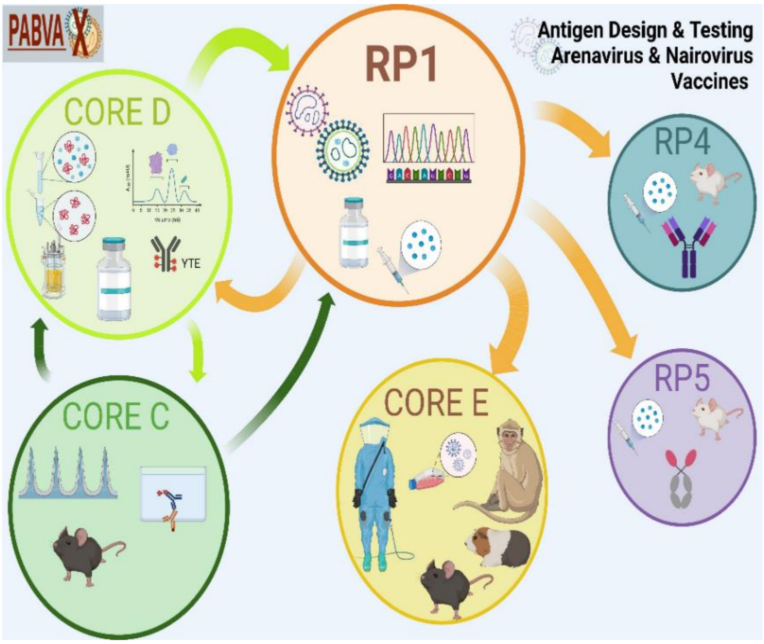

Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

Preliminary Results

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE

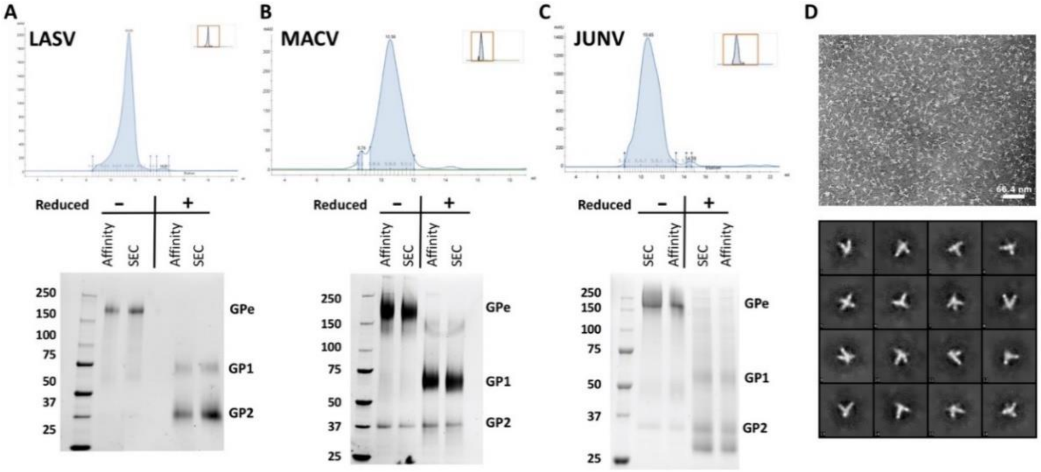

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were**

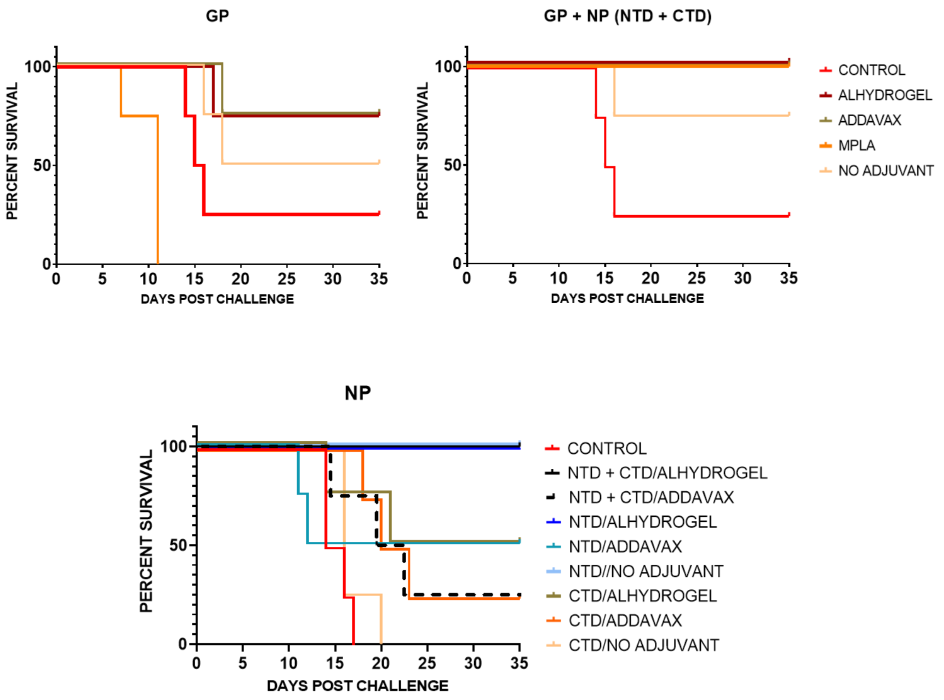

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 μg of GP, or 2x50 μg doses of GP + 2x25μg of NP-NTD + 2x25 μg of NP-CTD, or either 2x25 μg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV. Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival whereas Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

Engineering glycoproteins antigens for CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

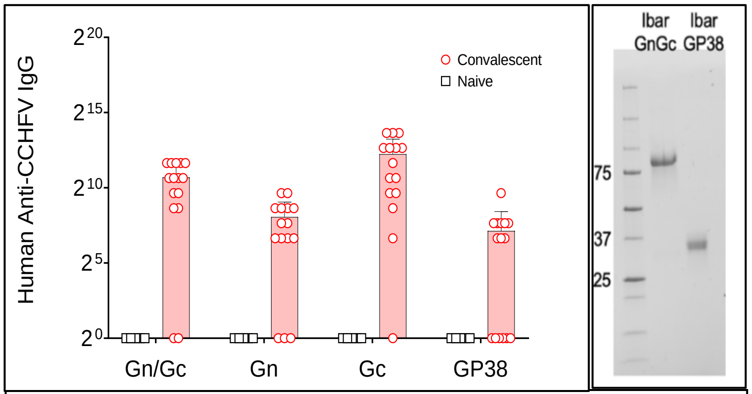

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

Scientific Approach: The choice of Bunyavirales Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Arenaviridae and the Nairoviridae. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *Old Word Arenaviruses (OWAV):* In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae [42-44] . There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *New World Arenaviruses (NWAV):* A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[45], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[46, 47]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[48]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *Nairoviruses:* In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the Nairoviridae family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[49]. A suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[50]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying

efficacy, advantages, and disadvantages[50]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[51]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[52]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model[53] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38. Once a candidate subunit-patch vaccine approach is selected, **RP1** will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative "test case" pathogen from each prototype virus group for which no vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa[54]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[55] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[56, 57]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[57]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV in the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat associated orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats[58]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[59]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[58]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[60]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families[46, 61, 62] . An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared

with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[63]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve. Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[64]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[46, 47].

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

For our MACV subunit vaccines, we will assess the potential to confer heterologous protection against three lineages of MACV genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core E** as outlined in **Table 4.** We will also utilize JUNV (Romero strain)[65] challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 4: Outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

***Milestone* 1.1.2.A: Development and optimization of patch vaccination approach employing nairovirus subunits:** Here we will determine if our GPe + NP-NTD subunit vaccine approach can be deployed against CCHFV.We will compare the protective efficacy of two adjuvants coupled to our CCHFV GP and NP-NTD proteins developed and manufactured in collaboration with **Core D** either as individual subunit vaccines or combinations as outlined in **Table 7** using an intramuscular (IM) vaccination approach. Eight 6-8 week STAT-1/KO mice (balanced sex) will be randomly assigned to groups as outlined in **Table 7.** Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core E** and challenged with 100 pfu of a low passage CCHF-Hoti[52]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Milestone1.1.2.B: Determination of pan-CCHF protective efficacy using optimized subunit-patch vaccination in STAT-1KO mice: Using the adjuvant and vaccination route down selected in 1.1.2.A, we will assess the potential for our CCHFV subunit vaccines to confer heterologous protection against four lineages of CCHFV endemic to geographically distinct areas from the prototype strain (CCHF-Hoti). Employing optimized strain 13 or outbred, Hartley guinea pig models for Clade 1(Uganda), 3 (Nigeria), 4 (Afghanistan) and 6(Greece) established in the **BSL4 evaluation Core C** as outlined in **Table 8.** The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.2.A above.

Milestone 2.1.2.C: Determination of protective efficacy using optimized subunit-patch vaccination in NHP: In collaboration with **Core E**, 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-CCHFV-GPC, demonstrated effective in mice[23] and NHP (Unpublished, Cross and Geisbert) with 5 animals, and a control group of five unvaccinated animals **(Table 9).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected CCHFV antigens, adjuvants, and vaccination route identified in 1.1.2.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post-boost for boosted animals), all animals will be challenged with 5000 PFU of CCHFV-Hoti. The disease of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after CCHFV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. PBMCs will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Milestone 1.1.2.D: Determination of protective efficacy against novel, emerging arenaviruses and nairovirus "test case" viruses using optimized subunit-patch vaccination in STAT-1/KO mice, guinea pigs and NHP: **RP1 and Core D** will produce optimized GPe and NP-NTD antigens to formulate vaccines for LUJV and CHAPV based off lessons learned from 1.1.1A-C. Protective efficacy studies then be carried out where **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10). RP1 and Core D** will also produce optimized KASV GP and NP-NTD antigens to formulate subunit/MNP vaccines based off lessons learned from 1.1.1A-C. Protective efficacy studies will then be carried **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10).**

***Milestone* 1.1.3: Determination of cellular and humoral immune correlates associated with protection.**

Milestone 1.1.3.A: Define the phenotype and function of arenavirus or nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: PBMC stimulations will be set up according to modifications of well established, previously published protocols[67, 68]. PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

Data Analysis: We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone 1.1.3.A:: Systems serology characterization of arenavirus and nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups*:* We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[69-71] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the

GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument[70, 72]. Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

***Milestone* 1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:** We will use existing mammarenaviruses[62, 73] and orthonairovirus[61] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog[74] but is still pathogenic in mice and humans. There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months[34-37].

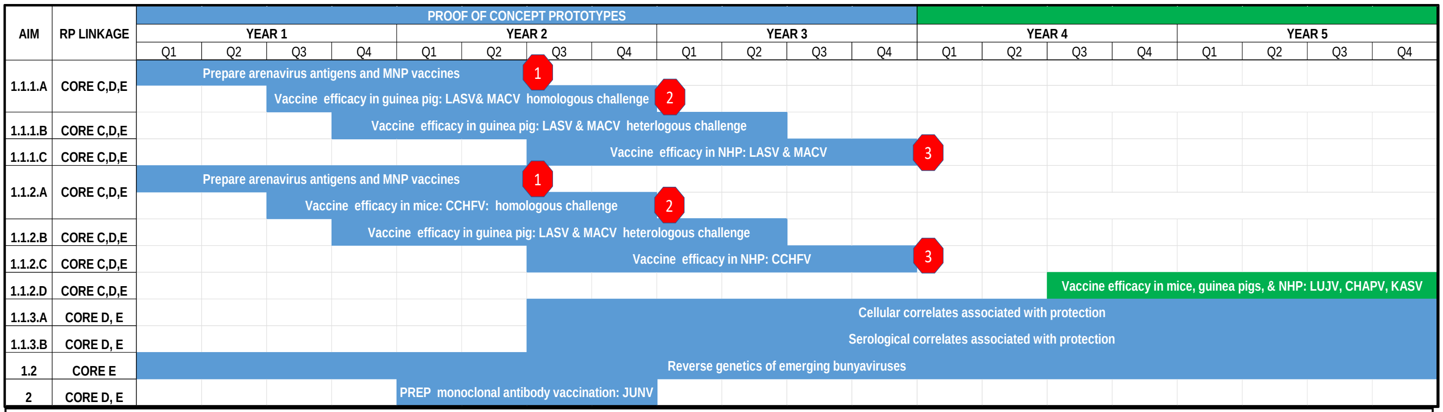
PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

Table 11: PREP schedule outline in Milestone 2

Scientific Approach:

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine: In conjunction with **Cores D** and **E**, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[75, 76] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11) Further** details are described in **Core E**. These data will be reviewed by Scientific Advisory Board (SAB) to aid decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three "test case" viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the "go" criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and **SAB**. *Please note: Discussion of expected results, other alternative approaches, and criteria for "go" or "no go" decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*



AIM	RP LINKAGE	PROOF OF CONCEPT PROTOTYPES
1.1.1.A	CORE C,D,E	Prepare arenavirus antigens and MNP vaccines 1 Vaccine efficacy in guinea pig: LASV& MACV homologous challenge 2

1.1.3.A	CORE D, E	Cellular correlates associated with protection
1.1.3.B	CORE D, E	Serological correlates associated with protection
1.2	CORE E	Reverse genetics of emerging bunyaviruses
2	CORE D, E	PREP monoclonal antibody vaccination: JUNV

RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

RESEARCH STRATEGY:

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) – are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness[3]. Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success[4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability[5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other Arenaviruses and Nairoviruses.

<u>The Arenaviridae</u>**:** All Mammarenaviruses (Arenaviridae genus of viruses infecting mammals) share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge[7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible.[9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

<u>The *Nairoviridae*</u><u>:</u> Unique from other Bunyaviruses, Orthonairoviruses (Nairoviridae genus of human pathogens) are transmitted primarily by ticks in nature. While there are a number of human pathogenic Orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited

Formatted: Space After: 3 pt

efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC[20]. Like Arenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens: The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine ~~in active development by Inovio Pharmaceuticals~~. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the ~~surface of arenavirus~~virion), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine[9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Formatted: Space After: 3 pt

Unique Nairovirus subunit vaccine strategy utilizing GP and NP immunogens: CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation[20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface[20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge[33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control Arenaviruses: For situations where a vaccine does not exist or is not appropriate (*e.g.*, immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE[34, 35] and LA[36, 37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** species. This will

Formatted: Space After: 3 pt

be achieved by tailoring antigen design from prototype applicable to related members of these viral families. These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for select Mammarenaviruses and Orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop BSL4 research tools and animal models for viruses that are otherwise not available to the research community.

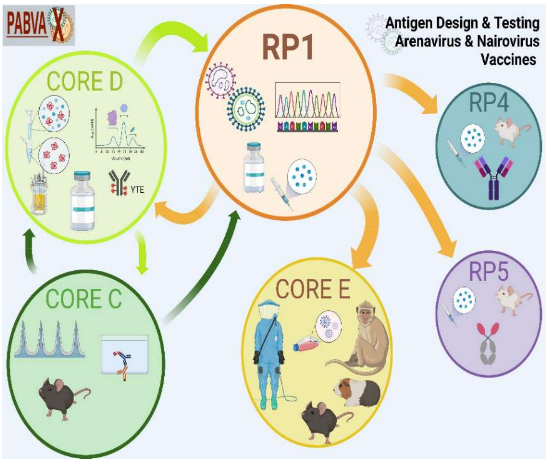

Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

~~PRELIMINARY RESULTS~~

Preliminary Results

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to

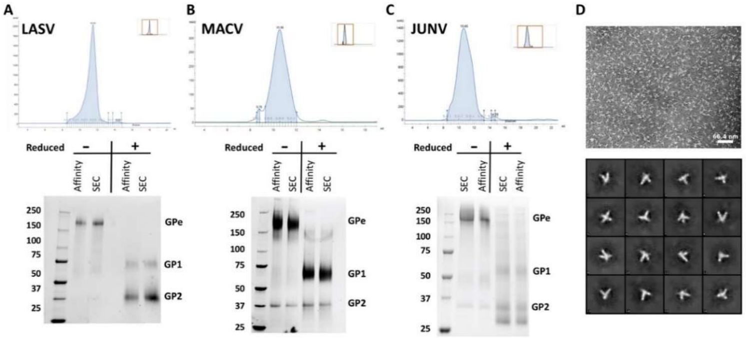

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

Formatted: Space After: 3 pt

stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

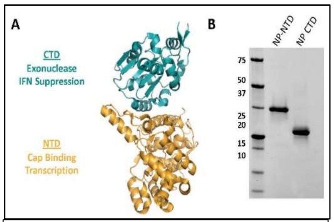

Figure 3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

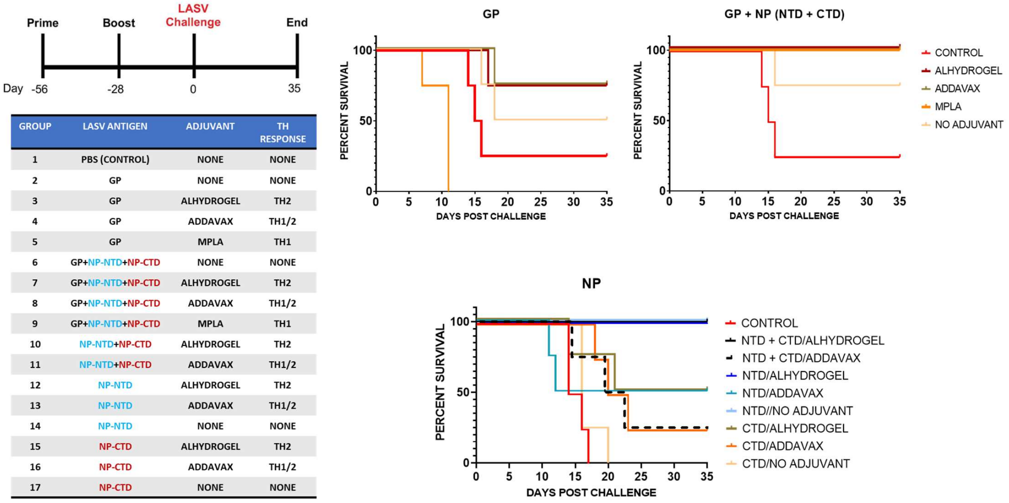
LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the



GROUP	LASV ANTIGEN	ADJUVANT	TH RESPONSE

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

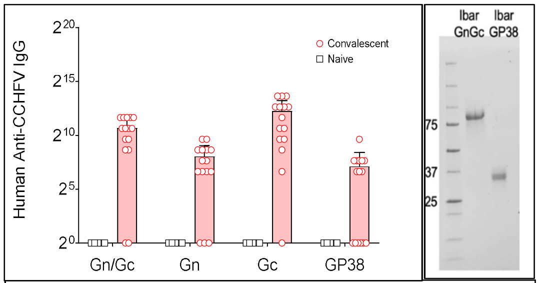

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

__Engineering glycoproteins antigens for CCHFV:__ The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

__Scientific Approach:__ The choice of Arenavirus Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Arenaviridae and the Nairoviridae. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *__Old Word Arenaviruses (OWAV):__* In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae [42-44] . There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *__New World Arenaviruses (NWAV):__* A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[45], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[46, 47]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[48]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *__Nairoviruses:__* In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the Nairoviridae family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[49]. A suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in

Formatted: Space After: 3 pt

Bulgaria but has numerous safety concerns and limited demonstrated efficacy[50]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[50]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[51]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[52]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model[53] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38.

- Once a candidate subunit-patch vaccine approach is selected, ~~this~~ **RP1** will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative~~,~~ "test case" ~~human~~ pathogen from each prototype virus group for which no ~~research grade~~ vaccines have been created and tested in animal models.

Formatted: Indent: Left: 0", Hanging: 0.13", Bulleted + Level: 1 + Aligned at: 0.25" + Indent at: 0.5"

Formatted: Font: Bold

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa[54]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[55] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne Mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[56, 57]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[57]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV ~~as part of~~in the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats[58]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[59]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[58]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Formatted: Indent: Left: 0", Hanging: 0.13", Space After: 3 pt

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[60]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families-[46, 61, 62] . An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Table 1: Outline of LASV Vaccination Schedule for Milestone 1.1.1.A

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[63]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Table 2: Outline of MACV Vaccination Schedule for Milestone 1.1.1.A

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[64]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[46, 47].

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

TOTALS	40	40	24	24

Table 3: Outline of PAN-LASV Vaccine Efficacy Schedule for Milestone 1.1.1.B

For our MACV subunit vaccines, we will assess the potential to confer heterologous protection against three lineages of MACV genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core E** as outlined in **Table 4.** We will also utilize JUNV (Romero strain)[65] challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), ~~all~~ animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after ~~LASV~~ challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

Milestone 1.1.2.D: Determination of protective efficacy against novel, emerging arenaviruses and nairovirus "test case" viruses using optimized subunit-patch vaccination in STAT-1/KO mice, guinea pigs and NHP: **RP1 and Core D** will produce optimized GPe and NP-NTD antigens to formulate vaccines for LUJV and CHAPV based off lessons learned from 1.1.1A-C. Protective efficacy studies then be carried out where **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10). RP1 and Core D** will also produce optimized KASV GP and NP-NTD antigens to formulate subunit/MNP vaccines based off lessons learned from 1.1.1A-C. Protective efficacy studies will then be carried **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10)**

Formatted: Space After: 3 pt

***Milestone* 1.1.3: Determination of cellular and humoral immune correlates associated with protection.**

Milestone 1.1.3.A: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Formatted: Space After: 3 pt

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences~~, Franklin Lakes, NJ~~) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: PBMC stimulations will be set up according to modifications of well established, previously published protocols~~.~~[67, 68]. PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative ~~(BD Biosciences, Franklin Lakes, NJ~~) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

Data Analysis: We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone 1.1.3.A:: Systems serology Characterization of Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups*:* We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[69-71] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Formatted: Space After: 3 pt

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument~~.~~[70, 72]. Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

***Milestone* 1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:** We will use existing Mammarenaviruses[62, 73] and Orthonairovirus[61] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog[74] but is still pathogenic in mice and humans. There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months~~(~~[34-37]~~)~~.

PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

Table 11: PREP schedule outline in Milestone 2

Scientific Approach: *A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine:* In conjunction with **Cores D** and **E**, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[75, 76] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11)**~~.~~ ~~For f~~Further details ~~of the NHP testing, please~~are described in~~ see~~ **Core E**. These data will be ~~used by the~~reviewed by Scientific Advisory Board (SAB) to ~~inform~~ aid decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three "test case" viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the "go" criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and SAC. *Please note: Discussion of expected results, other alternative approaches, and criteria for "go" or "no go" decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*

1.1.2.B	CORE C,D,E	Vaccine efficacy in guinea pig: LASV & MACV heterologous challenge (Year 1 Q4 – Year 3 Q2)
1.1.2.C	CORE C,D,E	Vaccine efficacy in NHP: CCHFV (Year 2 Q3 – Year 3 Q4) ③
1.1.2.D	CORE C,D,E	Vaccine efficacy in mice, guinea pigs, & NHP: LUJV, CHAPV, KASV (Year 4 Q3 – Year 5 Q4)
1.1.3.A	CORE D, E	Cellular correlates associated with protection (Year 2 Q3 – Year 5 Q4)
1.1.3.B	CORE D, E	Serological correlates associated with protection (Year 2 Q3 – Year 5 Q4)
1.2	CORE E	Reverse genetics of emerging bunyaviruses (Year 1 Q1 – Year 5 Q4)
2	CORE D, E	PREP monoclonal antibody vaccination: JUNV (Year 2 Q1 – Year 2 Q4)

RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and

Formatted: Font: Bold

Formatted: Font: Bold

Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future “plug and play” pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

Hello Dr. Cross,

I have a few comments/edits in the attached research strategy. Primarily, there are a few discrepancies between the table legends and text for specific aim 1. I tried to correct as I saw appropriate, but please review and edit as needed.

Thanks,
Sonja

Subject: RP1

hey Bob

here are some ideas to tighten up,
you are ok on space. but i would use 3pt breaks between major sections (less dense)
just have to remove text here and there to delete hanging sentences.

page 11 toi 12 has some weird anchor
might have to cut and move fig or text

there some weird stuff, like forced font capitals on preliminary results header.
i didnt want to keep going but i can, because i figured you have already started another version
reads great
cb

A. Significance

Henipaviruses (HNV) and arenaviruses (ARV) are two families of viruses that pose significant global public health concerns[1-5]. HNV, which includes Nipah virus (NiV) and Hendra virus (HeV), has caused outbreaks in Asia and Australia, resulting in severe respiratory and central nervous system (CNS) illnesses in humans[6-8]. These infections have been associated with high mortality rates ranging from 40% to 90%[4,9-13]. Similarly, ARV, such as Lassa virus (LASV) and Machupo virus (MACV), can cause severe illness and death in humans, with LASV being endemic in West Africa and MACV responsible for Bolivian hemorrhagic fever[14-19]. The geographical distribution and diversity of these viruses make them a global public health threat. While there are some vaccines and antiviral drugs available[4,13,20,21], there are no licensed treatments specifically targeting these viruses. Thus, there is a pressing need to develop new therapies that can effectively neutralize and prevent the spread of these viruses.

Significance of Developing Nanobody Therapy

The urgent need for effective treatments against HNV and ARV infections, highlighted by the ongoing COVID-19 pandemic, emphasizes the importance of rapid drug development and innovative antiviral therapies. Nanobodies, also known as VHH or single-domain antibodies, derived from camelid animals, offer unique advantages that make them promising candidates for antiviral therapy[22-25].

One significant advantage of nanobodies is their inherent stability[26-28]. Their small size and single-domain structure make them highly resistant to denaturation and degradation, allowing them to maintain their binding activity under various conditions. Nanobodies also offer ease of engineering. Their single-domain format simplifies the modification and optimization of their binding properties. Through techniques such as affinity maturation and structure-guided design, nanobodies can be readily engineered to enhance their affinity, specificity, and neutralization potency against specific viral targets. This flexibility in engineering enables the development of tailored nanobodies with improved therapeutic properties[29,30].

Also, nanobodies exhibit modular characteristics[26]. Their small size and independent folding domains allow for the construction of multi-specific or bi-specific nanobodies, where different specificities can be combined into a single molecule[31,32]. This modularity opens up possibilities for targeting multiple epitopes on viral proteins or simultaneously targeting different viral strains, providing enhanced breadth and efficacy in combating HNV and ARV infections.

Combined with their specificity, small size, stability, ease of engineering, and modular nature, nanobodies represent a promising approach for developing effective antiviral therapies against HNV and ARV infections.

Three nanobody development platforms to enhance diversity and coverage

The use of multiple nanobody development platforms, including camelid animals, nanomice, and low-immunogenic human nanobody libraries (**Fig.1**), enhances the diversity and coverage of nanobody libraries, increasing the likelihood of identifying potent nanobody candidates. Notably, **Dr. Jianliang Xu**, a nanobody research expert, is **the inventor of the "nanomice" platform**[29], which was commented by *Nature News and Views* that "*Just as the development of mice with antibodies containing human variable domains (such as Regeneron's VelocImmune mouse) has helped to deliver the 100th FDA-approved monoclonal antibody, perhaps the nanomouse will give nanobody-based therapeutics a push in the same direction*"[33]. In addition, we have recently cloned the CDR regions of human antibodies (IgM, IgD, IgG1-4, IgE, IgA1-2) heavy chain from 60 healthy donors of various demographic backgrounds, assembled them on Ighv3 family framework, and generated a human nanobody library that is close to natural human antibody heavy chain variable domain. The potentially low immunogenicity of such a library will enable us to quickly identify nanobody leads that need minimum optimization for clinical use.

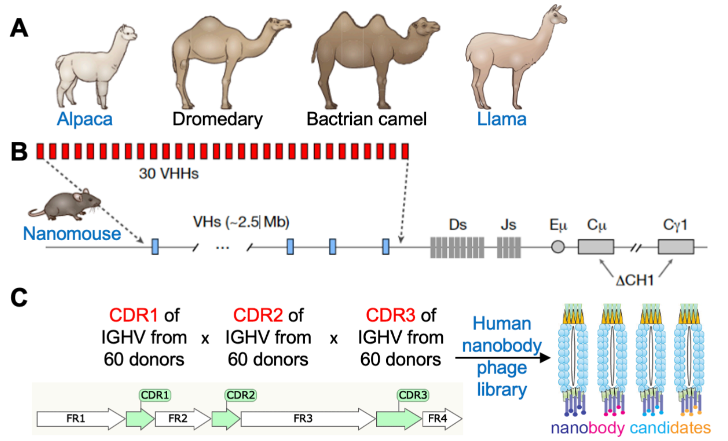

Figure 1: Three nanobody development platforms. (A) Camelid animals; (B) Nanomouse; (C) Human nanobody phage library.

The deep sequencing of antigen-specific enriched nanobody libraries ensures a comprehensive exploration of the nanobody repertoire[29], allowing for the rapid identification of leads with minimal optimization required for clinical use. This expedited development process is critical in responding to emerging viral threats and addressing the urgent need for effective antiviral therapies.

Targeting CNS diseases caused by viral infection

Nanobodies hold great promise for targeted therapy of CNS diseases as they can efficiently cross the blood-brain barrier (BBB) due to their small size[34-37]. To further enhance brain delivery, we have developed a bi-specific nanobody strategy by coupling another nanobody that targets TfR1[38,39], a receptor expressed at the BBB. This bi-specific nanobody can cross-react with both human and mouse TfR1, facilitating enhanced cargo delivery to the brain. In our upcoming study, we will compare the brain delivery and therapeutic efficacy of un-engineered nanobodies with the bi-specific nanobodies using animal models in **RP3 and Core E**. This study aims to evaluate the abilities of these two approaches to effectively penetrate the BBB and deliver therapeutic nanobodies to the central nervous system. Through this evaluation, we hope to understand the benefits of utilizing bi-specific nanobodies for targeted therapy of CNS diseases caused by HNV and ARV infections.

Generalizable research strategy

The significance of developing nanobody therapy extends beyond the four selected prototypic viruses in HNV and ARV. By applying and testing the research strategy developed in this project during **phase 2** of the project, the scope can be expanded to include other members of these viral groups, such as Langya virus (LayV)[40], Lujo virus (LUJV)[41], and Chapare virus (CHAV)[42]. This approach expands the scope of nanobody-based therapies, tackling global health risks from emerging viral diseases.

B. Innovation

The study incorporates several innovative aspects in the development of nanobody-based therapies for HNV and ARV infections:

- Utilization of diverse nanobody sources: The study leverages nanobodies derived from camelid animals, nanomice, and low-immunogenic human nanobody libraries. This approach expands the repertoire of nanobodies available for antiviral therapy development.
- Targeting viral entry machinery: Nanobodies are employed to target and neutralize viral proteins involved in viral attachment and entry. This innovative approach provides a novel avenue to inhibit viral infection at the early stages.
- Integration of structural characterization techniques: The study integrates advanced structural characterization techniques such as X-ray crystallography and Electron Microscopy Single Particle Analysis. This enables a detailed understanding of nanobody epitopes and viral neutralization mechanisms, facilitating the rational design of nanobody-based therapies.
- Development of BBB-penetrating nanobodies: The study focuses on designing nanobodies with the ability to penetrate the BBB, enabling effective targeting of the central nervous system. This is particularly relevant for combating the severe neurological manifestations associated with HNV and ARV infections.
- Generalizable research strategy: The research strategy developed in this study can be applied to other members of the HNV and ARV viral groups, such as Langya virus, Lujo virus, and Chapare virus. This expands the potential impact of nanobody therapies to address a broader range of emerging viral diseases.
- Deep sequencing for comprehensive coverage: The study utilizes deep sequencing to ensure comprehensive coverage of antigen-specific enriched nanobody libraries. This approach facilitates the rapid identification of potent nanobody leads with minimal optimization required for clinical use.
- Rapid and efficient therapy development: By leveraging the advantages of nanobodies and employing a well-designed research strategy, the study aims to rapidly and efficiently develop nanobody-based therapies. This contributes to the field of antiviral research and addresses the urgent need for effective treatments against HNV and ARV infections, thereby enhancing public health protection.

