~~SPECIFIC AIMS~~

~~The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparednessThreats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **Research Project 1 (RP1)** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches which can be adapted across members of each viral family in a **"plug-and-play"** manner. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates a concerns tied to efficacy as newer related viruses continue to emerge and cause disease in humans. Recent advances in reverse genetics of viruses have allowed the generation of infectious genetic clones of several arenaviruses (LASV, MACV, LUJV, JUNV) and nairoviruses (CCHFV) which may make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most arenaviruses and nairoviruses has largely centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized-trimeric antigen for the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GP co-delivered with LASV NP subunits or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP) which harness the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs coupled to recombinant viral glycoprotein antigens and adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of this proposal are two-fold: (1) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed in or monoclonal antibody PREP strategies which can provide protective immunity against Old and New World arenaviruses or emerging nairoviruses. (2) Develop reverse genetics tools to evaluate emerging arenaviruses and nairoviruses for which no isolates are available. Specifically, we will:~~

~~Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:~~

~~**1.1 Subunit immunogens and MNP vaccination:** Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches. We will then utilize lessons learned to address related "test case" arenaviruses and nairoviruses to develop a subunit/MNP approach for an old world arenavirus (LUJV) a new world arenavirus (CHPV), and an emerging bat borne nairovirus, Kasokero virus.We will generate recombinant infectious clones (and reporter-gene versions) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**.~~

~~**1.2 Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments:** Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.~~

~~Milestone 2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:~~

~~We will generate recombinant infectious clones (and reporter-gene versions) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**.~~

RESEARCH STRATEGY:

~~1.~~ SIGNIFICANCE~~:~~

1.

~~The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.~~

T~~T~~he viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1].~~–~~ Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% ~~XX~~ and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens [2] ~~(REF)~~ where six rodent borne arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens.~~—~~ This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness [3] ~~(REF)~~. Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e., the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the universal safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success [4]. The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability [5]. Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.

***The Mammarenaviruses*:** All mammarenaviruses share a common genomic organization consisting of two ambi-sense RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP)[6]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge [7]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe) [8]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. [9-11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

The Orthonairoviruses: Unique from other bunyaviruses, orthonairoviruses are transmitted primarily by ticks in nature. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[15], Issyk-Kul virus[16], Songling virus[17]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[18] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[19]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[20]. CCHFV is listed on the WHO priority pathogen list[2] and is also a NIH-NIAID category A pathogen[3]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[21] (REF). Ribivirin has been used to treat infections with limited success[22]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [20]. Like mammarenaviruses, CCHFV NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[20]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[20]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[23].

~~**Research Project 1(RP1)** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.~~

- ~~**Old Word Mammarenaviruses (OWAV):** RP1 will utilize **LASV as the prototype OWAV** due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with **XX** deaths across West Africa(REF). LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to over **XX** countries (REFS). Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) (REFS). Most of these vaccines utilize the LASV (glycoprotein) GP or the LASV GP + Nucleoprotein (NP) as the target immunogens in these vectors (REFs).~~
- ~~**New World Mamarenaviruses (NWAV):** A live attenuated vaccine for JUNV is currently in use in Argentina [2], but there is conflicting evidence of whether cross protection with other NWAV is possible [3, 4] and there are safety concerns related to reversion to pathogenic versions. This proposal will use **MACV and JUNV as the prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.~~
- ~~**Orthonairoviruses:** Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated **XXX** cases per year across Europe, Africa, and Asia. CCHFV outbreaks are often very large list some recent examples. A suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974, but has numerous safety concerns and limited demonstrated efficacy(**REFS**). Since then, a number of vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages(REF); however only an MVA-CCHFV vaccine has begun to advance towards clinical trials (REF).~~

~~Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e. the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the safety of live-attenuated vaccines and suggests more pathologically~~

~~benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success (**REFS**). The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability(REFS). Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.~~

~~**Subunit vaccines** have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments [5]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from the each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.~~

~~Once a candidate subunit-patch vaccine approach is selected, this approach will use lessons learned to produce plug-and-play approach to develop vaccines against a representative human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.~~

- ~~In 2008, Lujo virus was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [6]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, underscoring the need for antiviral tools against this emerging threat.~~
- ~~First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [7, 8]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [8]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective, but the phylogenetic divergence of CHAPV of XX% from JUNV suggests it may not be.~~
- ~~In 1977, Kasokero virus (KASV), a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [9]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for *Ornithodoros faini* ticks to participate in enzootic maintenance of KASV [10]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised.~~

~~**Pre-exposure prophylaxis (PREP)**, and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high- risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis (REFS). The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will also perform pilot studies to examine the feasibility of PREP utilizing with a serum half-life extended mAb against JUNVs. Clinically validated Fc mutations can result in an improvement in serum~~

~~half-life from 3-4 weeks to 2-4 months which can increase the instant barrier immunity from 30-45 days to 60+ days ([11-13] [14]refs).~~

~~The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.~~

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens:

The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[24] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[24]. Further, four of ~~the five~~the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[25-30]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[9]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model.~~ ~~ Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective ~~vaccine(~~vaccine [9, 10, 31, 32]~~REFS)~~.~~ ~~ Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens:

CCHFV is a divergent virus with up to ~~seven~~ six genetic ~~lineages~~ clades~~(REFS)~~. ~~ ~~This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages which can be less than 75% amino acid conservation [20].~~ ~~ Given the glycoprotein is a pivotal protein dictating viral entry ~~and immune~~and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on~~ (REF)~~. Conversely, NP is highly conserved but not exposed on the virus surface cellular surface [20] ~~(REFs)~~.~~ ~~ Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [33]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control mammarenaviruses:

For situations where a vaccine does not exist or is not appropriate (*e.g.* immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE [34, 35] and LA [36-37] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

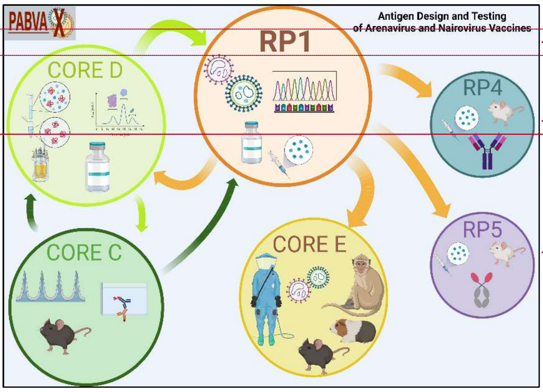
~~*Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses*~~

3. ~~Add blurb discussing unique access to field samples from across the world and established expertise to generate infectious clones from emerging arenaviruses and nairoviruses:~~



~~3.~~ APPROACH

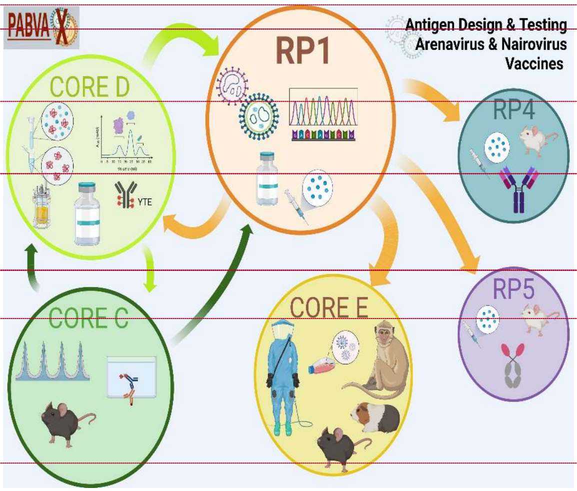


Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales (Figure 1).** In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope-based subunit vaccines allowing for broad cross-protection across **mammarenavirus** and **orthonairovirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families. These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C.** Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for mammarenaviruses and orthonairoviruses to **RP4** and **RP5** to produce broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop **BSL4 research tools and animal models** for viruses that are otherwise not available to the research community.

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable ~~disulfide-linked~~disulfide linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[8]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[8] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure ~~xx~~2).** Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure ~~3~~2).** Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure ~~xx~~2).** Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

~~Our trimeric arenavirus GPs support efforts to isolate novel ultra-potent mAbs and to develop a second-generation arenavirus immunotherapeutic with reduced dosing requirements and broader reactivity compared to current LASV mAb candidates[25]. This significantly lowers the cost of goods while increasing ease of use for clinicians, both essential for a product used in developing nations where arenaviruses are prevalent.~~

While classical vaccine approaches ~~have~~ largely focus~~ed~~ on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[25-30] suggests that the cellular response, mediated by T cells, can play a ~~highly important~~ potent and complementary role in the long-term protection against pathogens. ~~Based on literature reports that~~ Understanding that T cell responses highly correlate with LASV recovery~~,~~ and that LASV NP plays a significant role in inducing those responses[25, 38], we also generated LASV NP antigens. We also chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle **(Figure ~~xx~~3)** and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks.

We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 3~~6~~)** to assess whether immune responses to GPe ~~only~~alone or~~,~~ ~~or~~ GPe+NP ~~-~~would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking **(Figure 3~~6~~)~~, and)~~** and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP ~~but~~ with no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

Engineering glycoproteins antigens for ~~the~~ CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of ~~—~~ soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to ~~test~~ observe potent serum reactivity in CCHF survivors **(Figure ~~XX~~4).** ~~——~~ We will use established protocols~~—~~[39] as a template to optimize expression of CCHFV and Kasokero NP proteins.

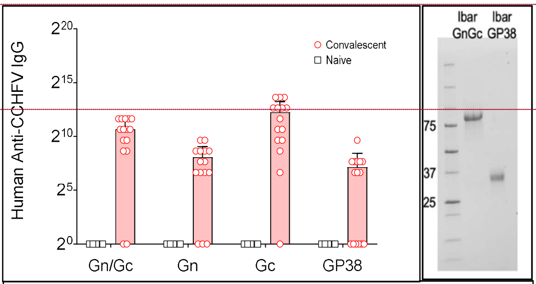

Figure ~~XX~~4: ~~–~~ ~~Engineered CCHFV proteins are reactive with serum from CCHFV~~ survivors (left bar graph). SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification (right electrophoresis gel).

~~*Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses*~~

~~***Rescue of recombinant viruses.*** An important goal of the PABVAX Center is to generate tools for pandemic preparedness. An important component of both RP1 and RP2 is to generate and recombinant viruses to fill gaps and provide tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with RP1 Core E will assist in the development and rescue of New World arenaviruses and the henipavirus Langya virus as detailed in the Research Strategies for RP1 and RP2.~~

~~**APPROACH**~~

~~***Overall Hypothesis:FILL THIS IN***~~

Specific Aim 1: Subunit immunogens and MNP vaccination ~~Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:~~

Rationale:

Scientific Approach: The choice of Mammarenavirus Prototype Pathogens is justified as follows:

- ~~*Old World Mammarenaviridae:* We propose LASV Josiah strain (Lineage 4) as the prototype pathogen due to the depth of available research data, availability of established rodent (**REF**) and nonhuman primate(NHP) models (**REFS**), frequency of exportation (**REFS**), and large number of annual cases throughout West Africa where the case fatality rate can be up to 60% in hospitalized cases (**REF**).~~
- ~~*New World Mammarenaviridae:* Due to the availability of a JUNV vaccine in the endemic region where JUNV circulates and the lack of cross protection against challenge with other NWAV, MACV, the causative agent of Bolivian hemorrhagic fever, will be used as the prototype pathogen for NWAV for studies outlined in Milestone 1.1. There are established guinea pig (**REF**) and NHP (**REF**) models for MACV. JUNV is the New World arenavirus with the largest knowledge base at present [**REF**]. For a pilot efficacy study outlined in Milestone 1.2, we will use JUNV Espindola Strain as a natural extension of previous published work demonstrating protective efficacy of the template PREP mAb (**REF**).~~
- ~~*Nairoviridae.* We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of~~

~~the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].~~

RP1 proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *Old Word Mammarenaviruses (OWAV)*: In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa[40]. LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to close to 40 times[41]. Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae (REFS). There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *New World Mamarenaviruses (NWAV):* A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina [42], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine [43, 44]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations[45]. For Phase 1, **RP1** will use **MACV-Chicava Strain (Clade 2)** and **JUNV-Espindola (Lineage XX)** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *Orthonairoviruses*: In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated 10,000-15000 cases across Europe, Africa, and Asia with an estimated 500 deaths per year[46]. A suckling mouse brain derived, inactivated whole virus vaccine for CCHFV has been approved for use only in Bulgaria but has numerous safety concerns and limited demonstrated efficacy[47]. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[47]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[48]. UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice[23] (Unpublished, Cross and Geisbert [23]) and CCHF-Hoti (Clade 4) and CCHF-Afghan-09(Clade V) in NHP[49]. Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model [50] and that human survivors **(Figure 4)** generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38.

~~*Nairoviridae*. We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].~~

Once a candidate subunit-patch vaccine approach is selected, this RP1 will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative, "test case" human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa[51]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach[52] and working with Core E, RP1 will work to establish a LUJV NHP model for use as the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Formatted ... [15]

- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60%[53, 54]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment[54]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV),** a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [55]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini*, ticks to participate in enzootic maintenance of KASV[56]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible[55]. (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments[57]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families (REFS). An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.~~**Paragraph about subunit vaccines and PREP study.**~~

Milestone **1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals **(Table ~~XX~~5).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.3.A~~1~~F.

2.1.2.C: Determination of protective efficacy using optimized subunit-patch vaccination in NHP**:** In collaboration with **Core E**, 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-CCHFV-GPC, demonstrated effective in mice[23] and NHP (Unpublished, Cross and Geisbert) with 5 animals, and a control group of five unvaccinated animals **(Table 9).** Animals in vaccine groups 1 and 2 will be vaccinated using the down selected CCHFV antigens, adjuvants, and vaccination route identified in 1.1.2.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post-boost for boosted animals), all animals will be challenged with 5000 PFU of CCHFV-Hoti. The disease of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after CCHFV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Milestone

~~*2.1.2.E: Determination of protective efficacy against novel, emerging nairovirus using optimized subunit-patch vaccination in STAT-1KO mice and NHP*~~

Table: XX outline of NHP efficacy studes for MACV
Milestone 1.1.1.B

1.1.3~~1.F~~: Determination of cellular and humoral immune correlates associated with ~~protection~~protection.

Milestone 1.1.3.A~~1.F.a~~: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups:

We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard ~~whole blood~~ flow cytometric staining protocols will be used for surface and intracellular staining markers. ~~, b~~Briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye ~~for 20 minutes at room temperature~~. ~~C~~Cells are then washed again and ~~,~~ surface stain cocktail is added to the tubes, incubated ~~for 20~~

~~minutes~~, and washed. Cells are fixed ~~for 1 hour~~ with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed ~~in PBS~~. ~~Stained, fixed cells will then either be acquired directly.~~ Cell populations are then acquired and quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments: ~~-~~PBMC stimulations will be set up according to modifications of well established, previously published protocols.[62, 63] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldin A will then be added ~~at a concentration of 10mg/mL and~~ then incubated ~~at 37°C for~~prior ~~until~~ to flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays ~~will be set up~~ in 96-well plates and supernatants ~~will be~~ will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye ~~for 20 minutes at room temperature~~, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated ~~for 20 minutes~~, and washed. Cells are incubated in BD Cytofix/Cytoperm solution ~~for 20 minutes~~ followed by a wash. ~~with BD Perm/Wash Buffer.~~ Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed ~~in PBS~~. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a multi~~4~~-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated ~~for 3 hours at room temperature, protected from light~~ and subsequently washed by pelleted centrifugation. ~~1mL of wash buffer will be added and beads will be pelleted by centrifugation at 200g for 5 minutes.~~ Wash buffer will be removed and discarded. Beads will be resuspended ~~in 300uL wash buffer~~ and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection ~~antibody~~antibody, and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes. ~~at room temperature, protected from light.~~ Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer~~**need model**~~ ~~ELISPOT Fluorescence Microplate Reader.~~

Data Analysis: We will ~~look at the~~examine differences in immune responses across groups between each timepoint and baseline. ~~Model assumptions will be checked for a one-way ANOVA to compare the three groups. we will run the analysis after checking model assumptions, if those are not met then we will adjust to a nonparametric model or transform the outcome appropriately. To look at the longitudinal aspect of the data, we will investigate measurements over time between groups, the interaction of group and time can be analyzed using covariance pattern models (or linear mixed models), where the correlation between observations measured over time can be handled more flexibly. As a more exploratory analysis we will also look at adjusting for possible confounding variables such as sex and age. For categorical variables, comparisons will be made using Chi-Square tests.~~ Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

1.1.3.A:~~1.1.1.F.b~~: Systems serology Characterization of~~–~~ Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups:

We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform ~~developed by Dr. Gunn in~~ with **Core D**[64-66] to define the Fc-mediated humoral antiviral functions associated with ~~vaccination~~vaccine protection. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, ~~CCHFV,LUJV~~CCHFV, LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens ~~utilized~~ used for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages~~.~~, ~~W~~we will use a multiplexed analysis to determine ~~the~~ levels of antibodies against ~~the~~ viral antigens using ~~on~~ a MagPix xMAP instrument ~~as described~~.[65, 67] Specifically, each viral antigen will be coupled to coded magnetic beads ~~(Luminex)~~, mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM.~~—~~ For quantitation of bound antibody, we will ~~make a standard~~ use~~ing~~ pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions:~~–~~ We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry.~~ at KGH.~~

ADCC**:** Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates ~~for 5 hours at 37C 5% CO_2,~~ and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses ~~were~~ will be performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction ~~was used~~ to determine statistical significance ~~between groups.~~. ~~A network analysis will be performed to identify significant antibody features. Associations between antibody features will be determined using nonparametric Spearman correlation coefficient. Statistically significant associations after Bonferroni correction for multiple comparisons (adjusted P < .05) were used to generate networks in Cytoscape (version 3.4.0).~~

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and ~~additional clinical information (ie~~clinical signs into the network analysis.~~; PES symptoms). These will be included in the network analysis.~~

***Milestone* 1.~~AIM 2~~2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:** We will use existing mammarenaviruses[68, 69] and orthonairovirus[70] reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog but is still pathogenic in mice and humans (REFS). There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: ~~1.2~~ Pre-exposure Prophylaxis (PREP) using half-life extension antibody ~~treatments~~treatments.

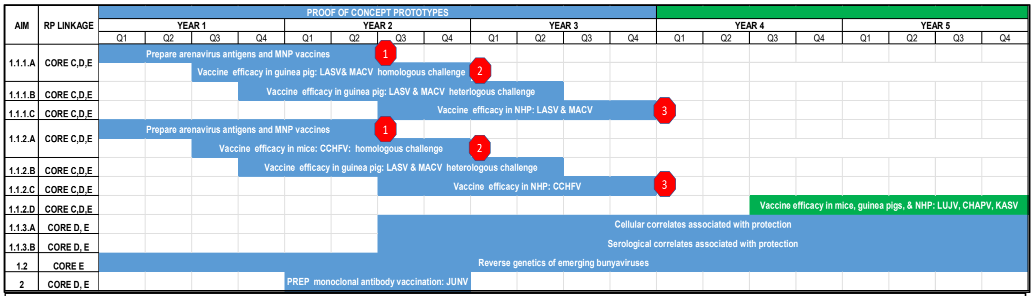
PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5
Control animals (NO PREP)	5
TOTALS	15

Table 11: PREP schedule outline in Milestone 2

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis. The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in improvement in serum half-life up 2-4 months(34-37).

***Scientific Approach*:**

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine: ~~-~~ In conjunction with ~~RP1~~ Cores D and ~~Core~~ E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb ~~with~~ whose potent therapeutic efficacy~~-~~[71, 72] ~~(guinea pig and NHP references)~~ we have previously described ~~by Abelson, Geisbert and Zeitlin~~ will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb~~(Table 4)~~. ~~The pharmacokinetics (PK) of these two variants will be evaluated in NHPs (Bioqual, Inc.; Rockville, MD~~see Core D~~) to select a lead candidate~~



RP1 Gant Chart with Go/No Go Decision Points (red octagons). (1) Successful fabrication and validation of antigens and/or vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity and lack of antigenicity as determined in Core C (MNP only) is a ***No-go*** for respective vaccine component. (2) Protection in rodent models is a ***Go***. Lack of protection in rodents is a ***No-go***. (3) Protection in NHP models is a Go to project Phase II. Lack of protection is a ***No-go*** for respective vaccine component.

~~for testing in NHPs against Junin Romero challenge in~~ Core E. ~~For the PK study, two doses (15 and 5 mg/kg) of each mAb will be administered IM to groups of 3 cynomolgus macaques (mixed sex). Serum will be collected (pre-dosing, 15 min, 6 hours and at days 1, 2, 3, 7, 10, 14, 21, 28, 42, 56) and tested via ELISA and Octet to quantitate serum antibody concetrations. PK parameters will be modeled with WinNonlin Phoenix software (reference).~~ We will select t~~T~~he variant with the most favorable pharmacokinetic (described in **Core D**)~~s~~ ~~PK will be selected~~ for testing with ~~**by RP1/**~~**Core E.** Briefly, groups of ~~4~~5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV ~~(Espindola or Romero~~Espindola~~?)~~ delivered IV **(Table 11)**. For further details of the NHP testing, please see **Core E**. These data will be used by the Scientific Advisory ~~Committee~~ Board to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative ~~approaches and~~approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, ~~and~~ CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three "test case" viruses LUJV, CHAPV, and KASV in Phase II of the project.……. If ~~this~~ any~~is not the case any~~ of the~~se~~ Phase I vaccine projects have not met the "go" criteria, ~~three viruses by year 2~~ we will refocus ~~effects~~

Please note: Discussion of expected results, other alternative ~~approaches~~approaches, and criteria for “go” or “no go” decisions for MILESTONES 1~~-4~~ and 2 are discussed as required in RFA-AI-20-023 in the **Project Milestones and Timelines** *section.*

Formatted: Not Highlight

Industry Expertise and Regulatory Considerations: Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP1** (Subunit-MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based Bunyavirus vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future “plug and play” pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

SPECIFIC AIMS

The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparednessThreats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **Research Project 1 (RP1)** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches which can be adapted across members of each viral family in a **"plug-and-play"** manner. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates a concern tied to efficacy as newer related viruses continue to emerge and cause disease in humans. Recent advances in reverse genetics of viruses have allowed the generation of infectious genetic clones of several arenaviruses (LASV, MACV, LUJV, JUNV) and nairoviruses (CCHFV) which may make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most arenaviruses and nairoviruses has largely centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized-trimeric antigen for the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GPe alone, co-delivered with LASV NP subunits, or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP) which harness the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs coupled to recombinant viral glycoprotein antigens and adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of this proposal are two-fold: (1) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed against Old and New World arenaviruses or emerging nairoviruses. (2) Develop. in or monoclonal antibody PREP strategies which can provide protective immunity (2) Specifically, we will:

Specific Aim 1: Subunit immunogens and MNP vaccination. Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches.

- **Milestone 1.1.1.A-C: Development and optimization of patch vaccination approach employing mammarenavirus subunits in guinea pigs and non-human primates.**
- **Milestone 1.1.2.A-C: Development and optimization of patch vaccination approach employing orthonairvirus subunits; protection in STAT-1/KO mice and non-human primates.**
- **Milestone 1.1.2.D: Determination of protective efficacy against novel, emerging mammarenavirus and orthonairovirus "test case" viruses using optimized subunit-patch vaccination in STAT-1/KO mice, guinea pigs and NHP.**
- **Milestone 1.1.3. A-B: Determination of cellular and humoral immune correlates associated with protection.**
- **Milestone 1.2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates.**

Specific Aim 2: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments. Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.

SPECIFIC AIMS

The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to ~~XX~~ 60% and significant, long-term sequelae in survivors. These viruses are on the World Health Organization’s (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparednessThreats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **Research Project 1 (RP1)** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches **which can be adapted across members of each viral family in a “plug-and-play” manner**. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates a ~~concerns~~concern tied to efficacy as newer related viruses continue to emerge and cause disease in humans. Recent advances in reverse genetics of viruses have allowed the generation of infectious genetic clones of several arenaviruses (LASV, MACV, LUJV, JUNV) and nairoviruses (CCHFV) which may make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most arenaviruses and nairoviruses has largely centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized-trimeric antigen for the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GPe alone, co-delivered with LASV NP subunits, or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP) which harness the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs coupled to recombinant viral glycoprotein antigens and adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of this proposal are two-fold: (1) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed against Old and New World arenaviruses or emerging nairoviruses. (2) Develop. in or monoclonal antibody PREP strategies which can provide protective immunity ~~against Old and New World arenaviruses or emerging nairoviruses.~~ (2) ~~Develop reverse genetics tools to evaluate emerging arenaviruses and nairoviruses for which no isolates are available.~~ Specifically, we will:

~~Milestone~~ Specific Aim 1: ~~Develop novel arenavirus and nairovirus vaccination approaches:~~

~~1.1~~ **Subunit immunogens and MNP vaccination:** Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches. We will then utilize lessons learned to address related “test case” arenaviruses and nairoviruses to develop a subunit/MNP approach for an old world arenavirus (LUJV) a new world arenavirus (CHAP~~P~~V), and an emerging bat borne nairovirus, Kasokero ~~virus~~virus (KASV). We will also develop recombinant virus tools including ~~We will generate recombinant~~ infectious clones ~~(~~and reporter-gene versions~~)~~ of LASV, MACV, ~~and~~ and CCHFV ~~CCHFV isolates~~ for which isolates are not available using reverse genetics. Rescued viruses will be characterized in vitro using cell-based assays and~~. Recombinant viruses will be examined~~ *in vivo* *to develop new* ~~(~~ animal models ~~development)~~ within **Core E**. We will also develop an infectious clone recovery system for KASV for virulence determination studies.