C. Approach

Scientific Premise: Our hypothesis is that nanobodies targeting viruses' key entry machinery can effectively inhibit virus infection. By utilizing structure-based analysis and rational design, we can enhance the efficacy of nanobody therapy by increasing its potency and breadth. Through the design of bi-specific nanobodies coupled with brain receptor-mediated transcytosis, we aim to enhance their ability to penetrate the blood-brain barrier, thus effectively combating central nervous system diseases caused by HNVs and ARVs.

Aim 1: To identify cross-reactive nanobodies to HNVs.

Rationale and Preliminary Data:

Envelope fusion glycoprotein F and the attachment glycoprotein G of Hendra virus (HeV) and Nipah virus (NiV) play crucial roles in host cell receptor engagement and membrane fusion, making them the main targets of neutralizing antibodies[43-46]. The high degree of similarity, approximately 80-90%, between the glycoproteins of HeV and NiV presents an attractive opportunity to identify cross-reactive neutralizing nanobodies capable of providing broad protection against both viruses[1,47-49]. To achieve this goal, we conducted immunization experiments using four groups of nanomice, with each group consisting of four mice. The mice were immunized with soluble F and G proteins of HeV and NiV, namely HeV_sF, HeV_sG, NiV_sF, and NiV_sG. These proteins, designed by **Dr. Kai Xu** and **Dr. Christopher Broder's** group, served as the immunogens[43,50,51] (**Fig. 2A**).

Following four injections in the nanomice, we observed various levels of serum antibody responses against all four immunogens, as depicted in **Figure 2B** for F proteins (data for G proteins not shown). To validate our approach, we isolated RNA from the bone marrow and spleen of mice immunized with NiV_sF and constructed nanobody phage libraries. Through a series of three rounds of phage panning using NiV_sF, subsequent individual colony picking, ELISA screening, and Octet affinity validation, we successfully identified several nanobody binders specific to NiV_sF. Of particular significance, one of the identified nanobodies, NiV_sF_Nb9, exhibited the ability to bind not only to NiV-sF protein but also to HeV-sF protein (**Fig. 2C**). This finding suggests that NiV_sF_Nb9 recognizes an epitope shared by the F proteins of both NiV and HeV. The results obtained from these experiments clearly demonstrate the potential of nanomice as a convenient and efficient model for the development of nanobodies. Consequently, we are confident in our ability to identify nanobodies against other F/G proteins of HeV and NiV using the same approach applied to the immunized mice.

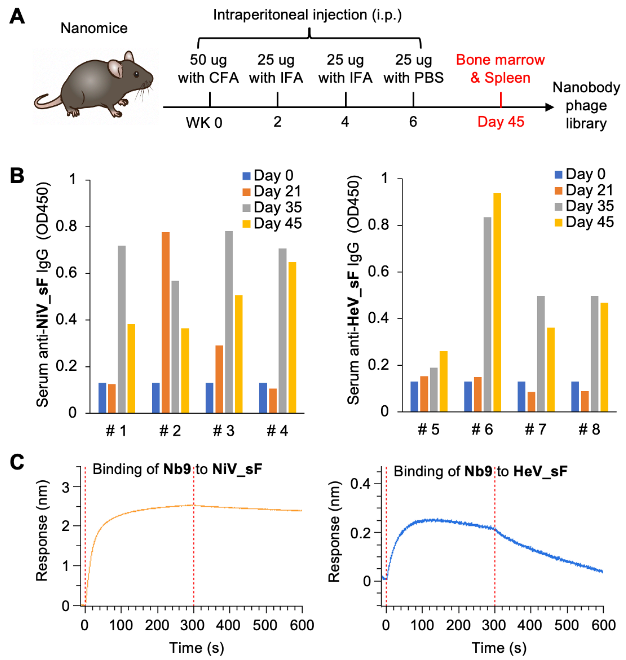

Figure 2: Nanomouse immunization and NiV_sF_Nb9 characterization. (A) Nanomouse immunization scheme. (B) HNV F proteins immunized nanomice serum response to the respective immunogen determined by ELISA; (C) Binding of NiV_sF_Nb9 to NiV_sF and HeV_sF determined by Octet.

In addition to the nanomice immunization strategy, we have also made significant progress using a **human library version 1.0 (Fig. 1C)** for screening purposes. Notably, we sequentially screened this human nanobody library with spikes of omicron variants (BA.4/5, BA.1) and WA-1, leading to the enrichment of numerous nanobody candidates. Among them, nine nanobodies exhibited binding affinity to the receptor-binding domain (RBD) of BA.4/5, BA.1, WA-1, SARS, and WIV16, indicating their ability to recognize a range of sarbecoviruses (**Fig. 3**). Importantly, all nine of these human nanobodies demonstrated potent neutralization against WA-1, and five of them exhibited cross-neutralization of Omicron subvariants (BA.4/5, BQ.1.1, XBB.1), SARS1, and Bat-WIV1. These results underscore the power and versatility of the human nanobody library platform, which holds significant potential for targeting various other antigens.

human nanobodies	WA1	Omicron (BA.4/5)	SARS1	Bat-WIV1	BQ.1.1	XBB.1
CoV2.hNb3	0.056	9.1	0.2	30.0	16.4	17.9
CoV2.hNb6	0.027	4.5	0.3	33.1	17.9	19.8
CoV2.hNb17	0.228	16.3	0.8	20.9	44.7	21.2
CoV2.hNb18	0.158	13.9	0.4	27.5	18.4	45.6
CoV2.hNb31	0.089	9.7	0.2	15.2	15.0	28.0
CoV2.hNb35	0.028	10.9	0.4	>50		
CoV2.hNb9	0.011	>50	4.4	>50

Figure 3: SARS-CoV-2 neutralizing nanobodies identified by human nanobody library. Neutralization IC50 (ug/ml) of 9 human nanobodies against various pseudotyped sarbecoviruses.

Experimental Design:

To expand our search for cross-reactive nanobodies against HeV and NiV glycoproteins, we will immunize additional groups of nanomice sequentially with either HeV or NiV F or G proteins. Each group will serve as a source for constructing *in vivo* matured nanobody phage libraries, using bone marrow, spleen, and/or peripheral blood mononuclear cells (PBMCs). These libraries will undergo sequential screening with HeV and NiV F or G proteins to identify nanobodies that exhibit cross-recognition of the F or G proteins of both viruses. To ensure comprehensive coverage of potential binders, we will employ a two-pronged approach. Firstly, we will randomly pick colonies from the libraries, and secondly, we will subject the enriched libraries to deep sequencing using the MiSeq platform. This approach will enable us to identify nanobody candidates from all complementarity-determining region 3 (CDR3) families. Subsequently, we will assess the target specificity of individual nanobodies through enzyme-linked immunosorbent assay (ELISA). Moreover, the neutralization activity of the identified nanobody candidates will be evaluated using RP2 assays.

While nanomice have proven to be valuable for generating in vivo matured nanobodies, it is important to consider the potential immunogenicity associated with animal-derived nanobodies. Therefore, in parallel with the nanomice immunization strategy, we will also screen for F or G protein binders using a human nanobody library. By utilizing the human nanobody library, we can significantly minimize the risk of immunogenicity and obtain nanobody candidates that are better suited for therapeutic testing in human subjects.

1.1: Nanomice immunization. Four groups of nanomice have already been immunized with soluble HNV F and G separately. Our preliminary data showed that almost all mice developed good immune response after 3 injections. We will next immunize 2 more groups, 8 mice each, sequentially with HNV F or G proteins (**Fig.4**). Injections (i.p.) will be performed at 3 weeks interval to allow more time for mouse immune system to react to each immunization. Specifically, for F proteins, mice will be immunized with HeV_sF at week 0, 3, 6, NiV_sF at week 9, 12, and a mixture of HeV_sF and NiV_sF at week 15, followed by a final boost (i.v.) with HeV_sF and NiV_sF mixture 3 days later. Bone marrow, spleen and PBMCs will be harvested 3 days after the final i.v. injection. HeV_sG and NiV_sG proteins immunization will follow the same scheme. Test blood/serum will be collected one week after each injection except for the first and last two injections, and serum antibody response to F or G proteins will be monitored by ELISA. The same serum will be used for HNV neutralization **test by RP2**.

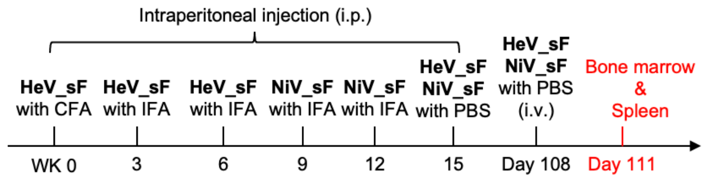

Figure 4: Nanomice sequential immunization scheme for HNV F proteins.

1.2: Nanobody phage library construction. We have extracted RNA from bone marrow and spleen from NiV_sF immunized mice, constructed nanobody phage library, screened for NiV_sF binders, and identified NiV_sF_Nb9 to be NiV_sF and HeV-sF cross binder (**Fig.2**). We will complete the nanobody phage library construction for all immunization groups and perform sequential screening to identify cross binders. Specifically, total RNA will be extracted from bone marrow, spleen and PBMCs from the best responding mice based on ELISA and neutralization test results. Two-step PCR will be performed to amply VHH-DJ (nanobody sequence) from the matured heavy chain-only IgG1 mRNA molecules (**Fig. 5**). First, we will amplify VHH-DJ-CH2 domain from IgG1 using 30 forward primers aligning to the leading exons of 30 VHH genes and one reverse primer aligning to CH2 sequence of IgG1. Next, a mixture of 30 forward primers aligning to 5’ end of individual VHH exon and 4 reverse primers aligning to JH1~4 will be used to amplify nanobody sequences, which will be cloned to pMES4 phagemid and subsequently transformed to TG1 E.coli cells.

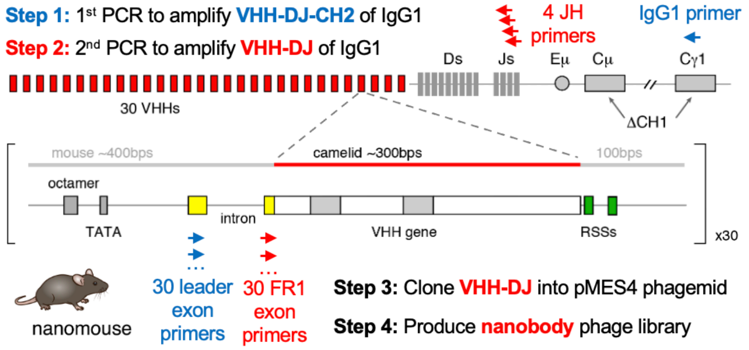

Figure 5: Nanobody phage library construction with nested PCR.

1.3: Screening nanobody libraries for HNV F/G binders. We will produce phages expressing individual nanobodies fused to their coat protein by infecting TG1 cells with VCSM13 helper phages. To identify nanobodies that recognize both HeV_sF and NiV_sF, libraries from F proteins immunized mice will be sequentially screened with HeV_sF and NiV_sF proteins in wells of 96-well Maxisorp plate; to identify nanobodies that recognize both HeV_sG and NiV_sG, libraries from G proteins immunized mice will be sequentially screened with HeV_sG and NiV_sG proteins. Multiple rounds of screening (phage panning) will be performed to ensure ideally over 100 times elution of phages from F or G protein coated wells than control wells (**Fig. 6A**). For each TG1 cell sub library from single or sequential F or G protein screening, 96 ~192 individual colonies will be picked and cultured in deep-well plates. Nanobodies (fused to phage coat protein pIII) induced by IPTG will be extracted from periplasmic region of TG1 cells and tested for binding to HNV F or G proteins by ELISA. Phagemid of ELISA positive clones will be extracted and Sanger sequenced, and then transformed into WK6 E.coli cells to produce individual nanobodies (monomer, 13 kDa). In addition, sub libraries will be deep sequenced (**Fig. 6B**) and nanobody sequences analyzed as described before[29]. Nanobodies will be clustered based on their CDR3 differences and cross checked with the sequences of ELISA-positive clones. Representative unique nanobodies from each CDR3 class will be codon optimized and synthesized, cloned into pMES4 phagemid, and nanobodies will be produced in WK6 cells. <u>We will perform step 1.3 with our newly designed and constructed human nanobody library to identify less immunogenic nanobodies against HNV F and G protein.</u>

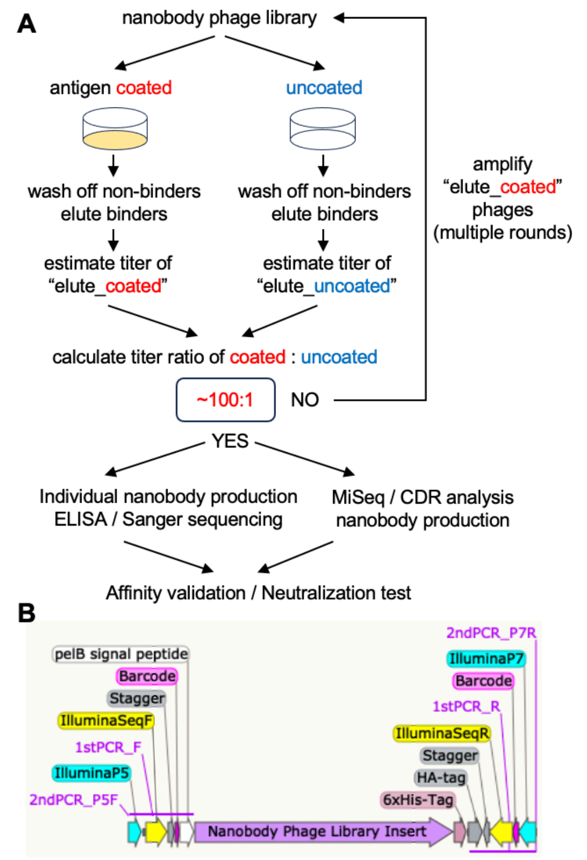

Figure 6: Phage screening, sanger sequencing, and MiSeq sequencing. (A) Nanobody phage screening strategy. (B) MiSeq sequencing library preparation. 1st round PCR will attach MiSeq F/R sequences to nanobodies, and 2nd round PCR will introduce P5/P7 adaptors to amplicon 5' and 3' ends.

1.4: Nanobody binding validation and neutralizing activity assessment. To validate the binding of nanobodies to HNV F/G proteins, we will employ two methods: ELISA and Octet Bio-Layer Interferometry (BLI) affinity analysis. ELISA will allow us to determine the binding of nanobodies to the target proteins, while Octet BLI will provide detailed information on affinity. Additionally, we will perform Octet epitope binning assays using available F/G antibodies to map the epitopes recognized by the nanobodies. Furthermore, we will assess the neutralizing activity of the identified nanobodies with the neutralization assay developed by **RP2**[52,53]. These comprehensive analyses will enable us to evaluate the binding specificity, affinity, and neutralizing capability of the nanobodies. We will further select representative neutralizing nanobodies for structural analysis (**Aim 3**) and consider various engineering approaches such as Fc conjugation and multimerization (**Aim 4**) to further optimize the properties and efficacy of the nanobodies.

<u>Expected results, potential pitfalls and alternatives:</u>

We expect to be able to produce 5-10 HNV F or G nanobodies that either specifically recognize and neutralize HeV or NiV, or cross-bind to HeV and NiV proteins and cross neutralize the two viruses. We also expect to identify nanobodies with novel epitopes compare to currently available human antibodies.

Based on our success in identifying HeV_sF and NiV_sF cross binder (NiV_sF_Nb9 from nanomouse immunization) and SARS-CoV-2/SARS/WIV1 cross neutralizers (hNb3, 6, 17, 18 and 31 from human nanobody library screening), we do not anticipate any major technical or methodological pitfalls. While we have high expectations for our study, there are potential pitfalls that we need to consider. One challenge could be the limited number of nanobody candidates that meet our criteria, particularly if their affinity or neutralizing activity is not optimal. In such cases, we have a strategy in place to perform in vitro PCR-based CDR maturation to generate nanobody variants with improved properties. Additionally, there is a possibility that our efforts to identify HNV F or G cross binders/neutralizers using nanomice or the human nanobody library may not yield satisfactory epitope diversity. To overcome this limitation, an alternative approach would involve immunizing camelid animals and applying the same selection and screening processes to identify target-specific nanobodies.

Aim 2: Identification of nanobodies to ARVs.

***<u>Rationale and Preliminary Data</u>*:**

The surface of LASV and MACV virions is covered by the heavily glycosylated trimeric type-1 fusion glycoprotein precursor (GPC)[54-57]. The GPC trimer consists of receptor-binding GP1, fusion machinery GP2, and the associated stable signal peptide (SSP)[57-62]. The extensive glycan shield on GP1 and GP2 poses a challenge for the immune system to generate a robust GPC-directed antibody response, resulting in weak and inconsistent neutralizing antibody development during natural infection[63-67]. Only a few LASV-neutralizing antibodies have been isolated from convalescent patients to date[68]. While LASV GPC has shown neutralizing response in rabbit and guinea pig studies, serum neutralization has not been achieved in mouse models[69-71]. In contrast, MACV neutralizing antibodies have been successfully isolated from GPC immunized mice[72]. However, there are currently no FDA-approved treatments or vaccines for LASV or MACV infections. In our study, we aim to leverage the small size of nanobodies to develop glycan shield-penetrating neutralizing nanobodies against LASV and MACV.

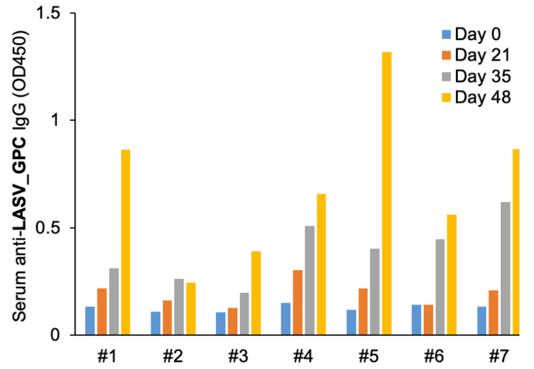

Figure 7: Antibody response aginst LASV GPC in immunized nanomice sera.

In our experiments, we immunized 8 nanomice with a stabilized LASV GPC trimer, following a modified scheme. We performed an intravenous boost injection on day 45 and harvested bone marrow and spleen on day 48. With one mouse accidentally died on day 46, 7 mice remain. Over time, 6 out of 7 mice developed an antibody response against GPC, reaching their highest titers on day 48 (**Fig.7**). Importantly, the serum from nanomouse #3 on day 48 showed weak but detectable neutralization activity against LASV Josiah strain. These findings demonstrate the potential of nanomice as a valuable model for developing neutralizing nanobodies against LASV and MACV.

Experimental Design:

We will construct nanobody phage library using the top responders from the LASV immunized nanomice, with a particular focus on nanomouse #3 due to its detectable neutralization activity. We will immunize nanomice with alternative versions of soluble stabilized trimeric LASV GPC and MACV GPC proteins **provided by RP1** and construct *in vivo* matured nanobody phage libraries. These libraries and the human nanobody library will be screened with GPC proteins to identify nanobody binders. Individual nanobodies will be assessed for target specificity by ELISA and Octet, and neutralization activity of nanobody candidates will be **evaluated by RP1**.

2.1: Nanomice immunization and nanobody phage library construction. In our previous LASV GPC immunization attempt, 1 out of 8 nanomice developed serum neutralization titer at day 48. We will immunize two groups of nanomice separately with LASV GPC or MACV GPC designed by RP1 with slightly modified immunization regimen. For both LASV and MACV, injections (i.p.) will be performed once every 3 weeks, and test blood/serum will be collected one week after each injection except for the first injection. Serum antibody response to GPC proteins will be monitored by ELISA and send to RP1 for neutralization test. Immunization (i.p.) will stop until serum neutralization titer is observed, or the 6th injection is performed on week 15. Three days after a final boost (i.v.), bone marrow, spleen and PBMCs will be harvested for nanobody phage library construction following the same strategy listed in Aim1.

2.2: Screening nanobody libraries for LASV GPC or MACV GPC binders. Nanobody phage library screening using LASV GPC or MACV GPC will be performed for multiple rounds until the ideally 100:1 ratio of eluted phages from coated vs uncoated wells is achieved. We will carry out random colony picking followed by ELISA and Sanger sequencing, as well as Miseq for comprehensive analysis of enrich sub libraries. Same screening will be applied to human nanobody library too. 13 kDa nanobody candidates will be produced in WK6 cells for further tests.

2.3: Nanobody binding analysis and neutralizing activity assessment. Individual nanobodies will be validated using ELISA and Octet assays to confirm their interaction with GPC proteins. Precise affinity will be measured by BLI method. Epitope competition mapping and binning will be performed using known human/mouse GPC antibodies. Nanobodies with positive binding will be evaluated for neutralization activity by **RP1**.

Expected results, potential pitfalls and alternatives: We expect to be able to produce 5-10 LASV or MACV neutralizing nanobodies targeting GPC proteins. The monoclonal antibodies that are currently known to have LASV neutralizing activity are categorized into four competition groups: GP1-A, GPC-A, GPC-B, and GPC-C[68]. We expect to identify LASV neutralizing nanobodies lie within these 4 groups. Given the small size of nanobodies and their potential to target hidden epitopes, we also expect to identify novel epitopes of vulnerability on LASV and MASC GPC surface. Even though the immunogenicity of LASV GPC seems to be very poor in mouse, nanomouse #3 developed serum neutralizing response to LASV Josiah strain. Furthermore, a nanobody neutralizer D5 was identified by screening the same LASV GPC with a naïve llama nanobody library[69]. Therefore, we do not anticipate any major technical or methodological pitfalls with nanomouse and human nanobody library platforms. However, if we are unsuccessful at isolating LASV/MACV binders and neutralizers using nanomice or human nanobody library, we will immunize camelid animals instead. We have a standing by llama from Capralogics Inc. ready for immunization. In the past a few years, we have immunized this animal with HIV envelop trimer, SARS-CoV-2 spike and HMPV F proteins, and all three studies led to the identification of potent nanobody neutralizers against these virus targets. We expect this llama will perform well against LASV and MACV. If our selected nanobody candidates are less-than-optimal, *in vitro* PCR-based CDR maturation will be performed and nanobody variants with improved activity will be screened.

Aim 3: Structural characterization.

Rationale and Preliminary Data.

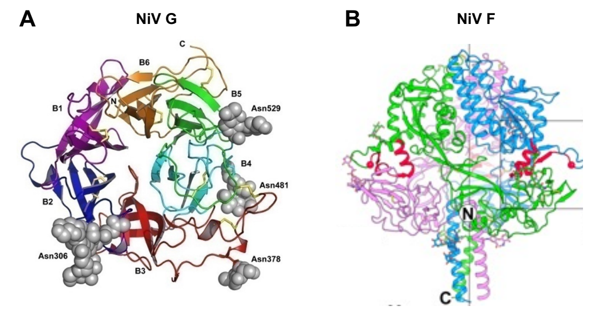

Figure 8: Structures of NiV G and F glycoproteins by X-ray crystallography. (A) NiV G head domain; (B) NiV F in the native prefusion conformation.

Dr. Kai Xu is a distinguished researcher with a proven track record in the structural determination of Henipavirus (HNV) glycoproteins and their complexes with receptors and monoclonal antibodies[50,73-75]. Notably, he achieved a significant milestone by determining the first crystal structures of the Nipah virus (NiV) G protein head domain and NiV F protein in the prefusion conformation (**Fig.8**). Moreover, Dr. Xu possesses exceptional expertise in designing HNV protein constructs that faithfully present their native conformation[43,74]. This capability enables him to create accurate representations of HNV glycoproteins, facilitating a deeper understanding of their functional properties and enabling investigations into their interactions with receptors and antibodies[51,76,77]. With his comprehensive skill set in protein design and structural determination, Dr. Xu stands as a leading authority in the field of HNV research.

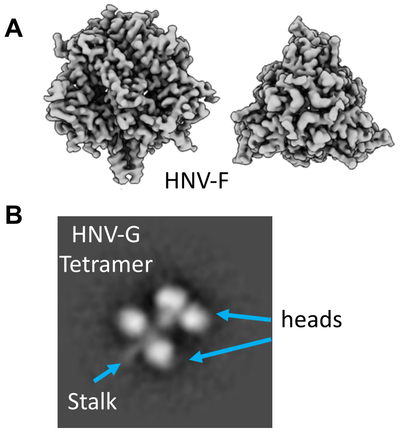

Figure 9: Validation of HNV F and G protein used in this study by EM single particle analysis. (A) Orthogonal views of HNV F protein cryo-EM 3D reconstruction at 2.5 A resolution; (B) 2D analysis of HNV G protein tetramer.

Our proposed research is driven by the need to present the native conformation of viral antigens, which is essential for antigenicity, immunogenicity, and the induction of protective immune responses. Glycoproteins of HNVs and ARVs are particularly prone to conformational flexibility, resulting in sample heterogeneity. To overcome this challenge, our preliminary data demonstrate the feasibility of creating viral antigens that display their native protein conformation. We have successfully stabilized viral antigens in their native states by designing prefusion conformation stabilizing mutations and incorporating specific stabilizing tags, such as GCNt and GCN4, to F and G proteins, respectively[50,73] (described in **RP1, 2 and Core D**). This stabilization approach has been validated through structural analysis (**Fig.9**), biochemical and biophysical characterization, and functional assessments, including receptor binding and the induction of neutralizing antibody responses.

Additionally, we have extensive experience in determining high-resolution structures of nanobodies in complex with viral antigens, such as SARS-CoV-2 spike proteins[29] (**Fig.10**). Leveraging advanced structural and functional characterization techniques such as X-ray crystallography, cryo-electron microscopy, and binding assays, we aim to unravel the detailed structural features and functional properties of the native-like viral antigens. This comprehensive understanding will provide critical insights into the interactions between antigens and antibodies, as well as the mechanisms of immune recognition. Ultimately, this knowledge will guide the rational design of effective vaccines and therapeutics targeting viral infections.

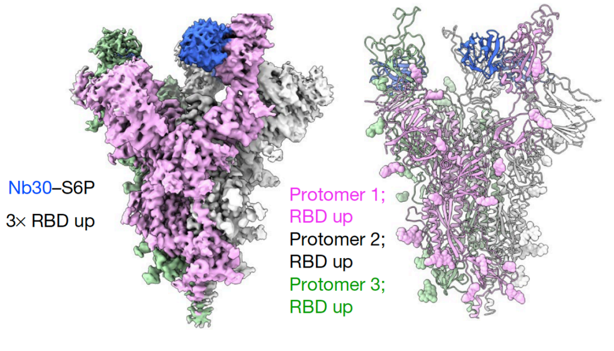

Figure 10: Cryo-EM single particle analysis of broadly protective nanobody against SARS-CoV2. 2.6 Angstrom high-resolution cryo-EM map (left) and structural model (right) of nanobody in complex with SARS-CoV2 spike protein. Nbs are in color blue.

Experimental Design:

Our experimental design aims to understand how nanobodies neutralize HNV and ARV viruses by analyzing their structure and interactions. Using X-ray crystallography and EM methods, we will determine the structures of nanobody-viral glycoprotein complexes, providing insights into their binding. Additionally, we will employ structure-based mutagenesis techniques to investigate the impact of specific mutations on viral entry and neutralization **in RP1 and 2**. By combining these approaches, we will gain detailed knowledge of nanobody epitopes and their interactions, contributing to the development of antiviral therapeutics for HNV and ARV.

3.1. Structural basis of nanobody cross-neutralization of both NiV and HeV. To determine the structure of the NiV or HeV F or G protein complexed with cross-neutralizing nanobodies, a series of steps will be undertaken. Initially, the NiV and HeV F and G proteins will be prepared in their native prefusion conformation by **Core D**. Subsequently, the purified nanobodies will be incubated with the F or G proteins to form stable complexes, optimizing the incubation conditions. High-resolution structures of the F or G protein complexes bound to the cross-neutralizing nanobodies will be determined using both X-ray crystallography and cryo-EM single particle analysis. Epitope analysis, including sequence analysis to identify conserved regions between the NiV and HeV F proteins, will provide insights into the potential neutralization mechanism. Additional experiments, such as site-directed mutagenesis, binding assays, and functional studies, will be conducted to validate the interaction between the nanobodies and the F proteins, confirming the importance of specific residues and regions identified in the structural analysis. Notably, a negative stain electron microscopy (ns-EM) analysis of a cross-neutralizing nanobody targeting both HeV and NiV G protein head domain has been performed, employing a compatible monoclonal antibody hAH1.3 to enhance particle 2D alignment (**Fig.11A**) and 3D reconstruction (**Fig. 11B**). This study demonstrates the feasibility of obtaining high-resolution cryo-EM structures. Ultimately, this study will yield crucial insights into the molecular mechanisms of neutralization and facilitate the development of effective antiviral therapies against HNVs.

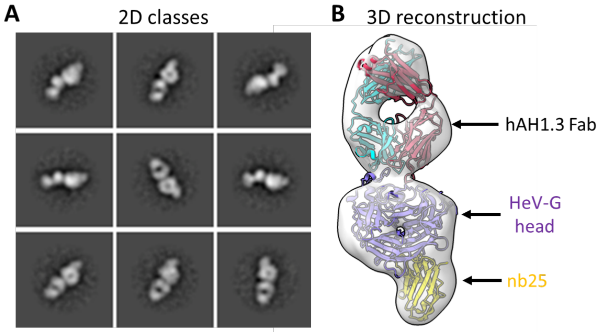

Figure 11: Anti-HeV-G nanobody epitope mapping by ns-EM analysis. (A) 2D classification; (B) 3D reconstruction showing a ternary complex of HeV-G head domain with a murine neutralizing antibody hAH1.3 and a nanobody nb25.

3.2. Structural analysis of LASV or MACV GPC proteins in complex with neutralizing nanobodies. The arenavirus glycoprotein precursor (GPC) proteins are key components of the viral envelope and play a crucial role in the entry and infection process of arenaviruses[78-80]. Arenaviruses are a family of RNA viruses that can cause severe diseases in humans, including hemorrhagic fevers[81,82]. The GPC proteins are synthesized as a single polypeptide chain, which undergoes post-translational processing to generate mature glycoproteins. The mature glycoproteins consist of two subunits, GP1 and GP2, that are responsible for receptor recognition and membrane fusion, respectively. The GP1 subunit is involved in receptor binding and determines the host tropism of the virus, while the GP2 subunit mediates membrane fusion between the viral envelope and host cell membrane. The GPC proteins are highly immunogenic and are targets for neutralizing antibodies. Understanding the structure and function of ARV GPC proteins is essential for developing effective antiviral strategies and vaccines against arenavirus infections. To investigate the structure of LASV and MACV GPC complexed with nanobodies using EM and X-ray crystallography, the experimental procedure involves preparation of stabilized GPC constructs, such as GPCysR4 and GPCysRRLL by **Core D**[58,83,84]. These constructs, developed with specific mutations, have been extensively used in structural studies of GPC-neutralizing antibodies. The purified GPC constructs are then mixed with the nanobodies of interest to form stable GPC-nanobody complexes. Cryo-EM analysis is performed by preparing cryo-EM grids, imaging them using a cryo-electron microscope, and generating a 3D reconstruction of the complex. X-ray crystallography is employed to crystallize the GPC-nanobody complex, collect diffraction data, and determine the crystallographic structure. The obtained structures are analyzed to identify nanobody-viral glycoprotein interactions and understand neutralization mechanisms. This combined approach provides valuable insights into the complex structures and guides the optimization of nanobody-based antiviral strategies.