Specific Aim 2~~1.2~~: Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments: Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.

~~Milestone 2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:~~

~~We will generate recombinant infectious clones (and reporter-gene versions) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**.~~

RESEARCH STRATEGY:

~~1.~~ SIGNIFICANCE~~:~~

1.

~~The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.~~

T~~T~~he viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens (REF) where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness (REF). Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e. the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success (**REFS**). The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability(REFS). Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.

***The Mammarenaviruses*~~;~~:** All mammarenaviruses share a common genomic organization consisting of two ambi-sense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP) [2]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP. Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge [3]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe) [4]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV

endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. To test these notions, investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccine approaches to test this idea and have demonstrated protection against lethal LASV-Josiah challenge using a stabilized prefusion, trimeric GPe, a highly conserved NP NTD epitope, or a combination of the two antigens using a lethal outbred guinea pig model. Despite the considerable molecular diversity in LASV strains, there is understood that there is some conservation in key antigenic sites within both the GPe and the NP, suggesting that a PAN-LASV vaccine may be possible[5-7]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[8], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[9] , Lineage III (Cross, Geisbert unpublished), Lineage V[10] and Lineage VI (Cross and Geisbert Unpublished).

The Orthonairoviruses: Unique from other bunyaviruses, orthonairovirues are transmitted primarily by ticks in nature (REF). While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[11], Issyk-Kul virus[12], Songling virus[13]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[14] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[15]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[16]. CCHFV is listed on the WHO priority pathogen list[17] and is also a NIH-NIAID category A pathogen[18]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[19] (REF). Ribivirin has been used to treat infections with limited success[20]. CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [16]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[16]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[16]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[21].

~~**Research Project 1(RP1)** proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.~~

- ~~**Old Word Mammarenaviruses (OWAV):** RP1 will utilize **LASV as the prototype OWAV** due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with **XX** deaths across West Africa(REF). LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to over **XX** countries (REFS). Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) (REFS). Most of these vaccines utilize the LASV (glycoprotein) GP or the LASV GP + Nucleoprotein (NP) as the target immunogens in these vectors (REFs).~~
- ~~**New World Mamarenaviruses (NWAV):** A live attenuated vaccine for JUNV is currently in use in Argentina [2], but there is conflicting evidence of whether cross protection with other NWAV is possible [3, 4] and there are safety concerns related to reversion to pathogenic versions. This proposal will use **MACV and JUNV as the prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.~~

- ~~**Orthonairoviruses:** Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated **XXX** cases per year across Europe, Africa, and Asia. CCHFV outbreaks are often very large list some recent examples. A suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974, but has numerous safety concerns and limited demonstrated efficacy(**REFS**). Since then, a number of vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages(REF); however only an MVA-CCHFV vaccine has begun to advance towards clinical trials (REF).~~

~~Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e. the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success (**REFS**). The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability(REFS). Members of PABVAX, have developed protective protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.~~

~~**Subunit vaccines** have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments [5]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from the each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.~~

~~Once a candidate subunit-patch vaccine approach is selected, this approach will use lessons learned to produce plug-and-play approach to develop vaccines against a representative human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.~~

- ~~In 2008, Lujo virus was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [6]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, underscoring the need for antiviral tools against this emerging threat.~~
- ~~First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [7, 8]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [8]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective, but the phylogenetic divergence of CHAPV of XX% from JUNV suggests it may not be.~~
- ~~In 1977, Kasokero virus (KASV), a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [9]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick~~

~~surveys have demonstrated the potential for *Ornithodoros faini* ticks to participate in enzootic maintenance of KASV [10]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised.~~

~~**Pre-exposure prophylaxis (PREP)** and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high- risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis (REFS). The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will also perform pilot studies to examine the feasibility of PREP utilizing with a serum half-life extended mAb against JUNVs. Clinically validated Fc mutations can result in an improvement in serum half-life from 3-4 weeks to 2-4 months which can increase the instant barrier immunity from 30-45 days to 60+ days ([11-13] [14]refs).~~

~~The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.~~

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens:

The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[22] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[22]. Further, four of ~~the five~~the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[23-28]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[5]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine(REFS). Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens:

CCHFV is a divergent virus with up to seven genetic lineages (REFS). This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on (REF). Conversely, NP is highly conserved but not exposed on the virus surface cellular surface (REFs). Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [29]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

For situations where a vaccine does not exist or is not appropriate (*e.g.* immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE **[30, 31]** and LA **[32]**-**[33]** Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

~~***Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses***~~

3. ~~Add blurb discussing unique access to field samples from across the world and established expertise to generate infectious clones from emerging arenaviruses and nairoviruses:~~

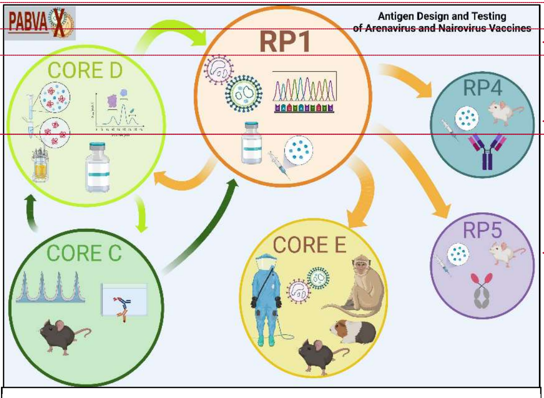

Figure 1: Overall Research Strategy for RP and demonstration of interactions with other RP and Cores of PABVAX

~~3.~~ APPROACH

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses. Collective expertise in virology, immunology, biological manufacturing, and vaccine innovation will be leveraged to develop cutting-edge vaccination approaches. **RP1** will work with several RPs and Cores in the center to advance two novel vaccination approaches targeting viral families within **Bunyavirales** (Figure **XX**). In collaboration with **Core D, RP1** will develop stabilized GP and NP epitope based subunit vaccines allowing for broad cross-protection across **mammarenavirus** and **orthonairovirus** species. This will be achieved by tailoring antigen design from prototype applicable to related members of these viral families. These optimized vaccines will be produced in **Core D** and evaluated for protective efficacy and determination of immune correlates associated with protection in animal models under maximum (BSL4) containment in collaboration with **Cores D and E** via intramuscular administration or Microneedle skin Patch (MNP). MNPs containing subunit vaccines manufactured in **Core D** and optimized for delivery efficiency in **Core C**.. Using optimized delivery methods developed in collaboration with **Cores C, D, and E, RP1** will provide stabilized GPe vaccines for mammarenaviruses and orthonairoviruses to **RP4** and **RP5** for the production of broadly reactive monoclonal antibodies or nanobodies, respectively. **RP1 and Cores D and E** will also collaborate on a pilot study to determine feasibility of PREP using half-life extended antibodies as an alternative to traditional vaccination. Lastly, **RP1** will work closely with **Core E** to develop infectious clones using reverse genetics to develop **BSL4 research tools and animal models** for viruses that are otherwise not available to the research community.

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide-linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[4]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[4] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization (**Figure xx**). Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV (**Figure 3**). Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes (**Figure xx**). Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

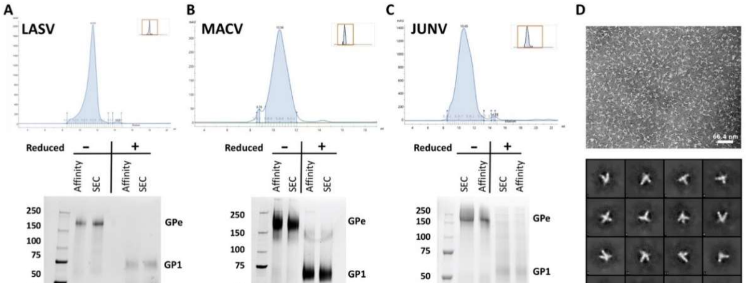

Figure XX. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

~~Our trimeric arenavirus GPs support efforts to isolate novel ultra-potent mAbs and to develop a second-generation arenavirus immunotherapeutic with reduced dosing requirements and broader reactivity compared to current LASV mAb candidates[25]. This significantly lowers the cost of goods while increasing ease of use for clinicians, both essential for a product used in developing nations where arenaviruses are prevalent.~~

LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches have largely focused on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[23-28] suggests that the cellular response, mediated by T cells, can play a highly important and complementary role in the long-term protection against pathogens. Based on literature reports that T cell responses highly correlate with LASV recovery, and that LASV NP plays a significant role in inducing those responses[23, 34], we also generated LASV NP antigens. We chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle (**Figure xx**) and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks.

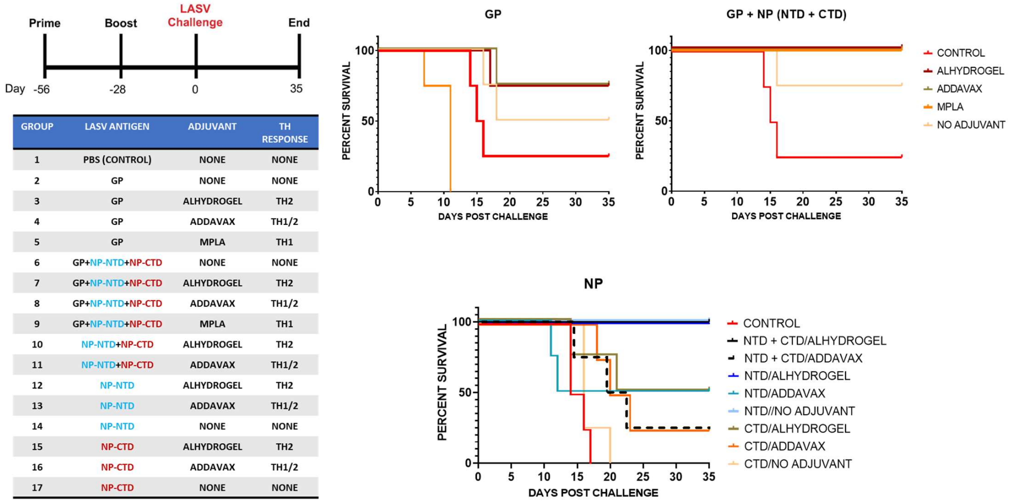
We then evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed **(Figure 6)** to assess whether immune responses to GP only, or GP+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking (**Figure 6**~~), and~~) and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP but no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.



GROUP	LASV ANTIGEN	ADJUVANT	TH RESPONSE

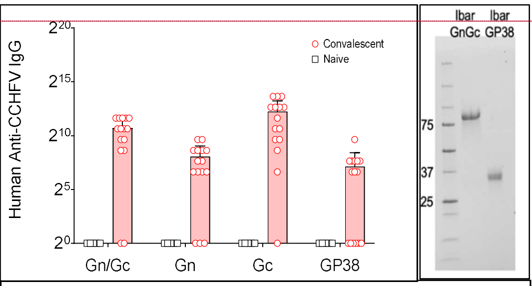

Figure XX: Engineered CCHFV proteins are reactive with serum from CCHFV survivors. SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification

Engineering glycoproteins antigens for ~~the~~ CCHFV: The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to test serum reactivity in CCHF survivors (Figure XX). We will use established protocols [35] as a template to optimize expression of CCHFV and Kasokero NP proteins.

~~*Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses*~~

~~***Rescue of recombinant viruses.*** An important goal of the PABVAX Center is to generate tools for pandemic preparedness. An important component of both RP1 and RP2 is to generate and recombinant viruses to fill gaps and provide tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with RP1 Core E will assist in the development and rescue of New World arenaviruses and the henipavirus Langya virus as detailed in the Research Strategies for RP1 and RP2.~~

APPROACH

~~***Overall Hypothesis:FILL THIS IN***~~

Specific Aim 1: Subunit immunogens and MNP vaccination ~~Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:~~

Rationale:

Overall rationale:

The choice of Mammarenavirus Prototype Pathogens is justified as follows:

- ~~*Old World Mammarenaviridae:* We propose LASV Josiah strain (Lineage 4) as the prototype pathogen due to the depth of available research data, availability of established rodent (**REF**) and nonhuman primate(NHP) models (**REFS**), frequency of exportation (**REFS**), and large number of annual cases throughout West Africa where the case fatality rate can be up to 60% in hospitalized cases (**REF**).~~
- ~~*New World Mammarenaviridae:* Due to the availability of a JUNV vaccine in the endemic region where JUNV circulates and the lack of cross protection against challenge with other NWAV, MACV, the causative agent of Bolivian hemorrhagic fever, will be used as the prototype pathogen for NWAV for studies outlined in Milestone 1.1. There are established guinea pig (**REF**) and NHP (**REF**) models for MACV. JUNV is the New World arenavirus with the largest knowledge base at present [**REF**]. For a pilot efficacy study outlined in Milestone 1.2, we will use JUNV Espindola Strain as a natural extension of previous published work demonstrating protective efficacy of the template PREP mAb (**REF**).~~
- ~~*Nairoviridae.* We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of~~

~~the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].~~

RP1 proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- *Old Word Mammarenaviruses (OWAV)*: In Phase 1, **RP1** will utilize **LASV Josiah strain (Lineage 4)** as the prototype OWAV due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with an estimated 5000 deaths across West Africa(REF). LASV has is the most imported to non-endemic countries viral hemorrhagic fever (VHF) next to dengue virus and has been imported to over **XX** countries (REFS). Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae (REFS). There are no approved vaccines for LASV; however clinical trials are beginning to evaluate 5 vaccine candidates, 4 of which are live attenuated recombinant viruses and the fifth is a DNA based vaccine. This creates a vacuum for vaccine options for special populations such as the pregnant, the elderly, and the immunocomprimised. There are existing guinea pig and NHP animal models.
- *New World Mamarenaviruses (NWAV)*: A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina [36], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine [37, 38]. Further, there are safety concerns related to potential for reversion to pathogenic versions and the use of a live attenuated vaccine in immunodepressed populations (Ksiazek reference) For Phase 1, **RP1** will use **MACV-Chicava Strain (Clade 2) and JUNV-Espindola (Lineage XX)** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- *Orthonairoviruses*: In phase 1, **CCHFV-Hoti strain (Clade 4) will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated **XXX** cases per year across Europe, Africa, and Asia. A suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974, but has numerous safety concerns and limited demonstrated efficacy(**REFS**). Since then, a number of vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages (REF); however only an MVA-CCHFV vaccine has begun to advance towards clinical trials (REF). UTMB has established animal models to enable testing of countermeasures against CCHF-Hoti and 5/6 clades in mice (Cross and Geisbert Unpublished, REFS) and CCHF-Hoti (Clade 4) and CCHF- Afghan-09(Clade V) in NHP(REF). Investigators in RP1 and Cores D and E have also previously demonstrated the protective efficacy of a CCHFV GP38 monoclonal antibody in a mouse model (REF) and that human survivors (Cross, Abelson, Zeitlin, and Geisbert) generate potent humoral responses against it suggesting that this cleaved nonstructural glycoprotein may also be leveraged as a vaccine component to induce targeted antibodies against GP38.

~~*Nairoviridae*. We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].~~

Once a candidate subunit-patch vaccine approach is selected, this RP1 will use lessons learned to enable a **plug-and-play** approach to develop subunit vaccines against a representative, “test case” human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, **Lujo virus (LUJV)** was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case’s medical evacuation to South Africa [39]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal “test case” OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. UTMB maintains a Strain 13 guinea pig model which can support efficacy studies in rodents using previously described approach (REF) and working with Core E, RP1 will work to establish a LUJV NHP model for use as

the test case. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

- First reported in 2003 in Bolivia, **Chapare virus (CHAPV)** is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [40, 41]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [41]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. UTMB has recently developed a uniformly lethal guinea pig model and a partially lethal infection model for CHAPV (unpublished, Cross and Geisbert). The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).
- In 1977, **Kasokero virus (KASV)**, a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [42]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini*, ticks to participate in enzootic maintenance of KASV [43]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. KASV has been demonstrated to be uniformly lethal in outbred mice suggesting a challenge model to determine vaccine efficacy is likely possible (REFS). (The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments [44]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from the each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Development of Recombinant Virus Tools: Rescue of recombinant viruses: An important objective of the PABVAX Center is to generate tools for pandemic preparedness. Investigators at UTMB have a long history of utilizing current molecular virology techniques to develop reverse genetics approaches to recover recombinant viruses for research and vaccine design for several different virus families (REFS). An additional goal of RP1 is to generate and recombinant viruses to fill gaps and provide research tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with Core E, RP1 develop and rescue of New World arenaviruses using existing reverse genetics approaches at UTMB or develop new ones to meet these needs.~~**Paragraph about subunit vaccines and PREP study.**~~

Table: XX outline of LASV Vaccination Schedule for Milestone 1.1.1.A

Milestone ~~Milestone~~ 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in table XX using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in Table XX. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core** E~~C~~ and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group (REFS). After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Control animals (NO VACCINE)	8		8	
Control vaccine (JUNV-Candid-1)	8		8	
	TOTALS	64	TOTALS	64

Table: XX outline of MACV Vaccination Schedule for Milestone 1.1.1.A

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table XX** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain **(REF).** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV **(REFs).**

Milestone

1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs. Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core** E~~C~~ as outlined in Table XX. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Milestone **1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP:** 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals (Table XX). Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Similarly, we will also determine the protective efficacy of MACV following the grouping described in **Table XX** using the identical experimental approach as outlined above for LASV challenge. The challenge virus will be the established MACV Chicava strain **(REF).** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will confirm protection in NHPs if demonstrated in guinea pigs **(REFs).**

Milestone

1~~2~~.1.2.A: Development and optimization of patch vaccination approach employing nairovirus subunits:~~.~~

Here we will determine if our GPe + NP-NTD subunit vaccine approach can be deployed against CCHFV.We will compare the protective efficacy of two adjuvants coupled to our CCHFV GP and NP-NTD proteins developed and manufactured in collaboration with **Core D** either as individual subunit vaccines or combinations as outlined in table XX using an intramuscular (IM) vaccination approach. Eight 6-8 week STAT-1/KO mice (balanced sex) will be randomly assigned to groups as outlined in Table XX. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core E** and challenged with 100 pfu of a low passage CCHF-Hoti (REFS). After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual

assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

1.1.3~~1.F~~: Determination of cellular and humoral immune correlates associated with ~~protection~~protection.

Milestone 1.1.3.A~~1.F.a~~: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups.

We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard whole blood flow cytometric staining protocols will be used for surface and intracellular staining markers, briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye for 20 minutes at room temperature. Cells are then washed again, surface stain cocktail is added to the tubes, incubated for 20 minutes, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed in PBS. Stained, fixed cells will then either be acquired directly. Cell populations are then quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments:. PBMC stimulations will be set up according to modifications of well established, previously published protocols. [45, 46] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37°C for 1 hour. A protein transport inhibitor such as brefeldinA will then be added at a concentration of 10mg/mL and incubated at 37°C for until flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37°C. Stimulations to assess secreted analytes by multiplex-bead based assays will be set up in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye for 20 minutes at room temperature, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated for 20 minutes, and washed. Cells are incubated in BD Cytofix/Cytoperm solution for 20 minutes followed by a wash with BD Perm/Wash Buffer. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed in PBS. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a 4-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated for 3 hours at room temperature, protected from light. 1mL of wash buffer will be added and beads will be pelleted by centrifugation at 200g for 5 minutes. Wash buffer will be removed and discarded. Beads will be resuspended in 300uL wash buffer and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37°C. Wells will be washed manually 3-times, followed by the addition of detection antibody and incubated either overnight at 4°C or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes at room temperature, protected from light. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37°C), and spot forming units (SPU) will be read on an S6 Universal M2 ELISPOT analyzer~~**need model**~~ ~~ELISPOT Fluorescence Microplate Reader.~~

Data Analysis: We will look at the differences in immune responses across groups between each timepoint and baseline. Model assumptions will be checked for a one-way ANOVA to compare the three groups. we will run the analysis after checking model assumptions, if those are not met then we will adjust to a nonparametric model or transform the outcome appropriately. To look at the longitudinal aspect of the data, we will investigate measurements over time between groups, the interaction of group and time can be analyzed using covariance pattern models (or linear mixed models), where the correlation between observations measured over time can be handled more flexibly. As a more exploratory analysis we will also look at adjusting for possible confounding variables such as sex and age. For categorical variables, comparisons will be made using Chi-Square tests. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

Milestone

1.1.3.A:~~1.1.1.F.b~~: Systems serology Characterization of Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups.

We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform developed by Dr. Gunn in **Core D**[47-49] to define the Fc-mediated humoral antiviral functions associated with vaccination. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV,LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens utilized for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages. We will use a multiplexed analysis to determine the levels of antibodies against the viral antigens using on MagPix xMAP instrument as described.[48, 50] Specifically, each viral antigen will be coupled to coded magnetic beads (Luminex), mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will make a standard using pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry at KGH.

ADCC: Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates for 5 hours at 37C 5% CO_2, and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses were performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction was used to determine statistical significance between groups. A network analysis will be performed to identify significant antibody features. Associations between antibody features will be determined using nonparametric Spearman correlation coefficient. Statistically significant associations after Bonferroni correction for multiple comparisons (adjusted P < .05) were used to generate networks in Cytoscape (version 3.4.0).

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and ~~additional clinical information (ie~~clinical signs into the network analysis.~~; PES symptoms). These will be included in the network analysis.~~

***Milestone* 1.~~AIM~~ ~~2~~2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:**

We will use existing mammarenaviruses (REFS) and orthonairovirus (REFS) reverse genetics systems present at UTMB to recover new isolates of LASV, JUNV, MACV, CHAPV, or CCHFV from recent outbreaks if natural isolates are not otherwise available. In parallel, will also create reporter constructs to enable high throughput screening of antivirals with these new isolates. CCHFV GP38 protein is speculated to serve as a virulence factor as protective antibodies targeting this protein have been identified. KASV does not have an equivalent GP38 homolog but is still pathogenic in mice and humans (REFS). There is currently no reverse genetics system for KASV. We will develop an infectious clone system for KASV to create a reporter virus for screening antivirals, but also to build a tool for beginning to understand KASV pathogenesis through loss of function studies.

Milestone 2: ~~1.2~~ Pre-exposure Prophylaxis (PREP) using half-life extension antibody ~~treatments~~treatments.

Rationale: PREP and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis (REFS). The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will perform pilot studies to examine the feasibility of PREP with a serum half-life extended mAb against JUNV. Clinically validated Fc mutations can result in an improvement in serum half-life from 3-4 weeks to 2-4 months ([30-33]).

PREP	JUNV NHP CHALLENGE
5 mg/kg	5
15mg/kg	5

TOTALS	15

Table:XX

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine~~:~~ In conjunction with ~~RP1~~ Cores D and ~~Core~~ E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb ~~with~~ whose potent therapeutic efficacy [51, 52] ~~(guinea pig and NHP references)~~ we have previously described ~~by Abelson, Geisbert and Zeitlin~~ will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb~~(Table 4)~~. The pharmacokinetics (PK) of these two variants will be evaluated in NHPs (~~Bioqual, Inc.; Rockville, MD~~see Core D) to select a lead candidate for testing in NHPs against Junin Romero challenge in Core E. ~~For the PK study, two doses (15 and 5 mg/kg) of each mAb will be administered IM to groups of 3 cynomolgus macaques (mixed sex). Serum will be collected (pre-dosing, 15 min, 6 hours and at days 1, 2, 3, 7, 10, 14, 21, 28, 42, 56) and tested via ELISA and Octet to quantitate serum antibody concetrations. PK parameters will be modeled with WinNonlin Phoenix software (reference).~~ We will select t~~T~~he variant with the most favorable pharmacokinetics ~~PK will be selected~~ for testing with ~~by RP1/~~Core E. Briefly, groups of ~~4~~5 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV ~~(Espindola or Romero~~Espindola~~?)~~ delivered IV (Table XX). For further details of the NHP testing, please see Core E. These data will be used by the Scientific Advisory ~~Committee~~ Board to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Expected results, alternative ~~approaches~~approaches, and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and ideally protective subunit-patch targeting LASV, MACV, ~~and~~ CCHFV and use lessons learned from this Phase I suite of studies to rapidly develop subunit-patch vaccines for three “test case” viruses LUJV, CHAPV, and KASV in Phase II of the project.~~…….~~ If ~~this~~ any~~is not the case any~~ of the~~se~~ Phase I vaccine projects have not met the “go” criteria, ~~three viruses by year 2~~ we will refocus ~~effects~~ efforts toward~~on~~ the remaining virus families adjusting the requested budgets accordingly after ~~consulation~~consultation with NIAID and SAC.