Expected results, potential pitfalls and alternatives:

We anticipate that our research efforts will result in the generation of high-resolution structures of nanobody-antigen complexes, providing detailed insights into the precise epitope information and neutralization mechanisms. However, obtaining high-quality crystals suitable for X-ray analysis can be a challenging task. We are aware that extensive optimization of crystallization conditions may be necessary to promote crystal formation.

To overcome this potential pitfall, we will employ various strategies and screening methods to enhance crystal quality and obtain the desired structural information. The conformational flexibility and heterogeneity of viral antigens and their complexes pose another challenge. In such cases, cryo-EM SPA can serve as a valuable alternative to X-ray crystallography. Through the application of computational algorithms, we can classify different particle conformations and extract high-resolution structural information from cryo-EM data. This approach will provide valuable insights into the structural features and dynamics of the viral antigens, despite their inherent flexibility. While our GPC stabilization strategy is primarily derived from LASV antigens, it may not be equally effective for MACV antigens due to their distinct structural and stability characteristics. As an alternative approach, we propose co-expressing MACV GPC with specific antibodies or nanobodies that can assist in stabilizing the native conformation of the antigens. This co-expression strategy will enhance the structural integrity of MACV antigens, enabling their characterization using various structural biology techniques.

Aim 4: Enhancing efficacy and CNS bioavailability of nanobodies.

Rationale and Preliminary Data.

Our aim is to enhance the therapeutic efficacy of nanobodies through engineering strategies. We will achieve this by extending the half-life of nanobodies, enhancing their interaction with immune effector cells, and increasing their binding avidity and neutralization potency. In addition, we will focus on improving the therapeutic effectiveness and availability of nanobodies within the CNS. The BBB presents a challenge in delivering therapeutic substances to the brain and spinal cord[85,86]. This barrier, formed by specialized brain capillary endothelial cells, tightly regulates the passage of molecules into the CNS, limiting the transport of drugs and antibodies[87-89]. Nanobodies, with their small size, show promise for targeted therapy of CNS diseases as they have demonstrated the ability to cross the BBB in recent studies[34-37]. In Aim 4, our research focuses on enhancing the therapeutic effectiveness and availability of nanobodies within the CNS, specifically for addressing viral infections that affect the CNS. We propose utilizing receptor-mediated transcytosis (RMT) as a strategy to facilitate the transport of nanobodies across the BBB[90,91]. RMT has emerged as a promising approach for delivering biologics, including antibodies, to the CNS[92]. RMT involves targeting specific receptors or transporters on brain capillary endothelial cells to enhance the uptake of nanobodies into the CNS. By engineering bi-specific nanobodies to selectively bind to these receptors or transporters, we can improve their transport across the BBB.

Our goal is to optimize the targeting and transcytosis efficiency of nanobodies through RMT, thereby improving their delivery and distribution within the CNS. This optimization will ultimately enhance the therapeutic efficacy of nanobodies in combating viral infections and CNS-related diseases.

Experimental Design:

4.1. Generate nanobody Fc-fusion and tri-valent nanobodies*:* In our previous study focusing on SARS-CoV-2 nanobody therapy development, we successfully implemented two crucial engineering strategies: Human IgG1 Fc fusion and nanobody multimerization[29] (**Fig.12**). These strategies have shown significant advancements in improving the effectiveness of nanobody-based therapeutics.

		IC_{50}	
Nb12 mouse	Monomer	11.7 nM	168.5
	Bivalent (llama)	0.7 nM	30.0
	Bivalent (human)	0.5 nM	21.6
	Trimer (human)	0.1 nM	7.7
	Trimer (llama)	65 pM	4.7

	Bivalent (human)	66 pM	2.5
	Trimer (human)	9 pM	0.7

Figure 12: Fc fusion and multimerization improve potency of nbs against SARS-CoV2. (A) Diagrams show nanobody monomers, dimer, and trimers (fused to human IgG1 Fc) (B). Comparison BLI binding of monomer and trimer binding 1000x affinity improvement due to avidity. (C). Neutralization shows of SARS-CoV-2 pseudovirus by various nbs and multimers. (D). Table summarizes pseudovirus neutralization potency of selected nanobodies. Values given in molarity and ng/ml.

To extend the half-life of nanobodies, we incorporated Human IgG1 Fc fusion through a flexible hinge region (**Fig.12A**). This fusion strategy substantially increased the duration of nanobody activity within the body by improving their stability and protection against degradation. The Fc region of the antibody played a crucial role in enhancing the therapeutic effect by providing enhanced durability. Furthermore, we designed nanobody multimers, specifically tri-valent structures, to enhance the binding affinity (**Fig.12B**) and neutralization potency of the nanobodies (**Fig.12C and D**). The multimeric arrangement allowed for stronger and more effective binding interactions with the target viral proteins, leading to improved neutralization of the virus and ultimately enhancing the therapeutic efficacy of the nanobodies.

Our experimental strategy involves extending the half-life and enhancing the therapeutic efficacy of our top nanobody candidates through the generation of nanobody Fc-fusion proteins and tri-valent nanobodies. To extend the half-life, we will fuse the Fc region of IgG1 to the nanobodies using either the human or mouse IgG1 hinge region or the llama IgG2a hinge region, taking advantage of the FcRn-mediated recycling process and stability conferred by these hinge regions, respectively. For the generation of nanobody trimers, we will design rational linkers based on structural information of viral glycoproteins and the approaching angle of nanobody recognition. This will ensure proper orientation and spatial arrangement of the nanobodies within the trimeric structure, leading to increased avidity, binding affinity, and improved target engagement. By implementing these strategies, we aim to enhance the stability, therapeutic potential, and neutralization potency of our nanobodies, ultimately contributing to the development of more effective therapeutic interventions against viral infections.

4.2. Design multi-specific nanobodies by combining nanobodies with non-overlapping epitopes: In this aim, we will design nanobodies that target distinct and non-overlapping epitopes on the viral glycoproteins. These nanobodies will be linked together in a tandem fashion to create a synergistic effect, enhancing their overall binding affinity and neutralization potency against the target viruses. The design of these multi-specific nanobodies will involve careful consideration of the orientation and flexibility of the linker regions, ensuring optimal cooperative binding properties. Through this approach, we aim to create a robust and comprehensive neutralizing response against viral infections, ultimately advancing the development of more effective therapeutic interventions. (**Fig.13A**)

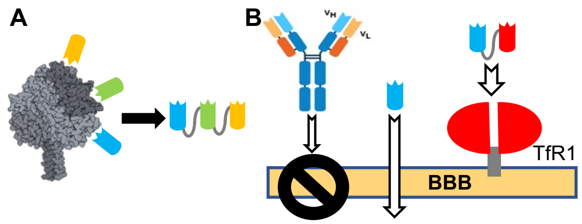

Figure 13: Bi-specific and multi-specific nanobody engineering. (A) Combination of epitope specificities to enable synergy, (B) Bi-specific nb with TfR1 specificity to improve brain targeted delivery.

4.3. Design Bi-specific nanobody by coupling with TfR1-targeting specificity to facilitate CNS delivery: In this aim, we will explore the incorporation of TfR1-specific nanobodies to enhance the delivery of nanobodies to the CNS (**Fig.13B**). The high expression of TfR1 on the blood-brain barrier makes it an attractive target for facilitating CNS delivery. To improve the penetration of nanobodies across the blood-brain barrier and enhance their bioavailability within the CNS, we will design bi-specific nanobodies by genetically fusing our candidate nanobodies against highly pathogenic neurotropic HNVs or ARVs with TfR1-specific nanobodies. By combining the targeting specificity of both nanobodies, we aim to achieve enhanced CNS delivery and therapeutic efficacy. We will evaluate several published TfR1-specific nanobodies, including FC5, a camelid single-domain antibody with known sequence[93]. FC5 has demonstrated the ability to transcytose across the blood-brain barrier and effectively deliver bioactive molecules to the CNS[36,94,95]. With its cross-reactivity across species and strong binding affinity to brain endothelial cells, FC5 holds promise for enhancing the CNS delivery of our nanobodies.

4.4. Efficacy test in both in vitro neutralization assay and animal studies. We will assess the efficacy of the original nanobodies identified in aims 1 and 2 and compare them with the engineered nanobodies in both *in vitro* neutralization assays and animal studies. Our goal is to evaluate the performance of the engineered nanobodies and determine their potential for therapeutic applications. The *in vitro* neutralization assays will assess the ability of the nanobodies to neutralize the target viruses, providing valuable insights into their antiviral potency. By measuring the reduction in viral replication or the inhibition of viral entry, we can determine the neutralization potency of the nanobodies. This will provide valuable insights into their antiviral activity and effectiveness. To further evaluate the efficacy of the nanobodies *in vivo*, we will utilize the rCedV-NiV-B chimera mouse model at the Uniformed Services University (USU) **in RP3** for HNVs, as well as animal models of ARVs developed at the University of Texas Medical Branch (UTMB) in **Core E**. These animal models will allow us to assess the therapeutic efficacy of the original and engineered nanobodies in terms of nanobody brain delivery efficiency, viral load reduction, disease progression, and overall survival rates. By comparing the outcomes between the two groups, we can determine the superiority of the engineered nanobodies in terms of therapeutic effectiveness.

Through these comprehensive in vitro and in vivo evaluations, we aim to demonstrate the improved efficacy of the engineered nanobodies compared to the original nanobodies. This assessment will provide crucial data for further development and optimization of nanobody-based therapeutics targeting HNVs and ARVs, with the ultimate goal of improving patient outcomes and combating viral infections.

Expected results, potential pitfalls and alternatives:

We anticipate that the design of tandemly linked nanobodies will result in enhanced neutralization potency and viral inhibition. The incorporation of a hinge and Fc region is expected to improve the half-life and stability of nanobodies, increasing their therapeutic potential. Coupling with TfR1-specific nanobodies is likely to improve brain delivery efficiency. However, potential pitfalls of using VHH FC5 as bi-specific nanobodies include short half-life due to susceptible to proteolytic degradation, thus limiting its development for clinical use. Alternative strategies, such as utilizing alternative receptor targeting or seeking to identify an antibody that binds to the same epitope, but that is derived from a fully human antibody library and has the requisite properties for clinical development, will be explored if necessary. Overall, these enhancements in efficacy and CNS bioavailability of nanobodies will significantly contribute to the development of potent antiviral therapies against CNS infections.

Aim 5: Expanding to other members of the viral groups.

Rationale

Building upon the valuable insights and progress achieved in Aims 1-4, Aim 5 aims to expand our nanobody-based therapeutic approach to target other members of the HNV and ARV in the **2nd phase** of this project. This expansion is based on the premise that the knowledge gained from studying NiV, HeV, LASV, and MACV can be extrapolated to other related viruses within these groups.

Experimental Design:

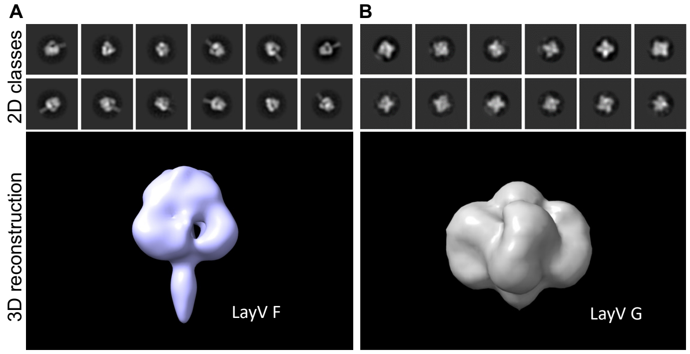

Figure 14: LayV F and G protein analysis. 2D classification and 3D reconstruction of LayV prefusion F (A), and G tetramer (B)

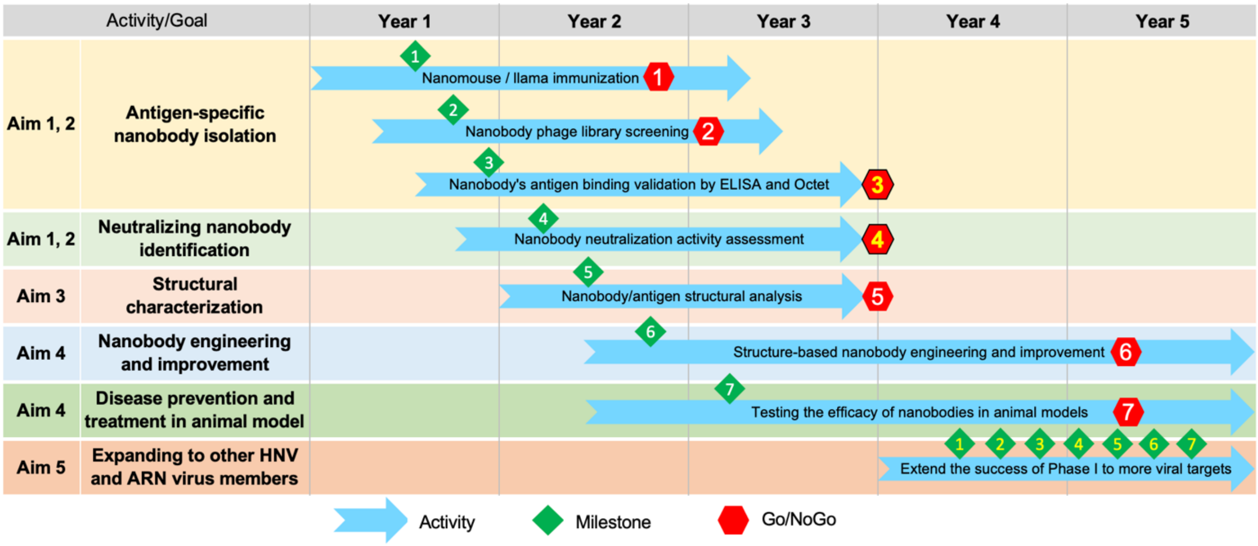
5.1. Langya virus: Langya virus (LayV) is a newly emerged member of the Henipavirus (HNV) family that has been linked to respiratory illness in humans[40,96]. LayV shares a close genetic relationship with Nipah virus and Hendra virus, both of which are known to cause severe disease in humans. To develop effective nanobody therapies against LayV infection, we have successfully generated native viral glycoprotein antigens by design, specifically the G and F glycoproteins (**Fig. 14**). By following our established research strategy, we will utilize nanobody development platforms, employ structural characterization techniques, and implement optimization approaches to identify nanobodies with protective properties against LayV. This process will involve evaluating the selected nanobodies with the neutralization assay and the animal disease model developed in collaboration with **RP2 and Core E**, and ready during the **phase 2** of this project. These efforts will not only contribute to development of nanobody-based therapies targeting LayV but also demonstrate the plug-and-play nature and rapid generalizability of our research strategy. By successfully applying our established approach to a newly emerged member of the Henipavirus family, we will showcase the versatility and effectiveness of our methodology in identifying and optimizing nanobodies against emerging viral pathogens. This will have broader implications for future studies on other viral infections, as our research strategy can be readily adapted and applied to different viral targets.

5.2. Lujo virus and Chapare virus: In our continued research, we will apply a similar strategy to the one used in Aim 2-4 for Lujo virus (LUJV)[41,97,98] and Chapare virus (CHAV)[42,99,100], which are closely related to the prototype LASV and MACV Arenaviruses. This strategy involves stabilizing the glycoprotein complex (GPC) using existing mutation designs transferred from LASV, isolating nanobodies specific to LUJV and CHAV, and performing structural characterization. By leveraging the knowledge and techniques gained from previous aims, we aim to identify nanobodies that can effectively neutralize LUJV and CHAV.

Expected results, potential pitfalls and alternatives:

We anticipate that our research strategy, combined with the knowledge gained from the phase 1 study, will enable us to identify potent neutralizing nanobodies against LayV, LUJV, and CHAV, providing promising therapeutic options for these viral infections. However, it is important to acknowledge potential challenges, such as limited cross-reactivity due to the genetic and antigenic differences between these additional viral targets and the prototypes studied in phase 1. In such cases, alternative approaches, including structure-guided rational design, may be explored to combine viral specificity and expand the protection breadth. Another potential limitation could be the difficulty to generate native prefusion GPC for the additional ARVs. In such instances, we will focus on utilizing the immune-dominant GP1 subunit, which is more stable and contains vulnerable sites for neutralizing antibody recognition. Rational design will be employed to shield non-native surfaces and minimize the generation of non-neutralizing nanobodies. Overall, the successful expansion of our research to other members of the HNV and ARV groups will make a significant contribution to broadening the effectiveness of nanobody-based therapies and addressing the global health risks associated with these viral pathogens.

D. Project Milestones and Timelines



<u>**Milestones**</u>: (<u>Same milestones are expected to be achieved during phase II with a faster pace).</u>

1. Serum neutralization activity observed (ID_{50}>10).
2. Nanobody phage library panning good enrichment achieved (enrichment>100:1).
3. High affinity viral protein-specific nanobodies isolated (affinity<1 nM).
4. Neutralizing nanobodies obtained (IC_{50}<1 ug/ml; neutralize multiple strains).
5. High resolution nanobody/antigen complex structure solved (resolution<3A).
6. Engineered nanobody molecules with improved activity obtained (IC_{50}<0.1 ug/ml; neutralize more strains).
7. Positive therapeutic effect of nanobodies in virus-induced diseases achieved (no symptoms or weight loss at 10 mg/kg or lower dose).

<u>**Criteria to be met for each activity before moving forward (Go/NoGo)**</u>:

1. ELISA signal of post-immunization sera is at least 3 times higher than pre-immunization sera.
2. Nanobody phage library panning reach to at least 5 times enrichment.
3. Viral protein-specific nanobody with at least 1 nM affinity <u>**(if not achieved, No Go for Phase II)**</u>.
4. Nanobodies neutralize at IC_{50}<10 ug/ml and/or multiple strains (<u>**if not achieved, NoGo for Phase II)**</u>.
5. Resolve structure with high enough resolution to define nanobody epitopes.
6. Engineered nanobodies achieve better potency and breadth (IC_{50}<0.1 ug/ml; neutralize more strains).
7. Positive therapeutic effect achieved (no symptoms or weight loss at 10 mg/kg or lower dose).

E. Industry Expertise and Regulatory Considerations:

If new lead nanobodies engineered nanobodies are identified from **Research Project 5 (RP5),** collaboration with industry and regulatory experts in **Core D** and the **Scientific Advisory Board (SAB)** will be initiated. This collaboration will involve seeking their expertise in various areas such as the identification of correlates of protection, lead optimization, stability testing, and manufacturability testing of the newly discovered nanobodies. Nanobody candidates can be engineered as desired in collaboration with investigators from **Core D**. This may involve modifications such as altered N-glycans, Fc mutations to enhance effector functions and prolong half-life, and evaluation of multimeric formats. The engineered nanobodies will then be further evaluated to correlate their mechanisms of action with maximal efficacy using the rCedV model explored in the **RP3**, and potentially transitioned to testing in authentic NiV/HeV animal models under the supervision of **Core E**. Throughout this process, stability and manufacturability assessment will be conducted to ensure the identification of a lead prototype format for further development. The goal will be to identify single domain mAb prototypes suitable for long-term intramuscular prophylaxis and/or intravenous post-exposure prophylaxis and therapy. As monoclonal antibodies are regulated by The Center for Drug Evaluation and Research (CDER), a division of the U.S. Food and Drug Administration. Therefore, all activities related to the development and evaluation of the mAbs will be performed in accordance with regulatory expectations set forth by CDER.

Hi Sherry,

Please see attached documents from Jianliang and me.
Including:

1. Authentication of key resource (not sure if you received this last time)
2. Abstract (not sure if you received this last time)
3. LOS from me. (not sure if you received this last time)
4. MPI plan
5. Updated vertebrate animal
6. Updated specific aims

Research plan will be ready later today.

Thanks,
Kai

Hi Sherry,

Thanks for the reminder. Attached please find my LOS for the application. Kai will be sending Abstract, Authentication of materials and his LOS shortly.

My GSU position starts today, June 1, 2023. I am ccing my GSU email **jxu40@gsu.edu** and I will communicate with the team from my GSU account from now on.

Best regards,
Jianliang

> Hello Dr. Xu and Dr. Xu,
> This is a reminder of the documents that we still need to get from you both for RP5 on the UTMB/USUHS U19 application. Our administrative review is this coming Thursday, June 1, so we will need all of the items listed below in final form by **EOB tomorrow, Wednesday, May 31**.
>
> - Abstract- 30 lines, 1 for RP5
> - Authentication of Key Biological Materials- 1 for RP5
> - Letter of Support – If both PI's could provide letters o support for your role on this project, we can include them. This is optional, but strengthens the proposal.
>
> For the final application, please provide the following by **EOB Monday June 5** *(hard deadline!)*.

- Research Strategy – Please remember to include references for both items listed below from the RFA for your research project:

Milestone Plan: In a clearly labeled section titled "Project Milestones and Timelines" include a clear delineation of goals with measurable milestones, including detailed quantitative and qualitative criteria for Go/No-Go decision-making, and a timeline for the attainment of each goal and milestone and should be reflected in the Milestone Plan for the overall Program. This plan must include Go/No-Go criteria to be met by the end of Year 3 of the award for continuation to Phase II. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, for example, identification of protective epitopes, animal model development, vaccine or mAb candidate down-selection, identification of correlates of protection, validation of vaccine or mAb strategies for other family members, and analysis, sharing and publication of final data. Milestone criteria should not simply be a restatement of the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research Center.

Industry Expertise and Regulatory Considerations: For projects proposing early vaccine development, describe how industry partners will be identified and incorporated into the proposed project including a timeline for inclusion. For projects proposing IND-enabling later stage vaccine development, NIAID requires Centers to include active participation of an industry partner to ensure access to vaccine technology platforms, expertise in manufacturing, clinical development, and regulatory pathways. Applicants should describe the role of this partner in the proposed project and/or team to facilitate discovery, candidate evaluation and/or product development. For the purpose of this FOA, "industry" is defined as a large or small, domestic or foreign, pharmaceutical, biotechnology, bioengineering, or chemical company, or a related non-profit entity.

Please let me know if you have any questions about these or have any concerns about getting them back to us by the deadlines.
Thank you,

RESEARCH STRATEGY:

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness [3] . Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success [4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability [5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other Arenaviruses and Nairoviruses.

***<u>The Arenaviridae</u>*:** All Mammarenaviruses (Arenaviridae genus of viruses infecting mammals) share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge [7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe) [8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. [9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

<u>The *Nairoviridae*</u>: Unique from other Bunyaviruses, Orthonairoviruses (Nairoviridae genus of human pathogens) are transmitted primarily by ticks in nature. While there are a number of human pathogenic Orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [20]. Like Arenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

<u>Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens:</u> The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine [9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

<u>Unique Nairovirus subunit vaccine strategy utilizing GP and NP immunogens:</u> CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation [20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface [20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

<u>PREP "vaccination" as a measure to control Arenaviruses:</u> For situations where a vaccine does not exist or is not appropriate (*e.g.*, immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE [34, 35] and LA [36, 37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families.

These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for select Mammarenaviruses and Orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop BSL4 research tools and animal models for viruses that are otherwise not available to the research community.

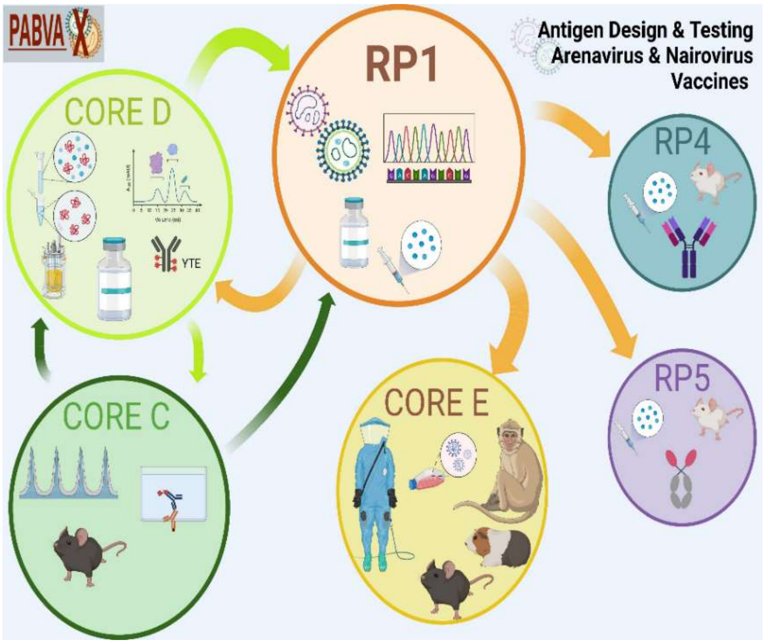

Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of

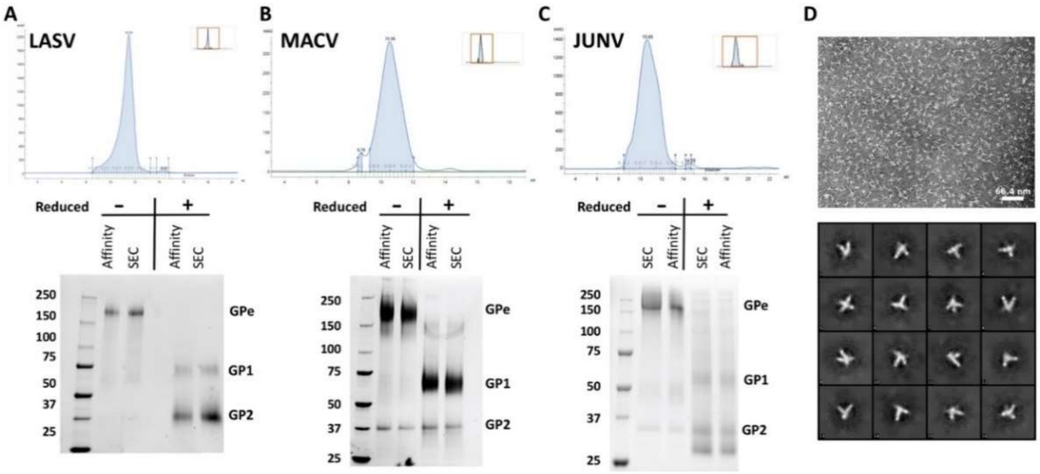

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

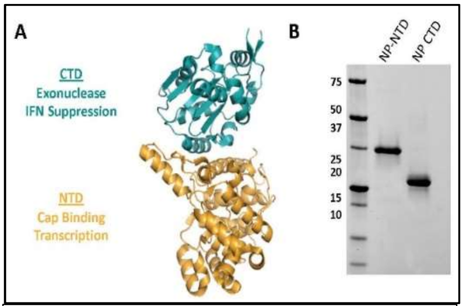

Figure 3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

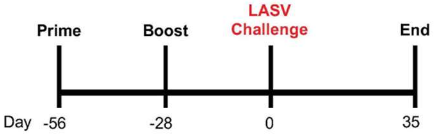
LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD**



GROUP	LASV ANTIGEN	ADJUVANT	TH RESPONSE
1	PBS (CONTROL)	NONE	NONE
2	GP	NONE	NONE
3	GP	ALHYDROGEL	TH2
4	GP	ADDAVAX	TH1/2

17	NP-CTD	NONE	NONE

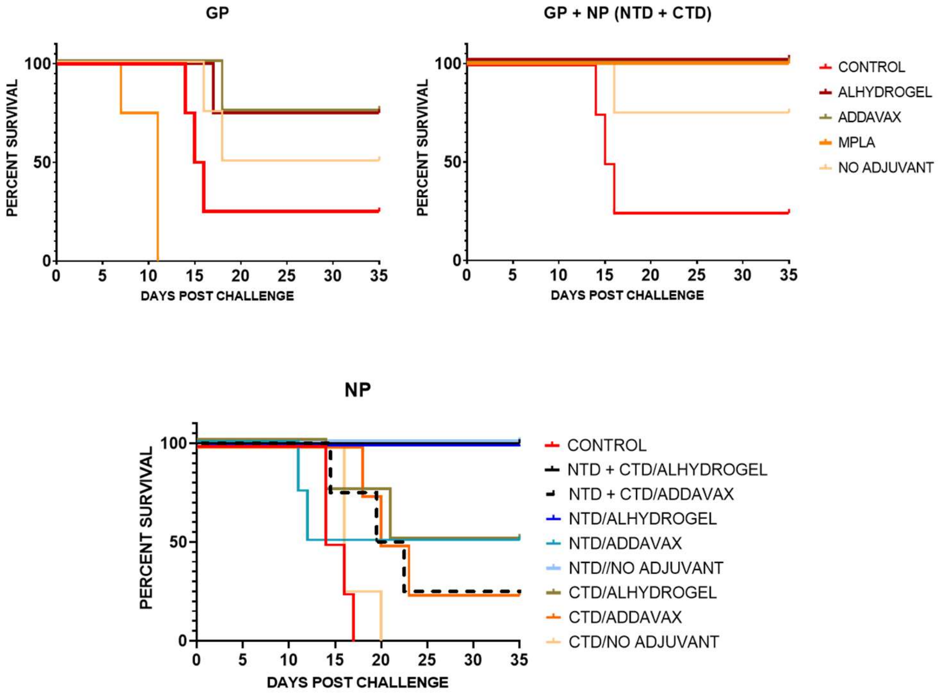

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

subunits and any of the adjuvants were completely protected from challenge with LASV. Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

Engineering glycoproteins antigens for CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

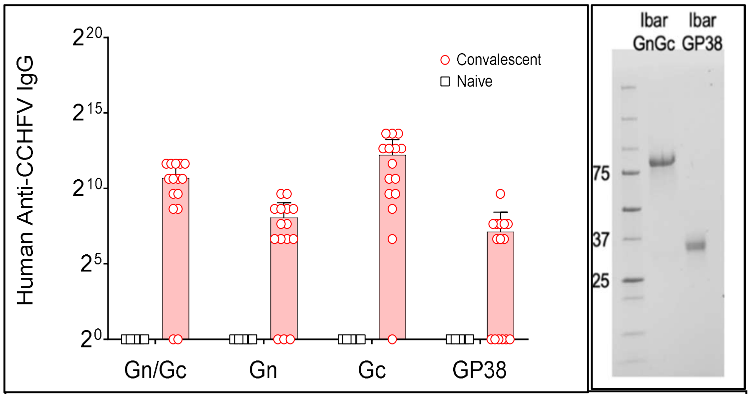

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

Scientific Approach: The choice of Arenavirus Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Arenaviridae and the Nairoviridae. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *Old Word Arenaviruses (OWAV):* In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae [42-44] . There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *New World Arenaviruses (NWAV):* A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina [45], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine [46, 47]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[48]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *Nairoviruses:* In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the Nairoviridae family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[49]. A suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[50]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[50]; however only an MVA-CCHFV vaccine has begun to advance

towards clinical trials[51]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[52]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model [53] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38.