Highlight

SPECIFIC AIMS

The viral order *Bunyavirales* is composed of several viral families known to contain several high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens due to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparednessThreats to public health are further heightened due to **lack of internationally approved vaccines** to address threats of natural epidemics as well as the potential bio-weaponization of these viruses. To address this unmet need, **Research Project 1 (RP1)** will leverage combined expertise in high-containment virology, immunology, and biological product development, to develop arenavirus and nairovirus research tools and vaccine approaches **which can be adapted across members of each viral family in a "plug-and-play" manner**. Much of the work developing vaccines against high containment viruses has relied heavily on viral isolates derived over 40 years ago or longer, which creates a concerns tied to efficacy as newer related viruses continue to emerge and cause disease in humans. Recent advances in reverse genetics of viruses have allowed the generation of infectious genetic clones of several arenaviruses (LASV, MACV, LUJV, JUNV) and nairoviruses (CCHFV) which may make vaccine testing of genetically divergent isolates more feasible. Vaccine development for most arenaviruses and nairoviruses has largely centered on the understanding of the critical role for viral glycoproteins (GP) and nucleoproteins (NP) to drive natural immunity. We have recently successfully engineered a recombinant, stabilized-trimeric antigen for the LASV GP to act as an antigenic mimic of viral surface displayed GP. We have found that this trimeric GP co-delivered with LASV NP subunits or NP subunits alone, **can fully protect guinea pigs against lethal challenge by LASV** underscoring the value of these antigens as vaccine components. Subunit vaccines are prime candidates for alternative vaccination approaches such as microneedle patches (MNP) which harness the potently immunoresponsive cutaneous microenvironments using dissolvable MNPs coupled to recombinant viral glycoprotein antigens and adjuvants to elicit robust, strong, and long-lasting protective immunity against the target pathogen. The importance of humoral immunity for affording potent protection or treatment against viral infections cannot be understated as evidenced by the recent success using monoclonal antibody therapies to treat Ebola virus disease or COVID-19, yet little is known for the potential for pre-exposure prophylactic (PREP) administration of antibody therapies and what kind of prophylactic windows are possible. The **goals** of this proposal are two-fold: (1) Develop novel vaccination approaches utilizing subunit-MNP vaccines developed in or monoclonal antibody PREP strategies which can provide protective immunity against Old and New World arenaviruses or emerging nairoviruses. (2) Develop reverse genetics tools to evaluate emerging arenaviruses and nairoviruses for which no isolates are available. Specifically, we will:

Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:

1.1 Subunit immunogens and MNP vaccination: Working with **Core C, D**, and **E**, we will determine optimal immunogen/MNP combination that affords pan-lineage protection against LASV, MACV, and CCHFV disease in animal models. We will define detailed multi-parameter cellular and systems level humoral correlates of protection of candidate vaccination approaches. We will then utilize lessons learned to address related "test case" arenaviruses and nairoviruses to develop a subunit/MNP approach for an old world arenavirus (LUJV) a new world arenavirus (CHPV), and an emerging bat borne nairovirus, Kasokero virus.

1.2 Pre-exposure Prophylaxis (PREP) using half-life extension antibody treatments: Working with **Core D**, we will develop vaccination approaches employing a potent therapeutic anti-JUNV monoclonal antibody re-engineered with YTE and LA Fc point mutation predicted to extend pharmacokinetics and determine protective efficacy and estimate conferred immunity correlates in animal studies performed in **Core E**.

Milestone 2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:

We will generate recombinant infectious clones (and reporter-gene versions) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**.

RESEARCH STRATEGY:
1. SIGNIFICANCE:
The viral order *Bunyavirales* is composed of 13 families of which five (*Peribunyaviridae*, *Phenuiviridae Hantaviridae*, *Arenaviridae, and Nairoviridae)* are known to contain several high priority human pathogens associated with sever fever, encephalitis, respiratory, and/or hemorrhagic disease[1]. Notably, Arenaviridae and Nairoviridae families contain viruses which cause severe hemorrhagic diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens (REF) where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV)– are identified as NIAID Category A pathogens. This classification stems is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness (REF). Threats to public health are further heightened due to lack of internationally approved vaccines to address threats of natural epidemics as well as the potential bio-weaponization of these viruses.

Research Project 1(RP1) proposes preclinical research that will support Investigational New Drug Application (IND)-applications to develop vaccine approaches against prototype viruses from two Bunyavirales viral families, the Mammarenaviruses and the Orthonairoviruses. Generation of effective vaccines against members of both has potential great global benefit as both viral families have sprawling geographic endemic ranges ranges which have resulted in marked genetic diversity within each viral family further challenging effective vaccine approaches.

- **Old Word Mammarenaviruses (OWAV):** RP1 will utilize **LASV as the prototype OWAV** due to its elevated public health burden throughout West Africa with hundreds of thousands of estimated cases annually with **XX** deaths across West Africa(REF). LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to over **XX** countries (REFS). Case fatality rates (CFR) up to 60% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) (REFS). Most of these vaccines utilize the LASV (glycoprotein) GP or the LASV GP + Nucleoprotein (NP) as the target immunogens in these vectors (REFs).
- **New World Mamarenaviruses (NWAV):** A live attenuated vaccine for JUNV is currently in use in Argentina [2], but there is conflicting evidence of whether cross protection with other NWAV is possible [3, 4] and there are safety concerns related to reversion to pathogenic versions. This proposal will use **MACV and JUNV as the prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted.
- **Orthonairoviruses:** Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family with an estimated **XXX** cases per year across Europe, Africa, and Asia. CCHFV outbreaks are often very large list some recent examples. A suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974, but has numerous safety concerns and limited demonstrated efficacy(**REFS**). Since then, a number of vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages(REF); however only an MVA-CCHFV vaccine has begun to advance towards clinical trials (REF).

Many of the vaccine approaches targeting the prototype viruses chosen for this proposal utilize live-attenuated viruses, which have many advantages in terms of being able to rapidly induce protective and often durable protection from debilitating disease and death. However, as the global human population grows, the number of special populations with depressed immune systems (i.e. the elderly, immunocomprimised, and/or pregnant) grows, which call in to the question the safety of live-attenuated vaccines and suggests more pathologically benign approaches may have value. The use of subunit vaccines designed from immunologically critical epitopes from different pathogens has been a central driver for a number of successful and approved vaccinee strategies including Tetanus, HPV, Hepatitis B, a suite of bacterial pathogens and is the basis for mRNA vaccine success (**REFS**). The success of many subunit vaccines is owed to targeted immunogenicity, ability to rapidly scale production, and potential for long-term, shelf stability(REFS). Members of PABVAX, have developed protective

protein-based subunit vaccines against LASV which will serve as the template to develop vaccines against other mammarenaviruses and orthonairoviruses.

Subunit vaccines have several advantages including potential for shelf stable formulations and utility in alternative delivery methods such as **microneedle skin patches (MNP).** Skin patch vaccination has several advantages over traditional IM vaccination which include needle free operation, compatibility with shelf stable subunit vaccines, and a delivery approach that harnesses the potently immunoresponsive cutaneous microenvironments [5]. RP1 will capitalize on PABVAX member expertise to couple protective subunit vaccines to MNPs targeting key antigens associated with survival from infection from the each prototype pathogen group, namely viral glycoproteins and nucleoproteins with the goal of eliciting robust, strong, and long-lasting protective immunity against the target pathogen.

Once a candidate subunit-patch vaccine approach is selected, this approach will use lessons learned to produce plug-and-play approach to develop vaccines against a representative human pathogen from each prototype virus group for which no research grade vaccines have been created and tested in animal models.

- In 2008, Lujo virus was isolated from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [6]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, underscoring the need for antiviral tools against this emerging threat.
- First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [7, 8]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [8]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective, but the phylogenetic divergence of CHAPV of XX% from JUNV suggests it may not be.
- In 1977, Kasokero virus (KASV), a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [9]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for *Ornithodoros faini* ticks to participate in enzootic maintenance of KASV [10]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised.

Pre-exposure prophylaxis (PREP) and Post exposure prophylaxis (PEP) using monoclonal antibodies or immunoglobulins has been employed for providing instant barrier immunity to high-~~-~~risk individuals for infections such as Respiratory syncytial virus (palivizumab for prophylaxis), rabies (polyclonal immunoglobulin for post-exposure prophylaxis) or COVID-19 (tixagevimab/cilgavimab for prophylaxis (REFS). The PABVAX consortium has a long track record of success developing monoclonal antibody (mAb) therapies against VHFs and emerging viruses. Building on this success, RP1 will ~~also~~ perform pilot studies to examine the feasibility of PREP ~~utilizing~~ with a serum half-life extended mAb against JUNV~~s~~. Clinically validated Fc mutations can result in an improvement in serum half-life from 3-4 weeks to 2-4 months ~~which can increase the instant barrier immunity from 30-45 days to 60+ days~~ ([44, 45][46] [47]~~refs~~).

The PABVAX consortium will build on over a decade of successful collaboration generating vaccines and therapeutics for emerging, high priority viruses where collective expertise in virology, immunology, biological manufacturing and vaccine device innovation to develop cutting edge vaccination approaches using plug-and-play approaches tailored from prototype mammarenaviruses and orthonairoviruses and applicable to related members of these viral families.

2. INNOVATION

Unique arenavirus subunit vaccine strategy utilizing GP and NP immunogens

The Coalition for Epidemic Preparedness Innovations (CEPI) is currently funding development of multiple LASV vaccine candidates[11] with four out of five candidates based on viral vector backbones. The remaining candidate is a DNA-based vaccine in active development by Inovio Pharmaceuticals. Of significance, very little pre-clinical data concerning the safety and efficacy of these vaccine candidates is currently available[11]. Further, four of the five deliver LASV GP as the sole immunogen, potentially limiting long-term durability and potential of the immune response.

In contrast, we are developing arenavirus subunit vaccines that co-deliver GP and NP immunogens. When engineering viral immunogens to be used as subunit vaccines, the recombinant antigens must structurally and antigenically represent the authentic viral antigen. Importantly, we have engineered a recombinant trimeric LASV GP spike antigen (the primary structural antigen on the surface of arenavirus), and to our knowledge, ours is the first LASV subunit vaccine candidate to utilize trimeric LASV GP. The trimeric GP immunogen, representative of the authentic viral antigen, induces a highly potent and protective anti-GP humoral immune response. In conjunction with humoral immunity, cellular immunity, mediated by a robust T cell response, is known to be highly predictive of recovery from a LASV infection[12-17]. Epitopes within LASV NP, and to a lesser extent GP, are known to substantially contribute to T cell mediated immunity[18]. Exploiting highly conserved N-terminal immunodominant epitopes on of LASV NP, we find that vaccination with only NP epitopes is sufficient to confer 100% protection in a lethal, outbred guinea pig model. Sequence conservation across NP is higher than GP across LASV lineages suggesting that vaccine strategies coupling NP and GP may provide a more broadly protective vaccine(REFS). Indeed, we have found that an immunogenic cocktail comprised of LASV GP and NP offered complete protection against LASV challenge in guinea pigs.

Commented [CRW1]: Need to confirm

Unique nairovirus subunit vaccine strategy utilizing GP and NP immunogens

CCHFV is a divergent virus with up to seven genetic lineages (REFS). This diversity is evident in the variation observed most clearly in glycoprotein sequences across lineages. Given the glycoprotein is a pivotal protein dictating viral entry and immune recognition, it is little wonder why CCHFV vaccines have struggled with heterologous challenge with strains of viruses outside of the clade the vaccine was based on (REF). Conversely, NP is highly conserved but not exposed on the virus surface cellular surface (REFs). Indeed, a recent report has demonstrated that an NP expressing replicating RNA vaccine was able to confer protection against heterologous challenge [19]. Taken together, a similar strategy of coupling GP and NP into a vaccine strategy likely has the greatest potential for potent, cross-clade protection.

PREP "vaccination" as a measure to control mammarenaviruses

For situations where a vaccine does not exist or is not appropriate (*e.g.* immunocompromised individuals or first responders who do not have the time to wait for natural immunity to develop from vaccination), mAbs with Fc mutations to extend serum-half-life offer an appealing alternative that can provide immediate protection lasting greater than 6 months. For this PABVAX proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by PABVAX researchers will be produced with YTE [44, 45] and LA [46] [47] Fc point mutations to determine the potential for delivering instantaneous, long-lasting (> 6 months) barrier immunity using monoclonal antibodies.

Commented [CRW2]: Larry, feel free to refine and/or elaborate.

Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses

Add blurb discussing unique access to field samples from across the world and established expertise to generate infectious clones from emerging arenaviruses and nairoviruses:

3. APPROACH

PRELIMINARY RESULTS

Engineering trimeric glycoprotein antigens for the arenaviruses

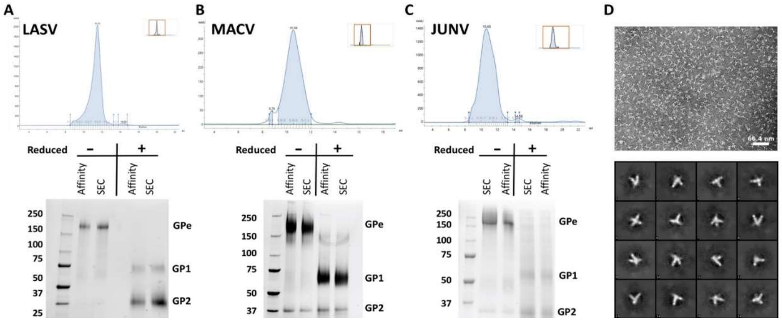

Figure XX. Arenavirus immunogens. (A) LASV, (B) MACV and (C) JUNV GP immunogens were expressed and purified and the trimeric nature confirmed with SEC and SDS-PAGE. (D) Negative stain EM and 2D class averages of JUNV GP-J199 Fab complex. EM courtesy of Dr. J. Mclellan, UT Austin.

Production of recombinant trimeric LASV GP has been particularly challenging within the LASV research community. The LASV GP ectodomain (GP) consists of two non-covalently associated subunits, GP1 and GP2, which readily disassociate in solution, historically hindering the expression and purification of a trimeric GPe. A recent study introduced a pair of cysteine mutations into GP1 and GP2, resulting in a stable disulfide-linked GP1/GP2 monomer amenable to structural studies when stabilized by a fiduciary antibody Fab fragment[20]. Mapp has since made structure-based improvements to generate a stable GP immunogen representative of the authentic viral GP spike and suitable for use as a vaccine. We reverted the E329P mutant, hypothesized to stabilize heptad repeat 1 in GP2[20] and added an additional trimerization motif to stabilize the GP spike in the absence of Fabs. The tagged trimeric LASV GP is expressed and secreted from Drosophila S2 cells and purified from supernatant via affinity chromatography using a StrepTrap HP column (GE Healthcare). SDS-PAGE and Size-exclusion chromatography (SEC) offer verification of trimerization **(Figure xx)**. Pilot stability studies inclusive of freeze thaw cycles and storage at 4˚C are supportive of the stability required for a vaccine candidate.

The engineering methodologies employed for LASV GP translated well to the NWA GPs from JUNV and MACV **(Figure 3)**. Negative stain EM of JUNV GP in complex with the neutralizing and protective Fab form of J199, reveals monodispersed trimeric GP/Fab complexes **(Figure xx)**. Both the interaction with a well-characterized mAb and the EM data suggest our GP antigens closely recapitulate the authentic viral GP trimeric spike and support their use as a vaccine immunogen.

Our trimeric arenavirus GPs support efforts to isolate novel ultra-potent mAbs and to develop a second-generation arenavirus immunotherapeutic with reduced dosing requirements and broader reactivity compared to current LASV mAb candidates[21]. This significantly lowers the cost of goods while increasing ease of use for clinicians, both essential for a product used in developing nations where arenaviruses are prevalent.

LASV subunit vaccine protects guinea pigs against lethal challenge

While classical vaccine approaches have largely focused on evoking a strong humoral response and high titers of nAbs to a target pathogen, increasing evidence[12-17] suggests that the cellular response, mediated by T cells, can play a highly important and complementary role in the long-term protection against pathogens. Based on literature reports that T cell responses highly correlate with LASV recovery, and that LASV NP plays a significant role in inducing those responses[12, 22], we also generated LASV NP antigens. We chose to deliver the C-terminal domain (CTD) and N-terminal domain (NTD) of LASV NP separately as they have distinct functions in the virus lifecycle (**Figure xx**) and express to high levels (50-100 mg/L) as two independent domains in bacteria using standard laboratory shaker flasks.

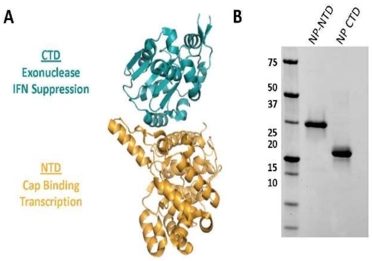

Figure xx. LASV NP subdomains and expression. (A) Crystal structure of LASV NP highlighting the two functional subdomains. (B)

Figure 6. A LASV subunit vaccine provides complete protection in the guinea pig model of LASV infection. (Left) Groups of 4 guinea pigs were immunized intraperitoneally in a prime-boost strategy with either PBS vehicle control, 2x50 µg of GP, or 2x50 µg doses of GP + 2x25µg of NP-NTD + 2x25 µg of NP-CTD, or either 2x25 µg NP antigen in combination or separately. Immunized animals were challenged with a lethal dose of LASV/Josiah 28 days post-boost. (Right) Animals were monitored for 35 days post-challenge, and survival curves and weight change are plotted.

We evaluated our LASV antigens as vaccine immunogens in the lethal Hartley guinea pig model of LASV infection. Our study was designed (**Figure 6**) to assess whether immune responses to GP only, or GP+NP would offer protective immunity from lethal LASV challenge. We chose to investigate several commercially available adjuvants with known properties for driving Th1 (MPLA) and Th2 (Alhydrogel) responses selectively or in combination (Addavax). All 3 adjuvants are currently utilized in either FDA- or EMA-approved vaccines, thus supporting the long-term feasibility of the approach for potential human use. The results of our vaccination/challenge study were quite striking (**Figure 6**), and indicate a clear benefit to a combination immunization strategy with LASV GP and NP. The maximum survival benefit in the GP only groups were observed in groups using Alhydrogel and Addavax as adjuvants (75% survival). Half of the animals in the unadjuvanted group survived, while the control group had one survivor. Surprisingly, animals that were administered GP with MPLA as an adjuvant displayed rapid onset of clinical signs and succumbed to infection early in the experiment. In contrast, **all animals that were immunized with LASV GP + NP-NTD + NP-CTD subunits and any of the adjuvants were completely protected from challenge with LASV.** Only one animal succumbed to infection in the group receiving GP+NP but no adjuvant. In a follow-up study, we further examined the potential for NTD and/or CTD of LASV NP to confer protection to lethal challenge. While combination of

NTD and CTD resulted in uniform protection when administered with Alhydryogel, the cohort supplemented with Addavax only resulted in 25% protection. Correspondingly, NTD vaccination with Allhydrogel resulted in 100% survival where as Addavax only conferred 50% protection. Interestingly, NP NTD vaccination with no adjuvant resulted in 100% survival. Conversely, the best protection from the LASV CTD was conferred when using Alhydrogel at 50% where both Addavax or no adjuvant groups were not protected.

*Engineering glycoproteins antigens for the CCHFV*The CCHF virus has a tripartite negative-sense RNA genome,composed of the the small (S), medium (M), and large (L) segments. The M segment encodes the viral glycoprotein precursor (GPC) complex, which is subsequently cleaved by host proteases into multiple proteins, including the envelope glycoprotein GnGc and secreted GP38 protein. GnGc is composed of Gn and Gc subunits, which are linked together by a multiple membrane spanning region. These transmembrane domains complicate the *in vitro* expression of soluble GnGc, but we have designed a construct that replaces the transmembrane domains with a linker and have generated a stable drosophila cell line that expresses up to 3mg/L. We have also generated stable cell lines expressing Gn, Gc, and GP38 proteins. We used these proteins to test serum reactivity in CCHF survivors (Figure XX). We will use established protocols [23] as a template to optimize expression of CCHFV and Kasokero NP proteins.

Generation of Infectious clones and reporter viruses of emergining Arenaviruses and Nairoviruses

Rescue of recombinant viruses. An important goal of the PABVAX Center is to generate tools for pandemic preparedness. An important component of both RP1 and RP2 is to generate and recombinant viruses to fill gaps and provide tools where wild type viruses do not exist either because 1) only sequence information is available or 2) isolates exist but viruses are unable to be shared with the research community. In collaboration with RP1 Core E will assist in the development and rescue of New World arenaviruses and the henipavirus Langya virus as detailed in the Research Strategies for RP1 and RP2.

Commented [CRW3]: VERBIAGE FROM CORE C, NEED TO ADAPT AND ELABORATE HERE.

APPROACH

Overall Hypothesis:FILL THIS IN

Milestone 1: Develop novel arenavirus and nairovirus vaccination approaches:

Rationale: The choice of Mammarenavirus Prototype Pathogens is justified as follows:

- *Old World Mammarenaviridae:* We propose LASV Josiah strain (Lineage 4) as the prototype pathogen due to the depth of available research data, availability of established rodent (**REF**) and nonhuman primate(NHP) models (**REFS**), frequency of exportation (**REFS**), and large number of annual cases throughout West Africa where the case fatality rate can be up to 60% in hospitalized cases (**REF**).
- *New World Mammarenaviridae:* Due to the availability of a JUNV vaccine in the endemic region where JUNV circulates and the lack of cross protection against challenge with other NWAV, MACV, the causative agent of Bolivian hemorrhagic fever, will be used as the prototype pathogen for NWAV for studies outlined in Milestone 1.1. There are established guinea pig (**REF**) and NHP (**REF**) models for MACV. JUNV is the New World arenavirus with the largest knowledge base at present [**REF**]. For a pilot efficacy study outlined in Milestone 1.2, we will use JUNV Espindola Strain as a natural extension of previous published work demonstrating protective efficacy of the template PREP mAb (**REF**).
- *Nairoviridae*. We propose CCHFV Hoti strain (Clade 5) as the nairovirus prototype pathogen. UTMB has established mouse models (**REF**) and NHP (**REF**) models to enable testing of CCHFV countermeasures against a number of the available clades. CCHF is the most important member of the *Nairoviridae* family with a major public-health impact across Western Asia, the Balkans, Southern Europe, and most of Africa [**REF**].

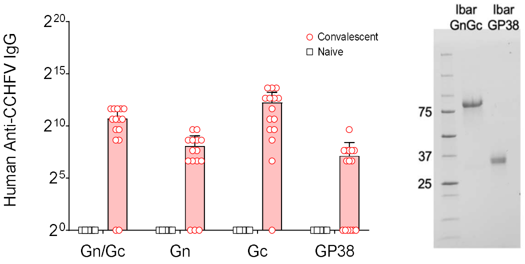

Figure XX: Engineered CCHFV proteins are reactive with serum from CCHFV survivors. SDS-PAGE gel of CCHF Ibar proteins GnGc and GP38 after 2 step purification

Paragraph about subunit vaccines and PREP study.

Milestone 1.1 Subunit immunogens and MNP vaccination

Milestone 1.1.1.A: Development and optimization of patch vaccination approach employing arenavirus subunits in guinea pigs: Building on the success of our GPe + NP-NTD LASV vaccine, we will compare the protective efficacy of two adjuvants coupled to our LASV GPe and NP-NTD proteins developed and manufactured in **Core D** either as individual subunit vaccines or combinations as outlined in table XX using an intramuscular (IM) vaccination approach. Eight outbred, 350 gram Hartley guinea pigs (balanced sex) will be randomly assigned to groups as outlined in Table XX. Blood will be collected prior to immunization and then on days 28 and 56-days post-immunization to evaluate humoral immune responses by ELISA and virus neutralization assays. After 28 days immunized animals will be boosted with an equivalent dose as the priming vaccination IM. On day 56 post-immunization, animals will be transferred to **BSL4 evaluation Core C** and challenged with 5000 pfu of a guinea pig adapted LASV-Josiah developed by our group (REFS). After virus challenge, animals will be monitored clinically a minimum of twice daily. Hands-on physical and visual assessment of infected animals may occur outside scheduled times, if required. Following challenge, additional biosamples collected at 1, 4, 7, 10, 14, 21 and 28 days will be processed for measurement of viremia by plaque assay and qRT-PCR. Results from the IM vaccination then be compared head-to-head against an equivalent vaccination/challenge cohort where the subunit vaccines will be administered using the MNP patches prepared by MNP Patch **CORE C**. Patches are administered after shaving a small section of the abdomen and applied using gentle pressure for 10-15 minutes so that the microneedles can fully dissolve.

Similarly, we will determine the protective efficacy using MACV GPe and NP-NTD proteins developed and manufactured in **Core D** following the grouping described in **Table XX** using the identical experimental approach as outlined above. The challenge virus will be the established MACV Chicava strain **(REF).** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will assess its utility as a positive control vaccine against lethal challenge with MACV **(REFs).**

1.1.1.B: Determination of pan-LASV and Pan-MACV protective efficacy using optimized subunit-patch vaccination in guinea pigs. Using the adjuvant and vaccination route down selected in 1.1.1.A, we will assess the potential for our LASV subunit vaccines to confer heterologous protection against four lineages of LASV endemic to geographically distinct from the prototype strain (Josiah-lineage 4, Sierra Leone). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 2 (Nigeria), 3 (Nigeria), 5 (Mali) and 6(Togo) established in the **BSL4 evaluation Core C** as outlined in Table XX. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

Table: XX outline of PAN-MACV Vaccine Efficacy Schedule for Milestone 1.1.1.B

Similarly, after down selecting the optimal adjuvant and vaccination route, we will assess the potential for our MACV subunit vaccines to confer heterologous protection against thre lineages of MACV endemic to genetically distinct from the prototype strain (Chicava-Lineage 2). Employing optimized strain 13 or outbred, Hartley guinea pig models for lineages 1, 5, and 8 established in the **BSL4 evaluation Core C** as outlined in Table XX. We will also utilize JUNV (Romero strain)(**REF**) challenge to assess heterologous protection against a related but distinct NWAV to begin to assess the potential for cross protection beyond MACV strains. The vaccination, challenge, and sample collection will be identical to that outlined in 1.1.1.A above.

1.1.1.C: Determination of LASV and MACV protective efficacy using optimized subunit-patch vaccination in NHP: 15 cynomolgus monkeys will be randomized into two experimental vaccine groups of 5 animals per group, a control vaccine (VSV-LASV-GPC) with 5 animals, and a control group of five unvaccinated animals (Table XX). Animals in vaccine groups 1 and 2 will be vaccinated using the down selected LASV antigens, adjuvants, and vaccination route identified in 1.1.1.A. Animals in vaccine group 1 will receive only the initial single administration of vaccine while animals in vaccine group 2 will receive the same vaccine as the prime vaccine 14 days post prime. At 35 days post prime (21 days post boost for boosted animals), all animals will be challenged with 3000 PFU of LASV-Josiah. The survival of infected macaques will be assessed, and clinical signs consistent with VHF (as measured by hematology, serum biochemistry, and blood coagulation assays) will be documented. Surviving animals will be euthanized at the study endpoint 4-5 weeks after LASV challenge. In addition, blood will be collected before and after vaccination and at the study endpoint for determination of binding antibody and neutralizing antibody titers. Blood and tissues will also be taken after virus challenge for histopathology, immunohistochemistry, virus isolation and genome detection. Peripheral blood mononuclear cells (PBMCs) will be isolated and cryopreserved for subsequent cellular phenotyping and functional analysis as outline in 1.1.1F.

Similarly, we will also determine the protective efficacy of MACV following the grouping described in **Table XX** using the identical experimental approach as outlined above for LASV challenge. The challenge virus will be the established MACV Chicava strain (**REF**)**.** Given the lack of clarity on the potential for the JUNV Candid-1 vaccine to afford protection from challenge with MACV, we will confirm protection in NHPs if demonstrated in guinea pigs **(REFs).**

1.1.1.F: Determination of cellular and humoral immune correlates associated with protection

1.1.1.F.a: Define the phenotype and function of Arenavirus or Nairovirus specific T-cell responses in in subunit/patch vaccinated NHP compared to unvaccinated groups.

We will perform a targeted analysis of T-cell phenotype and function in study participants with or without subunit-patch vaccination using established methods for measurement of cellular immune responses (flow cytometry, LegendPLex, ELISPOT). Particular interest will be paid to CD4+ and CD8+ T-cells due to their respective role as important correlates of protection in the NHP vaccine model and long-lasting response in natural immunity. Thus, we will measure the strength and diversity of arena or nairo-specific CD4 and CD8 T-cell responses and expect responses in vaccinated EVD survivors to be superior to natural immunity.

Immune subset phenotyping: We will develop and optimize multi-color flow cytometry panels phenotyping a range of immune subsets (B-cells, Monocytes, Dendritic Cells, and NK cells) but primarily focused on T-cell phenotype (CD3, CD4, CD8, CD95, CD28). Standard whole blood flow cytometric staining protocols will be used for surface and intracellular staining markers, briefly cryopreserved PBMCs no older than 3 months old are gently thawed then washed with 2% FBS/PBS and stained with a viability dye for 20 minutes at room temperature. Cells are then washed again, surface stain cocktail is added to the tubes, incubated for 20 minutes, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed in PBS.

Stained, fixed cells will then either be acquired directly. Cell populations are then quantified using a Cytek Aurora spectral flow cytometer using an NHP optimized panel of antibodies.

Viral protein stimulation experiments:. PBMC stimulations will be set up according to modifications of well established, previously published protocols. [24, 25] PBMCs will be directly stimulated with purified recombinant vaccine proteins or relevant GP or NP peptide pools using optimized concentrations. Samples will then be mixed incubated at 37ºC for 1 hour. A protein transport inhibitor such as brefeldinA will then be added at a concentration of 10mg/mL and incubated at 37ºC for until flow cytometry staining. Cells will then be washed and stained according to the flow cytometry protocol outlined below. Alternatively, isolated PBMC may be stimulated with purified recombinant GP and NP proteins or peptide pools using optimized concentrations diluted in R10 media (RPMI/1%Hepes/10%FBS). Cells will then be incubated overnight at 37ºC. Stimulations to assess secreted analytes by multiplex-bead based assays will be set up in 96-well plates and supernatants will be harvested for further analysis.

Intracellular cytokine staining: We will utilize NHP optimized multi-color flow cytometry panels measuring a range of functional responses including important T-cell functional markers (ie: IFNg, TNFa, IL-2, IL-4, IL-6, PD-1, CTLA-4). Cells are stained with a viability dye for 20 minutes at room temperature, then washed with 2% FBS/PBS. Surface stain cocktail is added to the tubes, incubated for 20 minutes, and washed. Cells are incubated in BD Cytofix/Cytoperm solution for 20 minutes followed by a wash with BD Perm/Wash Buffer. Intracellular antibodies are then added, incubated, and washed. Cells are fixed for 1 hour with Stabilizing Fixative (BD Biosciences, Franklin Lakes, NJ) then washed in PBS. Stained, fixed cells will then be acquired using a Cytek Aurora spectral flow cytometer.

Multiplex Bead based assays: As a measure of global response to arena or nairo-specific T-cell activation, we will measure secreted cytokines in supernatants of cells stimulated with or without viral antigens or control (Staphylococcal enterotoxin B, SEB) proteins. We will develop a 4-color multiplex panel using BioLegend LegendPlex technology. Samples will be assayed according to manufacturer's instructions. Briefly, cytokine capture beads will be mixed and added to assay tubes followed by addition of prepared standards and controls, or participants samples and incubated for 3 hours at room temperature, protected from light. 1mL of wash buffer will be added and beads will be pelleted by centrifugation at 200g for 5 minutes. Wash buffer will be removed and discarded. Beads will be resuspended in 300uL wash buffer and data acquired on a MagPix xMAP instrument.

IFNg/TNFa ELISPOT: ELISPOT assays will be performed utilizing classical ELISPOT approaches. Briefly, cells with or without GP or NP antigens or peptide pools or control (SEB) antigen will be incubated overnight at 37ºC. Wells will be washed manually 3-times, followed by the addition of detection antibody and incubated either overnight at 4ºC or for 2 hours at room temperature. Wells will be washed again and incubated with the development substrate for 1 hour at room temperature protected from light. Wells will then be decanted, rinsed with deionized water and Chromagen Solution will be added to each well and incubated for 20 minutes at room temperature, protected from light. Finally, wells will be decanted and rinsed, dried thoroughly (60-90 minutes at room temperature or 15-30minutes at 37ºC), and spot forming units (SPU) will be read on an **need model** ELISPOT Fluorescence Microplate Reader.

Data Analysis: We will look at the differences in immune responses across groups between each timepoint and baseline. Model assumptions will be checked for a one-way ANOVA to compare the three groups. we will run the analysis after checking model assumptions, if those are not met then we will adjust to a nonparametric model or transform the outcome appropriately. To look at the longitudinal aspect of the data, we will investigate measurements over time between groups, the interaction of group and time can be analyzed using covariance pattern models (or linear mixed models), where the correlation between observations measured over time can be handled more flexibly. As a more exploratory analysis we will also look at adjusting for possible confounding variables such as sex and age. For categorical variables, comparisons will be made using Chi-Square tests. Significance will be set at 0.05 and GraphPad/PRISM (Carlsbad, CA), SAS software (Cary, NC), and R will be used for analyses. Flow cytometry data will be analyzed in FlowJo version 10. Diversity of T-cell responses will be analyzed by t-SNE in R.

Alternative Strategies: Although unlikely based on the available literature, differences in T-cells dynamics across groups may not be prevalent predictors in this context. We are also including measures of innate immunity in our flow cytometry panels to assess the relative importance of these subsets. Additionally, serum samples will be banked to assess the presence of biomarkers associated with differences between groups.

1.1.1.F.b: Systems serology ***Characterization of Arenavirus and Nairovirus specific Ig subtypes and Fc-mediated innate effector function profiles in subunit/patch vaccinated NHP compared to unvaccinated groups.***

We will perform a comprehensive analysis of the humoral immune response using an Viral Systems Serology platform developed by Dr. Gunn in Core D[26-28] to define the Fc-mediated humoral antiviral functions associated with vaccination. Protective Fc-mediated humoral immune profiles have been identified in natural immunity to LASV and may serve as an effective baseline. Sera will be analyzed for 1) levels of LASV, MACV, CCHFV,LUJV, and CHAPV specific or cross-reactive antibodies; and 2) innate immune effector functions (phagocytosis, NK cell activation, and complement fixation).

Analysis of antibody levels by Multiplex immunoassay: Serum samples will be tested for antibody reactivity against a panel of viral antigens utilized for vaccination. To evaluate cross-reactive antibody responses against the GP of other LASV, MACV, or CCHFV lineages. We will use a multiplexed analysis to determine the levels of antibodies against the viral antigens using on MagPix xMAP instrument as described.[27, 29] Specifically, each viral antigen will be coupled to coded magnetic beads (Luminex), mixed together, and incubated with serial dilutions of patient samples. Beads are washed and the levels of different antibody isotypes/subclasses specific for each antigen will be determined using labeled secondary antibodies against human IgG1, IgG2, IgG3, IgG4, IgA1, IgA2, and IgM. For quantitation of bound antibody, we will make a standard using pooled banked serum from NHP survivors.

Analysis of Fc-mediated effector functions: We will characterize plasma samples for induction of innate immune effector functions including antibody-dependent phagocytosis (ADP), antibody-dependent cellular cytotoxicity (ADCC), and antibody-dependent complement deposition (ADCD). All assays will include an NHP derived seropositive standard curve, and seronegative/isotype control.

ADP/ADCD: Recombinant EBOV GP protein will be biotinylated and coupled to fluorescent Neutravidin (Life Tech) beads, and serial dilutions of plasma samples/mAbs will be incubated with beads. To measure ADP, primary human monocytes, neutrophils, or THP-1 cells will be incubated with immune complexes, and uptake of beads will be measured by flow cytometry. To measure ADCD, freshly reconstituted guinea pig complement will be incubated with immune complexes. C3 deposition onto beads will be detected using an anti-C3 antibody conjugated to FITC (MP Biomedicals) and measured by flow cytometry at KGH.

ADCC: Primary human NK cells or NK92 cells with CD16 overexpression (ATCC) will be incubated with EBOV GP immune complexes bound to MaxiSorp ELISA plates for 5 hours at 37C 5% CO_2, and surface expression of CD107a will be measured to identify level of degranulation, a surrogate of ADCC, and intracellular cytokine staining will be used to detect production of pro-inflammatory cytokines and chemokines IFNg, MIP-1b, and TNFa by flow cytometry.

Data Analysis: Univariate analyses were performed using Prism 9.5.0 software. Kruskal–Wallis with Dunn multiple correction test or Mann–Whitney with Bonferroni correction was used to determine statistical significance between groups. A network analysis will be performed to identify significant antibody features. Associations between antibody features will be determined using nonparametric Spearman correlation coefficient. Statistically significant associations after Bonferroni correction for multiple comparisons (adjusted $P < .05$) were used to generate networks in Cytoscape (version 3.4.0).

Alternative Strategies: If we are unable to define clear immune profiles associated with each group, we will integrate our humoral immune profiing data with the larger dataset that includes antibody neutralization, cellular and inflammatory immune profiles, genetic markers (HLA-type), and additional clinical information (ie: PES symptoms). These will be included in the network analysis.

TOTALS	15

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine. In conjunction with ~~RP1~~ Cores D and ~~Core~~ E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an existing anti-Junin virus mAb ~~with~~ whose potent therapeutic efficacy [39, 43] ~~(guinea pig and NHP references)~~ we have previously described ~~by Abelson, Geisbert and Zeitlin~~ will be produced with YTE and LA Fc point mutations to extend the serum half-life of the mAb~~(Table 4)~~. The pharmacokinetics (PK) of these two variants will be evaluated in NHPs (~~Bioqual, Inc.; Rockville, MD~~see Core D) to select a lead candidate for testing in NHPs against Junin Romero challenge in Core E. ~~For the PK study, two doses (15 and 5 mg/kg) of each mAb will be administered IM to groups of 3 cynomolgus macaques (mixed sex). Serum will be collected (pre-dosing, 15 min, 6 hours and at days 1, 2, 3, 7, 10, 14, 21, 28, 42, 56) and tested via ELISA and Octet to quantitate serum antibody concetrations. PK parameters will be modeled with WinNonlin Phoenix software (reference).~~ We will select t~~T~~he variant with the most favorable pharmacokinetics ~~PK will be selected~~ for testing with ~~by **RP1/**~~**Core E**. Briefly, groups of 4 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV (~~Espindola or~~ Romero~~?~~) delivered IV. For further details of the NHP testing, please see **Core E**. These data will be used by the Scientific Advisory ~~Committee~~ Board to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes against other viruses.

Commented [CRW4]: From Larry, adapt from this.

Expected results, alternative approaches and Go-No-Go decisions (brief summary – see also Project Milestones and Timelines). We expect to be able to construct an immunogenic and protective subunit-patch targeting LASV, MACV, and CCHFV ……. If this is not the case any of these three viruses by year 2 we will refocus effects on the remaining virus families adjusting the requested budgets accordingly after consulation with NIAID and SAC

Please note: Discussion of expected results, other alternative approaches and criteria for "go" or "no go" decisions for MILESTONES 1-4 are discussed as required in RFA-AI-20-023 in the **Project Milestones and Timelines** *section.*

JUNV GP/NP as alternative strategy, mRNA as an alternative strategy,

AIM 2: Rescue recombinant arenaviruses and nairoviruses circulating in nature with no available isolates:

Attached is the latest version. I still need to deal with the minor highlighted refs and table/figure descriptions but will do it tomorrow. There is a little room to mess around with how the milestones/objectives are presented, I just kept them in paragraph form for now but we can enumerate if it makes more sense to do so. Otherwise space is pretty tight until I can get the refs in and table/figure descriptions fixed.

I'm out of gas for now, welcome any feedback for refinement or if I left something important out.

I just talked with Tom to walk through some of RP1 and we have a plan to improve readability and flow. Aims will stay largely the same, but I will add more context and clarify a few items to help with readability and flow. I will send an updated if not complete version to the group by late tomorrow. Adding Court as a fresh set of eyes to help with review and refinement.

Subject: Re: ReVAMPP Bunyavirales Project

Total free association here and I have been running a lot of things by Courtney this week to get a different opinion. So this below is really more along the lines of thinking about cross lineage and clade protection. And maybe some naivety on my part in the interactions with Core C. So I am guessing that antigens are made and then tested for immunogenicity by Core C and D and maybe Core C is involved earlier in an example below? I think for RP1 and RP2 in terms of recombinant viruses that for RP2 there is an obvious need to make Langya. For RP1 I think it is more of an alternate strategy if we cannot get authentic viruses and maybe as the RFA makes a point of tools for something like Chapare where there is no reverse genetics system we make one. So I am not sure that I would have making recombinant viruses a stand alone Aim for RP1 rather I wonder if it goes more in whatever Aim assesses protective efficacy where it is needed to make a new virus that pops up that we cannot get?

> Specific Aims:

I will try to take a look at this today. If not addressed here one theme that I think we need to get across are the problems that occurred with SARS-CoV-2 with the vaccines and treatments not offering broad coverage against different variants. So while on one hand being able to address that quickly with plug and play approaches is great on the other hand developing vaccines that can provide broad coverage from the beginning is even better. I think that is probably being addressed here by having the NP approach added as a comparator. One thing that I think may give our Center an advantage over some others is access to a more diverse group of viruses than other applications, e.g., for Lassa there are seven lineages and we have animal models that can cover a lot of those and even in the case of Machupo we can cover the most commonly used as well as the most diverse lineage VIII. For henipaviruses thanks to Chris we now have Hendra Redlands which is a beast as well as the HeVg2. Even where maybe we don't have established animal models we at least have viruses that cover most of the genetic diversity for the viruses in our Center so we can at least assess the immune response by ELISA and neut against wild type viruses.

Subject: RE: ReVAMPP Bunyavirales Project

Hi Chris,

Some thoughts…

On the PREP, this is just the one study being proposed as proof of concept. Will let Larry elaborate, but we will need to wordsmith to suggest that if successful this may be an avenue to look at with other viruses with the support of SAC and program.

On the cellular and humoral part. Space is a big issue here and I'm not sure we will need to describe in detail in every RP or core, but it needs to be outlined somewhere clearly and that will eat up some space. I put it in my RP since there was no room in the animal core and Larry's core didn't detail it too much either (so far). My version will likely need to be whittled down as well to make everything fit, so but not so much that the gist is lost. I wonder if we could find a small amount of space to describe the immunology work up I described will be carried out in the scientific cores (and in collaboration with RP1) as outlined in RP1? That said, we can maybe refer to methods used in RP1 for the core as well since that write-up is already having issues with space? Also note that I'm not doing any immunology on rodents since the patch core mentioned they would do rudimentary serology and ELISPOTs, all this advanced immunology work will be done with primates only due to lack of reagents.

Subject: Re: ReVAMPP Bunyavirales Project

hi all
RP2 is not looking anything like this post-vaccination subject analysis on the CD4/CD8 and cellular responses or the serological studies.

We were allowing the Upitt core to explore the mice with cellular responses as the pilot.
The plan for the MNP vaccines is to test efficacy in ferrets then proceed to AGMs.

Not sure what to do or how to proceed here! Are there analysis text sections
from what the animal core can or should propose here or outline here, as Bob laid
out? I dont have anything like this in hand,

also, i saw the comment on PREP
We dont have any plans for PREP for NiV/HeV included here either, our best candidates
are already in Mapp's pipeline, or in the CETR

Subject: Re: ReVAMPP Bunyavirales Project

Bob,

This is what is in Core D so far:

A mAb prototype for an intramuscular (IM) long-acting alternative to a vaccine. In conjunction with RP1 and Core E, an IM long-acting mAb prototype will be generated as a Go/No Go decision as to whether this product format will be an option for development with any of the other viruses being targeted by PABVAX. For this proof-of-concept effort, an anti-Junin virus mAb with potent therapeutic efficacy (guinea pig and NHP references) previously described by Abelson, Geisbert and Zeitlin will be produced with YTE and LA Fc point mutations (Table 4). The pharmacokinetics (PK) of these two variants will be evaluated in NHPs (Bioqual, Inc.; Rockville, MD) to select a lead candidate for testing in NHPs against Junin Romero challenge in Core E. For the PK study, two doses (15 and 5 mg/kg) of each mAb will be administered IM to groups of 3 cynomolgus macaques (mixed sex). Serum will be collected (pre-dosing, 15 min, 6 hours and at days 1, 2, 3, 7, 10, 14, 21, 28, 42, 56) and tested via ELISA and Octet to quantitate serum antibody concetrations. PK parameters will be modeled with WinNonlin Phoenix software (reference). The variant with the most favorable PK will be selected for testing by **RP1/Core E**. Briefly, groups of 4 cynomolgus macaques (mixed sex) will receive 15 or 5 mg/kg of the lead variant IM and the animals will be challenged one month later with 5000 pfu of JUNV (Espindola or Romero?) delivered IV. For further details of the NHP testing, please see **Core E**. These data will be used by the Advisory Committee to inform decision making around possible additional IM mAb prophylaxis plug and play prototypes.

Feel free to tweak so it fits with what you are thinking about. I can also give you some innovation language if you'd like on this topic.

Best

Subject: Re: ReVAMPP Bunyavirales Project

Tom,

I like the idea of it as a sub-aim. Core D will refer to it (manufacturing the mAb as well as performing PK to select the best Fc mutant). Depending on how much you are mentioning about the protocols in the Animal Core, you could also mention it there (e.g. "For studies looking at long-acting mAbs as an alternative to a vaccine, NHPs will receive a single dose 1 month prior to challenge…).

I can also if preferred, describe the study in Core D rather than RP1. I'm certainly setting up the idea of it with the PK work…

Larry, Dafna

How do you want to handle the Junin NHP prophylaxis study? At the very least I think RP1 has to mention it somewhere. Does it go into RP1 as a subaim? I don't think we can say it is alternate strategy as that route is usually taken when something proposed fails. Does it get pitched as a subaim to derisk the project? Not quite sure here.

Many thanks!

Tom

Subject: RE: ReVAMPP Bunyavirales Project

Great, thanks!

Yeah it was challenging to add a lot into the SA page. But we can refine to make it more inclusive of all points addressed. Definitely will stretch out in the Research strategy.

We can maybe add some reverse genetics, especially for missing MACV lineages…maybe CCHF for the same reason using the cassette approach. Need to think about it a little today, but this may work.

Do we need to add the JUNV prophy study into RP1? Or is that in the core?

Thanks Bob! One thing that we need to think about as Chris outlined for the rescue of Langya in the RP2 Aims is are we going to tackle reverse genetics at all for arenaviruses and CCHF? If so will need to tie that into the Animal Core in terms of rescue. Other thing is tie into Mapp Core for the Junin NHP prophylaxis study in Year 1 as an alternative approach to vaccination. And then need to think about if we need an approach to tie into RP4 and RP5. All of this of course does not need to be on the Aims page and can be addressed in the 12 page Research Strategy. If you tackle reverse genetics it could be its own Aim along the lines of what Chris has in RP2.

Hi Bob

Here's a draft of an SBIR that Crystal wrote in case that's helpful. It only has data from the first Guinea pig study.

Best,

Dafna

Agree, this SA page from Crystal is super helpful. Was going to start putting pen to paper to get a rough draft started for the Bunya RP. Unless you guys have already started?

Is there a format we need to follow for writing the proposal? I think we had 12 pages correct?

Assuming the standard NIH format?

Subject: Re: ReVAMPP Bunyavirales Project

Just a few thoughts:

1. It looks like we can have multiple prototypes per family if justified. I think lassa and junin would be great prototypes for old and new world arenas…seems easy to justify as we don't know if a single product could cover both and pursuing both could help to answer the question.
2. Might be good to confirm with program, but as I initially read it, it looks like if we start with CCHF we'd be expected in Y4-Y5 to expand to other nairos. Hantas may be a little easier – Jim has some mAbs and Mapp does as well, but those are encumbered a bit with Kartik's CETR so we'd have to have some conversations to make sure that would be kosher.
3. The RFA has a bit of mixed message on vaccines and mAbs. I do think they go well together and mAbs can be an alternative option to a vaccine.
4. Do the microneedle people have some experience transitioning to the clinic? I'm looking at this language: "Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine expertise in manufacturing, clinical development, and regulatory pathways." Mapp can fill that role for mAb vaccines, but not so well for traditional vaccines. It looks like we don't have to have them lined up yet, but might be nice to have a letter of support if needed. DVC is an option as is IBT.

Subject: Re: ReVAMPP Bunyavirales Project

Hi Tom

We do have the Junin PBMCs you sent and I like the idea of including Junin in the proposal because we already have cell lines in house to express Machupo, Junin and Lassa GPs. I think we could hit the ground running on arenavirus antibody discovery.

I don't have strong feelings on Hanta vs CCHF. Larry?

Subject: ReVAMPP Bunyavirales Project

All,

We need to think about the ReVAMPP Bunyavirales Project and what viruses and how to integrate with all of the other projects. I know it is tough to schedule a Zoom call so maybe we can kick this around on email a little. I think we all agree that the Mapp Lassa vaccine data is great. So maybe Lassa is the prototype even though we know CEPI is funding Lassa vaccines and it has a lot more attention than other things. But prototype with a plan to transition to other arenaviruses. So move the Lassa vaccine to the microneedle patch which ties in nicely with that Core. I guess we need to think about whether to have pan arenavirus vaccines or individual. I think Junin is a good choice as well. To that end I think we had sent PBMC from Junin Candid 1 vaccinees to Mapp right before COVID-19 hit. Do you still have those? If we go with Lassa do we have a plan for Lassa MAbs to support? Then for another family I think CCHF for Nairoviridae makes the most sense as we have already been working on it for MAbs as has Jim Crowe. We would need to sort out the vaccine angle that ties into the microneedle patch. So I guess then for arenaviruses we would have Lassa and maybe Junin as prototypes and for nairoviruses CCHFV. Where I get confused and am struggling is the transition in Years 4 and 5 that NIAID/NIH has to approve where I think the expectation is that you move from prototypes to more broad coverage. So do we say for example for Lassa since there are so many lineages that the prototype is lineage IV Josiah but in the out years we show that it protects against all lineages? Same thing for CCHF. Or is the expectation that you go beyond the prototype virus so for example from Lassa and Junin to also cover say Machupo, Guanarito, Chapare, etc.? Or is it better instead of CCHF say to start with Andes as the prototype and then move in the out years to Hantaan

> or vice versa? Thoughts?