Once a candidate subunit-patch vaccine approach is selected, this RP1 will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative, “test case” human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case’s medical evacuation to South Africa[54]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal “test case” OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[55] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center’s **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne Mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[56, 57]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[57]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV as part of the Center’s **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [58]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[59]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[58]. (The PABVAX Center will explore **KASV** as part of the Center’s **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[60]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families [46, 61, 62] . An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared

with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Table 1: Outline of LASV Vaccination Schedule for Milestone 1.1.1.A

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[63]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[64]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[46, 47].

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 3: Outline of PAN-LASV Vaccine Efficacy Schedule for Milestone 1.1.1.B

For our MACV subunit vaccines, we will assess the potential to confer heterologous protection against three lineages of MACV genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core E** as outlined in **Table 4.** We will also utilize JUNV (Romero strain)[65] challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 4: Outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

Similarly, we will also determine the protective efficacy of MACV following the grouping described in **Table 6** using the identical experimental approach as outlined above for LASV challenge. The challenge virus will be the established MACV Chicava strain[66]**.** If Candid-1 confers protection in guinea pig study outlined in 1.1.1.A we will confirm protection in NHPs if demonstrated in guinea pigs [46, 47]

***Milestone* 1.1.2.A: Development and optimization of patch vaccination approach employing nairovirus subunits:** Here we will determine if our GPe + NP-NTD subunit vaccine approach can be deployed against CCHFV.We will compare the protective efficacy of two adjuvants coupled to our CCHFV GP and NP-NTD proteins developed and manufactured in collaboration with **Core D** either as individual subunit vaccines or combinations as outlined in **Table 7** using an intramuscular (IM) vaccination approach. Eight 6-8 week STAT-1/KO mice (balanced sex) will be randomly assigned to groups as outlined in **Table 7.** Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core E** and challenged with 100 pfu of a low passage CCHF-Hoti[52]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Table 10: Outline of NHP efficacy studies for MACV Milestone 1.1.1.B

***Milestone* 1.1.3: Determination of cellular and humoral immune correlates associated with protection.**
Milestone 1.1.3.A: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

<u>Immune subset phenotyping</u>**:** We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

<u>*Viral protein stimulation experiments*</u>: PBMC stimulations will be set up according to modifications of well established, previously published protocols.[67, 68] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

<u>*Intracellular cytokine staining*: We</u> will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

<u>*Multiplex Bead based assays:* </u>As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

<u>*IFNg/TNFa ELISPOT*</u>: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

<u>*Data Analysis:*</u> We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

<u>*Alternative Strategies:*</u> Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

***Milestone 1.1.3.A:: Systems serology Characterization of Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups**:* We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[69-71] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument .[70, 72] Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

***Milestone* 1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:** We will use existing Mammarenaviruses[62, 73] and Orthonairovirus[61] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog [74] but is still pathogenic in mice and humans . There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months([34-37]).

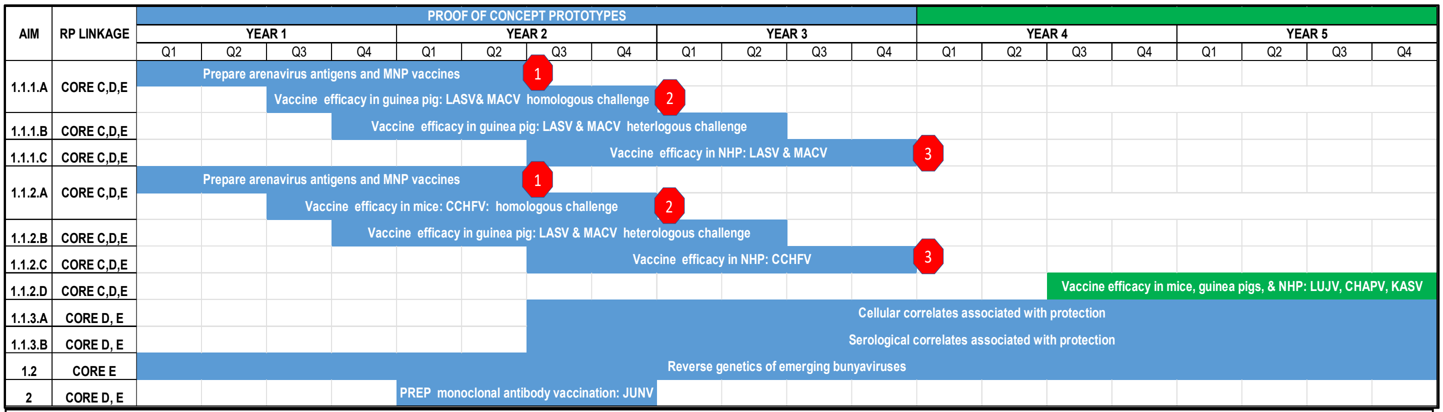
PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

Table 11: PREP schedule outline in Milestone 2

***Scientific Approach**: A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine:* In conjunction with Cores D and E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[75, 76] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11).** For further details of the NHP testing, please see **Core E**. These data will be used by the Scientific Advisory Board to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three "test case" viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the "go" criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and SAC. *Please note: Discussion of expected results, other alternative approaches, and criteria for "go" or "no go" decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.



RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

SPECIFIC AIMS

The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six Arenaviruses:Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV), are NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness. These threats are further heightened due to **lack of internationally approved vaccines** to counter natural epidemics and potential bio-weaponization. To address this unmet need, **Research Project 1 (RP1)** will leverage the combined expertise in high-containment virology, immunology, and biological product development, to develop Arenavirus and Nairovirus research tools and vaccine approaches which can be adapted across members of each viral family in a **"plug-and-play"** manner. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates concerns of efficacy as new related viruses continue to emerge and cause disease. However, recent advances in reverse genetics of viruses have allowed the generation of infectious clones and recombinant Arenaviruses (LASV, MACV, LUJV, JUNV) and Nairoviruses (CCHFV) which will make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most Arenaviruses and Nairoviruses has largely centered on the critical role of the viral glycoproteins (GP) and nucleoproteins (NP) to incur natural immunity. We recently successfully engineered a recombinant, stabilized-trimeric form of the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GPe alone, co-delivered with LASV NP subunits, or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as simple, safe, recombinant protein immunogens. Indeed, subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP), which harness the potently immunoresponsive cutaneous microenvironments, using dissolvable MNPs embedded with recombinant viral glycoprotein antigens and adjuvants to elicit robust and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease and COVID-19, however little is known of the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of **RP1** are two-fold: (**1**) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed against Old and New World Arenaviruses or emerging Nairoviruses. (**2**) Develop monoclonal antibody PREP strategies which can provide protective immunity. Specifically, we will:

Specific Aim 1: Subunit immunogens and MNP vaccination. Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches.

- **Milestone 1.1.1.A-C: Development and optimization of MNP vaccines using Arenavirus subunits in guinea pigs and non-human primates.**
- **Milestone 1.1.2.A-C: Development and optimization of MNP vaccines using Nairovirus subunits; protection in STAT-1/KO mice and non-human primates.**
- **Milestone 1.1.2.D: Determine the protective efficacy of optimized MNP vaccines against emerging Arenavirus and Nairovirus "test case" viruses in STAT-1/KO mice, guinea pigs and NHP.**
- **Milestone 1.1.3. A-B: Define the cellular and humoral immune correlates associated with protection.**
- **Milestone 1.2: Recombinantly rescue important naturally occurring Arenaviruses and Nairoviruses known only by genetic data.**

Specific Aim 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments. Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.

RESEARCH STRATEGY:

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness [3] . Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success [4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability [5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other Arenaviruses and Nairoviruses.

***<u>The Arenaviridae</u>*: All Mammarenaviruses (Arenaviridae genus of viruses infecting mammals) share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge [7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe) [8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. [9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

<u>The *Nairoviridae*</u><u>:</u> Unique from other Bunyaviruses, Orthonairoviruses (Nairoviridae genus of human pathogens) are transmitted primarily by ticks in nature. While there are a number of human pathogenic Orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [20]. Like Arenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens: The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine [9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique Nairovirus subunit vaccine strategy utilizing GP and NP immunogens: CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation [20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface [20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control Arenaviruses: For situations where a vaccine does not exist or is not appropriate (*e.g.*, immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE [34, 35] and LA [36, 37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families.

These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for select Mammarenaviruses and Orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop BSL4 research tools and animal models for viruses that are otherwise not available to the research community.

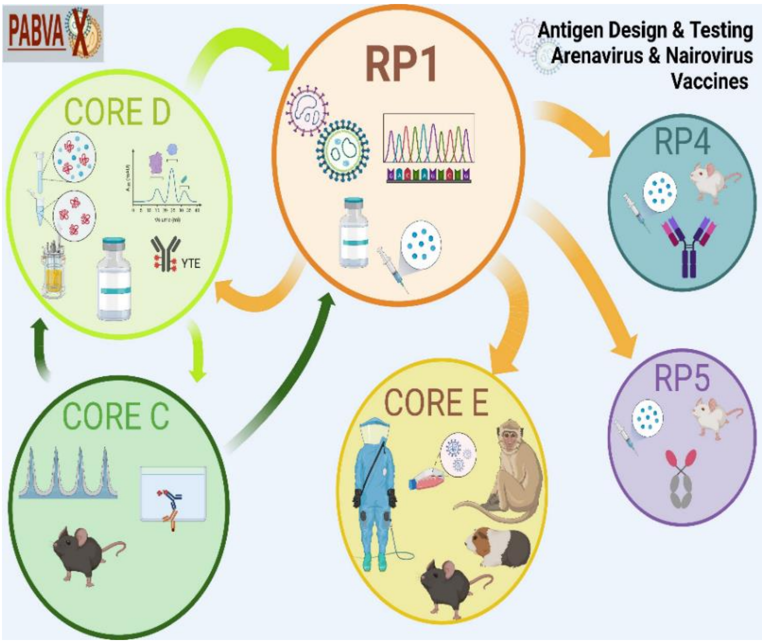

Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of

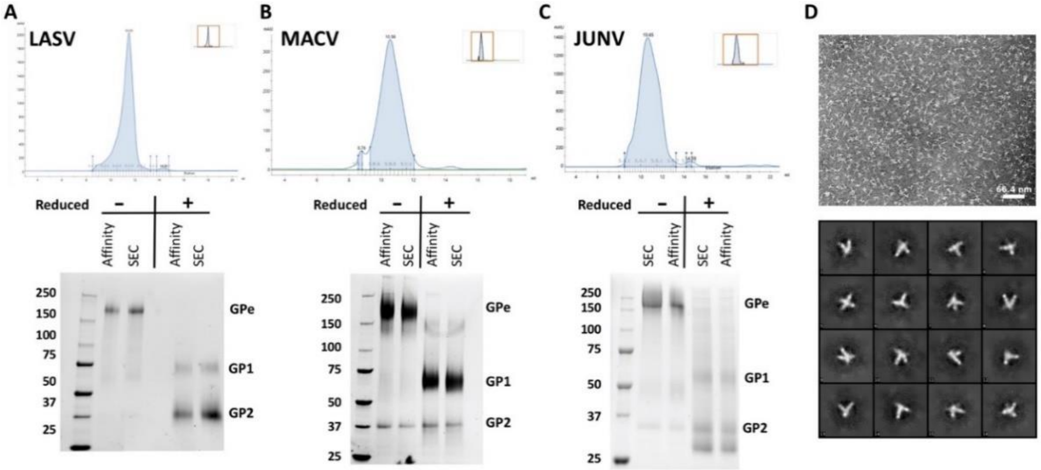

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

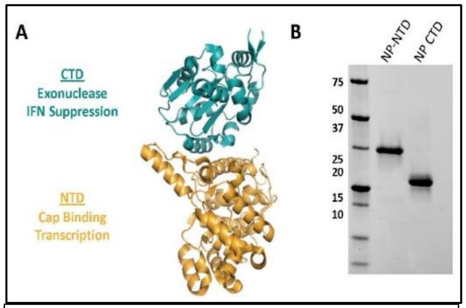

Figure 3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD**

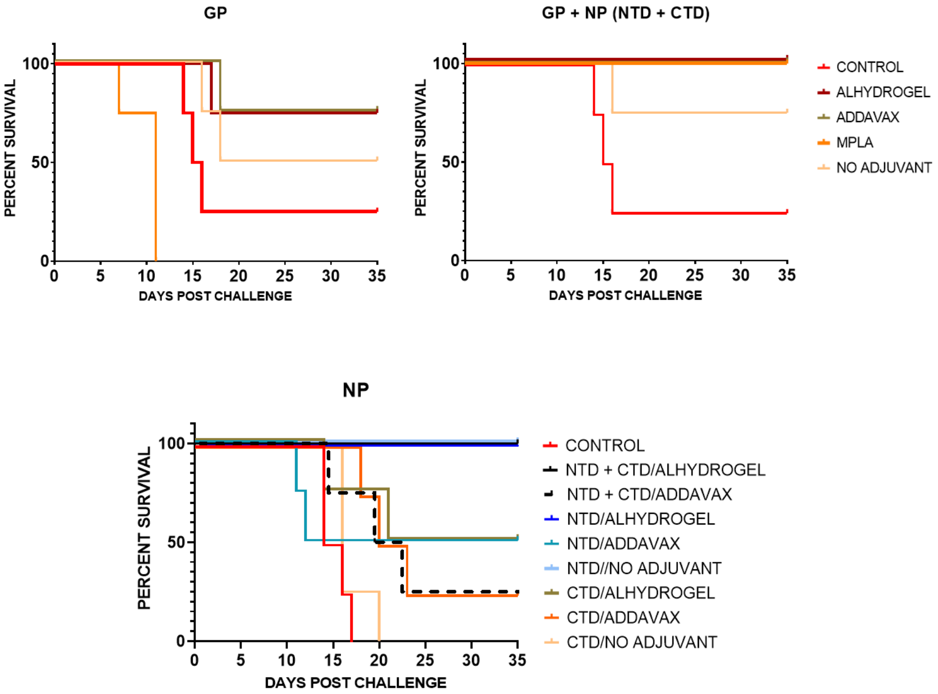

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

subunits and any of the adjuvants were completely protected from challenge with LASV. Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

Engineering glycoproteins antigens for CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

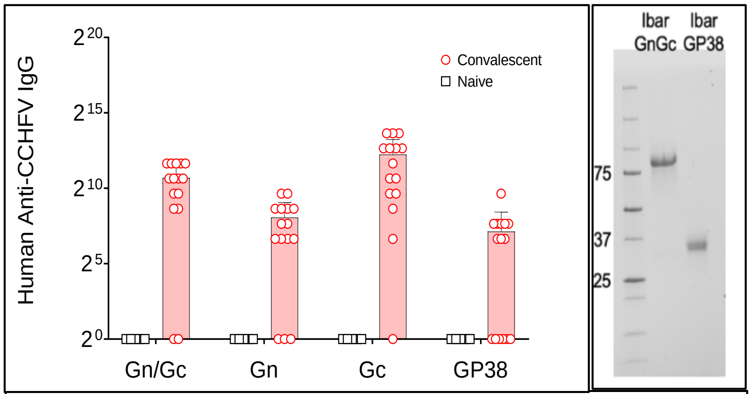

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

Scientific Approach: The choice of Arenavirus Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Arenaviridae and the Nairoviridae. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *Old Word Arenaviruses (OWAV):* In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae [42-44] . There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *New World Arenaviruses (NWAV):* A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina [45], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine [46, 47]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[48]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *Nairoviruses:* In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the Nairoviridae family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[49]. A suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[50]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[50]; however only an MVA-CCHFV vaccine has begun to advance

towards clinical trials[51]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[52]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model [53] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38.

Once a candidate subunit-patch vaccine approach is selected, this RP1 will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative, “test case” human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case’s medical evacuation to South Africa[54]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal “test case” OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[55] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center’s **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne Mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[56, 57]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[57]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV as part of the Center’s **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [58]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[59]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[58]. (The PABVAX Center will explore **KASV** as part of the Center’s **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[60]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families [46, 61, 62] . An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared

with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[63]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[64]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[46, 47].

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 3: Outline of PAN-LASV Vaccine Efficacy Schedule for Milestone 1.1.1.B

For our MACV subunit vaccines, we will assess the potential to confer heterologous protection against three lineages of MACV genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core E** as outlined in **Table 4.** We will also utilize JUNV (Romero strain)[65] challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 4: Outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

***Milestone* 1.1.2.A: Development and optimization of patch vaccination approach employing nairovirus subunits:** Here we will determine if our GPe + NP-NTD subunit vaccine approach can be deployed against CCHFV.We will compare the protective efficacy of two adjuvants coupled to our CCHFV GP and NP-NTD proteins developed and manufactured in collaboration with **Core D** either as individual subunit vaccines or combinations as outlined in **Table 7** using an intramuscular (IM) vaccination approach. Eight 6-8 week STAT-1/KO mice (balanced sex) will be randomly assigned to groups as outlined in **Table 7.** Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core E** and challenged with 100 pfu of a low passage CCHF-Hoti[52]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Milestone 2.1.2.C: Determination of protective efficacy using optimized subunit-patch vaccination in NHP: In collaboration with **Core E**, 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-CCHFV-GPC, demonstrated effective in mice[23] and NHP (Unpublished, Cross and Geisbert) with 5 animals, and a control group of five unvaccinated animals **(Table 9).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected CCHFV antigens, adjuvants, and vaccination route identified in 1.1.2.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post-boost for boosted animals), all animals will be challenged with 5000 PFU of CCHFV-Hoti. The disease of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after CCHFV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Milestone 1.1.2.D: Determination of protective efficacy against novel, emerging arenaviruses and nairovirus "test case" viruses using optimized subunit-patch vaccination in STAT-1/KO mice, guinea pigs and NHP: **RP1 and Core D** will produce optimized GPe and NP-NTD antigens to formulate vaccines for LUJV and CHAPV based off lessons learned from 1.1.1A-C. Protective efficacy studies then be carried out where **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10). RP1 and Core D** will also produce optimized KASV GP and NP-NTD antigens to formulate subunit/MNP vaccines based off lessons learned from 1.1.1A-C. Protective efficacy studies will then be carried **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10)**

Table 10: Outline of NHP efficacy studies for MACV Milestone 1.1.1.B

***Milestone* 1.1.3: Determination of cellular and humoral immune correlates associated with protection.**

Milestone 1.1.3.A: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping**:** We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: PBMC stimulations will be set up according to modifications of well established, previously published protocols.[67, 68] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

Data Analysis: We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone 1.1.3.A:: Systems serology Characterization of Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[69-71] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument .[70, 72] Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

***Milestone* 1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:** We will use existing Mammarenaviruses[62, 73] and Orthonairovirus[61] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog [74] but is still pathogenic in mice and humans . There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months(34-37).

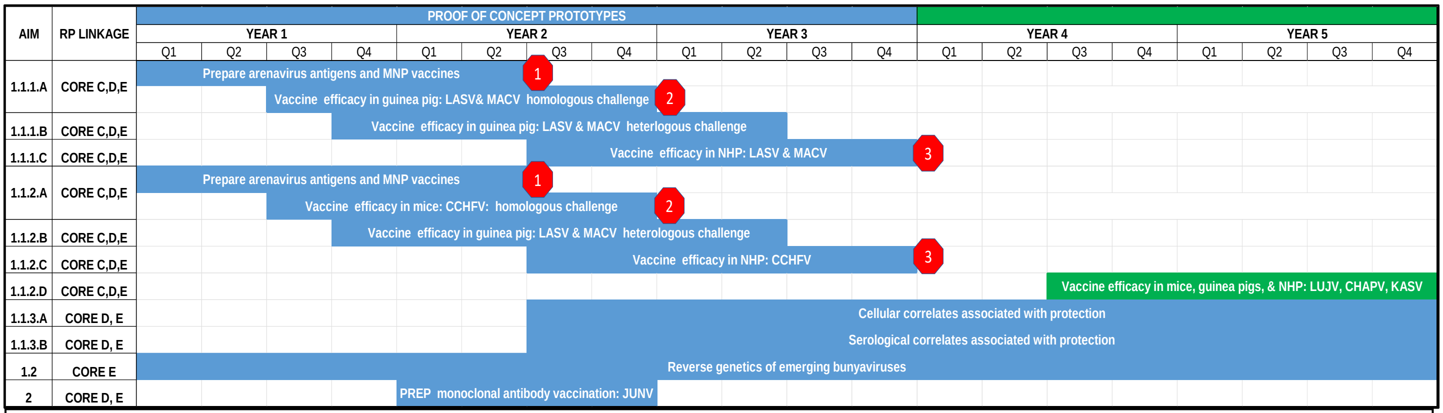
PREP	JUNV NHP CHALLENGE
5 mg/kg	**5**
15mg/kg	**5**
Control animals (NO PREP)	**5**
TOTALS	**15**

Table 11: PREP schedule outline in Milestone 2

Scientific Approach*: A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine:* In conjunction with Cores D and E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[75, 76] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11).** For further details of the NHP testing, please see **Core E**. These data will be used by the Scientific Advisory Board to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three “test case” viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the “go” criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and SAC. *Please note: Discussion of expected results, other alternative approaches, and criteria for “go” or “no go” decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future “plug and play” pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.



RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

ABSTRACT:

The viral order *Bunyavirales* contains several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and some are associated with significant, long-term sequelae in survivors. Of these, rodent borne arenaviruses – Lassa (LASV), Lujo, Chapare, Guanarito, Junin and Machupo viruses and one tickborne Nairovirus-Crimean-Congo Hemorrhagic Fever Virus- are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, production of significant morbidity and mortality, and have potential for major public health impact, and require special action for public health preparedness. Threats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **PABVAX RP1** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches using prototype members of each viral group which can be adapted across each viral family using a **"plug-and-play"** approach. Much of the work developing vaccines for these viruses has relied on isolates derived over 40 years ago, recent advances in viral reverse for these viral families is making vaccine testing of emerging isolates more feasible by improving access. Vaccine development for most arenaviruses and nairoviruses has centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized prefusion LASV GPe to act as an antigenic mimic of viral surface displayed GP and found this trimeric GPe alone, co-delivered with NP, or NP subunits alone, can protect guinea pigs against lethal challenge by LASV underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches like microneedle patches (MNP). MNP coupled antigens and adjuvants directly interact with the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs to elicit robust and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. In this proposal, we will develop protective protein-based subunit-MNP vaccines, PREP treatment strategies, and recombinant virus tools using prototyped arenaviruses and nairoviruses which will template development of countermeasures against other related Bunyaviridae members.

PROJECT SUMMARY – CORE D: ANIMAL MODELS AND VACCINE EVALUATION

Among viruses that cause disease in humans viral zoonoses within the family Paramyxoviridae and order Bunyavirales contain pathogens that cause significant lethality. Importantly, within the Paramyxovirdae the zoonotic henipavirus Hendra virus (HeV) is on the World Health Organizations (WHO) Priority Pathogens list. Notably, henipaviruses stand out for their impressive lethality with case fatality rates averaging about 75%. The Arenaviridae and Phelboviridae families contain viruses that cause severe hemorrhagic disease in humans. These viruses include the arenaviruses Lassa virus (LASV) and Junin virus (JUNV) and the phleboviruses Rift Valley fever virus (RVFV) and severe fever with thrombocytopenia syndrome virus (SFTSV). LASV and RVFV are also included among the WHO List of Priority Pathogens and pose threats to global public health due to the absence of approved vaccines or therapeutics. There is a clear unmet need for medical countermeasures to combat the threat of natural outbreaks, epidemics, or deliberate release. The synergistic activities of the Center partners will be focused on developing novel vaccines, treatments, and tools to support pandemic preparedness. Federal law requires that the paramyxoviruses, arenaviruses, and phleboviruses used in the Center be handled in approved Biosafety Level (BSL)-3 and BSL-4 containment laboratories. Core D provides approved BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities and a trained and highly experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support Project 2 - 5. The services provided by Core D will include 1) a secure repository of well characterized seed stocks of BSL-3 and BSL-4 paramyxoviruses, arenaviruses, and phleboviruses and know-how to rescue synthetic infectious clones (e.g. Ghana virus, GhV for this U19); 2) *in vitro* antiviral activity assays; 3) procurement of UTMB IACUC approval of animal protocols; 4) procurement, housing, and husbandry of animals; 5); development and/or optimization of animal models for GhV, Sosuga virus (SOSV) and JUNV to fill gaps where models are needed; 6) virus challenge, treatment, and collection of samples from animals; 7) technical expertise and equipment to conduct clinical pathological, immunological, and virological analysis of samples and to perform necropsies in BSL-3 and BLS-4 containment; 8) histopathological analysis of tissues collected from animals infected with BSL-3 and BSL-4 viruses; and 9) quality systems management of all records and data collected from animal studies. The Animal Models and Vaccine Evaluation Scientific Core (Core D) provides BSL-3 and BSL-4 resources and expertise for Projects 2 – 5. The goal of Core D is to work closely with Research Project and Scientific Core Leaders and staff, the Scientific Advisory Board, and NIAID to advance the development of countermeasures against Paramyxoviridae and Bunyaviridae.

SPECIFIC AIMS – CORE D: ANIMAL MODELS AND VACCINE EVALUATION

The main objective of the Animal Models and Vaccine Evaluation Scientific Core is to test and characterize the host response and efficacy of the vaccines and monoclonal antibody (mAb) based treatments identified in **Projects 2, 3, 4 and 5** against paramyxoviruses, arenaviruses, and phleboviruses under BSL-3/ABSL-3 and BSL-4/ABSL-4 containment. The Core will also develop select reporter viruses and conduct cell-based assays to characterize vaccine-induced neutralizing antibody responses and mAbs.

The Specific Aims of the Animal Models and Vaccine Evaluation Scientific Core are to:

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well characterized seed stocks of paramyxoviruses, arenaviruses, and phleboviruses as well as develop reporter viruses and rescue a Ghana virus synthetic infectious cloneAim 2: Provide technical expertise and conduct *in vitro* assays.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, immunology assays, virology assays, necropsies, and histopathological analysis.

Aim 4: Develop and/or optimize animal models for Ghana virus, Sosuga virus and Junin virus.

The Aims will be achieved by the following specific functions to be carried out by the Animal Models and Vaccine Evaluation Scientific Core Leader, Co-Core Leaders, and personnel:

1. Maintain records of well characterized BSL-3 and BSL-4 Hendra virus (HeV), Sosuga virus (SOSV), Lassa virus (LASV), Junin virus (JUNV), Rift valley fever virus (RVFV), and severe fever with thrombocytopenia syndrome virus (SFTSV) seed stocks including background history, passage history, genomic information, periodic monitoring of titer, mycoplasma testing, endotoxin testing, and sterility testing.
2. Perform *in vitro* antiviral activity assays. Including high-throughput BSL-2 based neutralization testing of henipavirus vaccine responses and mAbs.
3. Assist Center Investigators in designing animal studies, prepare animal protocols, and obtain IACUC approval of BSL-3 and BSL-4 animal studies.
4. Perform animal challenges using well characterized HeV, SOSV, LASV, GhV, JUNV, RVFV, and SFTSV seed stocks for **Projects 2, 3, 4 and 5.**
5. Perform vaccination and treatment of animals with vaccines and treatments provided by **Projects 3, 4 and 5.**
6. Provide samples from animals collected during the vaccination portion of studies to **Project 2** for immunological analysis.
7. Perform all duties associated with animal challenge studies including monitoring of animals, collection of samples, and necropsies.
8. Perform clinical pathology assays including hematology and clinical chemistry assays.
9. Perform virology assays on blood and/or tissue samples collected from infected animals including viral load by plaque assay and RT-PCR.
10. Perform gross pathology analysis on all animals at necropsy.
11. Perform histopathologic analysis on tissues from animals collected at necropsy.
12. Develop and/or optimize animal models for SOSV and JUNV to fill gaps; make these models available to Center Research Projects and Scientific Cores as well as external ReVAMPP Centers
13. Provide all data generated in Core D to **Data Management Core B**.

RESEARCH STRATEGY – CORE D: ANIMAL MODELS AND VACCINE EVALUATION

SIGNIFICANCE

As discussed in the Overall Component, the Center will focus in Years 1-3 on Lassa Virus (LASV), Rift Valley fever virus (RVFV), and Hendra Virus (HeV) and in Years 4-5, will target Junín virus (JUNV; *Arenaviridae*), severe fever with thrombocytopenia syndrome virus (SFTSV; *Phenuiviridae*), Sosuga virus (SOSV; *Paramyxoviridae*), and Ghanianan bat henipavirus (GhV; *Paramyxoviridae*).As HeV, LASV, JUNV, and RVFV are CDC and/or USDA select agents, Federal regulations require that these viruses be handled in Biosafety Level (BSL)-3 or BSL-4 containment. **Core D provides approved BSL-3/ABSL-3 and BSL-4/BSL-4 facilities and a trained and experienced team of BSL-3 and BSL-4 investigators and staff to perform studies that support Projects 2, 3, 4, and 5.** The services provided by Core D will include 1) a secure repository of well characterized seed stocks of BSL-3 and BSL-4 paramyxoviruses, arenaviruses, and phenuiviruses and know-how to rescue synthetic infectious clones (e.g. GhV for this U19); 2) *in vitro* antiviral activity assays; 3) procurement of UTMB IACUC approval of animal protocols; 4) procurement, housing, and husbandry of animals; 5) development and/or optimization of animal models for strains or variants of Sosuga virus (SOSV), JUNV and Ghana virus (GhV) to fill gaps where models are needed; 6) virus challenge, treatment, and collection of samples from animals; 7) technical expertise and equipment to conduct clinical pathological, immunological, and virological analysis of samples and to perform necropsies in BSL-3 and BLS-4 containment; 8) histopathological analysis of tissues collected from animals infected with BSL-3 and BSL-4 viruses; and 9) quality systems management of all records and data collected from animal studies. **Core D** will work closely with the **Administrative Core** to ensure all biosafety work is adequately monitored.

INNOVATION

Scientific Core D will be co-located within the Galveston National Laboratory (GNL) and Robert Shope Laboratory at the University of Texas Medical Branch (UTMB) at Galveston. The GNL is a high and maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda and stands ready to assist local, state, and national public health efforts in the event of a public health emergency. The facility is unique in that it is one of two operational BSL-4 facilities in the United States that is located on an academic campus. This unique location benefits the Center in several ways. Regarding physical resources, the GNL is a state-of-the-art facility with many specialized assets including BSL-4 imaging, telemetry, and aerobiology equipment. In addition, being located on an academic campus **Drs. Geisbert, Cross, Freiberg, and Ikegami (Core D**) are faculty members in the Departments of Microbiology and Immunology and Pathology. This academic environment is a major strength that fosters creativity and collaboration with other UTMB investigators, which will be beneficial to the overall success of Core D. **Dr. Broder**, is faculty member of the Department of Microbiology and Immunology at Uniformed Services University (USU). Drs. Broder and Geisbert have a long-standing emerging virus research collaboration, which has included the development and characterization of the first nonhuman primate (NHP) models for HeV and Nipah virus (NiV) that will be employed by **Projects 2, 3, 4 and 5**. Another strength within the Core is that **Drs. Geisbert, Broder, Cross, and Veesler** currently collaborate and lead active henipavirus projects focused on translational countermeasure development, which includes more traditional vaccine and mAb therapeutics approaches. Their shared knowledge base and experience in these areas will greatly enhance the Core's abilities to support the Center's research goals in experimentally testing advanced machine learning-enabled designs of effective prototype pathogen vaccines and antibodies. Along with animal model development and animal modeling expertise, many of the unique virological tools that will be employed by the Core have been developed from the UTMB-USU collaboration, including recombinantly generated RNA viruses, reporter gene-encoding viruses, and other pseudotype virus technologies.

APPROACH

Aim 1: Provide BSL-3 and BSL-4 resources including a secure repository of well-characterized seed stocks of paramyxoviruses, arenaviruses, and phenuiviruses.

Paramyxovirus, arenavirus, and phenuivirus seed stocks. UTMB will provide fully equipped BSL-3/ABSL-3 and BSL-4/ABSL-4 facilities that are required to work with HeV, SOSV, LASV, JUNV, RVFV, SFTSV and GhV. UTMB will also provide and maintain all required approvals to work with these viruses. The BSL-3 and BSL-4 paramyxovirus, arenavirus, and phenuivirus seed stocks have been or will be titered by conventional standard plaque assay and qRT-PCR as detailed in **Aim 2** below. The virus strain identity of each seed stock has been or will be confirmed through sequencing, and deep-sequencing will be used to verify the complete viral genome of each virus seed stock used for animal challenge studies. We have or will test each seed stock for mycoplasma contamination. Endotoxin testing has been or will be performed on paramyxovirus, arenavirus, and phenuivirus stocks using the Endosafe PTS system (Charles River Laboratories) following the manufacturer's instructions. The Endosafe PTS system is a cartridge-based testing system utilizing FDA-licensed cartridges for ultrasensitive testing. Seed stocks will also be evaluated for morphological identity by transmission electron microscopy (TEM). Virus particle counts will be determined using a Virus Counter and confirmed by conventional TEM methods, if needed. The bacteriological and mycological sterility of the product will be determined by selection of aliquots of the dispensed stock, inoculation of a sterile 500 ml bottle of Dulbecco's high glucose MEM with 10% FBS, and then after 3 days subcultured to FTM and TBS media. Paramyxovirus, arenavirus, and phenuivirus seed stocks will be inventoried in the UTMB BSL-4 and BSL-4 virus stock databases and secured in dedicated controlled access alarmed -80°C freezers in the GNL or Robert Shope Laboratory. Paramyxovirus, arenavirus, and phenuivirus seed stocks are monitored periodically for any changes in virus titer.

Plan for staffing, managing, and prioritizing Core use. The Core Leader and Co-Leaders have a cadre of staff that are trained and highly experienced in all BSL-3 and BSL-4 procedures and assays needed to conduct the proposed work. In addition to the Core Leader and Co-Leaders, this staff includes an ACVP board certified veterinary pathologist, two BSL-4 contributing scientists, a BSL-4 Technical Director, a BSL-4 trained postdoctoral fellow, six BSL-4 experienced technical staff, a BSL-4 trained histotechnologist, and a BSL-4 trained graduate student. We do not anticipate any BSL-3 or BSL-4 scheduling problems regarding studies proposed in **Projects 2, 3, 4, and 5**. However, we have developed a mitigation strategy if unforeseen events cause any needed prioritization of resources. A committee consisting of the Core D Leader, the PIs of the Center, and the members of the external Scientific Advisory Board (SAB) will review the status of these Projects and any circumstances necessitating a reprioritization of work. The SAB will also hold a meeting or teleconference (Zoom, Teams) with the Project Leaders and Key Personnel to gather additional information. After careful review of all available information, the SAB will then make a recommendation on prioritization to the Center PI. The Center PI will then consult with NIAID/NIH program staff and make the final determination on prioritization.

Aim 2: Provide technical expertise and conduct *in vitro* assays.

***In vitro* antiviral activity assays. Core D** will perform authentic virus neutralization assays for **Projects 2, 3, 4, and 5** to determine the ability of sera/plasma from immunized animals and mAbs to inhibit the replication of paramyxoviruses, arenaviruses, and phenuiviruses *in vitro* using infectious viruses in the UTMB BSL-3 and BSL-4 laboratories. In brief, cultures of Vero, Vero E6, SW13, or other cell types will be infected with a range of multiplicity of infection (MOI) of paramyxoviruses, arenaviruses, and bunyaviruses and subsequently treated various dilutions of sera/plasma or antibodies. Cells and/or culture fluids will be harvested at various time points after infection and infectious virus enumerated by conventional plaque assay as detailed below.

Develop chimeric reporter-gene encoding viruses and virus neutralization assays for BSL-2 use. We have previously used reverse genetics to generate several types of replication competent VSV-GFP reporter viruses including those encoding Australian bat lyssavirus (ABLV) G glycoproteins (VSV-ABLV G-GFP)[1,2], as well as employed reverse genetics to rescue authentic ABLV and various reporter gene-encoding viruses[3,4]. In addition, we have generated a reverse genetics platform for generating recombinant Cedar virus (rCedV) and rCedV chimeras, whereby the fusion (F) and attachment (G) glycoprotein genes of rCedV were replaced with those of NiV-Bangladesh (NiV-B) or HeV, generating replication competent chimeric viruses (rCedV-NiV-B and rCedV-HeV), both with and without reporter genes[4-8]. The rCedV chimeras are a replication competent authentic henipavirus platform that is a high-throughput surrogate neutralization assay that is rapid, cost-effective, and can be utilized outside high containment. Similar approaches will be applied here to generate new reporter viruses for Ghana bat virus (GhV). We will design, construct, and rescue both VSV and rCedV chimeras that encode the envelope glycoproteins (fusion (F) and attachment (G) glycoproteins) of GhV. Two reporter-gene encoding versions will be developed for VSV-GhV: one encoding GFP (VSV-GhV-GFP) and the other encoding the *Photinus pyralis* (firefly) luciferase gene (VSV-GhV-Luc). We will also construct and rescue GFP and Luc reporter gene encoding versions of rCedV chimeras encoding the GhV F and G genes (rCedV-GhV-GFP and rCedV-GhV-Luc) (**Fig. 1**). The rescued viruses will be characterized using cell-based infection tropism and growth kinetics assays.

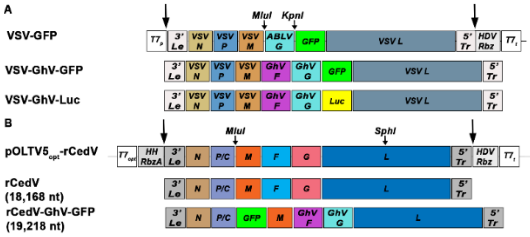

Fig. 1. Schematic of chimeric reporter viruses. (**A**)The VSV-ABLV G-GFP plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and KpnI to construct VSV-GhV-GFP and VSV-GhV-Luc. (**B**) pOLTV5$_{opt}$-rCedV plasmid. Arrows indicate regions of self-cleavage. Unique sites MluI and SphI used to construct rCedV-GhV-GFP.

The **rCedV (NiV-B and HeV) chimeric virus platform serves as a robust surrogate neutralization assay system for quantifying antibody neutralization potency of anti-NiV and anti-HeV antisera and mAbs[8].** The neutralizing potencies of several well-characterized cross-reactive NiV/HeV F and G-directed mAbs against rCedV-NiV-B-GFP and rCedV-HeV-GFP are highly correlated with those obtained using authentic NiV-B and HeV when tested in parallel by plaque reduction neutralization test (PRNT) and high-throughput quantitative assay based on the reduction of GFP foci (fluorescent reduction neutralization test (FRNT) (**Fig. 2a-b**). The **Broder, Cross, Geisbert, and Veesler labs** have previously used this platform for high-throughput characterization of neutralizing mAbs and sera collaboratively[5,49].

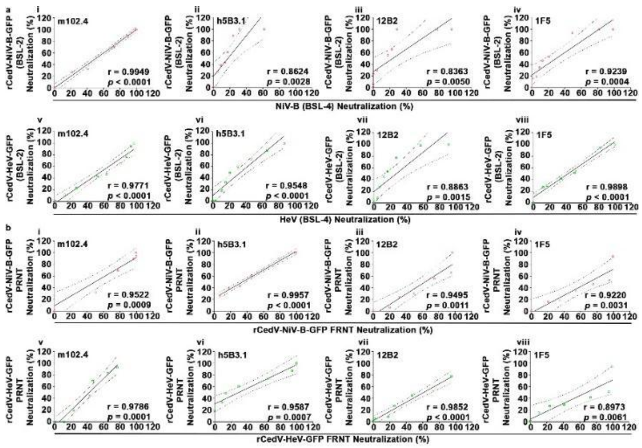

Figure 2. A) Pearson correlation for BSL-2 PRNT vs BSL-4 PRNT (rCedV-NiV-B-GFP versus NiV-B (**i-iv**) and rCedV-HeV-GFP versus HeV (**v-viii**)). **B)** Pearson correlation for PRNT vs FRNT ((rCedV-NiV-B-GFP (**i-iv**) and rCedV-HeV-GFP (**v-viii**)).

Generation of a VSV encoding GhV envelope glycoproteins. We will construct reporter gene-encoding versions of a replication-competent VSV encoding the GhV F and G glycoproteins (GFP and Luc) (**Fig. 1A)**, which are highly divergent from their HeV counterparts with which they share 55% and 30% amino acid sequence identity. A large gene cassette comprising VSV untranslated intergenic regions flanking the GhV F and G coding sequences will be synthesized. The GhV F and G coding sequences will be based on the GhV isolate Eid_hel/GH-M74a/GHA/2009 (GenBank: NC_025256.1). The GenBank accession number for GhV F is YP_009091837.1 and that for the GhV G protein is YP_009091838.1. Unique restriction enzyme sites, MluI and KpnI will facilitate the insertion of the GhV F and G gene cassette into the VSV backbone plasmid. The VSV-GhV-Luc will be similarly made. Cloning procedures are performed in *E. coli* Stbl2 and all plasmids verified by sequencing. Rescue will be performed in BSR-T7/5 cells, transfected helper plasmids, VSV-N, VSV-P, and VSV-L and the VSV-GhV-GFP or VSV-GhV-Luc antigenome plasmids. After 48hrs the cells and supernatants are collected and subjected to freeze-thawing and clarified by centrifugation. Amplification of rescued virus is performed using HEK293T cells by inoculation with the supernatant from step 1. When GFP fluorescence and/or cytopathic effects (CPE) is observed, the cells and supernatants are harvested as above, and the virus stocks stored at -80°C. All virus stocks are deep sequenced. Virus stocks are titered by serial dilution on HEK293T cells by plaque assay[9].

Generation of rCedV encoding GhV envelope glycoproteins. rCedV-GhV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the GhV F and G coding sequences. The CedV non-coding intergenic regions are retained as is adherence to the genomic "rule of six". Unique restriction sites, MluI and SphI will facilitate the insertion of the GhV F and G gene cassette into the genome clone (pOLTV5$_{opt}$-rCedV) generating rCedV-GhV-GFP (**Fig. 1B**). Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L, and pOLTV5$_{opt}$-rCedV-GhV-GFP antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (henipavirus CPE). At maximal syncytia and GFP (~2–3 days), supernatants are collected, clarified, and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C[7,10,11].

Characterization of the recombinant reporter viruses in cell-based infection assays. The replication kinetics of the VSV-based and rCedV-based GhV F/G encoding viruses will be assayed by VeroE6 cell culture infection using MOIs of 0.01, 0.1 and 1, and progeny virus recovered in several 24hr intervals and titered. VSV-GhV F/G virus replication can be compared to expected virus production of wildtype VSV or VSV-ABLV G[1]. Similarly, rCedV-GhV-GFP virus replication can be compared to rCedV or rCedV NiV/HeV chimeras. Unlike NiV and HeV, GhV G engages only the ephrin-B2 ligand to trigger membrane fusion[12]. The

GhV F/G bearing reporter viruses will be verified for this specific ephrin ligand tropism in cell infection and/or syncytia formation experiments and comparisons made to wildtype VSV or VSV-ABLV G as well as to rCedV, and rCedV NiV/HeV chimeras. The **Broder lab** has generated murine mAbs to GhV F and G (10C4-LY and 10D5-LY to GhV G; and 5B7-LY and 7C11-LY to GhV F) and these will be used in neutralization tests and assay validation. The VSV-GhV-GFP assays will be conducted by FRNTs and VSV-GhV-Luc in luciferase assays.

Rescue of a GhV infectious clone. UTMB will synthesize and rescue a GhV infectious clone, which will be propagated in VeroE6 cells and sequenced-verified. Replication kinetics will be assessed as described above and optimal infectious doses will be evaluated and determined in the hamster model based on prior work done with NiV and HeV in this challenge model[32]. All experiments will be conducted at BSL-4, as done with NiV and HeV work.

High-throughput neutralization assays. The **Veesler lab** has developed a high-throughput workflow for ELISAs and pseudovirus neutralization assays using a Biomek robotic platform enabling 24/7 automation. The neutralization assays use a safe, non-replicating vesicular stomatitis virus (VSV) encoding for luciferase instead of the native G glycoprotein or murine leukemia virus (MLV) encoding for luciferase, which we extensively used throughout the COVID-19 pandemic[54-58]. For henipaviruses, we will additionally use the chimeric recombinant CedV harboring the HeV and NiV glycoproteins developed in the **Broder lab**[5,49]. In collaboration with **Projects 2, 3, 4, and 5**, this platform will support evaluation of vaccine-elicited antibody responses to guide and iteratively refine immunogen designs against paramyxoviruses, phenuiviruses and arenaviruses, which have all been previously pseudotyped using the VSV or MLV backbones: Lassa virus[42], Junin virus[43], RVFV[44], and SFTFV[45].

Evaluation of neutralization for mAbs and vaccine-elicited antibodies. Our rCeV chimeras (rCedV-NiV-B-GFP and rCedV-HeV-GFP) will allow this Core to conduct large numbers of neutralization tests by FRNT, using vaccine-elicited sera and mAbs that will be generated in **Projects 2, 3, 4, and 5**. In Center years 1-3 the focus will be on HeV, and in years 4-5 the Core is expected to shift to GhV test case. The FRNT assay is rapid (36hrs), high throughput, and performed in 96-well plates to establish typical 7-point dose response virus neutralization data and performed at BSL-2. Typically, immune sera or mAbs are analyzed by serial dilution and mixed with virus (rCedV-NiV-B-GFP or rCedV-HeV-GFP) for 2hrs then samples used in triplicate to infect confluent Vero 76 cells in black-walled clear bottom 96-well plates and incubated 24hrs, and then plates are fixed and imaged and fluorescent foci quantitated with CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) is determined by 50% reduction in fluorescent foci versus untreated controls.

Generation and validation of neutralizing antibody titration assays using recombinant reporter phenuiviruses. We plan to generate a recombinant strain of Rift Valley fever virus (RVFV), specifically the MP-12 strain (rMP- 12), with the luciferase gene (such as NanoLuc) replacing the NSs gene utilizing our existing reverse genetics system[40,50]. By comparing the luciferase activities with the neutralizing antibody titers obtained from the plaque reduction neutralizing test[51] (PRNT), we will establish the correlation between the two assays for validation. This reporter assay will be employed for screening the antisera, while we will also perform the authentic PRNT to determine the neutralizing antibody titers of selected antisera. Additionally, we will develop a reverse genetics system for the SFTSV HB29 strain in order to establish a similar recombinant SFTSV luciferase assay. As SFTSV does not form plaques in Vero cells, we will utilize the focus reduction neutralization test (FRNT) with anti-SFTSV N antibody to determine the neutralizing antibody titers and validate the reporter assay[52,53].

Anticipated Results, Potential Pitfalls and Alternative Strategies. We anticipate the reporter viruses will replicate to titers fit for purpose based on our success with these chimeric viruses. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9. If we encounter unexpected limitations in rescuing VSV-based or rCedV-based GhV F/G bearing reporter viruses; we will 1) test different ratios of helper plasmids and antigenome plasmids; 2) perform rescue using different cell lines; 3) construct alternate versions of the GhV F and G genes within the antigenome plasmids, such as truncating the GhV G protein which has been shown to enhance GhV mediated F/G membrane fusion[13]. Alternatively, fusion of the GhV F and G ectodomains with the transmembrane and cytoplasmic tail domains of the corresponding CedV F and G elements may facilitate virus particle formation and membrane fusion activity. Reporter assays for RVFV and SFTSV will enhance the throughput of screening of antisera-containing neutralizing antibodies. If the secretion of luciferase proves suboptimal for assessing relative virus replication levels, we will evaluate non-secreting luciferases, such as Renilla luciferase, utilizing cell lysates.

Aim 3: Provide technical expertise and conduct animal challenges, vaccinations, treatments, clinical pathology assays, immunology assays, virology assays, necropsies, and histopathological analysis. The Core D Leader and Co-Leaders will work closely with the Project Leaders and key staff of **Projects 2, 3, 4 and 5** to develop vaccination, treatment and sampling regimens, study protocols, and animal protocols that utilize countermeasures identified in **Projects 2, 3, 4 and 5**. The Core Leader and Co-Leaders will write and obtain UTMB IACUC approval for all animal protocols performed in Core D. The animal models and clinical pathology, immunology, virology, and histopathology assays employed for **Aim 3** are detailed below. All raw, graphed, and tabulated data generated by Core D will be handled and analyzed in coordination with **Core B.**

Core D will employ established animal models for HeV, LASV, JUNV, RVFV, and SFTSV. While animal models exist for SOSV and JUNV we will optimize these models to fill gaps and provide new tools as detailed in **Aim 4** below. Mice, guinea pigs, hamsters, ferrets, and cats have been used as small animal models of HeV infection[14]. This project will employ Syrian golden hamsters as the small animal model of HeV disease because they are more suitable than other small animals for screening large numbers of vaccines and mAbs. Using hamsters will allow us to select optimal vaccine and mAb formulations and regimens prior to efficacy testing in NHPs. In 2010 **Drs. Geisbert and Broder** developed the first highly lethal NHP model for henipavirus infection (Nipah virus) using African green monkeys (AGM)[15]. They subsequently developed a lethal AGM model for HeV infection[16]. Henipavirus NHP models mirror human disease with animals showing severe respiratory pathology, neurological disease, and generalized vasculitis. Based on our extensive prior experience working with NiV and HeV, we will develop a hamster challenge model for GhV, which uses the human ephrin B2 receptor[59,60] (similar to NiV and HeV). For LASV and JUNV, Core D will use established lethal outbred guinea pig models that cover several lineages of LASV[17-21] and several genetically distinct strains of JUNV[22-25] as guinea pigs are the only immunocompetent small animal model for LASV and JUNV disease. Core D will also use established cynomolgus monkey models that cover several genetically distinct lineages of LASV[26-29] and strains of JUNV[30]. For RVFV we will use established mouse models (such as BALB/c and C57/BL6 mice. In addition, we will utilize the recently described ferret model to evaluate vaccine candidates and mAbs[34]. For SFTSV, we will use the interferon a/b receptor knockout mouse model[62].

Animal vaccinations. All animals will be obtained from commercial vendors and allowed to acclimate prior to vaccination (~ 3-7 days for mice, hamsters, and guinea pigs and ~ 14 days for ferrets and NHPs). Mice, hamsters, and guinea pigs will be vaccinated by intramuscular (i.m.) or intraperitoneal (i.p.) injection of the vaccines provided by **Projects 3, 4, and 5** whereas ferrets and NHPs will be vaccinated by i.m. injection. All animals will be vaccinated in ABSL-2. Animals will be monitored daily for any reaction or adverse events caused by the vaccination. Blood will be collected for plasma, serum, and PBMC isolations before vaccination and at times after vaccination for assessment of the host immune response.

Animal challenges. Hamsters and NHPs will be challenged with infectious HeV or SOSV as previously described[31-33]. After appropriate acclimation, hamsters and ferrets will be exposed to HeV or SOSV by intranasal (i.n.) or i.p. administration of virus. NHPs will be challenged with HeV by the intratracheal (i.t.) and/or i.n. routes. Mice, guinea pigs, and ferrets will be exposed to arenaviruses and phenuiviruses by i.p. injection[19,24,25,34,35]. NHPs will be exposed to LASV or JUNV by i.m. injection[28-30]. For all animals, blood will be collected with or without anticoagulants for plasma and serum isolations, respectively, before paramyxovirus, arenavirus, or phenuivirus challenge, on the day of challenge, and daily after challenge. Animals will be monitored for clinical signs daily. We will apply a scoring sheet approved by the UTMB IACUC depicted in the Vertebrate Animals Section to assist in determining the time of euthanasia depending on clinical signs (e.g., respiratory distress, anorexia, activity, appearance, neurologic signs, etc.). Animals will be euthanized according to the 2013 AVMA Guidelines on Euthanasia. Any surviving animals will be euthanized on day 35-42 days after paramyxovirus, arenavirus, or phenuiviruses challenge.

Clinical pathology assays. For NHP studies, we will measure the following parameters at time points before and after HeV, LASV, or JUNV challenge using Abaxis VetScan HM5: total white blood cell counts (WBC), percent lymphocytes (LY), percent monocytes (MO), percent neutrophils (NEU), percent eosinophils (EOS), percent basophils (BAS), total lymphocyte counts (LY#), total monocyte counts (MO#), total neutrophil counts (NEU#), total eosinophil counts (EOS #), total basophil counts (BAS #), red blood cell counts (RBC), total hemoglobin (Hgb), hematocrit values (HCT), mean cell volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red cell distribution width (RDW), platelets (PLT), and mean platelet volume (MPV), and Plateletcrit (PCT). **Clinical chemistry on serum.** The following parameters will be measured before and after viral challenge using Abaxis Piccolo chemistry analyzer: Albumin (ALB), amylase (AMY), alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), gamma-glutamyltransferase (GGT), glucose (GLU), total protein (TP), blood urea nitrogen (BUN), and creatinine (CRE), C-reactive protein (CRP), Calcium (Ca2+), and uric acid (UA).

Viral load assays. *PCR Assay:* To assess viral loads in whole blood and tissues, RNA will be extracted using a virus RNA isolation kit followed by TaqMan PCR for the viral genome being studied. Qiagen buffers have been safety-tested for inactivation of paramyxoviruses, arenaviruses, and phenuiviruses. PCR assays employed for HeV, SOSV, LASV, JUNV, RVFV, and SFTSV as previously described[28-30,33,37-39].

Plaque Assay. The plaque assays employed for paramyxoviruses, arenaviruses, and phenuiviruses have previously been described[28-30,33,40]. Briefly, 10-fold dilutions (10-1 to 10-6) of serum, plasma, or whole blood samples are prepared in cell maintenance medium (DMEM/10%FBS/gentamicin) and adsorbed to 70-90% confluent monolayers of Vero E6 cells in 6-well plates. The incubation period is followed by addition of 1% agarose-containing medium (2X EBME/Hepes/10% FBS/gentamicin) to each well. After the agarose has solidified, the plates are returned to the C02 incubator and maintained for 2-14 days until plaques are visualized. At this time, PBS containing 5% neutral red and 5% FBS is added to each well incubated overnight. The following day, the liquid stain overlay is removed from each well and plaques are counted.

Bead-based multiplex assays. Plasma inflammatory mediators, thrombosis markers, and fibrinolysis analytes will be measured by FACS using Biolegend LegendPlex assays and a FACS Canto-II cytometer (Becton Dickson). Samples will be processed in duplicate for each Nonhuman Primate Inflammation 13-plex , Human Thrombosis , and Human Fibrinolysis panel as previously described[41-43].

Gross pathology and histopathology. A necropsy will be performed on all animals. We will examine the external surfaces of the body, all orifices, and the thoracic and peritoneal cavities and their contents. Core D will prepare a written report of the gross pathology findings of each animal. The following tissues will be collected at necropsy, formalin fixed, embedded in paraffin, and stained by H&E: liver, spleen, lung, kidney, adrenal gland, pancreas, axillary lymph node, inguinal lymph node, mesenteric lymph node, duodenum, ileum, colon, brain, cervical spinal cord, urinary bladder, ovary or testis, prostate or uterus, and eye. A microscopic evaluation will be performed on H&E slides of tissues collected from all animals by an ACVP board certified veterinary pathologist. Reports of the histologic findings of each tissue from each animal will be provided to the leaders of **Projects 2, 3, 4, and 5**. In consultation with them, Core D may also perform immunohistochemical and/or special stains such as PTAH for fibrin as previously described[28-30,33].

Quality systems management of all records and data collected from animal studies. Although the animal studies conducted by Core D will not be required to be performed under GLP compliance, UTMB will provide Quality Assurance that will achieve data quality and integrity when conducting animal experiments. Quality refers to whether the study was conducted in accordance with the protocol, standard operating procedures, and applicable standards of research. Integrity refers to assurance that the raw data and documentation are consistent with reported results. All animal study personnel will be trained by the UTMB Office of Regulated Nonclinical Studies (ORNcS). on Good Documentation Practices (GDP). All animal study data generated by Core D will be provided to **Core B** as detailed in the **Core B** Research Strategy.

Aim 4: Develop and/or optimize animal models for GhV, SOSV and JUNV.

For HeV and LASV Core D will employ animal models that have already been developed and are well established[32,61]. However, while animal models exist for JUNV, RVFV, and SFTSV, there are gaps that need to be addressed. Recently, it was shown that i.n. or i.p. infection of hamsters with SOSV resulted in viremia and mild clinical disease[37] but there is no lethal model for SOSV. Core D will further explore the hamster model for SOSV by 1) using higher challenge doses of SOSV which is often required to produce lethal disease in other paramyxovirus hamster models[32,44] or 2) serial passage of tissues in hamsters (i.e., repeated passage of 10% organ homogenates until uniform lethality is achieved). Core D will also assess the pathogenic potential of SOSV in ferrets as they are often used as animal models for paramyxoviruses. For arenaviruses such as JUNV, serial adaptation is often required to produce lethal disease in outbred guinea pigs. While adapted viruses have utility in assessing the protecting efficacy of medical countermeasures in animal models, non-adapted wild type viruses are preferred to better assess vaccines and treatments. We and others recently showed that for Ebolaviruses, while serial adaptation is required to produce lethality in mice, hamsters, and guinea pigs, infection of ferrets with *Zaire ebolavirus*, *Sudan ebolavirus*, *Bundibugyo ebolavirus*, or *Reston ebolavirus* resulted in uniform lethality with wild type viruses and did not require adaptation[45-48]. Therefore, Core D will assess the pathogenic potential of JUNV in ferrets. Finally, we will investigate GhV replication and pathogenicity in hamsters which is our small animal challenge model for HNVs since both HeV and GhV utilize ephrin B2 as entry receptor[59,60], to develop a suitable challenge model.

---

Hi Tom, Bob, Chris, Alex, and Tetsuro,

Please find attached the documents we will be submitting within the next hour for Core D. The documents required some editing to fit within the required page limits and to introduce synergies with other parts of the Center.

Please let me know within the next 45 minutes or so if you see anything that needs to be fixed.

We'll report back once UW has submitted the proposal to the sponsor.

Hope everything is going well finishing up your application too!

Best,
Neil

A. Significance

Henipaviruses (HNV) and arenaviruses (ARV) are two families of viruses that pose significant global public health concerns[1-5]. HNV, which includes Nipah virus (NiV) and Hendra virus (HeV), has caused outbreaks in Asia and Australia, resulting in severe respiratory and central nervous system (CNS) illnesses in humans[6-8]. These infections have been associated with high mortality rates ranging from 40% to 90%[4,9-13]. Similarly, ARV, such as Lassa virus (LASV) and Machupo virus (MACV), can cause severe illness and death in humans, with LASV being endemic in West Africa and MACV responsible for Bolivian hemorrhagic fever[14-19]. The geographical distribution and diversity of these viruses make them a global public health threat. While there are some vaccines and antiviral drugs available[4,13,20,21], there are no licensed treatments specifically targeting these viruses. Thus, there is a pressing need to develop new therapies that can effectively neutralize and prevent the spread of these viruses.

Significance of Developing Nanobody Therapy

The urgent need for effective treatments against HNV and ARV infections, highlighted by the ongoing COVID-19 pandemic, emphasizes the importance of rapid drug development and innovative antiviral therapies. Nanobodies, also known as VHH or single-domain antibodies, derived from camelid animals, offer unique advantages that make them promising candidates for antiviral therapy[22-25].

One significant advantage of nanobodies is their inherent stability[26-28]. Their small size and single-domain structure make them highly resistant to denaturation and degradation, allowing them to maintain their binding activity under various conditions. Nanobodies also offer ease of engineering. Their single-domain format simplifies the modification and optimization of their binding properties. Through techniques such as affinity maturation and structure-guided design, nanobodies can be readily engineered to enhance their affinity, specificity, and neutralization potency against specific viral targets. This flexibility in engineering enables the development of tailored nanobodies with improved therapeutic properties[29,30].

Also, nanobodies exhibit modular characteristics[26]. Their small size and independent folding domains allow for the construction of multi-specific or bi-specific nanobodies, where different specificities can be combined into a single molecule[31,32]. This modularity opens up possibilities for targeting multiple epitopes on viral proteins or simultaneously targeting different viral strains, providing enhanced breadth and efficacy in combating HNV and ARV infections.

Combined with their specificity, small size, stability, ease of engineering, and modular nature, nanobodies represent a promising approach for developing effective antiviral therapies against HNV and ARV infections.

Three nanobody development platforms to enhance diversity and coverage

The use of multiple nanobody development platforms, including camelid animals, nanomice, and low-immunogenic human nanobody libraries (**Fig.1**), enhances the diversity and coverage of nanobody libraries, increasing the likelihood of identifying potent nanobody candidates. Notably, **Dr. Jianliang Xu**, a nanobody research expert, is **the inventor of the "nanomice" platform**[29], which was commented by *Nature News and Views* that "*Just as the development of mice with antibodies containing human variable domains (such as Regeneron's VelocImmune mouse) has helped to deliver the 100th FDA-approved monoclonal antibody, perhaps the nanomouse will give nanobody-based therapeutics a push in the same direction*"[33]. In addition, we have recently cloned the CDR regions of human antibodies (IgM, IgD, IgG1-4, IgE, IgA1-2) heavy chain from 60 healthy donors of various demographic backgrounds, assembled them on Ighv3 family framework, and generated a human nanobody library that is close to natural human antibody heavy chain variable domain. The potentially low immunogenicity of such a library will enable us to quickly identify nanobody leads that need minimum optimization for clinical use.

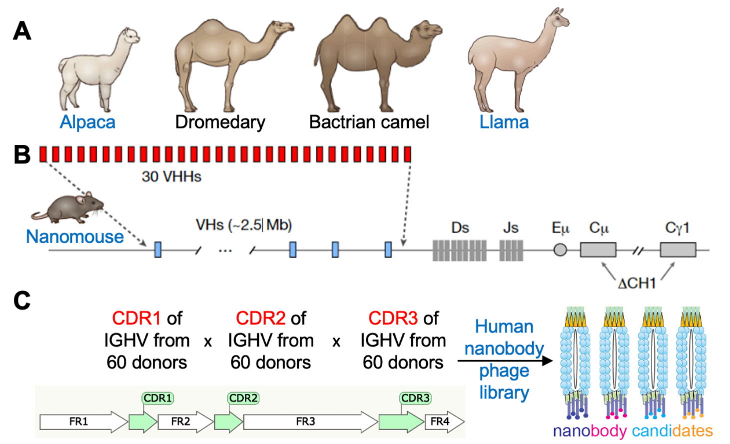

Figure 1: Three nanobody development platforms. (A) Camelid animals; (B) Nanomouse; (C) Human nanobody phage library.

The deep sequencing of antigen-specific enriched nanobody libraries ensures a comprehensive exploration of the nanobody repertoire[29], allowing for the rapid identification of leads with minimal optimization required for clinical use. This expedited development process is critical in responding to emerging viral threats and addressing the urgent need for effective antiviral therapies.