Research Strategy

Significance

The constant threat posed to global public health by emerging and reemerging zoonotic viruses emphasizes the importance for pandemic preparedness by developing countermeasures. The highly pathogenic Hendra virus (HeV) and Nipah virus (NiV) are the prototype members in the genus *Henipavirus* in the family Paramyxoviridae[1], and the selected prototypes chosen for **RP2**. HeV was first discovered in 1994, in Queensland, Australia where it was the causative agent of a severe and fatal respiratory disease among horses along with a human case fatality[1,2]. Whereas, in 1998-1999 in Malaysia and Singapore an outbreak of encephalitis in people and respiratory disease in pigs was eventually determined to be caused by a closely related virus - to NiV[3,4]. These viruses are capable of causing a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with fatality rates ranging from 40-100%[5,6]. As a result of this high lethality and lack of approved vaccines or antivirals, HeV and NiV are classified as Biosafety Level-4 (BSL-4) pathogens. NiV and henipaviral diseases are also included in the WHO's Blueprint List of Priority Pathogens[7], and NiV is among the Coalition for Epidemic Preparedness Innovations (CEPI) list of Priority Diseases needing urgent research and countermeasure development and are recognized as agents of pandemic threat potential[8,9]. HeV, though apparently restricted to Australia, has spilled over 66 times, most recently in 2022[10]. HeV has caused the death or euthanasia of >100 horses, 2 HeV positive and euthanized dogs, and 4 fatalities of 7 human cases[10,11]. Whereas NiV is present throughout a large area including South and Southeast Asia from the Philippines to western India. The frequent outbreaks of NiV in Bangladesh and India have high human case fatality rates 70-100%. NiV transmission in Bangladesh to humans has been linked to contaminated fruits or date palm sap, and person-to-person transmission[12-15]. In total, there have been >620 human cases of NiV infections >330 fatalities, the most recent in 2023[16]. The genus *Henipavirus* now includes nine other species; the four viral isolates of CedV, Gamak virus, Daeryong virus, and Langya virus (LayV)[17-19] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiang virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[20-23]. Pteropid fruit bats, known as flying foxes, are recognized natural reservoir hosts for NiV, HeV[24,25], CedV[18], GhV and AngV. One of these, CedV, has been shown to be nonpathogenic in several animals susceptible to HeV and NiV disease including mice, guinea pigs and ferrets[18,26] and African green monkeys (AGMs) (Geisbert and Broder, unpublished). The remaining six reported henipaviruses (HNVs) are likely of rodent origins. One of these six, the isolate LayV, is associated with nonfatal febrile illness in humans[19].

HNVs are enveloped, single-stranded, negative sense RNA viruses that share a similar genomic makeup. The viruses have two membrane anchored glycoproteins involved in entry: the attachment (G) glycoprotein that engages the host cell receptor and the fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F proteins are the major targets of neutralizing antibodies and the focus of all vaccine and therapeutic antibody strategies[27,28]. However, CedV is distinct from other HNVs, and the phosphoprotein (*P*) gene does not encode the interferon antagonist proteins V and W[18,29-31]. The nonpathogenic phenotype of CedV is most likely attributed to the lack of these nonstructural proteins. Based on genetic data, all identified HNVs, except CedV, can potentially express the V and W proteins. CedV is recognized as a BSL-2 restricted agent[32].

Innovation

There are multiple layers of innovation within **RP2**. **First**, the proposed development of henipavirus (HNV) subunit vaccine candidates using an innovative microneedle array patch (MNP) technology that may be suitable for the incorporation of immunogens derived from other undiscovered pathogenic HNVs or paramyxoviruses in the future. **Second**, the construction of a rLayV reverse genetics system will be highly valuable in the HNV toolbox to study putative differences in pathogenesis and vaccine design between HNVs of bat and rodent origin, and significant resource to the ReVAMPP network's objectives. **Third**, generation of BSL-2 surrogate platforms that are based on rCedV and VSV will allow for a wide-variety of *in vitro* studies to support infection and host response studies and to screen in a high throughput manner the neutralization activity of immune sera and monoclonal antibodies (mAbs) and nanobodies (nabs) without the requirement for high containment. **Fourth**, considering that the LayV and AngV F and G proteins are functionally fusion active, the generation of viable rCedV chimeras bearing either LayV or AngV F and G glycoproteins is feasible.

Approach

Scientific Premise

To date, the most extensively studied NiV/HeV vaccine is a soluble, recombinant, oligomeric form (dimers and/or tetramers) of the G glycoprotein of HeV (HeV-sG)[11,27,33], and has been demonstrated to confer complete protection against lethal challenge with NiV-M (Malaysia), NiV-B (Bangladesh) or HeV in multiple animal models[34-40]. It has most recently been shown to provide complete protection of AGMs against NiV-B challenge performed one week post-immunization (single dose)[41]. The HeV-sG vaccine is marketed by Zoetis, Inc., for equine use in Australia since 2012 and is the first commercialized vaccine against any BSL-4 pathogen. HeV-sG /Alum intramuscular formulation is currently in clinical trial as an anti-NiV vaccine. **RP2** proposes to enhance the formulation, immunogenicity, and delivery of recombinant subunit protein based HNV vaccines.

We have developed rCedVs as new tools to study HNV host cell interactions, including ephrin receptor use and infection tropism, and in the development of HNV countermeasures. Experiments with rCedV can be conducted in a BSL-2 containment setting. The rCedV reverse genetics system[42,43] allowed us to develop a rCedV chimeric platform, where the CedV F and G glycoproteins are replaced with that of either NiV-B or with HeV, generating replication competent chimeric viruses (rCedV-NiV-B and rCedV-HeV). We have successfully rescued and characterized the chimeric viruses with and without reporter genes[44]. The neutralizing potencies of several well-characterized cross-reactive NiV/HeV F and G specific mAbs against these rCedV chimeras highly correlate with the potencies obtained for the same antibodies to neutralize authentic NiV-B and HeV by plaque reduction neutralization tests (PRNTs). The green fluorescent protein (GFP) reporter chimeras were employed to develop a rapid, high-throughput, and quantitative fluorescence reduction neutralization test (FRNT). The antibody potencies to neutralize the reporter gene containing chimeras in the FRNT highly corelated with the respective potencies obtained by PRNT[44]. The rCedV chimera assay has been employed in several studies and its high-throughput ability has also allowed for the conduct of NiV/HeV mAb synergy neutralization tests[45-47]. The rCedV chimeras have their most important application in an authentic HNV-based surrogate neutralization assay that is rapid, cost-effective, and can be utilized in BSL-2 containment. We believe that the rCedV reverse genetics system may be able to serve as a plug-and-play platform for other emerging or pathogenic HNVs. To accomplish this, **RP2** will develop a variety of rCedV variants with reporter genes that will serve as important tools for the PABVAX Center RPs and Cores, and also for the NIAID, ReVAMPP network for pandemic preparedness.

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed. rCedV laboratory manipulation guidelines and standard operating procedures under BSL-2 conditions were developed for the laboratory and staff, and all procedures were reviewed and approved by the Uniformed Services University Institutional Biosafety Committee in accordance with NIH guidelines. The rCedV tools described here have been transferred to multiple institutions and research organizations which have also reviewed and approved their use at BSL-2 containment.

Aim 1: Develop PPZ-MNP-based sG_{tet} and sF_{stb} prototype HNV subunit vaccines.

Rationale and Preliminary Data. It is well documented that the HNV G and F glycoproteins are the primary targets for virus neutralizing antibodies[27,45,48-53]. As such, HeV-sG subunit has clinically advanced in the development of HeV and NiV vaccines. Building on this work, Aim 1 will compare the immunogenicity and efficacy of alternate NiV vaccine immunogens (NiV-sG_{tet}, NiV-sF_{stb}), HeV vaccine immunogen (HeV-sF_{stb}), and a bivalent HNV vaccine candidate (NiV-sF_{stb}+HeV-sG) along with the clinical subunit HeV-sG. All immunogens will be delivered as polyphasphazene (PPZ) adjuvanted MNP vaccines in three animal species (mice, ferrets, and non-human primates-NHPs (AGMs)). Immunogenicity will initially be performed in mice by **Core C**. The neutralizing potencies of the immunized mouse sera will then be evaluated by *in vitro* neutralization assays using rCedV-NiV-B-GFP and rCedV-HeV-GFP[44]. The superior neutralizing antibody inducing MNP vaccine type(s) will be evaluated by animal challenge studies ferrets (first-tier) challenged with NiV-B or HeV and the lead vaccine candidate(s) from those studies will then be evaluated in AGM (second-tier) challenge studies.

Adjuvants are included in vaccine designs to generate a robust and durable vaccine induced immune response. We will utilize a synthetic PPZ macromolecule as the adjuvant to complement the proposed NiV and HeV vaccine immunogens. The PPZ macromolecule has many distinctive properties that make it an attractive choice as an adjuvant; 1) water-soluble and biodegradable, 2) spontaneously self-assembles with antigens in aqueous solutions, 3) forms nanoassemblies that mimick the dimensions of a virus (60-100nm)[54,55] and 4) is completely compatible with MNPs[56-58], the delivery mechanism that will be employed for the HNV immunogens. The extensive clinical use and experimental evidence supports the safety and potency of PPZ in enhancing vaccine-induced protective immune responses[54-60]. In particular, the most commonly used PPZ adjuvant is the clinical stage *poly[di(carboxylato-phenoxy)phosphazene] (PCPP)* and its structural homologue *poly[di(carboxylato-ethylphenoxy) phosphazene] (PCEP)*, which, significantly boosts vaccine immunogenicity without the requirement for large amounts of antigen while providing long-lasting protection in live viral challenge studies[60-62]. MNPs are promising resources to achieve systemic effects by transdermal delivery. They are a minimally invasive, painless system, which can bypass the stratum corneum and overcome the potential drawbacks of subcutaneous injections[63]. (See **Core C** Research Plan).

Manufacturing and characterization of HeV-sG±PCEP MNPs. The technology for fabricating MNPs pioneered by Bediz et al.,[64] was developed and is described in detail in the **Core C** Research Plan). We have conducted preliminary studies with the dissolvable MNPs incorporating HeV-sG antigen with or without PPZ adjuvants including PCEP (HeV-sG±PCEP MNPs) in collaboration with the investigators of **Core C**. Spin-casting of carboxymethyl cellulose and trehalose was used to create MNPs incorporating HeV-sG AF555±PCEP into obelisk-shaped microneedles having the vaccine components at the tip region to maximize the vaccine delivery efficiency by locating the vaccine components at the skin-penetrating regions of the microneedles (**Figure 1a**). The HeV-sG±PCEP MNPs can have a pre-determined array size of 10x10mm (for mice studies) and 20x20mm or greater (for larger animal studies). Images of the HeV-sG AF555±PCEP MNPs before (**Figure 1a**) and after (**Figure 1b**) application (15-20 mins), confirm a nearly complete dissolution of the microneedles into the skin demonstrating that the vaccine was effectively deposited into the skin. To facilitate the characterization and to visualize skin penetration of the developed HeV-sG±PCEP MNPs, HeV-sG was fluorescently labeled with Alexa Fluor 555 dye, HeV-sG AF555. To test the intracutaneous delivery capacity, HeV-sG AF555±PCEP MNPs were applied to the abdomen skin of C57BL/6 mice for 15 min and then removed. The HeV-sG AF555±PCEP MNP-treated mice were imaged before and after *in vivo* skin applications by using an *in vivo* live animal fluorescent imaging system (IVIS Lumina XR) and the acquired images were post-processed using Living Image software (PerkinElmer). **Figures 1c** and **1d** further corroborate the microscopy analysis of these MNPs and show effective deposition of vaccine components to murine skin (**Figure 1c**: HeV-sG AF555 and **Figure 1d**: HeV-sG AF555+PCEP). Together, these data support the feasibility of our PPZ MNP vaccine platform for the translational development of skin-targeted HNV vaccines that could also be employed using recombinant protein immunogens (or even virus-like particles) from other viral agents from a wide-variety of virus families.

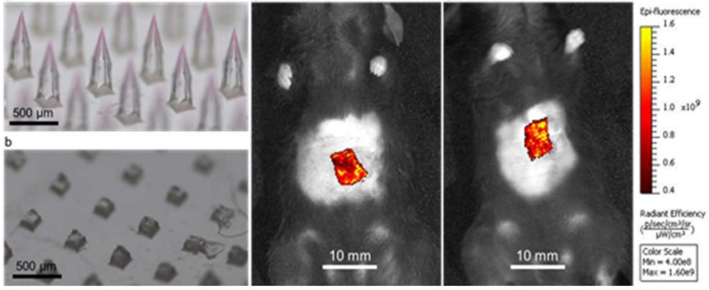

Figure 1: *In vivo* intracutaneous delivery efficacy of HeV-sG±PCEP MNPs in mice. An optical stereomicroscopy image of HeV-sG AF555+PCEP CMC/Trehalose microneedles before (**a**) and after (**b**) *in vivo* skin application. Administration of HeV-sG AF555 **(c)** and HeV-sG AF555+PCEP **(d)** to mouse skin *in vivo* with MNPs, captured by using a fluorescence *in vivo* imaging system (IVIS).

HeV-sG±PCEP MNPs with unlabeled HeV-sG were fabricated and the immunogenicity tested in C57BL/6 mice. Groups of 5 mice were immunized on Day 0 (D0) (prime) and D21 (boost) with HeV-sG±PCEP MNPs. Sera were collected on D35 and analyzed by ELISA for total binding antibodies (endpoint titers) (**Figure 2a**) and HNV neutralizing capacity of serum in the rCedV chimeras FRNT[44] (**Figure 2b**). These results show that MNPs are highly effective in inducing antigen-specific binding and neutralization antibodies, and improved with PCEP adjuvant. Additional data also demonstrate that the PPZ MNP platforms are superior to intramuscular injection of the current clinical Alum-formulated HeV-sG vaccine (**Core C; Figure 4a**). In addition, temperature stability was tested by storing the HeV-sG±PCEP MNPs at room temperature without refrigeration. Mice were immunized with fresh (group 1) and 30-day old MNP (group 2) by single dose immunization. Mice were bled on D14 post immunization and the

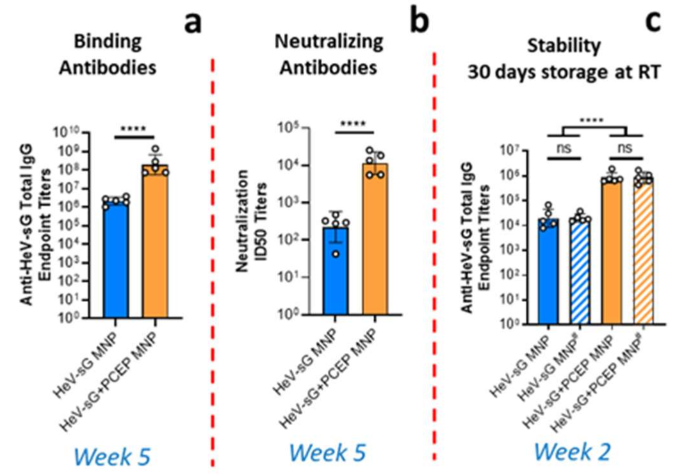

Figure 2: MNPs induced humoral responses and initial MNP stability data. Mice immunized prime/boost. MNPs applied to the abdominal skin of C57BL/6 mice 15 min, D0 (prime) and D21 (boost). Endpoint binding titers **(a)** ELISA. Neutralizing ID_{50} titers **(b)** by FRNT. Stability of MNPs **(c)** measured at D14 endpoint binding titers using a 30-day-old MNP compared to fresh MNP. Neutralizing ID_{50} titers with HeV-sG MNP (1:272) and HeV-sG+PCEP MNP (1:11,445) against rCedV-HeV-GFP.

endpoint titers of total IgG levels were determined by ELISA. **Figure 2c** suggests that MNP-embedded vaccine components retain their immunogenicity for at least a month without refrigeration with no statistically significant differences in the antibody binding titers between fresh and the 30-day-old MNPs.

Experimental Design.

Aim 1.1: Manufacturing and characterization of PPZ MNPs with HNV glycoprotein antigens. We have tested GLP-like HeV-sG antigen (above), manufactured by Catalent Pharma Solutions, and it is currently available. The remaining 3 immunogens (NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb}$) will be prepared by Genovac, Inc., and **Core C** will prepare MNPs with each of NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb}$, HeV-sG+NiV-sF$_{stb}$ and HeV-sG, all adjuvanted with PCEP. Each fabricated batch of PPZ MNPs will be tested *in vitro* for geometric integrity, mechanical integrity, vaccine loading accuracy and reproducibility, biological integrity, endotoxin content, vaccine stability, and *in vivo* skin delivery performance before the animal immunization studies. The specific quantitative release criteria are as follows: 1) geometric integrity and accuracy – >95% high-quality microneedles across a PPZ MNP vaccine and <10% deviation from the target geometric values; 2) structural integrity – factor of safety (FOS) > 2 (FOS is equal to the failure forces/penetration forces); 3) vaccine loading accuracy and reproducibility – 10% deviation from the mean of theoretical amounts and <10% standard deviation of the mean value; 4) biological integrity – no significant aggregation of adjuvant-antigen complexes and no significant loss of antigenicity ($p>0.05$); 5) endotoxin content – < 1 endotoxin unit per PPZ MNP vaccine; 6) thermostability – biological integrity at elevated temperatures; 7) skin delivery performance – <10% of remaining materials in terms volume and <15% of remaining materials in terms of vaccine after 20 min murine skin application *in vivo* and 20 min the RP-specific animal-skin application *ex vivo* (See **Core C** application for more details). Based on the preliminary data and experience with fabricating HeV-sG MNP, we expect the technology to be plug and play applicable with the new HNV immunogens and with the combination of two different HNV immunogens.

Aim 1.2: Immunogenicity assessment HeV/NiV antigen PPZ MNPs in mice. To evaluate the immunogenicity of PCEP MNP platform with NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb,}$ HeV-sG, and HeV-sG+NiV-sF$_{stb}$, murine immunization studies will be conducted (**Core C)**. The immunization strategy will be performed as single-dose (D0) and prime(D0)-boost(D21) with female C57BL/6 mice (n = 5 mice per group). A schematic of the immunization and bleeding schedule is shown in **Figure 3**. Naïve or unimmunized mice will serve as negative controls and mice immunized with the intramuscular injection of Alum-complexed antigens will serve as positive controls. Serum levels of antigen-specific antibodies (IgM, total IgG, IgG1, IgG2c, and IgA) will be assayed by ELISA. The sera will be tested for neutralization activity using the respective reporter rCedV chimeras – rCedV-HeV-GFP and rCedV-NiV-B-GFP in the FRNT assay[44].

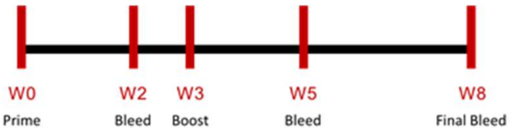

Figure 3. Immunization - bleeding schedule for mouse immunogenicity study.

Cellular immune responses will also be evaluated as described in the **Core C** Research Strategy. Briefly, mice will be sacrificed five days after the booster dose. Mouse blood PBMCs and cells from lymph nodes and spleen will be stimulated with a pool of antigenic peptides derived from the respective immunogen sequence(s). Antigen-specific polyfunctional cellular responses (IFN-γ, TNF-α, IL-2, IL-4, IL-17: CD4+ and CD8+ T-cell) will be determined by using multi-color flow cytometry and intracellular cytokine staining[65,66]. Studying the cellular responses for HNV immunogens has recently gained more interest and preliminary mouse studies have just begun using the HeV-sG vaccine subunit – antigenic peptides have been identified.

Aim 1.3: Evaluation of the immunogenicity and protection efficacy of PPZ MNP HNV vaccines in ferrets. The immunogenicity and efficacy of the lead PPZ MNP HNV vaccine candidates defined in Aim 1.2 will be tested in ferret challenge studies in Year 2 of the project (**Core E)**. Ferrets (n = 6 ferrets per group) will be immunized with the lead PPZ MNP HNV vaccine candidates via either single-dose (D0) or prime(D0)-boost(D21) immunization regimen. Unimmunized ferrets will serve as negative controls. (*Group 1*: Lead PPZ MNP HNV vaccine candidate 1 with the prime-boost regimen**.** *Group 2*: Lead PPZ MNP HNV vaccine candidate 2 with the prime-boost regimen. *Group 3*: Lead PPZ MNP HNV vaccine candidate 1 with the single-dose regimen. *Group 4*: Lead PPZ MNP HNV vaccine candidate 2 with the single-dose regimen. *Group 5*: Naïve/Unimmunized controls). The five groups will be challenged with a lethal dose (5000 TCID$_{50}$) of either NiV-B or HeV. Immunization, challenge and blood and swab sampling schedules are diagrammed in **Figure 4**. Vaccine-induced humoral responses in ferrets prior to virus challenge will be evaluated by **Core E** and **RP2**. All protected animals and survived controls will be euthanized on day 21 post-infection challenge (end of study) and lung and brain tissue along with swabs (oral and rectal) and blood samples will be collected. These will be tested for the presence of viral RNA by TaqMan PCR performed by using the primer sets and probes[35]. Virus isolation will only be attempted from specimens that were PCR positive for NiV-B or HeV genomes. Virus titration will be performed by plaque assay on Vero cells. The limit for detection will be 25 pfu/ml. The experimental details of the challenge studies in ferrets are described in **Core E**. End of study sera neutralization titers will also be measured by FRNT.

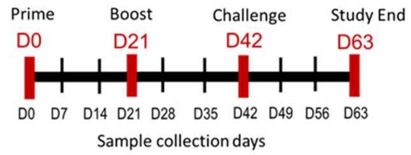

Figure 4. Expected schedule to immunize ferrets and AGMs in the planned efficacy studies. Blood and swabs, oral and rectal, samples will be taken weekly, on days 0, 7, 14, 21, 28, 35, 42, 49, 56 and 63. Single dose groups do not receive boost immunization on D21.

Antigen-specific stimulation of cytokine production by ferret PBMCs will be assayed. The custom-synthesized antigen-specific Peptivators obtained from **Core C** will be compatible with these studies, but we acknowledge that there is a lack of ferret-specific reagents for comprehensive evaluation of cytokine production of peptivator-stimulated PBMCs. Unlike comprehensive studies in mice and AGMs, these studies will quantify the production of cytokines, for which ELISA kits are commercially available, such as ferret IL-17A, IFN-γ, TNF-α, and IL-2, 48 hr after stimulation (See, e.g.,[67]).

Aim 1.4: Immunogenicity and protection efficacy of the lead PPZ MNP HNV vaccine in AGMs. This challenge study will be in year 3 (**Core E**). The immunogen(s) and MNP vaccine type that provides the best cross-protection in the ferret studies will be tested in AGM NiV-B or HeV challenge studies. Fresh MNPs will be fabricated for this study. The study will be conducted by **Core E** and will entail four groups of AGMs (n = 3 AGMs per group). Immunizations with the lead PPZ MNP HNV vaccine candidate will be either as a single-dose (D0) or prime(D0)-boost(D21) regimen. Groups 1 and 2 will be immunized as a prime-boost strategy while groups 3 and 4 will be immunized with a single dose. Naïve unimmunized AGMs will serve as negative controls. The immunization, challenge and blood and swab sampling schedules will follow that as outlined in **Figure 4**. Groups 1 and 3 will be challenged with a lethal dose of NiV-B, while groups 2 and 4 will be challenged with a lethal dose of HeV (lethal dose = $1x10^5$ $TCID_{50}$). Sera from blood samples taken before the challenge will be tested by **RP2** to measure the serum neutralization titers using the same procedure as for mice and ferret sera. Antigen-specific total IgG levels will be determined by commercially available ELISA. Virus-specific neutralization activity against each of HeV and NiV-B will be tested by FRNT assay in the same way as proposed for mice and ferret sera samples. The AGM sera samples will also be tested for neutralization activity against authentic viruses (**Core E**) by using the BSL-4 PRNT assay. Antigen-specific stimulation of key cytokine production by AGM PBMCs, which will be obtained prior to live virus challenge studies, and will also be assessed as described in Aim 1.2.

Aim 1.5: Identifying the correlates of immunization with the lead PPZ MNP HNV vaccine across multiple species. Here we propose to determine the correlates of immunization with the lead PPZ MNP HNV vaccine candidate across multiple species – mice, ferrets, and AGMs. This aim will be inherently integrated with the Aims 1.2-1.4. During these experiments, 3hr post immunization, skin biopsies and serum samples will be obtained from mice, ferrets and AGMs. Prior to challenge studies in AGMs, serum and skin samples from the three different species (mice, ferrets, and AGMs) immunized with the lead PPZ MNP vaccine candidate will be assayed to quantify their cytokine levels (IL-6, TNF-α, IL-17A, IL-10, IL-1β, IL-6, IL-4, IL-5, TNF-α, IFN-α, IFN-β, IFN-γ, and IL-12p70). We note a limitation that while the multiplex assays are commercially available for mice and AGMs, we will have to use the cytokine-specific ELISAs for ferrets to determine only those cytokine levels for which ELISA kits are available, such as ferret IL-17A, IFN-γ, and TNF-α. We expect to identify within the obtained results correlates of immunization across the three species for the lead PPZ MNP vaccine candidate. We also expect that these correlates of immunization might be predictive for the vaccine protective efficacy.

Aim 1.6: Evaluate stability of the lead PPZ MNP HNV vaccine candidate. Here, we will test the thermostability of the lead PPZ MNP HNV vaccine candidates based on retention of their immunogenicity upon storage at room temperature and at 40°C for an extended period of time (1-, 3-, 6-, and 12-month storage). Mice (n = 5 mice per group) will be immunized with fresh and stored PPZ MNP HNV vaccines in a single-dose regimen and blood samples will be collected 2 weeks after immunization. To test the stability of PPZ MNP HNV vaccine candidates, serum levels of total IgG antibodies will be determined by **Core C** and the virus-specific neutralization capacity of these antibodies will be evaluated by the FRNT assay (**RP2**). Stability will be indicated by no statistically significant differences between binding antibody levels and neutralization titers induced by fresh PPZ MNP HNV vaccines compared to those elicited by stored PPZ MNP HNV vaccines. Additional stability testing will be initiated with the freshly manufactured MNP for the AGM challenge study.