Targeting CNS diseases caused by viral infection

Nanobodies hold great promise for targeted therapy of CNS diseases as they can efficiently cross the blood-brain barrier (BBB) due to their small size[34-37]. To further enhance brain delivery, we have developed a bi-specific nanobody strategy by coupling another nanobody that targets TfR1[38,39], a receptor expressed at the BBB. This bi-specific nanobody can cross-react with both human and mouse TfR1, facilitating enhanced cargo delivery to the brain. In our upcoming study, we will compare the brain delivery and therapeutic efficacy of un-engineered nanobodies with the bi-specific nanobodies using animal models in **RP3 and Core E**. This study aims to evaluate the abilities of these two approaches to effectively penetrate the BBB and deliver therapeutic nanobodies to the central nervous system. Through this evaluation, we hope to understand the benefits of utilizing bi-specific nanobodies for targeted therapy of CNS diseases caused by HNV and ARV infections.

Generalizable research strategy

The significance of developing nanobody therapy extends beyond the four selected prototypic viruses in HNV and ARV. By applying and testing the research strategy developed in this project during **phase 2** of the project, the scope can be expanded to include other members of these viral groups, such as Langya virus (LayV)[40], Lujo virus (LUJV)[41], and Chapare virus (CHAV)[42]. This approach expands the scope of nanobody-based therapies, tackling global health risks from emerging viral diseases.

B. Innovation

The study incorporates several innovative aspects in the development of nanobody-based therapies for HNV and ARV infections:

- Utilization of diverse nanobody sources: The study leverages nanobodies derived from camelid animals, nanomice, and low-immunogenic human nanobody libraries. This approach expands the repertoire of nanobodies available for antiviral therapy development.
- Targeting viral entry machinery: Nanobodies are employed to target and neutralize viral proteins involved in viral attachment and entry. This innovative approach provides a novel avenue to inhibit viral infection at the early stages.
- Integration of structural characterization techniques: The study integrates advanced structural characterization techniques such as X-ray crystallography and Electron Microscopy Single Particle Analysis. This enables a detailed understanding of nanobody epitopes and viral neutralization mechanisms, facilitating the rational design of nanobody-based therapies.
- Development of BBB-penetrating nanobodies: The study focuses on designing nanobodies with the ability to penetrate the BBB, enabling effective targeting of the central nervous system. This is particularly relevant for combating the severe neurological manifestations associated with HNV and ARV infections.
- Generalizable research strategy: The research strategy developed in this study can be applied to other members of the HNV and ARV viral groups, such as Langya virus, Lujo virus, and Chapare virus. This expands the potential impact of nanobody therapies to address a broader range of emerging viral diseases.
- Deep sequencing for comprehensive coverage: The study utilizes deep sequencing to ensure comprehensive coverage of antigen-specific enriched nanobody libraries. This approach facilitates the rapid identification of potent nanobody leads with minimal optimization required for clinical use.
- Rapid and efficient therapy development: By leveraging the advantages of nanobodies and employing a well-designed research strategy, the study aims to rapidly and efficiently develop nanobody-based therapies. This contributes to the field of antiviral research and addresses the urgent need for effective treatments against HNV and ARV infections, thereby enhancing public health protection.

C. Approach

Scientific Premise: Our hypothesis is that nanobodies targeting viruses' key entry machinery can effectively inhibit virus infection. By utilizing structure-based analysis and rational design, we can enhance the efficacy of nanobody therapy by increasing its potency and breadth. Through the design of bi-specific nanobodies coupled with brain receptor-mediated transcytosis, we aim to enhance their ability to penetrate the blood-brain barrier, thus effectively combating central nervous system diseases caused by HNVs and ARVs.

Aim 1: To identify cross-reactive nanobodies to HNVs.

Rationale and Preliminary Data:

Envelope fusion glycoprotein F and the attachment glycoprotein G of Hendra virus (HeV) and Nipah virus (NiV) play crucial roles in host cell receptor engagement and membrane fusion, making them the main targets of neutralizing antibodies[43-46]. The high degree of similarity, approximately 80-90%, between the glycoproteins of HeV and NiV presents an attractive opportunity to identify cross-reactive neutralizing nanobodies capable of providing broad protection against both viruses[1,47-49]. To achieve this goal, we conducted immunization experiments using four groups of nanomice, with each group consisting of four mice. The mice were immunized with soluble F and G proteins of HeV and NiV, namely HeV_sF, HeV_sG, NiV_sF, and NiV_sG. These proteins, designed by **Dr. Kai Xu** and produced by our collaborator **Dr. Christopher Broder's** group, served as the immunogens[43,50,51] (**Fig. 2A**).

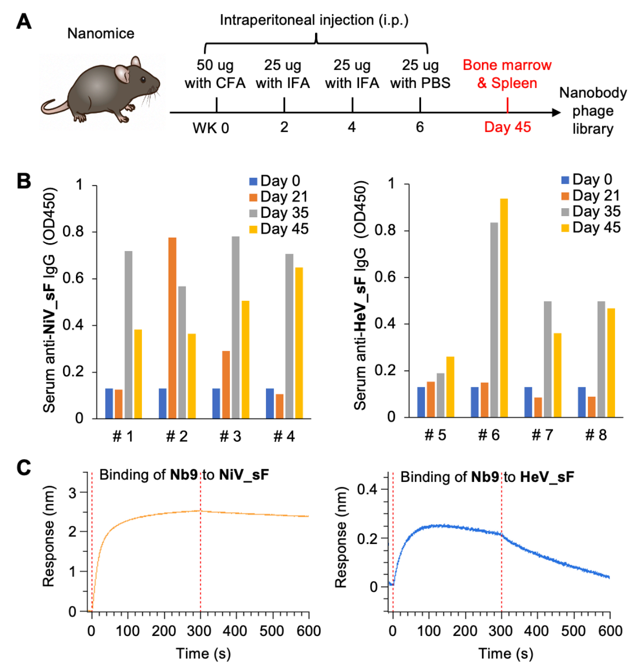

Figure 2: Nanomouse immunization and NiV_sF_Nb9 characterization. (A) Nanomouse immunization scheme. (B) HNV F proteins immunized nanomice serum response to the respective immunogen determined by ELISA; (C) Binding of NiV_sF_Nb9 to NiV_sF and HeV_sF determined by Octet.

Following four injections in the nanomice, we observed various levels of serum antibody responses against all four immunogens, as depicted in **Figure 2B** for F proteins (data for G proteins not shown). To validate our approach, we isolated RNA from the bone marrow and spleen of mice immunized with NiV_sF and constructed nanobody phage libraries. Through a series of three rounds of phage panning using NiV_sF, subsequent individual colony picking, ELISA screening, and Octet affinity validation, we successfully identified several nanobody binders specific to NiV_sF. Of particular significance, one of the identified nanobodies, NiV_sF_Nb9, exhibited the ability to bind not only to NiV-sF protein but also to HeV-sF protein (**Fig. 2C**). This finding suggests that NiV_sF_Nb9 recognizes an epitope shared by the F proteins of both NiV and HeV. The results obtained from these experiments clearly demonstrate the potential of nanomice as a convenient and efficient model for the development of nanobodies. Consequently, we are confident in our ability to identify nanobodies against other F/G proteins of HeV and NiV using the same approach applied to the immunized mice.

In addition to the nanomice immunization strategy, we have also made significant progress using a **human library version 1.0 (Fig. 1C)** for screening purposes. Notably, we sequentially screened this human nanobody library with spikes of omicron variants (BA.4/5, BA.1) and WA-1, leading to the enrichment of numerous nanobody candidates. Among them, nine nanobodies exhibited binding affinity to the receptor-binding domain (RBD) of BA.4/5, BA.1, WA-1, SARS, and WIV16, indicating their ability to recognize a range of sarbecoviruses (**Fig. 3**). Importantly, all nine of these human nanobodies demonstrated potent neutralization against WA-1, and five of them exhibited cross-neutralization of Omicron subvariants (BA.4/5, BQ.1.1, XBB.1), SARS1, and Bat-WIV1. These results underscore the power and versatility of the human nanobody library platform, which holds significant potential for targeting various other antigens.

human nanobodies	WA1	Omicron (BA.4/5)	SARS1	Bat-WIV1	BQ.1.1	XBB.1
CoV2.hNb3	0.056	9.1	0.2	30.0	16.4	17.9
CoV2.hNb6	0.027	4.5	0.3	33.1	17.9	19.8
CoV2.hNb17	0.228	16.3	0.8	20.9	44.7	21.2

Figure 3: SARS-CoV-2 neutralizing nanobodies identified by human nanobody library. Neutralization IC50 (ug/ml) of 9 human nanobodies against various pseudotyped sarbecoviruses.

Experimental Design:

To expand our search for cross-reactive nanobodies against HeV and NiV glycoproteins, we will immunize additional groups of nanomice sequentially with either HeV or NiV F or G proteins. Each group will serve as a source for constructing *in vivo* matured nanobody phage libraries, using bone marrow, spleen, and/or peripheral blood mononuclear cells (PBMCs). These libraries will undergo sequential screening with HeV and NiV F or G proteins to identify nanobodies that exhibit cross-recognition of the F or G proteins of both viruses. To ensure comprehensive coverage of potential binders, we will employ a two-pronged approach. Firstly, we will randomly pick colonies from the libraries, and secondly, we will subject the enriched libraries to deep sequencing using the MiSeq platform. This approach will enable us to identify nanobody candidates from all complementarity-determining region 3 (CDR3) families. Subsequently, we will assess the target specificity of individual nanobodies through enzyme-linked immunosorbent assay (ELISA). Moreover, the neutralization activity of the identified nanobody candidates will be evaluated using RP2 assays.

While nanomice have proven to be valuable for generating in vivo matured nanobodies, it is important to consider the potential immunogenicity associated with animal-derived nanobodies. Therefore, in parallel with the nanomice immunization strategy, we will also screen for F or G protein binders using a human nanobody library. By utilizing the human nanobody library, we can significantly minimize the risk of immunogenicity and obtain nanobody candidates that are better suited for therapeutic testing in human subjects.

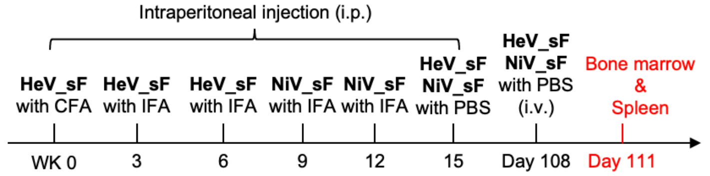

Figure 4: Nanomice sequential immunization scheme for HNV F proteins.

1.1: Nanomice immunization. Four groups of nanomice have already been immunized with soluble HNV F and G separately. Our preliminary data showed that almost all mice developed good immune response after 3 injections. We will next immunize 2 more groups, 8 mice each, sequentially with HNV F or G proteins (**Fig.4**). Injections (i.p.) will be performed at 3 weeks interval to allow more time for mouse immune system to react to each immunization. Specifically, for F proteins, mice will be immunized with HeV_sF at week 0, 3, 6, NiV_sF at week 9, 12, and a mixture of HeV_sF and NiV_sF at week 15, followed by a final boost (i.v.) with HeV_sF and NiV_sF mixture 3 days later. Bone marrow, spleen and PBMCs will be harvested 3 days after the final i.v. injection. HeV_sG and NiV_sG proteins immunization will follow the same scheme. Test blood/serum will be collected one week after each injection except for the first and last two injections, and serum antibody response to F or G proteins will be monitored by ELISA. The same serum will be used for HNV neutralization test by RP2.

1.2: Nanobody phage library construction. We have extracted RNA from bone marrow and spleen from NiV_sF immunized mice, constructed nanobody phage library, screened for NiV_sF binders, and identified NiV_sF_Nb9 to be NiV_sF and HeV-sF cross binder (**Fig.2**). We will complete the nanobody phage library construction for all immunization groups and perform sequential screening to identify cross binders. Specifically, total RNA will be extracted from bone marrow, spleen and PBMCs from the best responding mice based on ELISA and neutralization test results. Two-step PCR will be performed to amply VHH-DJ (nanobody sequence) from the matured heavy chain-only IgG1 mRNA molecules (**Fig. 5**). First, we will amplify VHH-DJ-CH2 domain from IgG1 using 30 forward primers aligning to the leading exons of 30 VHH genes and one reverse primer aligning to CH2 sequence of IgG1. Next, a mixture of 30 forward primers aligning to 5' end of individual VHH exon and 4 reverse primers aligning to JH1~4 will be used to amplify nanobody sequences, which will be cloned to pMES4 phagemid and subsequently transformed to TG1 E.coli cells.

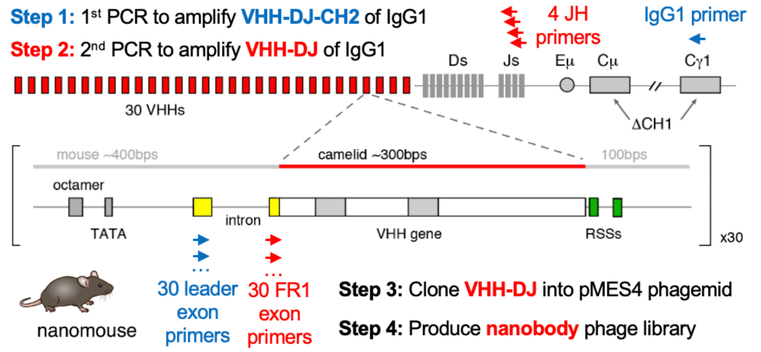

Figure 5: Nanobody phage library construction with nested PCR.

1.3: Screening nanobody libraries for HNV F/G binders. We will produce phages expressing individual nanobodies fused to their coat protein by infecting TG1 cells with VCSM13 helper phages. To identify nanobodies that recognize both HeV_sF and NiV_sF, libraries from F proteins immunized mice will be sequentially screened with HeV_sF and NiV_sF proteins in wells of 96-well Maxisorp plate; to identify nanobodies that recognize both HeV_sG and NiV_sG, libraries from G proteins immunized mice will be sequentially screened with HeV_sG and NiV_sG proteins. Multiple rounds of screening (phage panning) will be performed to ensure ideally over 100 times elution of phages from F or G protein coated wells than control wells (**Fig. 6A**). For each TG1 cell sub library from single or sequential F or G protein screening, 96 ~192 individual colonies will be picked and cultured in deep-well plates. Nanobodies (fused to phage coat protein pIII) induced by IPTG will be extracted from

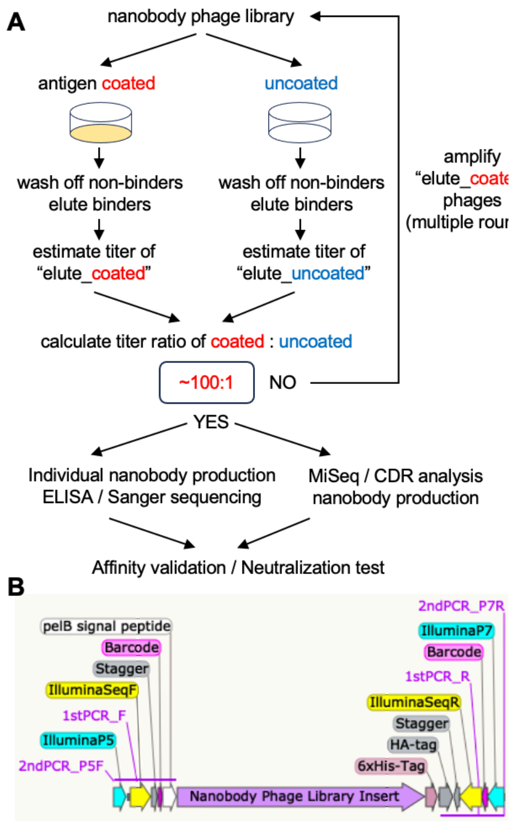

Figure 6: Phage screening, sanger sequencing, and MiSeq sequencing. (A) Nanobody phage screening strategy. (B) MiSeq sequencing library preparation. 1st round PCR will attach MiSeq F/R sequences to nanobodies, and 2nd round PCR will introduce P5/P7 adaptors to amplicon 5' and 3' ends.

periplasmic region of TG1 cells and tested for binding to HNV F or G proteins by ELISA. Phagemid of ELISA positive clones will be extracted and Sanger sequenced, and then transformed into WK6 E.coli cells to produce individual nanobodies (monomer, 13 kDa). In addition, sub libraries will be deep sequenced (**Fig. 6B**) and nanobody sequences analyzed as described before[29]. Nanobodies will be clustered based on their CDR3 differences and cross checked with the sequences of ELISA-positive clones. Representative unique nanobodies from each CDR3 class will be codon optimized and synthesized, cloned into pMES4 phagemid, and nanobodies will be produced in WK6 cells. <u>We will perform step 1.3 with our newly designed and constructed human nanobody library to identify less immunogenic nanobodies against HNV F and G protein.</u>

1.4: Nanobody binding validation and neutralizing activity assessment. To validate the binding of nanobodies to HNV F/G proteins, we will employ two methods: ELISA and Octet Bio-Layer Interferometry (BLI) affinity analysis. ELISA will allow us to determine the binding of nanobodies to the target proteins, while Octet BLI will provide detailed information on affinity. Additionally, we will perform Octet epitope binning assays using available F/G antibodies to map the epitopes recognized by the nanobodies. Furthermore, we will assess the neutralizing activity of the identified nanobodies with the neutralization assay developed by **RP2**[52,53]. These comprehensive analyses will enable us to evaluate the binding specificity, affinity, and neutralizing capability of the nanobodies. We will further select representative neutralizing nanobodies for structural analysis (**Aim 3**) and consider various engineering approaches such as Fc conjugation and multimerization (**Aim 4**) to further optimize the properties and efficacy of the nanobodies.

<u>Expected results, potential pitfalls and alternatives:</u>

We expect to be able to produce 5-10 HNV F or G nanobodies that either specifically recognize and neutralize HeV or NiV, or cross-bind to HeV and NiV proteins and cross neutralize the two viruses. We also expect to identify nanobodies with novel epitopes compare to currently available human antibodies.

Based on our success in identifying HeV_sF and NiV_sF cross binder (NiV_sF_Nb9 from nanomouse immunization) and SARS-CoV-2/SARS/WIV1 cross neutralizers (hNb3, 6, 17, 18 and 31 from human nanobody library screening), we do not anticipate any major technical or methodological pitfalls. While we have high expectations for our study, there are potential pitfalls that we need to consider. One challenge could be the limited number of nanobody candidates that meet our criteria, particularly if their affinity or neutralizing activity is not optimal. In such cases, we have a strategy in place to perform in vitro PCR-based CDR maturation to generate nanobody variants with improved properties. Additionally, there is a possibility that our efforts to identify HNV F or G cross binders/neutralizers using nanomice or the human nanobody library may not yield satisfactory epitope diversity. To overcome this limitation, an alternative approach would involve immunizing camelid animals and applying the same selection and screening processes to identify target-specific nanobodies.

Aim 2: Identification of nanobodies to ARVs.

***<u>Rationale and Preliminary Data</u>*:**

The surface of LASV and MACV virions is covered by the heavily glycosylated trimeric type-1 fusion glycoprotein precursor (GPC)[54-57]. The GPC trimer consists of receptor-binding GP1, fusion machinery GP2, and the associated stable signal peptide (SSP)[57-62]. The extensive glycan shield on GP1 and GP2 poses a challenge for the immune system to generate a robust GPC-directed antibody response, resulting in weak and inconsistent neutralizing antibody development during natural infection[63-67]. Only a few LASV-neutralizing antibodies have been isolated from convalescent patients to date[68]. While LASV GPC has shown neutralizing response in rabbit and guinea pig studies, serum neutralization has not been achieved in mouse models[69-71]. In contrast, MACV neutralizing antibodies have been successfully isolated from GPC immunized mice[72]. However, there are currently no FDA-approved treatments or vaccines for LASV or MACV infections. In our study, we aim to leverage the small size of nanobodies to develop glycan shield-penetrating neutralizing nanobodies against LASV and MACV.

In our experiments, we immunized 8 nanomice with a stabilized LASV GPC trimer, following a modified scheme. We performed an intravenous boost injection on day 45 and harvested bone marrow and spleen on day 48. With one mouse accidentally died on day 46, 7 mice remain. Over time, 6 out of 7 mice developed an antibody response against GPC, reaching their highest titers on day 48 (**Fig.7**). Importantly, the serum from nanomouse #3 on day 48 showed weak but detectable neutralization activity against LASV Josiah strain. These findings demonstrate the potential of nanomice as a valuable model for developing neutralizing nanobodies against LASV and MACV.

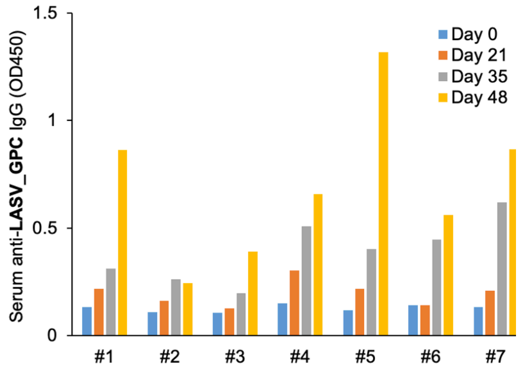

Figure 7: Antibody response aginst LASV GPC in immunized nanomice sera.

Experimental Design:

We will construct nanobody phage library using the top responders from the LASV immunized nanomice, with a particular focus on nanomouse #3 due to its detectable neutralization activity. We will immunize nanomice with alternative versions of soluble stabilized trimeric LASV GPC and MACV GPC proteins **provided by RP1** and construct *in vivo* matured nanobody phage libraries. These libraries and the human nanobody library will be screened with GPC proteins to identify nanobody binders. Individual nanobodies will be assessed for target specificity by ELISA and Octet, and neutralization activity of nanobody candidates will be **evaluated by RP1**.

2.1: Nanomice immunization and nanobody phage library construction. In our previous LASV GPC immunization attempt, 1 out of 8 nanomice developed serum neutralization titer at day 48. We will immunize two groups of nanomice separately with LASV GPC or MACV GPC designed by RP1 with slightly modified immunization regimen. For both LASV and MACV, injections (i.p.) will be performed once every 3 weeks, and test blood/serum will be collected one week after each injection except for the first injection. Serum antibody response to GPC proteins will be monitored by ELISA and send to RP1 for neutralization test. Immunization (i.p.) will stop until serum neutralization titer is observed, or the 6th injection is performed on week 15. Three days after a final boost (i.v.), bone marrow, spleen and PBMCs will be harvested for nanobody phage library construction following the same strategy listed in Aim1.

2.2: Screening nanobody libraries for LASV GPC or MACV GPC binders. Nanobody phage library screening using LASV GPC or MACV GPC will be performed for multiple rounds until the ideally 100:1 ratio of eluted phages from coated vs uncoated wells is achieved. We will carry out random colony picking followed by ELISA and Sanger sequencing, as well as Miseq for comprehensive analysis of enrich sub libraries. Same screening will be applied to human nanobody library too. 13 kDa nanobody candidates will be produced in WK6 cells for further tests.

2.3: Nanobody binding analysis and neutralizing activity assessment. Individual nanobodies will be validated using ELISA and Octet assays to confirm their interaction with GPC proteins. Precise affinity will be measured by BLI method. Epitope competition mapping and binning will be performed using known human/mouse GPC antibodies. Nanobodies with positive binding will be evaluated for neutralization activity by **RP1**.

***Expected results, potential pitfalls and alternatives*:** We expect to be able to produce 5-10 LASV or MACV neutralizing nanobodies targeting GPC proteins. The monoclonal antibodies that are currently known to have LASV neutralizing activity are categorized into four competition groups: GP1-A, GPC-A, GPC-B, and GPC-C[68]. We expect to identify LASV neutralizing nanobodies lie within these 4 groups. Given the small size of nanobodies and their potential to target hidden epitopes, we also expect to identify novel epitopes of vulnerability on LASV and MASC GPC surface. Even though the immunogenicity of LASV GPC seems to be very poor in mouse, nanomouse #3 developed serum neutralizing response to LASV Josiah strain. Furthermore, a nanobody neutralizer D5 was identified by screening the same LASV GPC with a naïve llama nanobody library[69]. Therefore, we do not anticipate any major technical or methodological pitfalls with nanomouse and human nanobody library platforms. However, if we are unsuccessful at isolating LASV/MACV binders and neutralizers using nanomice or human nanobody library, we will immunize camelid animals instead. We have a standing by llama from Capralogics Inc. ready for immunization. In the past a few years, we have immunized this animal with HIV envelop trimer, SARS-CoV-2 spike and HMPV F proteins, and all three studies led to the identification of potent nanobody neutralizers against these virus targets. We expect this llama will perform well against LASV and MACV. If our selected nanobody candidates are less-than-optimal, *in vitro* PCR-based CDR maturation will be performed and nanobody variants with improved activity will be screened.

Aim 3: Structural characterization.

Rationale and Preliminary Data.

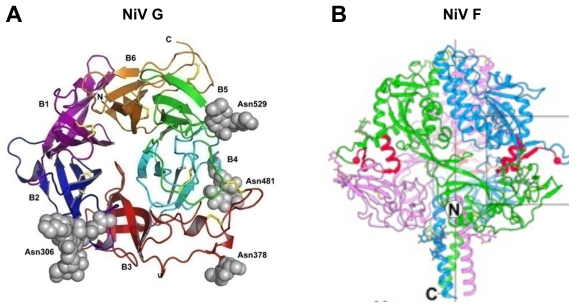

Figure 8: Structures of NiV G and F glycoproteins by X-ray crystallography. (A) NiV G head domain; (B) NiV F in the native prefusion conformation.

Dr. Kai Xu is a distinguished researcher with a proven track record in the structural determination of Henipavirus (HNV) glycoproteins and their complexes with receptors and monoclonal antibodies[50,73-75]. Notably, he achieved a significant milestone by determining the first crystal structures of the Nipah virus (NiV) G protein head domain and NiV F protein in the prefusion conformation (**Fig.8**). Moreover, Dr. Xu possesses exceptional expertise in designing HNV protein constructs that faithfully present their native conformation[43,74]. This capability enables him to create accurate representations of HNV glycoproteins, facilitating a deeper understanding of their functional properties and enabling investigations into their interactions with receptors and antibodies[51,76,77]. With his comprehensive skill set in protein design and structural determination, Dr. Xu stands as a leading authority in the field of HNV research.

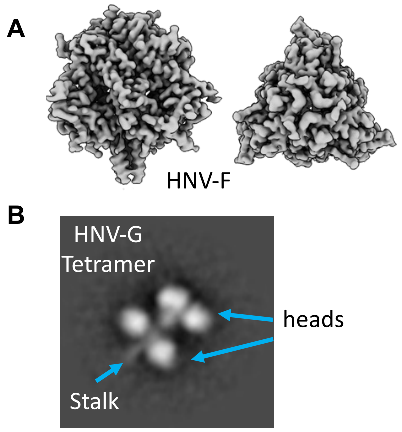

Figure 9: Validation of HNV F and G protein used in this study by EM single particle analysis. (A) Orthogonal views of HNV F protein cryo-EM 3D reconstruction at 2.5 A resolution; (B) 2D analysis of HNV G protein tetramer.

Our proposed research is driven by the need to present the native conformation of viral antigens, which is essential for antigenicity, immunogenicity, and the induction of protective immune responses. Glycoproteins of HNVs and ARVs are particularly prone to conformational flexibility, resulting in sample heterogeneity. To overcome this challenge, our preliminary data demonstrate the feasibility of creating viral antigens that display their native protein conformation. We have successfully stabilized viral antigens in their native states by designing prefusion conformation stabilizing mutations and incorporating specific stabilizing tags, such as GCNt and GCN4, to F and G proteins, respectively[50,73] (described in **RP1, 2 and Core D**). This stabilization approach has been validated through structural analysis (**Fig.9**), biochemical and biophysical characterization, and functional assessments, including receptor binding and the induction of neutralizing antibody responses.

Additionally, we have extensive experience in determining high-resolution structures of nanobodies in complex with viral antigens, such as SARS-CoV-2 spike proteins[29] (**Fig.10**). Leveraging advanced structural and functional characterization techniques such as X-ray crystallography, cryo-electron microscopy, and binding assays, we aim to unravel the detailed structural features and functional properties of the native-like viral antigens. This comprehensive understanding will provide critical insights into the interactions between antigens and antibodies, as well as the mechanisms of immune recognition. Ultimately, this knowledge will guide the rational design of effective vaccines and therapeutics targeting viral infections.

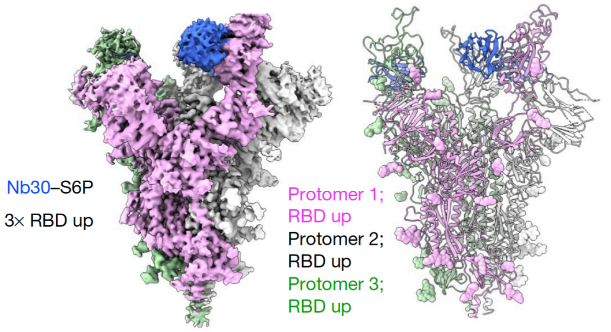

Figure 10: Cryo-EM single particle analysis of broadly protective nanobody against SARS-CoV2. 2.6 Angstrom high-resolution cryo-EM map (left) and structural model (right) of nanobody in complex with SARS-CoV2 spike protein.

Experimental Design:

Our experimental design aims to understand how nanobodies neutralize HNV and ARV viruses by analyzing their structure and interactions. Using X-ray crystallography and EM methods, we will determine the structures of nanobody-viral glycoprotein complexes, providing insights into their binding. Additionally, we will employ structure-based mutagenesis techniques to investigate the impact of specific mutations on viral entry and neutralization **in RP1 and 2**. By combining these approaches, we will gain detailed knowledge of nanobody epitopes and their interactions, contributing to the development of antiviral therapeutics for HNV and ARV.

3.1. Structural basis of nanobody cross-neutralization of both NiV and HeV. To determine the structure of the NiV or HeV F or G protein complexed with cross-neutralizing nanobodies, a series of steps will be undertaken. Initially, the NiV and HeV F and G proteins will be prepared in their native prefusion conformation by **Core D**. Subsequently, the purified nanobodies will be incubated with the F or G proteins to form stable complexes, optimizing the incubation conditions. High-resolution structures of the F or G protein complexes bound to the cross-neutralizing nanobodies will be determined using both X-ray crystallography and cryo-EM single particle analysis. Epitope analysis, including sequence analysis to identify conserved regions between the NiV and HeV F proteins, will provide insights into the potential neutralization mechanism. Additional experiments, such as site-directed mutagenesis, binding assays, and functional studies, will be conducted to validate the interaction between the nanobodies and the F proteins, confirming the importance of specific residues and regions identified in the structural analysis. Notably, a negative stain electron microscopy (ns-EM) analysis of a cross-neutralizing nanobody targeting both HeV and NiV G protein head domain has been performed, employing a compatible monoclonal antibody hAH1.3 to enhance particle 2D alignment (**Fig.11A**) and 3D reconstruction (**Fig. 11B**). This study demonstrates the feasibility of obtaining high-resolution cryo-EM structures. Ultimately, this study will yield crucial insights into the molecular mechanisms of neutralization and facilitate the development of effective antiviral therapies against HNVs.

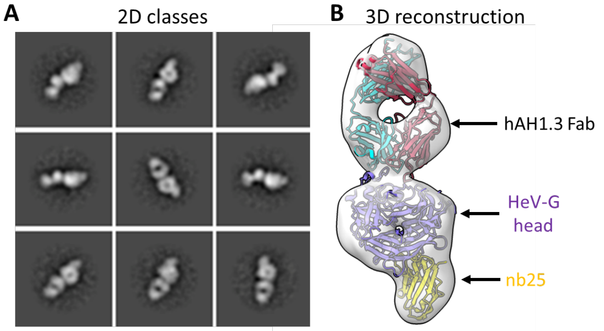

Figure 11: Anti-HeV-G nanobody epitope mapping by ns-EM analysis. (A) 2D classification; (B) 3D reconstruction showing a ternary complex of HeV-G head domain with a murine neutralizing antibody hAH1.3 and a nanobody nb25.

3.2. Structural analysis of LASV or MACV GPC proteins in complex with neutralizing nanobodies*.* The arenavirus glycoprotein precursor (GPC) proteins are key components of the viral envelope and play a crucial role in the entry and infection process of arenaviruses[78-80]. Arenaviruses are a family of RNA viruses that can cause severe diseases in humans, including hemorrhagic fevers[81,82]. The GPC proteins are synthesized as a single polypeptide chain, which undergoes post-translational processing to generate mature glycoproteins. The mature glycoproteins consist of two subunits, GP1 and GP2, that are responsible for receptor recognition and membrane fusion, respectively. The GP1 subunit is involved in receptor binding and determines the host tropism of the virus, while the GP2 subunit mediates membrane fusion between the viral envelope and host cell membrane. The GPC proteins are highly immunogenic and are targets for neutralizing antibodies. Understanding the structure and function of ARV GPC proteins is essential for developing effective antiviral strategies and vaccines against arenavirus infections. To investigate the structure of LASV and MACV GPC complexed with nanobodies using EM and X-ray crystallography, the experimental procedure involves preparation of stabilized GPC constructs, such as GPCysR4 and GPCysRRLL by **Core D**[58,83,84]. These constructs, developed with specific mutations, have been extensively used in structural studies of GPC-neutralizing antibodies. The purified GPC constructs are then mixed with the nanobodies of interest to form stable GPC-nanobody complexes. Cryo-EM analysis is performed by preparing cryo-EM grids, imaging them using a cryo-electron microscope, and generating a 3D reconstruction of the complex. X-ray crystallography is employed to crystallize the GPC-nanobody complex, collect diffraction data, and determine the crystallographic structure. The obtained structures are analyzed to identify nanobody-viral glycoprotein interactions and understand neutralization mechanisms. This combined approach provides valuable insights into the complex structures and guides the optimization of nanobody-based antiviral strategies.

Expected results, potential pitfalls and alternatives:

We anticipate that our research efforts will result in the generation of high-resolution structures of nanobody-antigen complexes, providing detailed insights into the precise epitope information and neutralization mechanisms. However, obtaining high-quality crystals suitable for X-ray analysis can be a challenging task. We are aware that extensive optimization of crystallization conditions may be necessary to promote crystal formation. To overcome this potential pitfall, we will employ various strategies and screening methods to enhance crystal quality and obtain the desired structural information. The conformational flexibility and heterogeneity of viral antigens and their complexes pose another challenge. In such cases, cryo-EM SPA can serve as a valuable alternative to X-ray crystallography. Through the application of computational algorithms, we can classify different particle conformations and extract high-resolution structural information from cryo-EM data. This approach will provide valuable insights into the structural features and dynamics of the viral antigens, despite their inherent flexibility. While our GPC stabilization strategy is primarily derived from LASV antigens, it may not be equally effective for MACV antigens due to their distinct structural and stability characteristics. As an alternative approach, we propose co-expressing MACV GPC with specific antibodies or nanobodies that can assist in stabilizing the native conformation of the antigens. This co-expression strategy will enhance the structural integrity of MACV antigens, enabling their characterization using various structural biology techniques.

Aim 4: Enhancing efficacy and CNS bioavailability of nanobodies.

Rationale and Preliminary Data.

Our aim is to enhance the therapeutic efficacy of nanobodies through engineering strategies. We will achieve this by extending the half-life of nanobodies, enhancing their interaction with immune effector cells, and increasing their binding avidity and neutralization potency. In addition, we will focus on improving the therapeutic effectiveness and availability of nanobodies within the CNS. The BBB presents a challenge in delivering therapeutic substances to the brain and spinal cord[85,86]. This barrier, formed by specialized brain capillary endothelial cells, tightly regulates the passage of molecules into the CNS, limiting the transport of drugs and antibodies[87-89]. Nanobodies, with their small size, show promise for targeted therapy of CNS diseases as they have demonstrated the ability to cross the BBB in recent studies[34-37]. In Aim 4, our research focuses on enhancing the therapeutic effectiveness and availability of nanobodies within the CNS, specifically for addressing viral infections that affect the CNS. We propose utilizing receptor-mediated transcytosis (RMT) as a strategy to facilitate the transport of nanobodies across the BBB[90,91]. RMT has emerged as a promising approach for delivering biologics, including antibodies, to the CNS[92]. RMT involves targeting specific receptors or transporters on brain capillary endothelial cells to enhance the uptake of nanobodies into the CNS. By engineering bi-specific nanobodies to selectively bind to these receptors or transporters, we can improve their transport across the BBB.

Our goal is to optimize the targeting and transcytosis efficiency of nanobodies through RMT, thereby improving their delivery and distribution within the CNS. This optimization will ultimately enhance the therapeutic efficacy of nanobodies in combating viral infections and CNS-related diseases.

Table summarizes pseudovirus neutralization potency of selected nanobodies. Values given in molarity and ng/ml.

Experimental Design:

4.1. Generate nanobody Fc-fusion and tri-valent nanobodies*:* In our previous study focusing on SARS-CoV-2 nanobody therapy development, we successfully implemented two crucial engineering strategies: Human IgG1 Fc fusion and nanobody multimerization[29] (**Fig.12**). These strategies have shown significant advancements in improving the effectiveness of nanobody-based therapeutics.

To extend the half-life of nanobodies, we incorporated Human IgG1 Fc fusion through a flexible hinge region (**Fig.12A**). This fusion strategy substantially increased the duration of nanobody activity within the body by improving their stability and protection against degradation. The Fc region of the antibody played a crucial role in enhancing the therapeutic effect by providing enhanced durability. Furthermore, we designed nanobody multimers, specifically tri-valent structures, to enhance the binding affinity (**Fig.12B**) and neutralization potency of the nanobodies (**Fig.12C and D**). The multimeric arrangement allowed for stronger and more effective binding interactions with the target viral proteins, leading to improved neutralization of the virus and ultimately enhancing the therapeutic efficacy of the nanobodies.

Our experimental strategy involves extending the half-life and enhancing the therapeutic efficacy of our top nanobody candidates through the generation of nanobody Fc-fusion proteins and tri-valent nanobodies. To extend the half-life, we will fuse the Fc region of IgG1 to the nanobodies using either the human or mouse IgG1 hinge region or the llama IgG2a hinge region, taking advantage of the FcRn-mediated recycling process and stability conferred by these hinge regions, respectively. For the generation of nanobody trimers, we will design rational linkers based on structural information of viral glycoproteins and the approaching angle of nanobody recognition. This will ensure proper orientation and spatial arrangement of the nanobodies within the trimeric structure, leading to increased avidity, binding affinity, and improved target engagement. By implementing these strategies, we aim to enhance the stability, therapeutic potential, and neutralization potency of our nanobodies, ultimately contributing to the development of more effective therapeutic interventions against viral infections.

4.2. Design multi-specific nanobodies by combining nanobodies with non-overlapping epitopes: In this aim, we will design nanobodies that target distinct and non-overlapping epitopes on the viral glycoproteins. These nanobodies will be linked together in a tandem fashion to create a synergistic effect, enhancing their overall binding affinity and neutralization potency against the target viruses. The design of these multi-specific nanobodies will involve careful consideration of the orientation and flexibility of the linker regions, ensuring optimal cooperative binding properties. Through this approach, we aim to create a robust and comprehensive neutralizing response against viral infections, ultimately advancing the development of more effective therapeutic interventions. (**Fig.13A**)

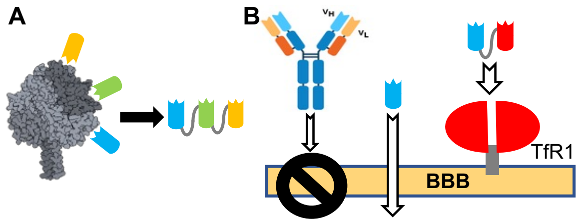

Figure 13: Bi-specific and multi-specific nanobody engineering. (A) Combination of epitope specificities to enable synergy, (B) Bi-specific nb with TfR1 specificity to improve brain targeted delivery.

4.3. Design Bi-specific nanobody by coupling with TfR1-targeting specificity to facilitate CNS delivery: In this aim, we will explore the incorporation of TfR1-specific nanobodies to enhance the delivery of nanobodies to the CNS (**Fig.13B**). The high expression of TfR1 on the blood-brain barrier makes it an attractive target for facilitating CNS delivery. To improve the penetration of nanobodies across the blood-brain barrier and enhance their bioavailability within the CNS, we will design bi-specific nanobodies by genetically fusing our candidate nanobodies against highly pathogenic neurotropic HNVs or ARVs with TfR1-specific nanobodies. By combining the targeting specificity of both nanobodies, we aim to achieve enhanced CNS delivery and therapeutic efficacy. We will evaluate several published TfR1-specific nanobodies, including FC5, a camelid single-domain antibody with known sequence[93]. FC5 has demonstrated the ability to transcytose across the blood-brain barrier and effectively deliver bioactive molecules to the CNS[36,94,95]. With its cross-reactivity across species and strong binding affinity to brain endothelial cells, FC5 holds promise for enhancing the CNS delivery of our nanobodies.

4.4. Efficacy test in both in vitro neutralization assay and animal studies. We will assess the efficacy of the original nanobodies identified in aims 1 and 2 and compare them with the engineered nanobodies in both *in vitro* neutralization assays and animal studies. Our goal is to evaluate the performance of the engineered nanobodies and determine their potential for therapeutic applications. The *in vitro* neutralization assays will assess the ability of the nanobodies to neutralize the target viruses, providing valuable insights into their antiviral potency. By measuring the reduction in viral replication or the inhibition of viral entry, we can determine the neutralization potency of the nanobodies. This will provide valuable insights into their antiviral activity and effectiveness. To further evaluate the efficacy of the nanobodies *in vivo*, we will utilize the rCedV-NiV-B chimera mouse model at the Uniformed Services University (USU) **in RP3** for HNVs, as well as animal models of ARVs developed at the University of Texas Medical Branch (UTMB) in **Core E**. These animal models will allow us to assess the therapeutic efficacy of the original and engineered nanobodies in terms of nanobody brain delivery efficiency, viral load reduction, disease progression, and overall survival rates. By comparing the outcomes between the two groups, we can determine the superiority of the engineered nanobodies in terms of therapeutic effectiveness.

Through these comprehensive in vitro and in vivo evaluations, we aim to demonstrate the improved efficacy of the engineered nanobodies compared to the original nanobodies. This assessment will provide crucial data for further development and optimization of nanobody-based therapeutics targeting HNVs and ARVs, with the ultimate goal of improving patient outcomes and combating viral infections.

<u>Expected results, potential pitfalls and alternatives</u>:

We anticipate that the design of tandemly linked nanobodies will result in enhanced neutralization potency and viral inhibition. The incorporation of a hinge and Fc region is expected to improve the half-life and stability of nanobodies, increasing their therapeutic potential. Coupling with TfR1-specific nanobodies is likely to improve brain delivery efficiency. However, potential pitfalls of using VHH FC5 as bi-specific nanobodies include short half-life due to susceptible to proteolytic degradation, thus limiting its development for clinical use. Alternative strategies, such as utilizing alternative receptor targeting or seeking to identify an antibody that binds to the same epitope, but that is derived from a fully human antibody library and has the requisite properties for clinical development, will be explored if necessary. Overall, these enhancements in efficacy and CNS bioavailability of nanobodies will significantly contribute to the development of potent antiviral therapies against CNS infections.

Aim 5: Expanding to other members of the viral groups.

<u>Rationale</u>

Building upon the valuable insights and progress achieved in Aims 1-4, Aim 5 aims to expand our nanobody-based therapeutic approach to target other members of the HNV and ARV in the **2nd phase** of this project. This expansion is based on the premise that the knowledge gained from studying NiV, HeV, LASV, and MACV can be extrapolated to other related viruses within these groups.

<u>Experimental Design:</u>

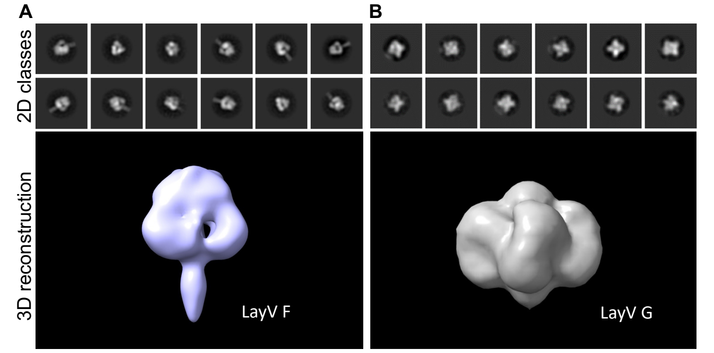

Figure 14: LayV F and G protein analysis. 2D classification and 3D reconstruction of LayV prefusion F (A), and G tetramer (B)

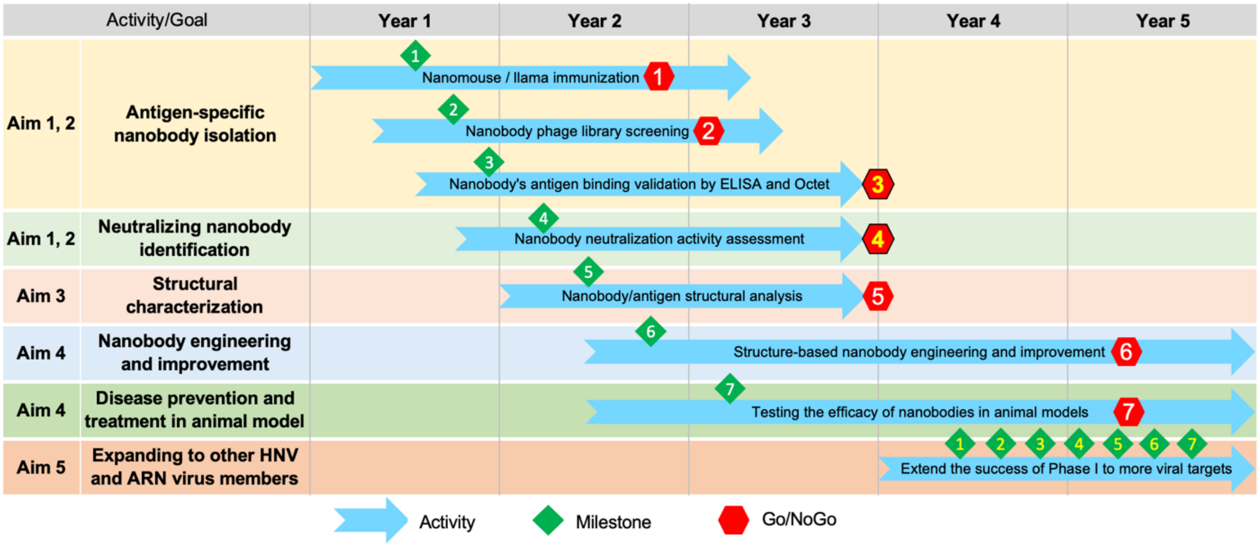
5.1. Langya virus: Langya virus (LayV) is a newly emerged member of the Henipavirus (HNV) family that has been linked to respiratory illness in humans[40,96]. LayV shares a close genetic relationship with Nipah virus and Hendra virus, both of which are known to cause severe disease in humans. To develop effective nanobody therapies against LayV infection, we have successfully generated native viral glycoprotein antigens by design, specifically the G and F glycoproteins (**Fig. 14**). By following our established research strategy, we will utilize nanobody development platforms, employ structural characterization techniques, and implement optimization approaches to identify nanobodies with protective properties against LayV. This process will involve evaluating the selected nanobodies with the neutralization assay and the animal disease model developed in collaboration with **RP2 and Core E**, and ready during the **phase 2** of this project. These efforts will not only contribute to development of nanobody-based therapies targeting LayV but also demonstrate the plug-and-play nature and rapid generalizability of our research strategy. By successfully applying our established approach to a newly emerged member of the Henipavirus family, we will showcase the versatility and effectiveness of our methodology in identifying and optimizing nanobodies against emerging viral pathogens. This will have broader implications for future studies on other viral infections, as our research strategy can be readily adapted and applied to different viral targets.

5.2. Lujo virus and Chapare virus: In our continued research, we will apply a similar strategy to the one used in Aim 2-4 for Lujo virus (LUJV)[41,97,98] and Chapare virus (CHAV)[42,99,100], which are closely related to the prototype LASV and MACV Arenaviruses. This strategy involves stabilizing the glycoprotein complex (GPC) using existing mutation designs transferred from LASV, isolating nanobodies specific to LUJV and CHAV, and performing structural characterization. By leveraging the knowledge and techniques gained from previous aims, we aim to identify nanobodies that can effectively neutralize LUJV and CHAV.

<u>Expected results, potential pitfalls and alternatives</u>:

We anticipate that our research strategy, combined with the knowledge gained from the phase 1 study, will enable us to identify potent neutralizing nanobodies against LayV, LUJV, and CHAV, providing promising therapeutic options for these viral infections. However, it is important to acknowledge potential challenges, such as limited cross-reactivity due to the genetic and antigenic differences between these additional viral targets and the prototypes studied in phase 1. In such cases, alternative approaches, including structure-guided rational design, may be explored to combine viral specificity and expand the protection breadth. Another potential limitation could be the difficulty to generate native prefusion GPC for the additional ARVs. In such instances, we will focus on utilizing the immune-dominant GP1 subunit, which is more stable and contains vulnerable sites for neutralizing antibody recognition. Rational design will be employed to shield non-native surfaces and minimize the generation of non-neutralizing nanobodies. Overall, the successful expansion of our research to other members of the HNV and ARV groups will make a significant contribution to broadening the effectiveness of nanobody-based therapies and addressing the global health risks associated with these viral pathogens.

D. Project Milestones and Timelines



<u>Milestones</u>: <u>(Same milestones are expected to be achieved during phase II with a faster pace).</u>

1. Serum neutralization activity observed (ID_{50}>10).
2. Nanobody phage library panning good enrichment achieved (enrichment>100:1).
3. High affinity viral protein-specific nanobodies isolated (affinity<1 nM).
4. Neutralizing nanobodies obtained (IC_{50}<1 ug/ml; neutralize multiple strains).
5. High resolution nanobody/antigen complex structure solved (resolution<3A).
6. Engineered nanobody molecules with improved activity obtained (IC_{50}<0.1 ug/ml; neutralize more strains).
7. Positive therapeutic effect of nanobodies in virus-induced diseases achieved (no symptoms or weight loss at 10 mg/kg or lower dose).

<u>Criteria to be met for each activity before moving forward (Go/NoGo)</u>:

1. ELISA signal of post-immunization sera is at least 3 times higher than pre-immunization sera.
2. Nanobody phage library panning reach to at least 5 times enrichment.
3. Viral protein-specific nanobody with at least 1 nM affinity **<u>(if not achieved, No Go for Phase II)</u>**.
4. Nanobodies neutralize at IC_{50}<10 ug/ml and/or multiple strains (**<u>if not achieved, NoGo for Phase II)</u>**.
5. Resolve structure with high enough resolution to define nanobody epitopes.
6. Engineered nanobodies achieve better potency and breadth (IC_{50}<0.1 ug/ml; neutralize more strains).
7. Positive therapeutic effect achieved (no symptoms or weight loss at 10 mg/kg or lower dose).

E. Industry Expertise and Regulatory Considerations:

If new lead nanobodies engineered nanobodies are identified from **Research Project 5 (RP5),** collaboration with industry and regulatory experts in **Core D** and the **Scientific Advisory Board (SAB)** will be initiated. This collaboration will involve seeking their expertise in various areas such as the identification of correlates of protection, lead optimization, stability testing, and manufacturability testing of the newly discovered nanobodies. Nanobody candidates can be engineered as desired in collaboration with investigators from **Core D**. This may involve modifications such as altered N-glycans, Fc mutations to enhance effector functions and prolong half-life, and evaluation of multimeric formats. The engineered nanobodies will then be further evaluated to correlate their mechanisms of action with maximal efficacy using the rCedV model explored in the **RP3**, and potentially transitioned to testing in authentic NiV/HeV animal models under the supervision of **Core E**. Throughout this process, stability and manufacturability assessment will be conducted to ensure the identification of a lead prototype format for further development. The goal will be to identify single domain mAb prototypes suitable for long-term intramuscular prophylaxis and/or intravenous post-exposure prophylaxis and therapy. As monoclonal antibodies are regulated by The Center for Drug Evaluation and Research (CDER), a division of the U.S. Food and Drug Administration. Therefore, all activities related to the development and evaluation of the mAbs will be performed in accordance with regulatory expectations set forth by CDER.

Hi Sherry,

Here is the research strategy of RP5.

Thanks,
Kai

Here is an update for resource sharing plan.

Do we need project narrative?

Thanks,
Kai

Hi Sherry,

Please see attached documents from Jianliang and me.
Including:

1. Authentication of key resource (not sure if you received this last time)
2. Abstract (not sure if you received this last time)
3. LOS from me. (not sure if you received this last time)
4. MPI plan
5. Updated vertebrate animal
6. Updated specific aims

Research plan will be ready later today.

Thanks,
Kai

Hi Sherry,

Thanks for the reminder. Attached please find my LOS for the application. Kai will be sending Abstract, Authentication of materials and his LOS shortly.

My GSU position starts today, June 1, 2023. I am ccing my GSU email **jxu40@gsu.edu** and I will communicate with the team from my GSU account from now on.

Best regards,
Jianliang

> Hello Dr. Xu and Dr. Xu,
> This is a reminder of the documents that we still need to get from you both for RP5 on the UTMB/USUHS U19 application. Our administrative review is this coming Thursday, June 1, so we will need all of the items listed below in final form by **EOB tomorrow, Wednesday, May 31**.
>
> - Abstract- 30 lines, 1 for RP5
> - Authentication of Key Biological Materials- 1 for RP5
> - Letter of Support – If both PI's could provide letters o support for your role on this project, we can include them. This is optional, but strengthens the proposal.
>
> For the final application, please provide the following by **EOB Monday June 5** *(hard deadline!).*
>
> - Research Strategy – Please remember to include references for both items listed below from the RFA for your research project:
>
>   **Milestone Plan:** In a clearly labeled section titled "Project Milestones and Timelines" include a clear delineation of goals with measurable milestones, including detailed quantitative and qualitative criteria for Go/No-Go decision-making, and a timeline for the attainment of each goal and milestone and should be reflected in the Milestone Plan for the overall Program. This plan must include Go/No-Go criteria to be met by the end of Year 3 of the award for continuation to Phase II. Milestones must specify the outcome(s) for each activity. Milestones should be quantifiable and scientifically justified, and include the completion of major research study activities, for example, identification of protective epitopes, animal model development, vaccine or mAb candidate down-selection, identification of correlates of protection, validation of vaccine or mAb strategies for other family members, and analysis, sharing and publication of final data. Milestone criteria should not simply be a restatement of

the specific aims. Using a Gantt chart or equivalent tool, describe the associated timelines and identified outcomes for the research Center.

Industry Expertise and Regulatory Considerations: For projects proposing early vaccine development, describe how industry partners will be identified and incorporated into the proposed project including a timeline for inclusion. For projects proposing IND-enabling later stage vaccine development, NIAID requires Centers to include active participation of an industry partner to ensure access to vaccine technology platforms, expertise in manufacturing, clinical development, and regulatory pathways. Applicants should describe the role of this partner in the proposed project and/or team to facilitate discovery, candidate evaluation and/or product development. For the purpose of this FOA, "industry" is defined as a large or small, domestic or foreign, pharmaceutical, biotechnology, bioengineering, or chemical company, or a related non-profit entity.

Please let me know if you have any questions about these or have any concerns about getting them back to us by the deadlines.

Emerging Infectious Diseases

~~SPECIFIC AIMS~~

~~The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) - are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparednessThreats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **Research Project 1 (RP1)** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches which can be adapted across members of each viral family in a **"plug-and-play"** manner. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates a concerns tied to efficacy as newer related viruses continue to emerge and cause disease in humans. Recent advances in reverse genetics of viruses have allowed the generation of infectious genetic clones of several arenaviruses (LASV, MACV, LUJV, JUNV) and nairoviruses (CCHFV) which may make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most arenaviruses and nairoviruses has largely centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized-trimeric antigen for the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GP co-delivered with LASV NP subunits or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP) which harness the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs coupled to recombinant viral glycoprotein antigens and adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of this proposal are two-fold: (1) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed in or monoclonal antibody PREP strategies which can provide protective immunity against Old and New World arenaviruses or emerging nairoviruses. (2) Develop reverse genetics tools to evaluate emerging arenaviruses and nairoviruses for which no isolates are available. Specifically, we will:~~

~~**Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:**~~

~~**1.1 Subunit immunogens and MNP vaccination:** Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches. We will then utilize lessons learned to address related "test case" arenaviruses and nairoviruses to develop a subunit/MNP approach for an old world arenavirus (LUJV) a new world arenavirus (CHPV), and an emerging bat borne nairovirus, Kasokero virus. We will generate recombinant infectious clones (and reporter-gene versions) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**.~~

~~**1.2 Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments:** Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.~~

~~**Milestone 2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:**~~

RESEARCH STRATEGY:

~~1.~~ SIGNIFICANCE~~:~~

1.

~~The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.~~

T~~T~~he viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. ~~–~~ Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% ~~XX~~ and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] ~~(REF)~~ where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens. ~~—~~ This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness [3] ~~(REF)~~. Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success [4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability [5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.

The Mammarenaviruses: All mammarenaviruses share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge[7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. [9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13], Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

The Orthonairoviruses: Unique from other bunyaviruses, orthonairoviruses are transmitted primarily by ticks in nature. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [20]. Like mammarenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

~~**Research Project 1(RP1)** proposes preclinical research that will support Investigational New Drug Application (IND) applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.~~

- ~~**Old Word Mammarenaviruses (OWAV):** RP1 will utilize **LASV as the prototype OWAV** due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with **XX** deaths across West Africa(REF). LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to over **XX** countries (REFS). Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) (REFS). Most of these vaccines utilize the LASV (glycoprotein) GP or the LASV GP + Nucleoprotein (NP) as the target immunogens in these vectors (REFs).~~
- ~~**New World Mamarenaviruses (NWAV):** A live attenuated vaccine for JUNV is currently in use in Argentina [2], but there is conflicting evidence of whether cross protection with other NWAV is possible [3, 4] and there are safety concerns related to reversion to pathogenic versions. This proposal will use **MACV and JUNV as the prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.~~
- ~~**Orthonairoviruses:** Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated **XXX** cases per year across Europe, Africa, and Asia. CCHFV outbreaks are often very large list some recent examples. A suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974, but has numerous safety concerns and limited demonstrated efficacy(**REFS**). Since then, a number of vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages(REF); however only an MVA-CCHFV vaccine has begun to advance towards clinical trials (REF).~~

~~Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e. the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the safety of live-attenuated vaccines and suggests more pathologically~~

~~benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success (**REFS**). The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability(REFS). Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.~~

~~**Subunit vaccines** have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments [5]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from the each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.~~

~~Once a candidate subunit-patch vaccine approach is selected, this approach will use lessons learned to produce plug-and-play approach to develop vaccines against a representative human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.~~

- ~~In 2008, Lujo virus was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [6]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, underscoring the need for antiviral tools against this emerging threat.~~
- ~~First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [7, 8]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [8]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective, but the phylogenetic divergence of CHAPV of XX% from JUNV suggests it may not be.~~
- ~~In 1977, Kasokero virus (KASV), a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [9]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for *Ornithodoros faini* ticks to participate in enzootic maintenance of KASV [10]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised.~~

~~**Pre-exposure prophylaxis (PREP)**, and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high- risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis (REFS). The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will also perform pilot studies to examine the feasibility of PREP utilizing with a serum half-life extended mAb against JUNVs. Clinically validated Fc mutations can result in an improvement in serum~~

~~half-life from 3-4 weeks to 2-4 months which can increase the instant barrier immunity from 30-45 days to 60+ days ([11-13] [14]refs).~~

~~The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.~~

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens:

The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of ~~the five~~the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective ~~vaccine(~~vaccine [9, 10, 31, 32]~~REFS)~~. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens:

CCHFV is a divergent virus with up to ~~seven~~ six genetic ~~lineages~~ clades~~(REFS)~~. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation [20]. Given the glycoprotein is a pivotal protein dictating viral entry ~~and immune~~and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on ~~(REF)~~. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface [20] ~~(REFs)~~. Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control mammarenaviruses:

For situations where a vaccine does not exist or is not appropriate (*e.g.* immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE [34, 35] and LA [36,37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

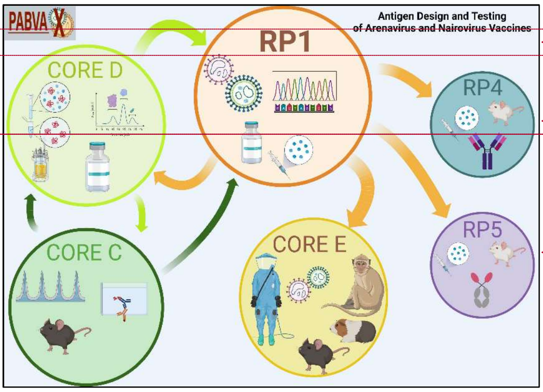
~~*Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses*~~

~~**3. Add blurb discussing unique access to field samples from across the world and established expertise to generate infectious clones from emerging arenaviruses and nairoviruses:**~~



~~3.~~ APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** and **orthonairovirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families. These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for mammarenaviruses and orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop **BSL4 research tools and animal models** for viruses that are otherwise not available to the research community.