Expected results, potential pitfalls and alternatives. Prior data on HNV vaccines support our expectations that we will be able to assess the potency and longevity of vaccine induced responses of lead PPZ MNP HNV vaccine candidates from the proposed studies. The HeV-sG immunogen has been tested as a HNV vaccine in multiple (2-dose prime-boost) prior studies and that protective pre-challenge ID_{50} neutralizing titers against NiV-

M can be as low as of 1:32 in the feline model[35,38]; that more than 1 year post-vaccination and pre-challenge neutralizing titers as low as 1:16 to 1:128 in the ferret model are protective against NiV-M[40]; as an equine vaccine, horses with pre-challenge HeV neutralizing titers ranging from 1:16 to 1:32 at 6 months post-vaccination are completely protected[36]; and in AGMs pre-challenge ID_{50} neutralizing titers ranging from 1:28 to 1:379 against NiV-M are completely protective[34]; and most recently, a HeV-sG/Alum formulation protects against NiV-B challenge in AGMs with pre-challenge ID_{50} titers ranging from only 1:10 to 1:160[41]. Almost without exception, complete protection from challenge in these studies also shows no gross or histologic evidence of infection in any of the vaccinated subjects at study completions, with all tissues examined negative for viral antigen, with no viral genome detected. We expect to obtain protection in AGMs with the lead PPZ MNP HNV vaccine candidate. From the stability study, we will determine the shelf-life of the lead PPZ MNP HNV vaccine candidate. We are confident that if the preliminary mouse immunogenicity studies reveal neutralizing antibody responses are robust, this will translate to protection in the planned challenge studies in ferrets. Indeed, preliminary data has shown robust neutralizing ID_{50} titers from the mouse immunizations. The non-adjuvanted HeV-sG MNP induced an ID_{50} titer of 1:272 and the adjuvanted form HeV-sG+PCEP MNP induced an ID_{50} titer of 1:11,445 against the HeV chimera; and an ID_{50} titer of 1:331 against the NiV chimera. There is a minimal risk of not finding any protecting immunogen (MNP vaccine type or immunogen combination). The PABVAX Center team is sufficiently experienced to handle and resolve any possible unforeseen issues and pitfalls.

<u>Aim 2:</u> Rescue Langya virus and construct LayV and AngV glycoprotein bearing reporter virus tools.

Rationale and Preliminary Data: Negative stain electron microscopy (EM) was performed on LayV F and G glycoproteins. The 2D and 3D classifications of LayV F (**Figure 5a**) and G (**Figure 5b**) revealed distinct trimer and tetramer assembly, respectively. In addition, using LayV-sF and LayV-sG, our previously generated mAbs to MojV F and G tested by ELISAs demonstrated that there was a dose dependent increase in LayV-sF (**Figure 5c**) and LayV-sG (**Figure 5d**) binding. This data forms the premise for rescuing a rCedV bearing LayV F and G glycoproteins (the sequences from LayV are likely correct). We will construct a full-length recombinant LayV sequence that encodes GFP. The LayV F and G coding sequences are the LayV isolate SDQD_H1801 (GenBank: OM101125.1); LayV F and LayV G; UUV47205.1 and UUV47206.1, respectively. The replication competent rCedV will be used. We will design, construct and rescue a new rCedV chimera that encodes the envelope glycoproteins (F and G glycoproteins) of LayV, i.e., a rCedV-LayV reporter virus encoding GFP. We will characterize it using cell-based infection tropism and growth kinetic assays. We have also utilized an established quantitative fusion assay based on a dual-split-luciferase reporter assay[42,43,68,69] to determine functionality of AngV envelope glycoproteins (F and G glycoproteins). Content mixing between F/G bearing effector cells and a

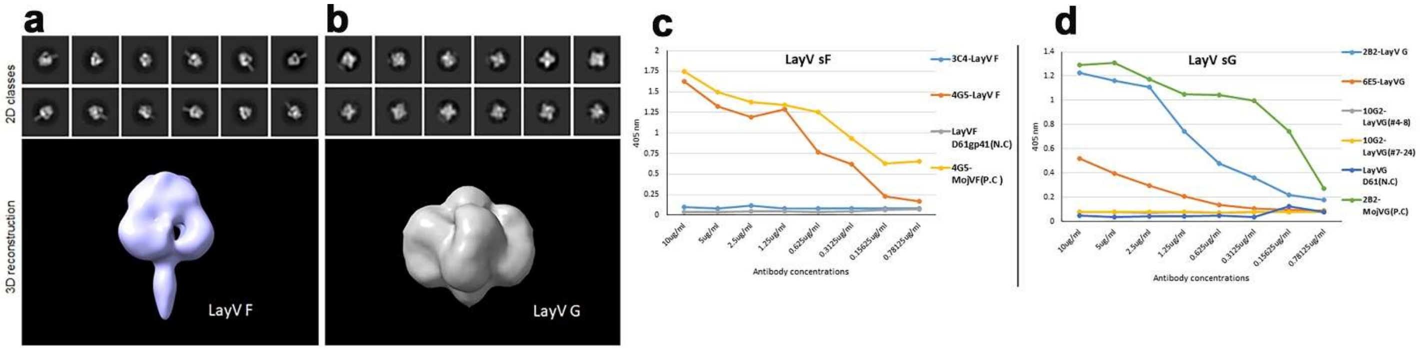

Figure 5. Negative stain EM analysis of LayV sF_{stb} and sG_{tet}. 2D and 3D classifications of LayV F trimers (**a**) and LayV G tetramers (**b**). ELISA cross-reactivity MojV F mAb (**c**, yellow) with LayV-sF and MojV G mAb (**d**, green) with LayV-sG.

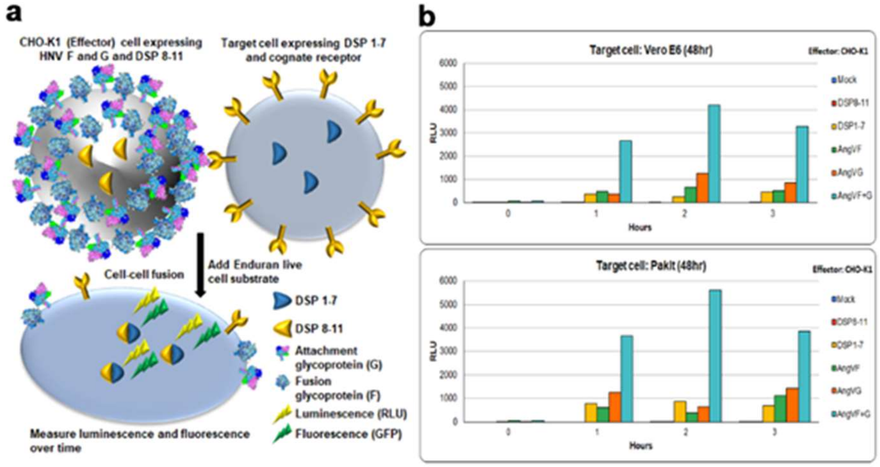

Figure 6. AngV F and G cell-cell fusion using a dual split luciferase. A schematic representation of the dual split-luc cell-cell fusion assay (**a**). Split-luc cell-cell fusion assay with AngV F and G plasmid constructs (**b**).

permissive target cell restores luciferase and a signal can be measured[43] (**Figure 6a**). In addition, we have already constructed AngV sG$_{tet}$ and sF proteins and their structural solutions (both pre-fusion and post-fusion sF and the tetrameric structure of sG$_{tet}$) have been made by the PL of **RP5**, and cell-fusion is observed in Vero E6 cells and the bat kidney cell line, PaKiT, indicating that full-length AngV F/G are functional (**Figure 6b**). Taken together, these data suggest that the rescue of reporter viruses with LayV and AngV F/G is feasible. We will characterize viruses in cell-based infection tropism and growth kinetics assays. Alternatively, we will also construct a set of reporter gene-encoding VSV-based (LayV and AngV F/G bearing) reporter viruses as previously done with Australian bat lyssavirus (ABLV) G glycoproteins[70,71] and authentic ABLV[72,73].

Experimental Design.

Aim 2.1: Design and construct a recombinant Langya virus reporter virus. Figure 7 diagrams each of the proposed virus constructs that will be generated. The genome design, length and position of the green fluorescent protein gene are shown, and the experimental plans are described below. LayV helper plasmids for the N, P, and L genes will be synthesized. To construct the rLayV-GFP antigenome plasmid, large gene fragments of LayV will be synthesized and sequentially cloned into pOLTV5$_{opt}$ (**Figure 7a**). Unique restriction sites will be chosen to facilitate ligation of the LayV DNA fragments and to ensure adherence to the genomic "rule of six". All cloning will be performed with *E.coli* Stbl2 cells. The fully sequenced plasmids will be transferred to **Core E**. Virus rescue and subsequent virus characterization by cell-based assays will be conducted in collaboration with **Core E**. In addition, rLayV will be examined by **Core E** in animal model development studies such including the hamster and/or ferret, both successful for the prototype HNVs.

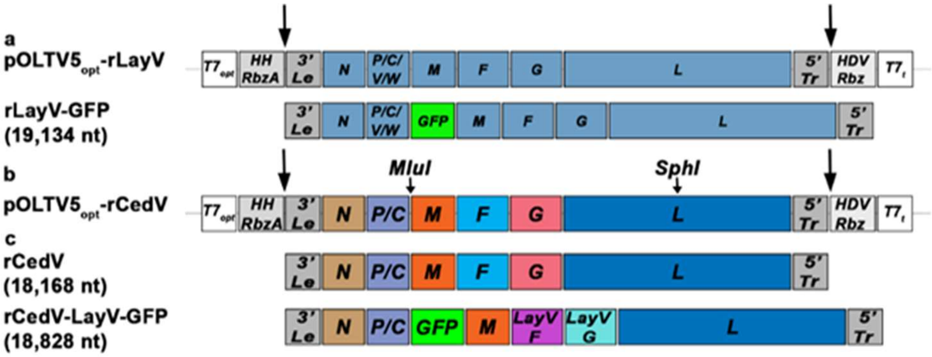

Figure 7. Schematic representation of recombinant reporter viruses. The pOLTV5$_{opt}$-rLayV plasmid (**a** top) and rLayV-GFP genome (**a** bottom). The arrows indicate regions of self-cleavage. The pOLTV5$_{opt}$-rCedV plasmid (**b**). The rLayV-GFP genome (**c** bottom). The long arrows indicate regions of self-cleavage. Shown are the unique restriction sites MluI and SphI that will be used to construct rCedV-LayV-GFP.

Aim 2.2: Construct, rescue and characterize a recombinant Cedar reporter virus encoding Langya virus envelope glycoproteins.

Generation of rCedV encoding LayV envelope glycoproteins. rCedV-LayV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the LayV F and G coding sequences. The CedV non-coding intergenic regions are retained to adhere to the genomic "rule of six". Unique restriction sites, will facilitate the insertion of the LayV F and G gene cassette into the genome clone (pOLTV5$_{opt}$-rCedV) (**Figure 7b**) generating rCedV-LayV-GFP (**Figure 7c**). All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-LayV-GFP antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (HNV-CPE). BSR-T7/5 cells and supernatants from successful rescue wells are collected and passaged onto naïve Vero 76 cells (T-75 flasks) to prepare a virus stock. When maximal syncytia and GFP is observed (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C[42-44,74].

***In vitro* characterization of rCedV-LayV-GFP**. The growth kinetics of rCedV-LayV-GFP compared to rCedV or rCedV-NiV/HeV chimeras will be assessed by infecting Vero cells with MOIs of 0.01, 0.1 and 1 and progeny virus recovered in 24hr intervals over a 72hr period and titered. In parallel experiments, infected cells will also be imaged for fluorescence and syncytia (HNV-CPE). **Figure 8** illustrates the syncytia (indicated by the yellow arrows) formed in Vero E6 cells infected with either rCedV-NiV-B-GFP or rCedV-HeV-GFP chimeras. The rCedV-LayV-GFP neutralization assays will be conducted by FRNT[44]. We have also already generated several murine mAbs to LayV F and G (3C4-LY and 4G5-LY to LayV F; and 2B2-LY and 6E5-LY to LayV F) and these will be used in neutralization assays. In addition, we will develop rabbit sera to LayV N, P and L proteins.

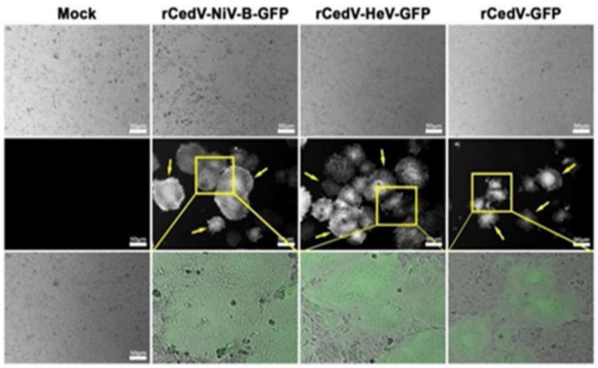

Figure 8. Syncytia induced by rCedV expressing NiV-B or HeV envelope glycoproteins. Vero E6 cells were uninfected (Mock) or infected with either rCedV-NiV-B-GFP, rCedV-HeV-GFP, or rCedV-GFP. All images are 24hrs post-infection. Zoomed-in fluorescence images (3rd row) are the yellow boxes. Arrows indicate giant multinucleated cells (syncytia). Representative images from three independent experiments are shown. Scale bar, 50 µm.

Aim 2.3: Construct, rescue and characterize recombinant reporter viruses encoding Angavokely virus envelope glycoproteins.

Generation of rCedV encoding AngV envelope glycoproteins. Figure 9 diagrams each of the proposed virus constructs that will be prepared. The genome designs, lengths and position of the *GFP* and *Luc* reporter genes are also shown. rCedV-AngV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the AngV F and G coding sequences. The AngV F and G coding sequences will be based on the GenBank: ON613535.1 sequence. The GenBank accession numbers for AngV F and AngV G are UVG43988.1 and UVG43989.1, respectively.

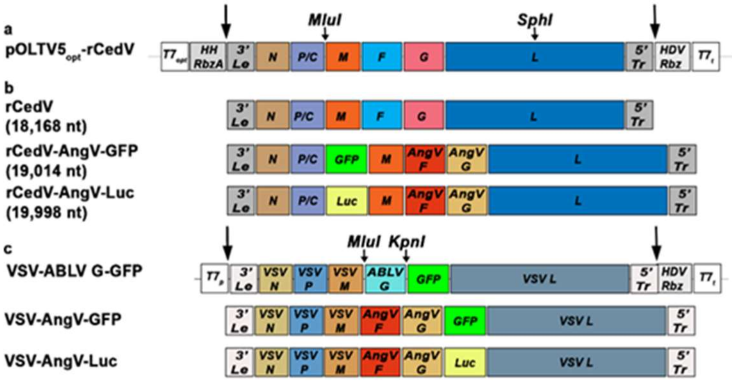

Figure 9. Schematic representation of the AngV chimeric reporter viruses. The pOLTV5$_{opt}$-rCedV plasmid (**a**). Shown are the unique restriction sites MluI and SphI that will be used to construct rCedV-AngV-GFP and rCedV-AngV-Luc. The rCedV-AngV-GFP and rCedV-AngV-Luc genome (**b**). Shown are the unique restriction sites MluI and KpnI that will be used to construct VSV-AngV-GFP and VSV-AngV-Luc (**c**). The long arrows indicate regions of self-cleavage.

CedV non-coding intergenic regions are retained to adhere to the genomic "rule of six". Unique restriction sites, will facilitate the insertion of the AngV F and G gene cassette into the rCedV antigenome plasmid (**Figure 9a**) generating rCedV-AngV-GFP (**Figure 9b**). The rCedV-AngV-Luc clone will be produced by swapping the reporter gene coding sequences. All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-AngV-GFP or pOLTV5$_{opt}$-rCedV-AngV-Luc antigenome plasmid. After 4 days cultures are examined for GFP expression and syncytia (HNV-CPE). BSR-T7/5 cells and supernatants from successful rescue are collected and passaged in Vero 76 cells (T-75 flasks) to prepare a virus stock. When maximal syncytia and GFP is observed (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C[42-44,74].

Generation of a VSV encoding AngV envelope glycoproteins. We will also construct reporter gene encoding versions of a replication competent VSV encoding the AngV F and G glycoproteins (GFP and Luc) (**Figure 9c)**. A large gene cassette comprising VSV untranslated intergenic regions flanking the AngV F and G coding sequences will be synthesized. Unique restriction enzyme sites, will facilitate the insertion of the AngV F and G gene cassette into the VSV backbone plasmid to generate VSV-AngV-GFP (**Figure 9c**). The VSV-AngV-Luc clone will be produced by swapping the reporter gene coding sequences. Cloning procedures are performed in *E. coli* Stbl2 cells and all plasmid clones verified by sequencing. Rescue of VSV-AngV-GFP and VSV-AngV-Luc, will be performed in BSR-T7/5 cells, in 12-well plates, transfected with helper plasmids, VSV-N, VSV-P, and VSV-L and the VSV-AngV-GFP or VSV-AngV-Luc antigenome plasmids. After 48hrs the cells and supernatants are collected and subjected to freeze-thawing and clarified by centrifugation. Amplification of rescued virus uses HEK293T cells (6-well plates) by inoculation with the supernatant from step 1. Typically, when GFP fluorescence and/or cytopathic effects (CPE) is observed, the cells and supernatants are harvested as above and the virus stocks stored at -80°C. Larger viral stocks are prepared in T-150 flasks in HEK293T cells, and harvested virus supernatants are purified by buffered sucrose cushion centrifugation and virus pellets resuspended in 10% sucrose/TNE buffer, and small volume single use aliquots stored at -80°C. All virus stocks are deep sequenced. Virus stocks (GFP) are titered (infectious units/ml (IU/ml)) by serial dilution on HEK293T cells in 96-well black walled plates. At 24hrs post-infection plates are fixed with 4% formaldehyde, washed 3x with diH$_2$0 and imaged (fluorescence) with a CTL S6 analyzer. Luciferase encoding VSV stocks are titered by plaque assay[75].

Characterization of the recombinant reporter viruses in cell-based infection assays. Replication kinetics of rCedV-based and VSV-based AngV F/G viruses are assayed by Vero cell culture infection using MOIs of 0.01, 0.1 and 1, and progeny virus recovered in 24hr intervals and titered. rCedV-AngV-GFP virus replication can be compared to rCedV or rCedV NiV/HeV chimeras. Similarly, VSV-AngV F/G virus replication can be compared to expected virus production of wildtype VSV or VSV-ABLV G[71]. The rCedV-AngV-GFP and VSV-AngV-GFP assays will be conducted by FRNTs[44] and rCedV-AngV-Luc and VSV-AngV-Luc in luciferase assays[42].

Expected results, potential pitfalls and alternatives. We expect that rCedV-LayV-GFP and rCedV-AngV reporter viruses can be rescued. In addition, we expect that these chimeric viruses will induce syncytia and replicate to high titers. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9. In the event that the rescue of rCedV chimeric viruses are not viable, multiple strategies may be examined. 1) test different ratios of helper plasmids and antigenome plasmid; 2) perform rescue in different cell lines; 3) construct alternate versions of the LayV and/or AngV F and G genes within the antigenome plasmids, such as, fuse the LayV and/or AngV F and G ectodomains with the transmembrane and/or cytoplasmic tail domains of the corresponding CedV F and G elements which may facilitate virus particle formation and membrane fusion activity.

<u>Aim 3:</u> Evaluate HNV-specific antibodies and nanobodies developed by the Center's RPs and Core D.

Rationale and Preliminary Data. The rCedV chimeric system we established replaces the need for authentic NiV-B and HeV in neutralization assays. Neutralization values of well-characterized NiV/HeV cross-reactive neutralizing mAbs highly correlated between rCedV-NiV-B-GFP and rCedV-HeV-GFP and authentic NiV-B and HeV at BSL-4 when tested by conventional PRNT[44]. The Pearson correlation analysis between the rCedV chimeras BSL-2 PRNT and the NiV-B or HeV BSL-4 PRNT is shown in **Figure 10a**. We further developed the rCedV-NiV-B-GFP and rCedV-HeV-GFP neutralization assay into a high-throughput and quantitative assay that is based on the reduction of GFP foci, a FRNT[44]. The Pearson correlation analysis between the chimeras PRNT and FRNT is shown in **Figure 10b**. Taken together, these data demonstrate that rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeric viruses are an ideal set of suitable surrogate viruses for conducting a rapid FRNT-based assay for assessing NiV and HeV antibody neutralization.

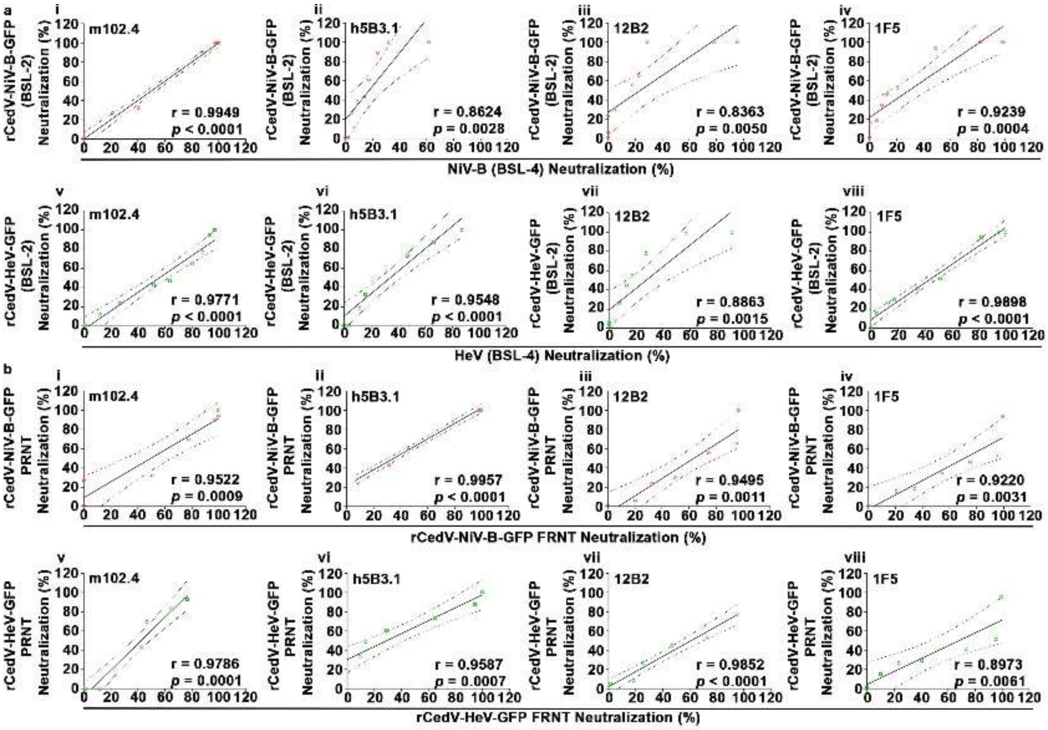

Figure 10. Pearson correlation analysis of rCedV chimeras. Pearson correlation analysis of PRNT neutralization (%) values of rCedV-NiV-B-GFP versus NiV-B (**a**, **i-iv**) and rCedV-HeV-GFP versus HeV (**a**, **v-viii**). Pearson correlation analysis from PRNTs (y-axes) and FRNTs (x-axes) of rCedV-NiV-B-GFP (**b**, **i-iv**) and rCedV-HeV-GFP (**b, v-viii**). Neutralization with mAbs m102.4, h5B3.1, 12B2 or 1F5 are shown. The Pearson correlation coefficient 'r,' p-value (two-tailed), linear regression line (solid lines), and 95% confidence intervals (dashed lines).

Experimental Design. Here, using the new tools (rCedV-LayV-GFP, rCedV-AngV-GFP, rCedV-AngV-Luc, VSV-AngV-GFP and VSV-AngV-Luc) we will assess neutralizing activity, of HNV specific mAbs and/or sera from HNV immunized mice that will be generated by **Core D**. The FRNT is high throughput and performed in 96-well plates to establish a 7-point dose response. Serially diluted immune sera or mAbs are mixed with either rCedV-NiV-B-GFP or rCedV-HeV-GFP for 2hrs. The virus-mAb or virus-sera mixtures are then added in triplicate to confluent pre-seeded Vero 76 cells in black-walled clear bottom 96-well plates and incubated for an additional 24hrs. Plates are then fixed and imaged and fluorescent foci counted using the CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) will be determined as the mAb concentration or serum dilution at which there was a 50% reduction in fluorescent foci versus untreated control wells. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9.

Expected results, potential pitfalls and alternatives. We do not anticipate any unexpected limitations in assessing the neutralization potential of antibodies and sera generated from other research projects and/or cores as we have successfully demonstrated that the rCedV-GFP chimeric FRNT platform can serve as a surrogate BSL-2 neutralization assay that is high throughput with a fast turnaround time.

Aim 4: Validate PPZ-MNP platform with another paramyxovirus-specific antigen in Phase 2.