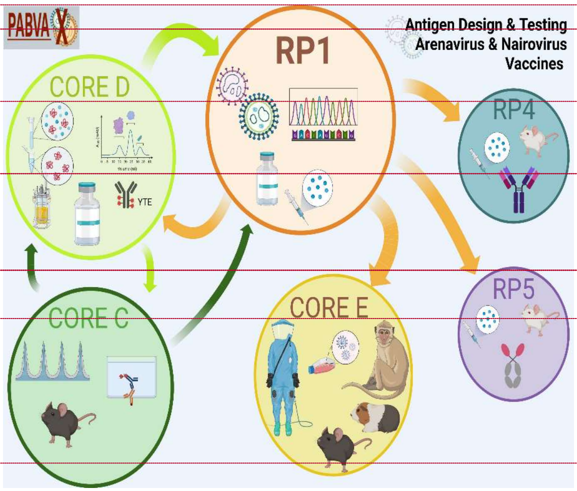


Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

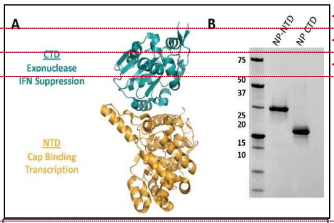

Figure ~~xx~~3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable ~~disulfide-linked~~disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and ~~-~~Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure ~~xx~~2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure ~~3~~2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure ~~xx~~2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

~~Our trimeric arenavirus GPs support efforts to isolate novel ultra-potent mAbs and to develop a second-generation arenavirus immunotherapeutic with reduced dosing requirements and broader reactivity compared to current LASV mAb candidates[25]. This significantly lowers the cost of goods while increasing ease of use for clinicians, both essential for a product used in developing nations where arenaviruses are prevalent.~~

LASV subunit vaccine protects guinea pigs against lethal challenge

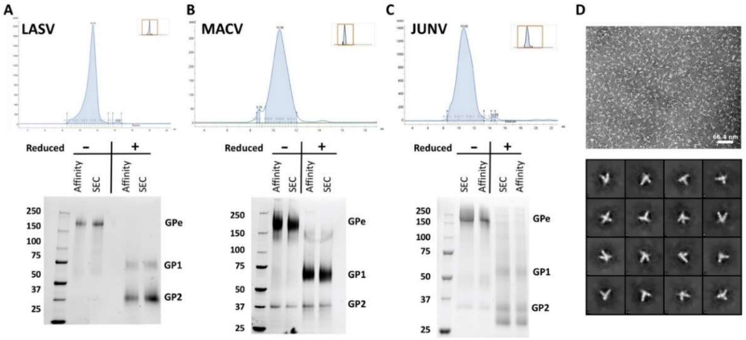

Figure ~~XX~~2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

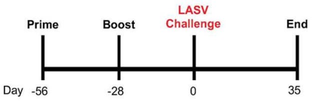
While classical vaccine approaches ~~have~~ largely focus~~ed~~ on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a ~~highly important~~ potent and complementary role in the long-term protection against pathogens. ~~Based on literature reports that~~ Understanding that T cell responses highly correlate with LASV recovery~~,~~ and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure ~~xx~~3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks.

We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3~~6~~)** to assess whether immune responses to GPe ~~only~~alone or~~,~~ ~~or~~ GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3~~6), and~~)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP ~~but~~ with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.



GROUP	LASV ANTIGEN	ADJUVANT	TH RESPONSE
1	PBS (CONTROL)	NONE	NONE
2	GP	NONE	NONE

Engineering glycoproteins antigens for ~~the~~ CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to ~~test~~ observe potent serum reactivity in CCHF survivors **(Figure ~~XX~~4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

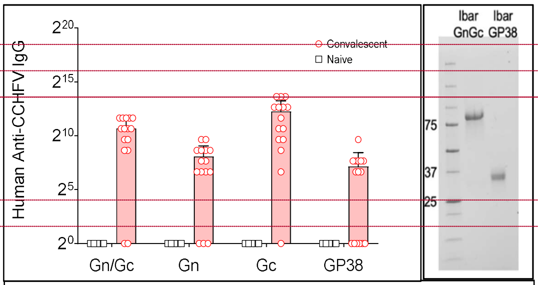

Figure ~~XX~~4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

~~*Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses*~~

~~***Rescue of recombinant viruses.*** An important goal of the PABVAX Center is to generate tools for pandemic preparedness. An important component of both RP1 and RP2 is to generate and recombinant viruses to fill gaps and provide tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with RP1 Core E will assist in the development and rescue of New World arenaviruses and the henipavirus Langya virus as detailed in the Research Strategies for RP1 and RP2.~~

~~**APPROACH**~~

~~***Overall Hypothesis:FILL THIS IN***~~

Specific Aim 1: Subunit immunogens and MNP vaccination ~~Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:~~

Rationale:

Scientific Approach: The choice of Mammarenavirus Prototype Pathogens is justified as follows:

- ~~*Old World Mammarenaviridae:* We propose LASV Josiah strain (Lineage 4) as the prototype pathogen due to the depth of available research data, availability of established rodent (**REF**) and nonhuman primate(NHP) models (**REFS**), frequency of exportation (**REFS**), and large number of annual cases throughout West Africa where the case fatality rate can be up to 60% in hospitalized cases (**REF**).~~
- ~~*New World Mammarenaviridae:* Due to the availability of a JUNV vaccine in the endemic region where JUNV circulates and the lack of cross protection against challenge with other NWAV, MACV, the causative agent of Bolivian hemorrhagic fever, will be used as the prototype pathogen for NWAV for studies outlined in Milestone 1.1. There are established guinea pig (**REF**) and NHP (**REF**) models for MACV. JUNV is the New World arenavirus with the largest knowledge base at present [**REF**]. For a pilot efficacy study outlined in Milestone 1.2, we will use JUNV Espindola Strain as a natural extension of previous published work demonstrating protective efficacy of the template PREP mAb (**REF**).~~
- ~~*Nairoviridae.* We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].~~

RP1 proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *Old Word Mammarenaviruses (OWAV)*; In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae (REFS). There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *New World Mamarenaviruses (NWAV):* A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[42] but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[43, 44]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[45]. For Phase 1, **RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola (Lineage XX)** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *Orthonairoviruses*; In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[46]. A suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[47]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[47]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[48]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert ~~[23]~~) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[49]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model [50] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38.

~~*Nairoviridae*. We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].~~

Once a candidate subunit-patch vaccine approach is selected, this RP1 will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative, “test case” human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case’s medical evacuation to South Africa[51]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal “test case” OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[52] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center’s **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[53, 54]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset

demonstrating a clear need to specialized management and treatment[54]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

- In 1977, **Kasokero virus (KASV)**, a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [55]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini*, ticks to participate in enzootic maintenance of KASV[56]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[55]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[57]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families (REFS). An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs. ~~**Paragraph about subunit vaccines and PREP study.**~~

Milestone ~~Milestone~~ 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in ~~table XX~~**Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in ~~Table XX~~Table 1. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E~~C~~** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[58] ~~(REFS)~~. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by ~~MNP Patch~~ **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

VACCINE	IM VACCINATION		PATCH VACCINATION

Control vaccine (VSV-LASV-GPC)	8			
	TOTALS	64	TOTALS	32

Table ~~: XX~~ **1:** ~~O~~Outline of LASV Vaccination Schedule for Milestone 1.1.1.A

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table ~~XX~~ 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[59] ~~(REF)~~. Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[43, 44]. ~~(REFs).~~

Table 2: Outline of MACV Vaccination Schedule for Milestone 1.1.1.A

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs. Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E~~C~~** as outlined in **Table ~~XX~~3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Control vaccine (VSV-LASV-GPC)	8	8	8	8
~~TOTALS~~	~~40~~	~~40~~	~~40~~	~~40~~

Table 3: ~~: XX o~~ Outline of PAN-LASV Vaccine Efficacy ~~S~~Schedule for Milestone 1.1.1.B

For our MACV subunit vaccines

~~Similarly, , after down selecting the optimal adjuvant and vaccination route,~~ we will assess the potential ~~for our MACV subunit vaccines~~ to confer heterologous protection against three lineages of MACV ~~endemic to~~ genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core ~~C~~E** as outlined in **Table ~~XX~~4**. We will also utilize JUNV (Romero strain)[60] ~~(REF)~~ challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

~~Table: XX~~Table 4: ~~o~~Outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table ~~XX~~5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.A~~1~~F.

Milestone 1~~2~~.1.2.A: Development and optimization of patch vaccination approach employing nairovirus subunits:

Here we will determine if our GPe + NP-NTD subunit vaccine approach can be deployed against CCHFV.We will compare the protective efficacy of two adjuvants coupled to our CCHFV GP and NP-NTD proteins developed and manufactured in collaboration with **Core D** either as individual subunit vaccines or combinations as outlined in **Table 7** using an intramuscular (IM) vaccination approach. Eight 6-8 week STAT-1/KO mice (balanced sex) will be randomly assigned to groups as outlined in **Table 7.** Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core E** and challenged with 100 pfu of a low passage CCHF-Hoti[49]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled

Milestone

~~*2.1.2.E: Determination of protective efficacy against novel, emerging nairovirus using optimized subunit-patch vaccination in STAT-1KO mice and NHP*~~

Table: XX outline of NHP efficacy studes for MACV
Milestone 1.1.1.B

1.1.3~~1.F~~: Determination of cellular and humoral immune correlates associated with ~~protection~~protection.

Milestone 1.1.3.A~~1.F.a~~: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups:

We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard ~~whole blood~~ flow cytometric staining protocols will be used for surface and intracellular staining markers. ~~, b~~Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye ~~for 20 minutes at room temperature~~. ~~C~~Cells are then washed again and ~~,~~ surface stain cocktail is added to the tubes, incubated ~~for 20~~

~~minutes~~, and washed. Cells are fixed ~~for 1 hour~~ with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed ~~in PBS~~. ~~Stained, fixed cells will then either be acquired directly.~~ Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: ~~–~~PBMC stimulations will be set up according to modifications of well established, previously published protocols.[62, 63] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37ºC for 1 hour. A protein transport inhibitor such as brefeldin A will then be added ~~at a concentration of 10mg/mL and~~ then incubated ~~at 37ºC for~~prior~~, until~~ to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37ºC. Stimulations to assess secreted analytes by multiplex-bead based assays ~~will be set up~~ in 96-well plates and supernatants ~~will be~~ will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye ~~for 20 minutes at room temperature~~, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated ~~for 20 minutes~~, and washed. Cells are incubated in BD Cytofix/Cytoperm solution ~~for 20 minutes~~ followed by a wash. ~~with BD Perm/Wash Buffer.~~ Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed ~~in PBS~~. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi~~4~~-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated ~~for 3 hours at room temperature, protected from light~~ and subsequently washed by pelleted centrifugation. ~~1mL of wash buffer will be added and beads will be pelleted by centrifugation at 200g for 5 minutes.~~ Wash buffer will be removed and discarded. Beads will be resuspended ~~in 300uL wash buffer~~ and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37ºC. Wells will be washed manually 3-times, followed by the addition of detection ~~antibody~~antibody, and incubated either overnight at 4ºC or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. ~~at room temperature, protected from light.~~ Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37ºC), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer~~**need model**~~ ~~ELISPOT Fluorescence Microplate Reader.~~

Data Analysis: We will ~~look at the~~examine differences in immune responses across groups between each timepoint and baseline. ~~Model assumptions will be checked for a one-way ANOVA to compare the three groups. we will run the analysis after checking model assumptions, if those are not met then we will adjust to a nonparametric model or transform the outcome appropriately. To look at the longitudinal aspect of the data, we will investigate measurements over time between groups, the interaction of group and time can be analyzed using covariance pattern models (or linear mixed models), where the correlation between observations measured over time can be handled more flexibly. As a more exploratory analysis we will also look at adjusting for possible confounding variables such as sex and age. For categorical variables, comparisons will be made using Chi-Square tests.~~ Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

1.1.3.A:~~1.1.1.F.b~~: Systems serology Characterization of~~ ~~ Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups: ~~.~~

We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform ~~developed by Dr. Gunn in~~ with **Core D**[64-66] to define the Fc-mediated humoral antiviral functions associated with ~~vaccination~~vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, ~~CCHFV,LUJV~~CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens ~~utilized~~ used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages~~.~~, ~~W~~we will use a multiplexed analysis to determine ~~the~~ levels of antibodies against ~~the~~ viral antigens using ~~on~~ a MagPix xMAP instrument ~~as described~~.[65, 67] Specifically, each viral antigen will be coupled to coded magnetic beads ~~(Luminex)~~, mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM.~~ ~~ For quantitation of bound antibody, we will ~~make a standard~~ us~~e~~ing pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions:~~ ~~ We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.~~ at KGH.~~

ADCC: Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates ~~for 5 hours at 37C 5% CO_2,~~ and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses ~~were~~ will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction ~~was used~~ to determine statistical significance ~~between groups.~~. ~~A network analysis will be performed to identify significant antibody features. Associations between antibody features will be determined using nonparametric Spearman correlation coefficient. Statistically significant associations after Bonferroni correction for multiple comparisons (adjusted P < .05) were used to generate networks in Cytoscape (version 3.4.0).~~

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and ~~additional clinical information (ie~~clinical signs into the network analysis.~~; PES symptoms). These will be included in the network analysis.~~

***Milestone** **1.~~AIM 2~~2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:** We will use existing mammarenaviruses[68, 69] and orthonairovirus[70] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog but is still pathogenic in mice and humans (REFS). There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: ~~1.2~~ Pre-exposure Prophylaxis (PREP) using half-life extension antibody ~~treatments~~treatments.

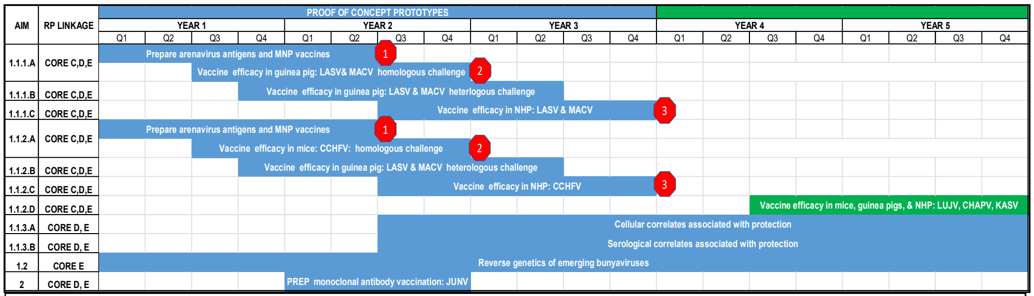
Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months(34-37).

PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

Table 11: PREP schedule outline in Milestone 2

Scientific Approach:

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine:~~.~~ In conjunction with ~~RP1~~ Cores D and ~~Core~~ E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb ~~with~~ whose potent therapeutic efficacy~~-~~[71, 72] ~~(guinea pig and NHP references)~~ we have previously described ~~by Abelson, Geisbert and Zeitlin~~ will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb~~(Table 4)~~. ~~The pharmacokinetics (PK) of these two variants will be evaluated in NHPs (Bioqual, Inc.; Rockville, MDsee Core D) to select a lead candidate for testing in NHPs against Junin Romero challenge in Core E.~~ ~~For the PK study, two doses (15 and 5 mg/kg) of each mAb will be administered IM to groups of 3 cynomolgus macaques (mixed sex). Serum will be collected (pre-dosing, 15 min, 6 hours and at days 1, 2, 3, 7, 10, 14, 21, 28, 42, 56) and tested via ELISA and Octet to quantitate serum antibody concetrations. PK parameters will be modeled with WinNonlin Phoenix software (reference).~~ We will select t~~T~~he variant with the most favorable pharmacokinetic (described in **Core D**)~~s~~ ~~PK will be selected~~ for testing with ~~by RP1/~~**Core E.** Briefly, groups of 45 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV ~~(Espindola or Romero~~Espindola~~?)~~ delivered IV **(Table 11)**. For further details of the NHP testing, please see **Core E**. These data will be used by the Scientific Advisory ~~Committee~~ Board to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.



RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

Expected results, alternative ~~approaches and~~approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, ~~and~~ CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three “test case” viruses LUJV, CHAPV, and KASV in Phase II of the project.……. If ~~this~~ any~~is not the case any~~ of these Phase I vaccine projects have not met the “go” criteria, ~~three viruses by year 2~~ we will refocus ~~effects~~ efforts toward~~on~~ the remaining viruses ~~families~~ adjusting the requested budgets accordingly after ~~consulation~~consultation with NIAID and SAC.

Please note: Discussion of expected results, other alternative ~~approaches~~approaches, and criteria for "go" or "no go" decisions for MILESTONES 1~~-4~~ and 2 are discussed as required in RFA-AI-20-023 in the ***Project Milestones and Timelines*** *section.*

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

RESEARCH STRATEGY:

1. SIGNIFICANCE

The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness [3] . Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success [4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability [5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.

__The Mammarenaviruses__**:** All mammarenaviruses share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge [7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe) [8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. [9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

__The Orthonairoviruses__: Unique from other bunyaviruses, orthonairoviruses are transmitted primarily by ticks in nature. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [20]. Like mammarenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens: The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine [9, 10, 31, 32]. Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens: CCHFV is a divergent virus with up to six genetic clades. This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation [20]. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface [20] . Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control mammarenaviruses: For situations where a vaccine does not exist or is not appropriate (*e.g*. immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE [34, 35] and LA [3637] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

3. APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** and **orthonairovirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families. These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for mammarenaviruses and orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop **BSL4 research tools and animal models** for viruses that are otherwise not available to the research community.

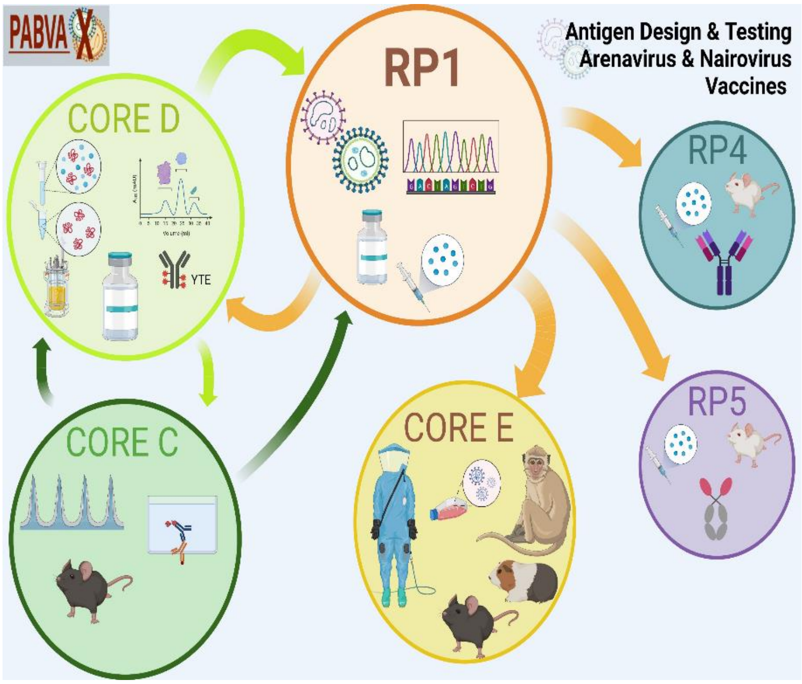

Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed.

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE

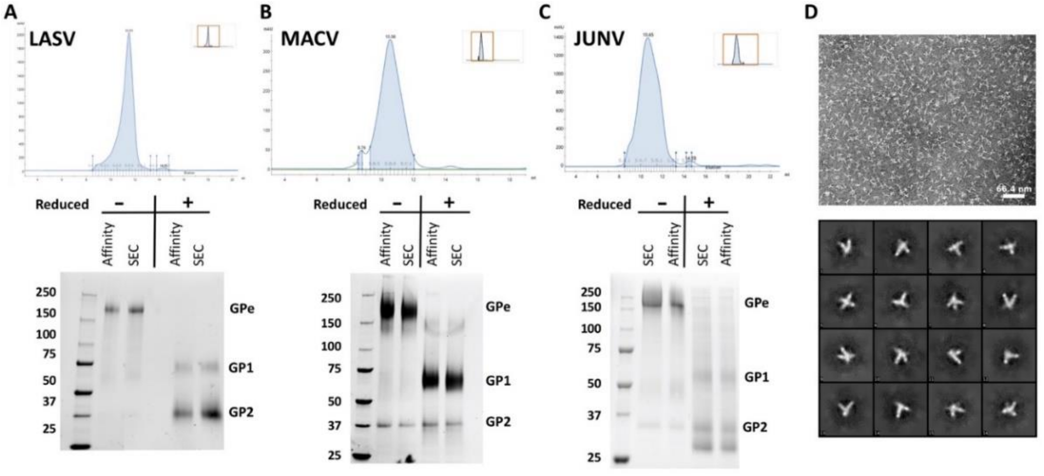

Figure 2. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure 2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

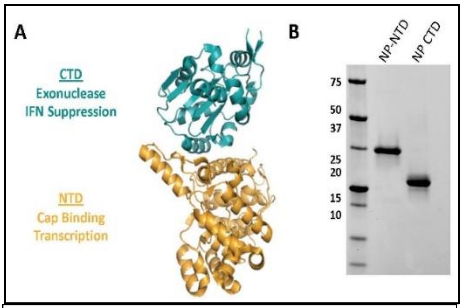

Figure 3. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B) SDS-PAGE gel showing highly purified LASV NP antigens for vaccine study.

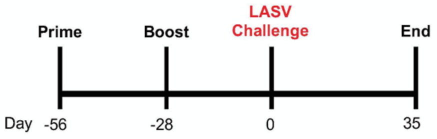
The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure 2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

<u>LASV subunit vaccine protects guinea pigs against lethal challenge</u>

While classical vaccine approaches largely focus on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a potent and complementary role in the long-term protection against pathogens. Understanding that T cell responses highly correlate with LASV recovery and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure 3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks. We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3)** to assess whether immune responses to GPe alone or GPe+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3)** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection



GROUP	LASV ANTIGEN	ADJUVANT	TH RESPONSE

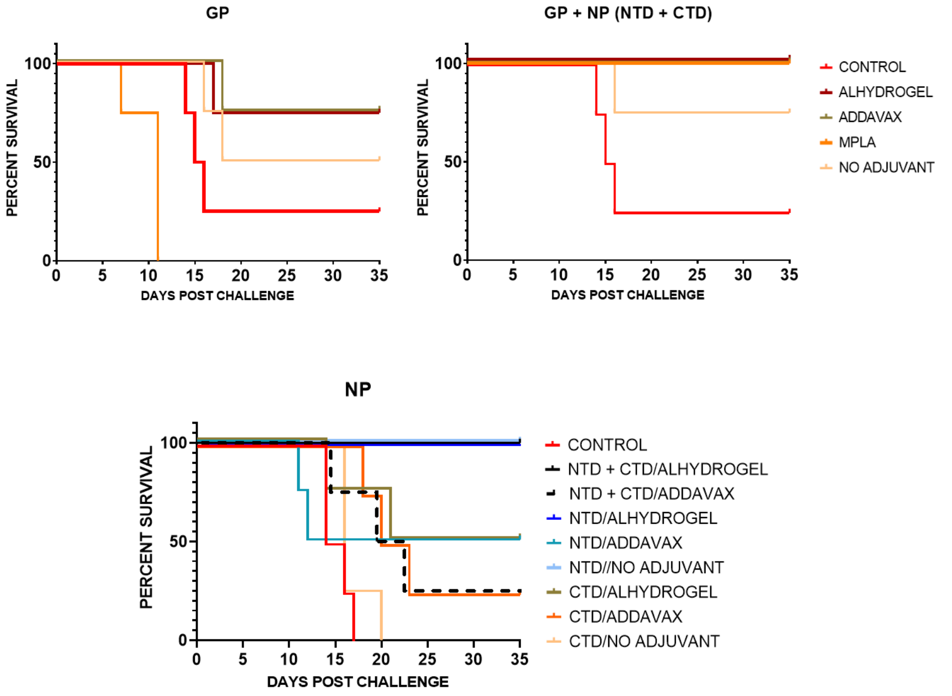

Figure 3. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

Engineering glycoproteins antigens for CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to observe potent serum reactivity in CCHF survivors **(Figure 4).** We will use established protocols[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

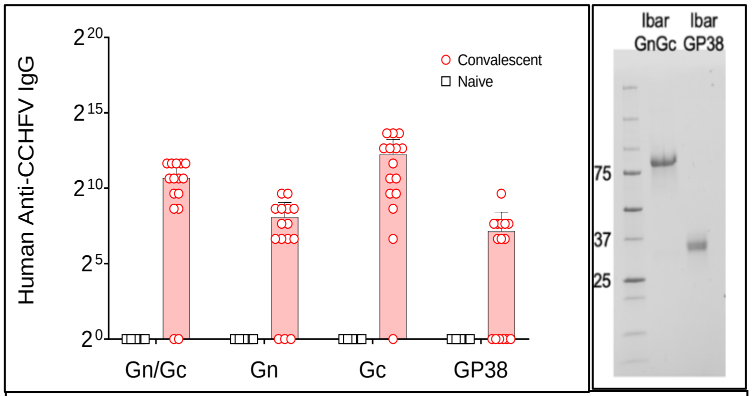

Figure 4: Engineered CCHFV proteins are reactive with serum from CCHFV survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

Specific Aim 1: Subunit immunogens and MNP vaccination Rationale:

Scientific Approach: The choice of Mammarenavirus Prototype Pathogens is justified as follows: **RP1** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- _Old Word Mammarenaviruses (OWAV):_ In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae (REFS). There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- _New World Mamarenaviruses (NWAV):_ A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina [42], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine [43, 44]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[45]. For Phase 1**, RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola (Lineage XX)** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- _Orthonairoviruses:_ In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[46]. A suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[47]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying

efficacy, advantages, and disadvantages[47]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[48]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[49]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model [50] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38.

Once a candidate subunit-patch vaccine approach is selected, this RP1 will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative, "test case" human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa[51]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[52] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[53, 54]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[54]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [55]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV[56]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[55]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[57]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families (REFS). An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.

Table 1: Outline of LASV Vaccination Schedule for Milestone 1.1.1.A

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in **Table 1** using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in **Table 1**. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to BSL4 evaluation **Core E** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group[58]. After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table 2** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain[59]**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV[43, 44].

Milestone 1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs: Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core E** as outlined in **Table 3**. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 3: Outline of PAN-LASV Vaccine Efficacy Schedule for Milestone 1.1.1.B

For our MACV subunit vaccines, we will assess the potential to confer heterologous protection against three lineages of MACV genetically distinct from the prototype strain (Chicava-Lineage 2) after down selecting the optimal adjuvant and vaccination rout. Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core E** as outlined in **Table 4.** We will also utilize JUNV (Romero strain)[60] challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table 4: Outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

***Milestone* 1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table 5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.AF.

Milestone 2.1.2.C: Determination of protective efficacy using optimized subunit-patch vaccination in NHP: In collaboration with **Core E**, 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-CCHFV-GPC, demonstrated effective in mice[23] and NHP (Unpublished, Cross and Geisbert) with 5 animals, and a control group of five unvaccinated animals **(Table 9).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected CCHFV antigens, adjuvants, and vaccination route identified in 1.1.2.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post-boost for boosted animals), all animals will be challenged with 5000 PFU of CCHFV-Hoti. The disease of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after CCHFV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Milestone 1.1.2.D: Determination of protective efficacy against novel, emerging arenaviruses and nairovirus "test case" viruses using optimized subunit-patch vaccination in STAT-1/KO mice, guinea pigs and NHP: **RP1 and Core D** will produce optimized GPe and NP-NTD antigens to formulate vaccines for LUJV and CHAPV based off lessons learned from 1.1.1A-C. Protective efficacy studies then be carried out where **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10). RP1 and Core D** will also produce optimized KASV GP and NP-NTD antigens to formulate subunit/MNP vaccines based off lessons learned from 1.1.1A-C. Protective efficacy studies will

then be carried **Core E** will vaccinate and challenge guinea pigs or NHP as outlined in 1.1.1A and 1.1.1C, respectively **(Table 10)**

***Milestone* 1.1.3: Determination of cellular and humoral immune correlates associated with protection.**

Milestone 1.1.3.A: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups: We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard flow cytometric staining protocols will be used for surface and intracellular staining markers. Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye. Cells are then washed again and surface stain cocktail is added to the tubes, incubated, and washed. Cells are fixed with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed. Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: PBMC stimulations will be set up according to modifications of well established, previously published protocols.[62, 63] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37^{o}C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added then incubated prior to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37^{o}C. Stimulations to assess secreted analytes by multiplex-bead based assays in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated, and washed. Cells are incubated in BD Cytofix/Cytoperm solution followed by a wash. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated and subsequently washed by pelleted centrifugation. Wash buffer will be removed and discarded. Beads will be resuspended and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37^{o}C. Wells will be washed manually 3-times, followed by the addition of detection antibody, and incubated either overnight at 4^{o}C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37^{o}C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer.

Data Analysis: We will examine differences in immune responses across groups between each timepoint and baseline. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone 1.1.3.A:: Systems serology Characterization of Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups*:* We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform with **Core D**[64-66] to define the Fc-mediated humoral antiviral functions associated with vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages, we will use a multiplexed analysis to determine levels of antibodies against viral antigens using a MagPix xMAP instrument .[65, 67] Specifically, each viral antigen will be coupled to coded magnetic beads , mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will use pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction to determine statistical significance.

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and clinical signs into the network analysis.

Milestone **1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:** We will use existing mammarenaviruses[68, 69] and orthonairovirus[70] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog but is still pathogenic in mice and humans (REFS). There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments.

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the

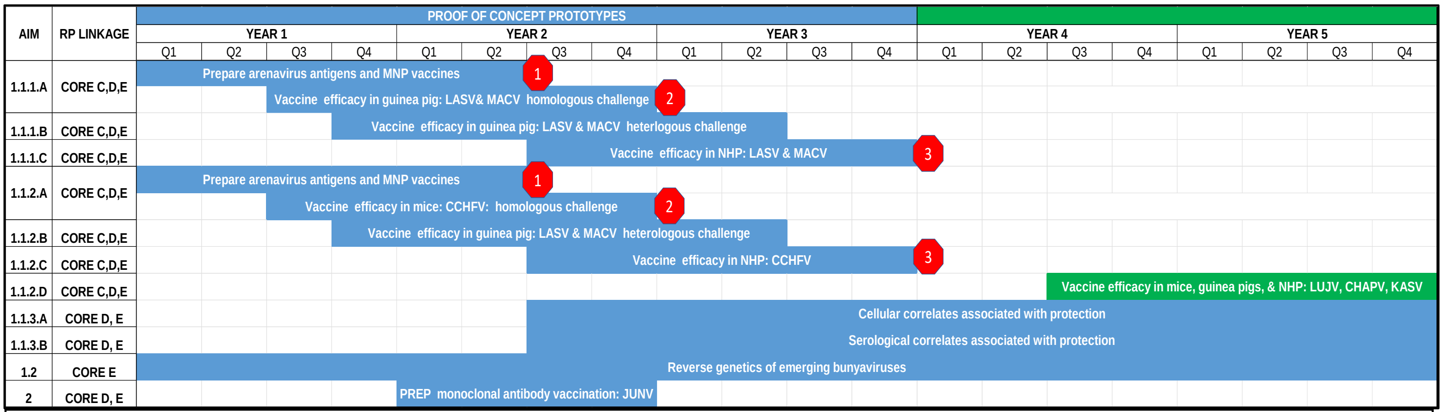
PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

Table 11: PREP schedule outline in Milestone 2

feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months([34-37]).

<u>Scientific Approach</u>: *A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine:* In conjunction with Cores D and E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb whose potent therapeutic efficacy[71, 72] we have previously described will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb. We will select the variant with the most favorable pharmacokinetic (described in **Core D**) for testing with **Core E.** Briefly, groups of 5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV Espindola delivered IV **(Table 11).** For further details of the NHP testing, please see **Core E**. These data will be used by the Scientific Advisory Board to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three "test case" viruses LUJV, CHAPV, and KASV in Phase II of the project. If any of the Phase I vaccine projects have not met the "go" criteria, we will refocus efforts toward the remaining viruses adjusting the requested budgets accordingly after consultation with NIAID and SAC. *Please note: Discussion of expected results, other alternative approaches, and criteria for "go" or "no go" decisions for MILESTONES 1 and 2 are discussed as required in RFA-AI-20-023 in the* **Project Milestones and Timelines** *section.*



RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***<u>Go</u>***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***<u>No-go</u>*** for respective vaccine component. (2) Protection in rodent models is a ***<u>Go</u>***. Lack of protection in rodents is a ***<u>No-go</u>***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***<u>No-go</u>*** for respective vaccine component.

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.