At completion of Phase I we will have i) a procedure to fabricate PPZ adjuvanted MNP using sG, sF or a combination of both viral glycoproteins; ii) generated rLayV with an associated animal model in collaboration with **Core E** with reporter virus construct (rCedV-LayV-GFP); and iii) generated reporter viruses AngV (rCedV-AngV-GFP, rCedV-AngV-Luc, VSV-AngV-GFP and VSV-AngV-Luc). Here, in Phase II we propose to test the hypothesis that the PPZ-MNP vaccine platform technology can be adapted and transferred as a ‘plug and play’ strategy for other paramyxoviruses, namely the divergent HNVs LayV and AngV. The major goal rests on the rescue of LayV and establishing an infection/disease model of this most recently discovered pathogenic, zoonotic, HNV. Nevertheless, if rescue of rLayV with an associated animal model is not achieved, we will still be able to test the MNP approach as proof-of-concept to the extent of generating robust immune responses in animals and testing neutralizing antibody responses using both LayV and AngV reporter virus systems.

PPZ-MNP manufacture. The fabrication of the MNPs by **Core C** will be prepared for both the F and G viral glycoproteins: LayV-sG, LayV-sF, AngV-sG and AngV-sF depending on the data and outcomes, and vaccine down-selection in Phase I we may also include a combination of sG and sF. Vaccine antigens will have been prepared by **Core D**. It may be important to evaluate both the attachment and fusion glycoprotein immunogens for LayV and AngV in Phase II. Although the preponderance of data to date for the pathogenic prototype HNVs (NiV/HeV) indicates that the attachment glycoprotein (G) alone can serve as an effective vaccine immunogen, this is presently unknown for these two divergent HNVs, so test both sF and sG for these HNVs is needed.

Immunogenicity. As in Aim 1, groups of 5 mice will be used for each immunogen(s) and a control of nonimmunized subjects. Sera will be drawn as scheduled in **Figure 3**. ELISA titers of sera to vaccine immunogens will be evaluated by **Core C** and sera will be evaluated for virus neutralization with newly developed reporter viruses. Cellular immune responses will be assessed as described in Aim 1.

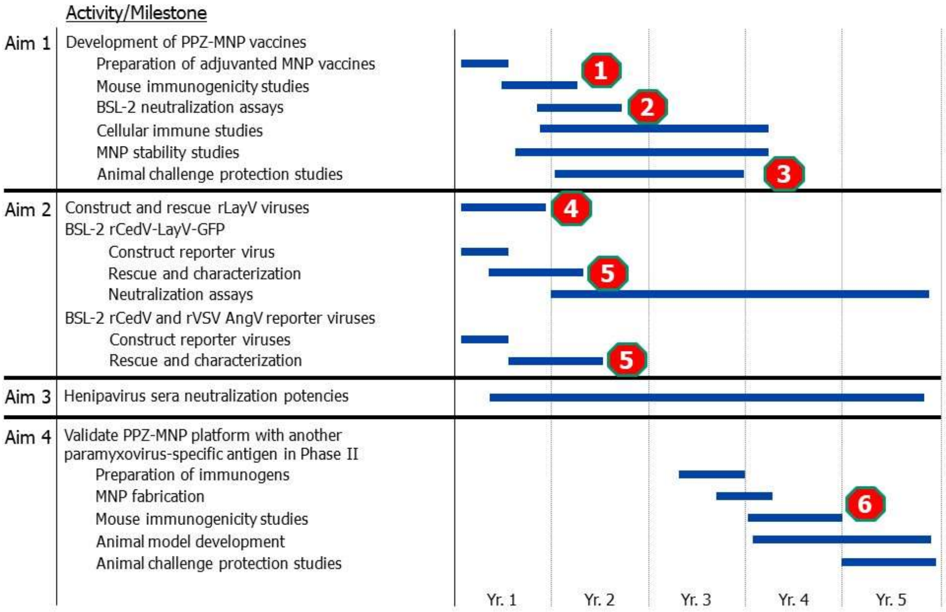
Animal challenge studies. The experimental design for these studies will be adjusted once the animal model has been developed. The basic design will follow those for ferrets and AGMs described in Aim 1. The immunogen will be chosen based on the results from the mouse sera neutralization tests.

Expected results, potential pitfalls and alternatives. We expect that LayV / AngV glycoproteins MNPs fabrication will be possible. Mouse immunization studies with MNPs are likely to be uncomplicated and we will be able to assess immune responses. These data will determine whether the sG or sF is the immunogen of choice for best virus neutralization antibody induction. If rescue of rLayV and establishing an animal model are not met, the ability to measure inhibition of virus in cell-based assays, using either the new reporter viruses or a cell-cell fusion surrogate assays will be done. The mouse immunogenicity studies, together with the virus neutralization assays will provide a foundation for potential anti-LayV and anti-AngV MNP vaccine approaches.

Project Milestones, Timelines, and Go/No-go decisions. The **RP2** Aims, milestones, and timeline with activities having periodic assessments by Center leaders, SAB, and NIAID staff as shown in the Gannt Chart.

Aim 1: Develop PPZ-MNP-based sG_{tet} and sF_{stb} prototype HNV subunit vaccines

Milestone 1: Adjuvanted MNP vaccines are successfully prepared: In year 1, the MNP vaccine fabrication by **Core C** will commence and formulation of recombinant antigens with PCEP adjuvant in the context of MNPs will be assessed. We are confident that this stage of the research plan will be achievable because we have already had success in MNP fabrication with the HeV-sG formulated with two different PPZ adjuvants (PCEP and PCPP) and the preliminary mouse immunization and cellular immune responses and induction of NiV/HeV cross-neutralizing antibody titers was excellent, with ID_{50} titers significantly greater than previously measured pre-challenge ID_{50} titers that provided complete protection across several prior studies in cats, ferrets, horses, and AGMs (preliminary data). We expect that the formulation of the remaining 3 prototype HNV immunogens (NiV-sG_{tet}, NiV-sF_{stb}, HeV-sF_{stb} (and the combination test: HeV-sG+NiV-sFstb)) adjuvanted with PCEP and applied to the MNPs will be fully achievable. Analysis will also include antigen stability studies by re-release of sG_{tet} and sF_{stb} immunogens and recognition by select conformation dependent mAbs. A go/no-go decision may be made pending the results of MNP fabrication and antigen analysis of each MNP vaccine type, poor fabrication or loss of antigen integrity will trigger termination of those individual vaccines prior to immunogenicity studies.



Gannt chart outlining project milestones (left). Solid lines represent periods of activity to achieve milestones. ***Go/No-go*** decision points are indicated by red octagons as follows:

(1) Successful fabrication of vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity is a ***No-go*** for the respective individual vaccine MNP.

(2) An SNT <10 is a ***No-go*** for the tested immunogen. The highest SNT >10 is a ***Go*** for the respective immunogen.

(3) Successful protection is a ***Go*** to the project Phase II. No protection is a ***No-go*** for the MNP vaccine platform.

(4) Successful rescue of rLayV is a ***Go*** to the development animal models in Aim 4. Otherwise is a ***No-go*** for the animal models development and the challenge protection studies in Aim 4.

(5) Successful rescue of a reporter virus is a ***Go*** for neutralization assays development. Inability to rescue a reporter virus is a ***No-go*** to that reporter virus neutralization assay development.

(6) Successful fabrication of vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity is a ***No-go*** for the respective individual vaccine MNP.

<u>Milestone 2: High immunogenicity and best in class immunogen(s) identified</u>: **Core C** will conduct immunogenicity studies in mice as detailed in the preliminary data and experimental plan and the Core research plan; multi-parameter humoral and cellular immune responses will be assessed (antigen specific antibody induction, virus-neutralization, and polyfunctional T-cell responses by in vitro stimulation). As sera are made available from the mice MNP vaccine cohorts, we will assess the NiV/HeV-neutralizing antibody activities of each of the MNP vaccine formulations of the prototype HNV immunogens (NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb}$, HeV-sG, and HeV-sG+NiV-sF$_{stb}$). The criteria to judge success and go/no-go decisions will be levels of cross-neutralizing antibody responses (neutralization of both HeV and NiV-B) induced by each vaccine type. We expect to be able to down-select to 'best-in-class' vaccine as a single antigen or perhaps the combination antigen MNP vaccine formulation at this stage prior to progressing to the first-round ferret challenge models.

<u>Milestone 3: MNP vaccination protection in animal challenge studies:</u> Here, the determination of whether MNP vaccination affords protection in animal model challenge experiments will be made. For the NiV and HeV prototypes the animal models (ferret and AGM) are extremely well-developed and the PABVAX Center leadership and staff have extensive experience in this area, and outcomes at this stage should be readily assessable. If we are successful in developing and validating the PPZ adjuvanted MNP recombinant protein vaccine approach for the HNV prototypes (NiV/HeV) and demonstrate protection in the planned homologous and heterologous HNV challenge studies, this will be expected to be a 'go' decision point in year 3, and the proposed Specific Aim 4 tasks (below) will continue in preparation for Phase II of the PABVAX Center. If in the unlikely event that the MNP vaccine approach fails (no-go) then further consultation with industry and regulatory expertise within **Core D** and partners and the **SAB** will be geared towards using the previously identified 'best-in-class' immunogens with alternative vaccine platforms (IM formulations; virus vectored such as a VSV technology held by the PABVAX Center PI and RP1 PI at UTMB; or mRNA, Moderna Inc., has provided the Center a letter of support).

<u>Aim 2: Rescue Langya virus and construct LayV and AngV glycoprotein bearing reporter virus tools.</u>

<u>Milestone 1: Successful rescue of recombinant Langya virus.</u> Since the genetic data on LayV is derived from an actual human virus isolate, it suggests that rescue of rLayV will be possible. **RP2** staff have extensive experience in HNV reverse genetics with rCedV (and VSV) with unique newly developed reagents. Virus rescue is in collaboration with **Core E**, followed by virus characterization in cell-based assays. **Core E** will then initiate small animal model development studies such as the hamster and/or ferret, both successful for the prototype HNVs. If rescue and animal modeling is successful, it will be very significant advancement for this pandemic preparedness initiative and objectives, and the virus, reagents, tools and models supplied to the ReVAMPP network. If rescue is not possible a no-go decision is obvious for animal model development. However, even if a LayV isolate remains unavailable by other means, we can still test the MNP approach with LayV and also our alternative divergent HNV prototype (AngV) by characterizing G and/or F vaccine-induced neutralizing antibodies using alternative reporter viruses (Milestone 2 below) or cell-based (cell-cell fusion assays; **Figure 6B**).

Milestone 2: Construction of rCedV and rVSV reporter viruses encoding LayV and AngV F/G glycoproteins: Here, we have reasonable confidence that one or both alternate reporter virus platforms will be possible. Successful rescue of these reporter viruses will enable the determination of immune sera neutralization titers and is a 'go' for the development of the neutralization assays. An unsuccessful rescue of either of the LayV or AngV reporters will be a no-go for those assay developments. If neither reporter virus is rescued we will proceed to cell-cell fusion assays development to study the immune sera neutralization titers. We have already successfully generated recombinant sF_{stb} and sG_{tet} glycoproteins from AngV and LayV based on available sequence data (AngV, **RP2** in collaboration with **Dr. Cara Brook,** The University of Chicago, and letter of support included in the PABVAX Overall component; and LayV, in collaboration with **RP5** leaders and **Genovac, Inc.**). In our prior experience, success in making soluble and secreted oligomeric forms of virus glycoproteins strongly indicates that genetic sequences are correct which should also translate into functional proteins. Rescued viruses will be characterized in various cell-based assays. These new virus tools will be used in collaboration with **RP4**, **RP5** and **Core D**, in assessing newly developed mAbs and nabs against LayV and AngV, and also vaccine-induced neutralizing antibody responses in PABVAX Center activities in Phase II.

Aim 3: Is also shown which is the collaborative support provided by **RP2** in assessing specific antibody development activities to HNVs by **RP4** and **RP5** is also included.

Aim 4: Validate PPZ-MNP platform with another paramyxovirus-specific antigen in Phase 2. At this stage one or both of the divergent HNV prototypes (LayV and/or AngV) would be selected and the milestones for progress would include MNP vaccine manufacture; mouse immunogenicity studies; and virus challenge protection. These milestones will be similar as described for Specific Aim 1. We have obtained preliminary structural characterizations of sF_{stb} and sG_{tet} glycoproteins from AngV and LayV (native-like oligomeric and stabilized glycoproteins) in collaboration with **RP5** leaders, and have also determined (preliminary data) that the LayV sF_{stb} and sG_{tet} glycoproteins are recognized by 3 previously generated mAbs to MojV F/G from our lab (**RP2**). As discussed above, the primary HNV target of **RP2** is LayV, and the alternate is AngV, but the go/no-go decisions on the virus target will depend on the progress and outcomes of the earlier studies. Also, as discussed above, even in the absence of rLayV rescue or its availability from another source and its characterization in animal models by **Core E**; or the possible isolation of AngV and its work-up *in vivo* and pathogenesis studies by Core E; we expect to still be able to assess and validate the recombinant subunit protein MNP vaccine approach with our already prepared immunogens and the other virus tools we plan on developing.

Industry Expertise and Regulatory Considerations

Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP2** (MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based HNV vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

If new neutralizing mAbs to the F glycoprotein of NiV/HeV (cross-reactive) or to LayV or AngV or nabs or bi-specific nabs that show antiviral activities to NiV/HeV, from the collaborations of **RP2, RP3, RP4** and **RP5** are found, we will seek industry and regulatory expertise in **Core D** and the **SAB** in areas such as; identification of correlates of protection, lead optimization, stability and manufacturability testing. Antibodies may be engineered (such as altered N-glycans, Fc mutations for effector functions and extended half-life, multimeric formats) by **Core D** and further evaluated to correlate mechanisms of action with maximal efficacy by **Core E** (authentic HNVs) and **RP3** (rCedV chimera model). This work will identify lead prototypes to transition to early process development. Further details on antibody development, milestones, and go/no-go decisions are discussed in the relevant RPs and **Cores D** and **E**.

Research Strategy

Significance

The constant threat posed to global public health by emerging and reemerging zoonotic viruses emphasizes the importance for pandemic preparedness by developing countermeasures. The highly pathogenic Hendra virus (HeV) and Nipah virus (NiV) are the prototype members in the genus *Henipavirus* in the family Paramyxoviridae[1], and the selected prototypes chosen for **RP2**. HeV was first discovered in 1994, in Queensland, Australia where it was the causative agent of a severe and fatal respiratory disease among horses along with a human case fatality[1,2]. Whereas, in 1998-1999 in Malaysia and Singapore an outbreak of encephalitis in people and respiratory disease in pigs was eventually determined to be caused by a closely related virus - to NiV[3,4]. These viruses are capable of causing a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with fatality rates ranging from 40-100%[5,6]. As a result of this high lethality and lack of approved vaccines or antivirals, HeV and NiV are classified as Biosafety Level-4 (BSL-4) pathogens. NiV and henipaviral diseases are also included in the WHO's Blueprint List of Priority Pathogens[7], and NiV is among the Coalition for Epidemic Preparedness Innovations (CEPI) list of Priority Diseases needing urgent research and countermeasure development and are recognized as agents of pandemic threat potential[8,9]. HeV, though apparently restricted to Australia, has spilled over 66 times, most recently in 2022[10]. HeV has caused the death or euthanasia of >100 horses, 2 HeV positive and euthanized dogs, and 4 fatalities of 7 human cases[10,11]. Whereas NiV is present throughout a large area including South and Southeast Asia from the Philippines to western India. The frequent outbreaks of NiV in Bangladesh and India have high human case fatality rates 70-100%. NiV transmission in Bangladesh to humans has been linked to contaminated fruits or date palm sap, and person-to-person transmission[12-15]. In total, there have been >620 human cases of NiV infections >330 fatalities, the most recent in 2023[16]. The genus *Henipavirus* now includes nine other species; the four viral isolates of CedV, Gamak virus, Daeryong virus, and Langya virus (LayV)[17-19] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiang virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[20-23]. Pteropid fruit bats, known as flying foxes, are recognized natural reservoir hosts for NiV, HeV[24,25], CedV[18], GhV and AngV. One of these, CedV, has been shown to be nonpathogenic in several animals susceptible to HeV and NiV disease including mice, guinea pigs and ferrets[18,26] and African green monkeys (AGMs) (Geisbert and Broder, unpublished). The remaining six reported henipaviruses (HNVs) are likely of rodent origins. One of these six, the isolate LayV, is associated with nonfatal febrile illness in humans[19].

HNVs are enveloped, single-stranded, negative sense RNA viruses that share a similar genomic makeup. The viruses have two membrane anchored glycoproteins involved in entry: the attachment (G) glycoprotein that engages the host cell receptor and the fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F proteins are the major targets of neutralizing antibodies and the focus of all vaccine and therapeutic antibody strategies[27,28]. However, CedV is distinct from other HNVs, and the phosphoprotein (*P*) gene does not encode the interferon antagonist proteins V and W[18,29-31]. The nonpathogenic phenotype of CedV is most likely attributed to the lack of these nonstructural proteins. Based on genetic data, all identified HNVs, except CedV, can potentially express the V and W proteins. CedV is recognized as a BSL-2 restricted agent[32].

Innovation

There are multiple layers of innovation within **RP2**. **First**, the proposed development of henipavirus (HNV) subunit vaccine candidates using an innovative microneedle array patch (MNP) technology that may be suitable for the incorporation of immunogens derived from other undiscovered pathogenic HNVs or paramyxoviruses in the future. **Second**, the construction of a rLayV reverse genetics system will be highly valuable in the HNV toolbox to study putative differences in pathogenesis and vaccine design between HNVs of bat and rodent origin, and significant resource to the ReVAMPP network's objectives. **Third**, generation of BSL-2 surrogate platforms that are based on rCedV and VSV will allow for a wide-variety of *in vitro* studies to support infection and host response studies and to screen in a high throughput manner the neutralization activity of immune sera and monoclonal antibodies (mAbs) and nanobodies (nabs) without the requirement for high containment. **Fourth**, considering that the LayV and AngV F and G proteins are functionally fusion active, the generation of viable rCedV chimeras bearing either LayV or AngV F and G glycoproteins is feasible.

Approach

Scientific Premise

To date, the most extensively studied NiV/HeV vaccine is a soluble, recombinant, oligomeric form (dimers and/or tetramers) of the G glycoprotein of HeV (HeV-sG)[11,27,33], and has been demonstrated to confer complete protection against lethal challenge with NiV-M (Malaysia), NiV-B (Bangladesh) or HeV in multiple animal models[34-40]. It has most recently been shown to provide complete protection of AGMs against NiV-B challenge performed one week post-immunization (single dose)[41]. The HeV-sG vaccine is marketed by Zoetis, Inc., for equine use in Australia since 2012 and is the first commercialized vaccine against any BSL-4 pathogen. HeV-sG /Alum intramuscular formulation is currently in clinical trial as an anti-NiV vaccine. **RP2** proposes to enhance the formulation, immunogenicity, and delivery of recombinant subunit protein based HNV vaccines.

We have developed rCedVs as new tools to study HNV host cell interactions, including ephrin receptor use and infection tropism, and in the development of HNV countermeasures. Experiments with rCedV can be conducted in a BSL-2 containment setting. The rCedV reverse genetics system[42,43] allowed us to develop a rCedV chimeric platform, where the CedV F and G glycoproteins are replaced with that of either NiV-B or with HeV, generating replication competent chimeric viruses (rCedV-NiV-B and rCedV-HeV). We have successfully rescued and characterized the chimeric viruses with and without reporter genes[44]. The neutralizing potencies of several well-characterized cross-reactive NiV/HeV F and G specific mAbs against these rCedV chimeras highly correlate with the potencies obtained for the same antibodies to neutralize authentic NiV-B and HeV by plaque reduction neutralization tests (PRNTs). The green fluorescent protein (GFP) reporter chimeras were employed to develop a rapid, high-throughput, and quantitative fluorescence reduction neutralization test (FRNT). The antibody potencies to neutralize the reporter gene containing chimeras in the FRNT highly corelated with the respective potencies obtained by PRNT[44]. The rCedV chimera assay has been employed in several studies and its high-throughput ability has also allowed for the conduct of NiV/HeV mAb synergy neutralization tests[45-47]. The rCedV chimeras have their most important application in an authentic HNV-based surrogate neutralization assay that is rapid, cost-effective, and can be utilized in BSL-2 containment. We believe that the rCedV reverse genetics system may be able to serve as a plug-and-play platform for other emerging or pathogenic HNVs. To accomplish this, **RP2** will develop a variety of rCedV variants with reporter genes that will serve as important tools for the PABVAX Center RPs and Cores, and also for the NIAID, ReVAMPP network for pandemic preparedness.

Scientific Rigor

The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed. rCedV laboratory manipulation guidelines and standard operating procedures under BSL-2 conditions were developed for the laboratory and staff, and all procedures were reviewed and approved by the Uniformed Services University Institutional Biosafety Committee in accordance with NIH guidelines. The rCedV tools described here have been transferred to multiple institutions and research organizations which have also reviewed and approved their use at BSL-2 containment.

Aim 1: Develop PPZ-MNP-based sG_{tet} and sF_{stb} prototype HNV subunit vaccines.

Rationale and Preliminary Data. It is well documented that the HNV G and F glycoproteins are the primary targets for virus neutralizing antibodies[27,45,48-53]. As such, HeV-sG subunit has clinically advanced in the development of HeV and NiV vaccines. Building on this work, Aim 1 will compare the immunogenicity and efficacy of alternate NiV vaccine immunogens (NiV-sG_{tet}, NiV-sF_{stb}), HeV vaccine immunogen (HeV-sF_{stb}), and a bivalent HNV vaccine candidate (NiV-sF_{stb}+HeV-sG) along with the clinical subunit HeV-sG. All immunogens will be delivered as polyphasphazene (PPZ) adjuvanted MNP vaccines in three animal species (mice, ferrets, and non-human primates-NHPs (AGMs)). Immunogenicity will initially be performed in mice by **Core C**. The neutralizing potencies of the immunized mouse sera will then be evaluated by *in vitro* neutralization assays using rCedV-NiV-B-GFP and rCedV-HeV-GFP[44]. The superior neutralizing antibody inducing MNP vaccine type(s) will be evaluated by animal challenge studies ferrets (first-tier) challenged with NiV-B or HeV and the lead vaccine candidate(s) from those studies will then be evaluated in AGM (second-tier) challenge studies.

Adjuvants are included in vaccine designs to generate a robust and durable vaccine induced immune response. We will utilize a synthetic PPZ macromolecule as the adjuvant to complement the proposed NiV and HeV vaccine immunogens. The PPZ macromolecule has many distinctive properties that make it an attractive choice as an adjuvant; 1) water-soluble and biodegradable, 2) spontaneously self-assembles with antigens in aqueous solutions, 3) forms nanoassemblies that mimick the dimensions of a virus (60-100nm)[54,55] and 4) is completely compatible with MNPs[56-58], the delivery mechanism that will be employed for the HNV immunogens. The extensive clinical use and experimental evidence supports the safety and potency of PPZ in enhancing vaccine-induced protective immune responses[54-60]. In particular, the most commonly used PPZ adjuvant is the clinical stage *poly[di(carboxylato-phenoxy)phosphazene] (PCPP)* and its structural homologue *poly[di(carboxylato-ethylphenoxy) phosphazene] (PCEP)*, which, significantly boosts vaccine immunogenicity without the requirement for large amounts of antigen while providing long-lasting protection in live viral challenge studies[60-62]. MNPs are promising resources to achieve systemic effects by transdermal delivery. They are a minimally invasive, painless system, which can bypass the stratum corneum and overcome the potential drawbacks of subcutaneous injections[63]. (See **Core C** Research Plan).

Manufacturing and characterization of HeV-sG±PCEP MNPs. The technology for fabricating MNPs pioneered by Bediz et al.,[64] was developed and is described in detail in the **Core C** Research Plan). We have conducted preliminary studies with the dissolvable MNPs incorporating HeV-sG antigen with or without PPZ adjuvants including PCEP (HeV-sG±PCEP MNPs) in collaboration with the investigators of **Core C**. Spin-casting of carboxymethyl cellulose and trehalose was used to create MNPs incorporating HeV-sG AF555±PCEP into obelisk-shaped microneedles having the vaccine components at the tip region to maximize the vaccine delivery efficiency by locating the vaccine components at the skin-penetrating regions of the microneedles (**Figure 1a**). The HeV-sG±PCEP MNPs can have a pre-determined array size of 10x10mm (for mice studies) and 20x20mm or greater (for larger animal studies). Images of the HeV-sG AF555±PCEP MNPs before (**Figure 1a**) and after (**Figure 1b**) application (15-20 mins), confirm a nearly complete dissolution of the microneedles into the skin demonstrating that the vaccine was effectively deposited into the skin. To facilitate the characterization and to visualize skin penetration of the developed HeV-sG±PCEP MNPs, HeV-sG was fluorescently labeled with Alexa Fluor 555 dye, HeV-sG AF555. To test the intracutaneous delivery capacity, HeV-sG AF555±PCEP MNPs were applied to the abdomen skin of C57BL/6 mice for 15 min and then removed. The HeV-sG AF555±PCEP MNP-treated mice were imaged before and after *in vivo* skin applications by using an *in vivo* live animal fluorescent imaging system (IVIS Lumina XR) and the acquired images were post-processed using Living Image software (PerkinElmer). **Figures 1c** and **1d** further corroborate the microscopy analysis of these MNPs and show effective deposition of vaccine components to murine skin (**Figure 1c**: HeV-sG AF555 and **Figure 1d**: HeV-sG AF555+PCEP). Together, these data support the feasibility of our PPZ MNP vaccine platform for the translational development of skin-targeted HNV vaccines that could also be employed using recombinant protein immunogens (or even virus-like particles) from other viral agents from a wide-variety of virus families.

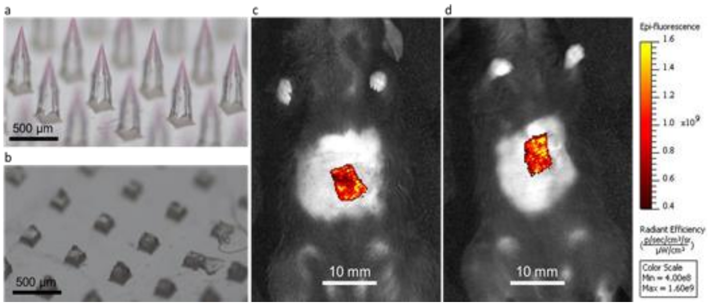

Figure 1: *In vivo* intracutaneous delivery efficacy of HeV-sG±PCEP MNPs in mice. An optical stereomicroscopy image of HeV-sG AF555+PCEP CMC/Trehalose microneedles before (**a**) and after (**b**) *in vivo* skin application. Administration of HeV-sG AF555 **(c)** and HeV-sG AF555+PCEP **(d)** to mouse skin *in vivo* with MNPs, captured by using a fluorescence *in vivo* imaging system (IVIS).

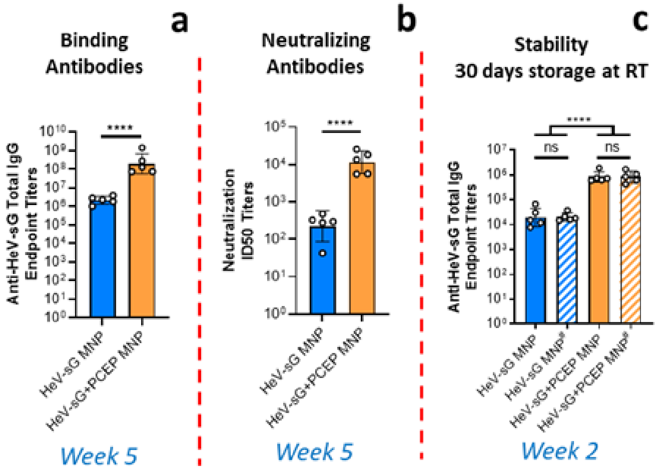

Figure 2: MNPs induced humoral responses and initial MNP stability data. Mice immunized prime/boost. MNPs applied to the abdominal skin of C57BL/6 mice 15 min, D0 (prime) and D21 (boost). Endpoint binding titers **(a)** ELISA. Neutralizing ID_{50} titers **(b)** by FRNT. Stability of MNPs **(c)** measured at D14 endpoint binding titers using a 30-day-old MNP compared to fresh MNP. Neutralizing ID_{50} titers with HeV-sG MNP (1:272) and HeV-sG+PCEP MNP (1:11,445) against rCedV-HeV-GFP.

HeV-sG±PCEP MNPs with unlabeled HeV-sG were fabricated and the immunogenicity tested in C57BL/6 mice. Groups of 5 mice were immunized on Day 0 (D0) (prime) and D21 (boost) with HeV-sG±PCEP MNPs. Sera were collected on D35 and analyzed by ELISA for total binding antibodies (endpoint titers) (**Figure 2a**) and HNV neutralizing capacity of serum in the rCedV chimeras FRNT[44] (**Figure 2b**). These results show that MNPs are highly effective in inducing antigen-specific binding and neutralization antibodies, and improved with PCEP adjuvant. Additional data also demonstrate that the PPZ MNP platforms are superior to intramuscular injection of the current clinical Alum-formulated HeV-sG vaccine (**Core C; Figure 4a**). In addition, temperature stability was tested by storing the HeV-sG±PCEP MNPs at room temperature without refrigeration. Mice were immunized with fresh (group 1) and 30-day old MNP (group 2) by single dose immunization. Mice were bled on D14 post immunization and the endpoint titers of total IgG levels were determined by ELISA. **Figure 2c** suggests that MNP-embedded vaccine components retain their immunogenicity for at least a month without refrigeration with no statistically significant differences in the antibody binding titers between fresh and the 30-day-old MNPs.

Experimental Design.

Aim 1.1: Manufacturing and characterization of PPZ MNPs with HNV glycoprotein antigens. We have tested GLP-like HeV-sG antigen (above), manufactured by Catalent Pharma Solutions, and it is currently available. The remaining 3 immunogens (NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb}$) will be prepared by Genovac, Inc., and **Core C** will prepare MNPs with each of NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb}$, HeV-sG+NiV-sF$_{stb}$ and HeV-sG, all adjuvanted with PCEP. Each fabricated batch of PPZ MNPs will be tested *in vitro* for geometric integrity, mechanical integrity, vaccine loading accuracy and reproducibility, biological integrity, endotoxin content, vaccine stability, and *in vivo* skin delivery performance before the animal immunization studies. The specific quantitative release criteria are as follows: 1) geometric integrity and accuracy – >95% high-quality microneedles across a PPZ MNP vaccine and <10% deviation from the target geometric values; 2) structural integrity – factor of safety (FOS) > 2 (FOS is equal to the failure forces/penetration forces); 3) vaccine loading accuracy and reproducibility – 10% deviation from the mean of theoretical amounts and <10% standard deviation of the mean value; 4) biological integrity – no significant aggregation of adjuvant-antigen complexes and no significant loss of antigenicity ($p>0.05$); 5) endotoxin content – < 1 endotoxin unit per PPZ MNP vaccine; 6) thermostability – biological integrity at elevated temperatures; 7) skin delivery performance – <10% of remaining materials in terms volume and <15% of remaining materials in terms of vaccine after 20 min murine skin application *in vivo* and 20 min the RP-specific animal-skin application *ex vivo* (See **Core C** application for more details). Based on the preliminary data and experience with fabricating HeV-sG MNP, we expect the technology to be plug and play applicable with the new HNV immunogens and with the combination of two different HNV immunogens.

Aim 1.2: Immunogenicity assessment HeV/NiV antigen PPZ MNPs in mice. To evaluate the immunogenicity of PCEP MNP platform with NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb,}$ HeV-sG, and HeV-sG+NiV-sF$_{stb}$, murine immunization studies will be conducted (**Core C)**. The immunization strategy will be performed as single-dose (D0) and prime(D0)-boost(D21) with female C57BL/6 mice (n = 5 mice per group). A schematic of the immunization and bleeding schedule is shown in **Figure 3**. Naïve or unimmunized mice will serve as negative controls and mice immunized with the intramuscular injection of Alum-complexed antigens will serve as positive controls. Serum levels of antigen-specific antibodies (IgM, total IgG, IgG1, IgG2c, and IgA) will be assayed by ELISA. The sera will be tested for neutralization activity using the respective reporter rCedV chimeras – rCedV-HeV-GFP and rCedV-NiV-B-GFP in the FRNT assay[44].

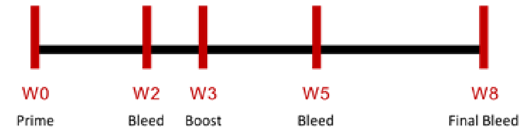

Figure 3. Immunization - bleeding schedule for mouse immunogenicity study.

Cellular immune responses will also be evaluated as described in the **Core C** Research Strategy. Briefly, mice will be sacrificed five days after the booster dose. Mouse blood PBMCs and cells from lymph nodes and spleen will be stimulated with a pool of antigenic peptides derived from the respective immunogen sequence(s). Antigen-specific polyfunctional cellular responses (IFN-γ, TNF-α, IL-2, IL-4, IL-17: CD4+ and CD8+ T-cell) will be determined by using multi-color flow cytometry and intracellular cytokine staining[65,66]. Studying the cellular responses for HNV immunogens has recently gained more interest and preliminary mouse studies have just begun using the HeV-sG vaccine subunit – antigenic peptides have been identified.

Aim 1.3: Evaluation of the immunogenicity and protection efficacy of PPZ MNP HNV vaccines in ferrets. The immunogenicity and efficacy of the lead PPZ MNP HNV vaccine candidates defined in Aim 1.2 will be tested in ferret challenge studies in Year 2 of the project (**Core E)**. Ferrets (n = 6 ferrets per group) will be immunized with the lead PPZ MNP HNV vaccine candidates via either single-dose (D0) or prime(D0)-boost(D21) immunization regimen. Unimmunized ferrets will serve as negative controls. (*Group 1*: Lead PPZ MNP HNV vaccine candidate 1 with the prime-boost regimen**.** *Group 2*: Lead PPZ MNP HNV vaccine candidate 2 with the prime-boost regimen. *Group 3*: Lead PPZ MNP HNV vaccine candidate 1 with the single-dose regimen. *Group 4*: Lead PPZ MNP HNV vaccine candidate 2 with the single-dose regimen. *Group 5*: Naïve/Unimmunized controls). The five groups will be challenged with a lethal dose (5000 TCID$_{50}$) of either NiV-B or HeV. Immunization, challenge and blood and swab sampling schedules are diagrammed in **Figure 4**. Vaccine-induced humoral responses in ferrets prior to virus challenge will be evaluated by **Core E** and **RP2**. All protected animals and survived controls will be euthanized on day 21 post-infection challenge (end of study) and lung and brain tissue along with swabs (oral and rectal) and blood samples will be collected. These will be tested for the presence of viral RNA by TaqMan PCR performed by using the primer sets and probes[35]. Virus isolation will only be attempted from specimens that were PCR positive for NiV-B or HeV genomes. Virus titration will be performed by plaque assay on Vero cells. The limit for detection will be 25 pfu/ml. The experimental details of the challenge studies in ferrets are described in **Core E**. End of study sera neutralization titers will also be measured by FRNT.

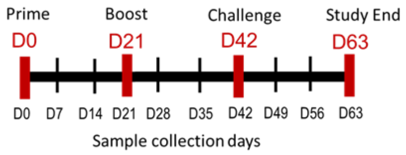

Figure 4. Expected schedule to immunize ferrets and AGMs in the planned efficacy studies. Blood and swabs, oral and rectal, samples will be taken weekly, on days 0, 7, 14, 21, 28, 35, 42, 49, 56 and 63. Single dose groups do not receive boost immunization on D21.

Antigen-specific stimulation of cytokine production by ferret PBMCs will be assayed. The custom-synthesized antigen-specific Peptivators obtained from **Core C** will be compatible with these studies, but we acknowledge that there is a lack of ferret-specific reagents for comprehensive evaluation of cytokine production of peptivator-stimulated PBMCs. Unlike comprehensive studies in mice and AGMs, these studies will quantify the production of cytokines, for which ELISA kits are commercially available, such as ferret IL-17A, IFN-γ, TNF-α, and IL-2, 48 hr after stimulation (See, e.g.,[67]).

Aim 1.4: Immunogenicity and protection efficacy of the lead PPZ MNP HNV vaccine in AGMs. This challenge study will be in year 3 (**Core E**). The immunogen(s) and MNP vaccine type that provides the best cross-protection in the ferret studies will be tested in AGM NiV-B or HeV challenge studies. Fresh MNPs will be fabricated for this study. The study will be conducted by **Core E** and will entail four groups of AGMs (n = 3 AGMs per group). Immunizations with the lead PPZ MNP HNV vaccine candidate will be either as a single-dose (D0) or prime(D0)-boost(D21) regimen. Groups 1 and 2 will be immunized as a prime-boost strategy while groups 3 and 4 will be immunized with a single dose. Naïve unimmunized AGMs will serve as negative controls. The immunization, challenge and blood and swab sampling schedules will follow that as outlined in **Figure 4**. Groups 1 and 3 will be challenged with a lethal dose of NiV-B, while groups 2 and 4 will be challenged with a lethal dose of HeV (lethal dose = $1x10^5$ TCID$_{50}$). Sera from blood samples taken before the challenge will be tested by **RP2** to measure the serum neutralization titers using the same procedure as for mice and ferret sera. Antigen-specific total IgG levels will be determined by commercially available ELISA. Virus-specific neutralization activity against each of HeV and NiV-B will be tested by FRNT assay in the same way as proposed for mice and ferret sera samples. The AGM sera samples will also be tested for neutralization activity against authentic viruses (**Core E**) by using the BSL-4 PRNT assay. Antigen-specific stimulation of key cytokine production by AGM PBMCs, which will be obtained prior to live virus challenge studies, and will also be assessed as described in Aim 1.2.

Aim 1.5: Identifying the correlates of immunization with the lead PPZ MNP HNV vaccine across multiple species. Here we propose to determine the correlates of immunization with the lead PPZ MNP HNV vaccine candidate across multiple species – mice, ferrets, and AGMs. This aim will be inherently integrated with the Aims 1.2-1.4. During these experiments, 3hr post immunization, skin biopsies and serum samples will be obtained from mice, ferrets and AGMs. Prior to challenge studies in AGMs, serum and skin samples from the three different species (mice, ferrets, and AGMs) immunized with the lead PPZ MNP vaccine candidate will be assayed to quantify their cytokine levels (IL-6, TNF-α, IL-17A, IL-10, IL-1β, IL-6, IL-4, IL-5, TNF-α, IFN-α, IFN-β, IFN-γ, and IL-12p70). We note a limitation that while the multiplex assays are commercially available for mice and AGMs, we will have to use the cytokine-specific ELISAs for ferrets to determine only those cytokine levels for which ELISA kits are available, such as ferret IL-17A, IFN-γ, and TNF-α. We expect to identify within the obtained results correlates of immunization across the three species for the lead PPZ MNP vaccine candidate. We also expect that these correlates of immunization might be predictive for the vaccine protective efficacy.

Aim 1.6: Evaluate stability of the lead PPZ MNP HNV vaccine candidate. Here, we will test the thermostability of the lead PPZ MNP HNV vaccine candidates based on retention of their immunogenicity upon storage at room temperature and at 40°C for an extended period of time (1-, 3-, 6-, and 12-month storage). Mice (n = 5 mice per group) will be immunized with fresh and stored PPZ MNP HNV vaccines in a single-dose regimen and blood samples will be collected 2 weeks after immunization. To test the stability of PPZ MNP HNV vaccine candidates, serum levels of total IgG antibodies will be determined by **Core C** and the virus-specific neutralization capacity of these antibodies will be evaluated by the FRNT assay (**RP2**). Stability will be indicated by no statistically significant differences between binding antibody levels and neutralization titers induced by fresh PPZ MNP HNV vaccines compared to those elicited by stored PPZ MNP HNV vaccines. Additional stability testing will be initiated with the freshly manufactured MNP for the AGM challenge study.

Expected results, potential pitfalls and alternatives. Prior data on HNV vaccines support our expectations that we will be able to assess the potency and longevity of vaccine induced responses of lead PPZ MNP HNV vaccine candidates from the proposed studies. The HeV-sG immunogen has been tested as a HNV vaccine in multiple (2-dose prime-boost) prior studies and that protective pre-challenge ID$_{50}$ neutralizing titers against NiV-

M can be as low as of 1:32 in the feline model[35,38]; that more than 1 year post-vaccination and pre-challenge neutralizing titers as low as 1:16 to 1:128 in the ferret model are protective against NiV-M[40]; as an equine vaccine, horses with pre-challenge HeV neutralizing titers ranging from 1:16 to 1:32 at 6 months post-vaccination are completely protected[36]; and in AGMs pre-challenge ID_{50} neutralizing titers ranging from 1:28 to 1:379 against NiV-M are completely protective[34]; and most recently, a HeV-sG/Alum formulation protects against NiV-B challenge in AGMs with pre-challenge ID_{50} titers ranging from only 1:10 to 1:160[41]. Almost without exception, complete protection from challenge in these studies also shows no gross or histologic evidence of infection in any of the vaccinated subjects at study completions, with all tissues examined negative for viral antigen, with no viral genome detected. We expect to obtain protection in AGMs with the lead PPZ MNP HNV vaccine candidate. From the stability study, we will determine the shelf-life of the lead PPZ MNP HNV vaccine candidate. We are confident that if the preliminary mouse immunogenicity studies reveal neutralizing antibody responses are robust, this will translate to protection in the planned challenge studies in ferrets. Indeed, preliminary data has shown robust neutralizing ID_{50} titers from the mouse immunizations. The non-adjuvanted HeV-sG MNP induced an ID_{50} titer of 1:272 and the adjuvanted form HeV-sG+PCEP MNP induced an ID_{50} titer of 1:11,445 against the HeV chimera; and an ID_{50} titer of 1:331 against the NiV chimera. There is a minimal risk of not finding any protecting immunogen (MNP vaccine type or immunogen combination). The PABVAX Center team is sufficiently experienced to handle and resolve any possible unforeseen issues and pitfalls.

Aim 2: Rescue Langya virus and construct LayV and AngV glycoprotein bearing reporter virus tools.

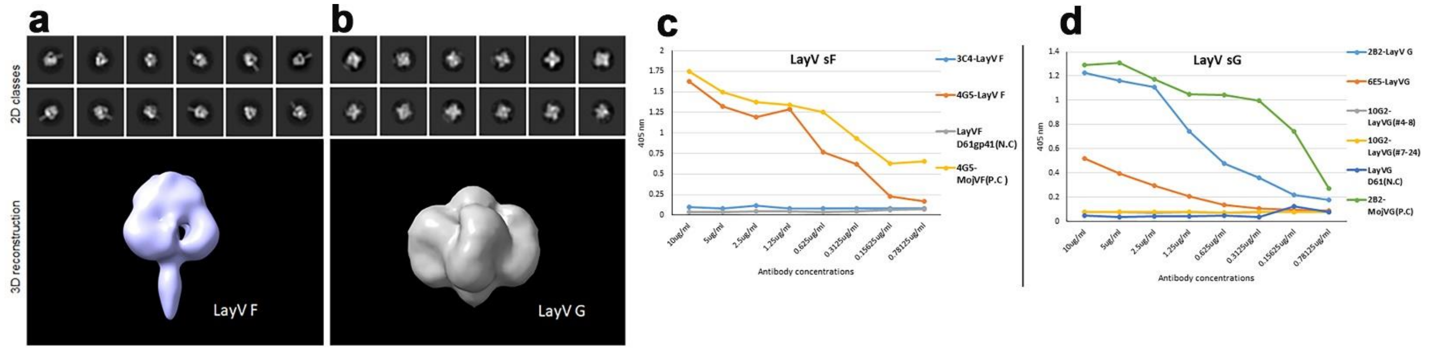

Figure 5. Negative stain EM analysis of LayV sF_{stb} and sG_{tet}. 2D and 3D classifications of LayV F trimers (**a**) and LayV G tetramers (**b**). ELISA cross-reactivity MojV F mAb (**c**, yellow) with LayV-sF and MojV G mAb (**d**, green) with LayV-sG.

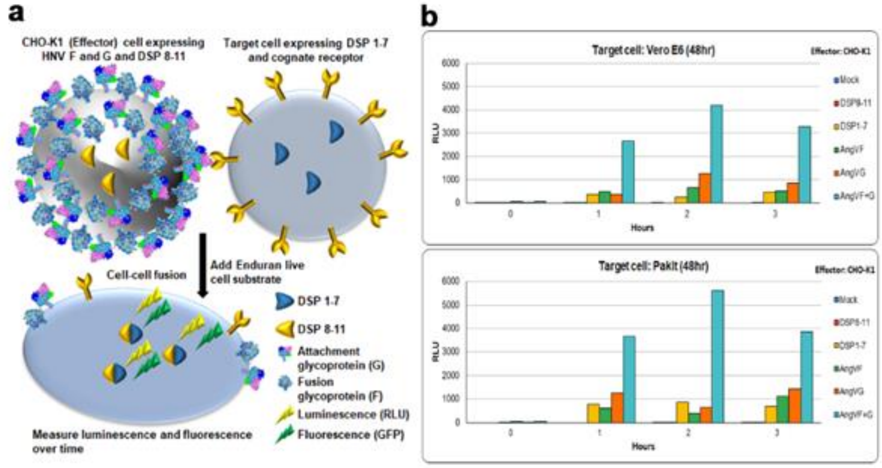

Figure 6. AngV F and G cell-cell fusion using a dual split luciferase. A schematic representation of the dual split-luc cell-cell fusion assay (**a**). Split-luc cell-cell fusion assay with AngV F and G plasmid constructs (**b**).

Rationale and Preliminary Data: Negative stain electron microscopy (EM) was performed on LayV F and G glycoproteins. The 2D and 3D classifications of LayV F (**Figure 5a**) and G (**Figure 5b**) revealed distinct trimer and tetramer assembly, respectively. In addition, using LayV-sF and LayV-sG, our previously generated mAbs to MojV F and G tested by ELISAs demonstrated that there was a dose dependent increase in LayV-sF (**Figure 5c**) and LayV-sG (**Figure 5d**) binding. This data forms the premise for rescuing a rCedV bearing LayV F and G glycoproteins (the sequences from LayV are likely correct). We will construct a full-length recombinant LayV sequence that encodes GFP. The LayV F and G coding sequences are the LayV isolate SDQD_H1801 (GenBank: OM101125.1); LayV F and LayV G; UUV47205.1 and UUV47206.1, respectively. The replication competent rCedV will be used. We will design, construct and rescue a new rCedV chimera that encodes the envelope glycoproteins (F and G glycoproteins) of LayV, i.e., a rCedV-LayV reporter virus encoding GFP. We will characterize it using cell-based infection tropism and growth kinetic assays. We have also utilized an established quantitative fusion assay based on a dual-split-luciferase reporter assay[42,43,68,69] to determine functionality of AngV envelope glycoproteins (F and G glycoproteins). Content mixing between F/G bearing effector cells and a permissive target cell restores luciferase and a signal can be measured[43] (**Figure 6a**). In addition, we have already constructed AngV sG$_{tet}$ and sF proteins and their structural solutions (both pre-fusion and post-fusion sF and the tetrameric structure of sG$_{tet}$) have been made by the PL of **RP5**, and cell-fusion is observed in Vero E6 cells and the bat kidney cell line, PaKiT, indicating that full-length AngV F/G are functional (**Figure 6b**). Taken together, these data suggest that the rescue of reporter viruses with LayV and AngV F/G is feasible. We will characterize viruses in cell-based infection tropism and growth kinetics assays. Alternatively, we will also construct a set of reporter gene-encoding VSV-based (LayV and AngV F/G bearing) reporter viruses as previously done with Australian bat lyssavirus (ABLV) G glycoproteins[70,71] and authentic ABLV[72,73].

Experimental Design.

Aim 2.1: Design and construct a recombinant Langya virus reporter virus. Figure 7 diagrams each of the proposed virus constructs that will be generated. The genome design, length and position of the green fluorescent protein gene are shown, and the experimental plans are described below. LayV helper plasmids for the N, P, and L genes will be synthesized. To construct the rLayV-GFP antigenome plasmid, large gene fragments of LayV will be synthesized and sequentially cloned into pOLTV5$_{opt}$ (**Figure 7a**). Unique restriction sites will be chosen to facilitate ligation of the LayV DNA fragments and to ensure adherence to the genomic "rule of six". All cloning will be performed with *E.coli* Stbl2 cells. The fully sequenced plasmids will be transferred to **Core E**. Virus rescue and subsequent virus characterization by cell-based assays will be conducted in collaboration with **Core E**. In addition, rLayV will be examined by **Core E** in animal model development studies such including the hamster and/or ferret, both successful for the prototype HNVs.

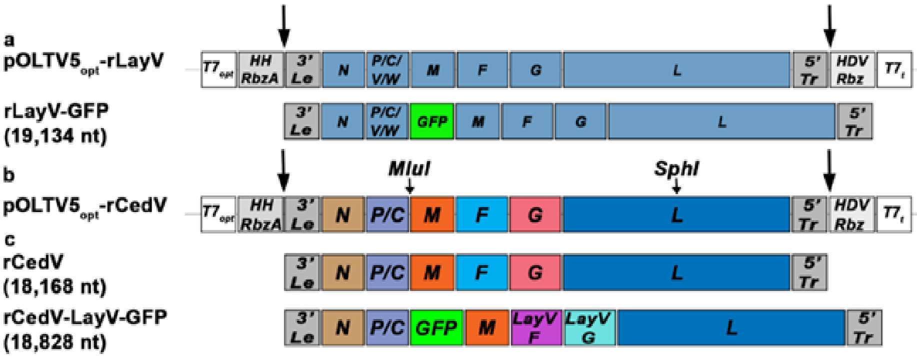

Figure 7. Schematic representation of recombinant reporter viruses. The pOLTV5$_{opt}$-rLayV plasmid (**a** top) and rLayV-GFP genome (**a** bottom). The arrows indicate regions of self-cleavage. The pOLTV5$_{opt}$-rCedV plasmid (**b**). The rLayV-GFP genome (**c** bottom). The long arrows indicate regions of self-cleavage. Shown are the unique restriction sites MluI and SphI that will be used to construct rCedV-LayV-GFP.

Aim 2.2: Construct, rescue and characterize a recombinant Cedar reporter virus encoding Langya virus envelope glycoproteins.

Generation of rCedV encoding LayV envelope glycoproteins. rCedV-LayV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the LayV F and G coding sequences. The CedV non-coding intergenic regions are retained to adhere to the genomic "rule of six". Unique restriction sites, will facilitate the insertion of the LayV F and G gene cassette into the genome clone (pOLTV5$_{opt}$-rCedV) (**Figure 7b**) generating rCedV-LayV-GFP (**Figure 7c**). All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-LayV-GFP antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (HNV-CPE). BSR-T7/5 cells and supernatants from successful rescue wells are collected and passaged onto naïve Vero 76 cells (T-75 flasks) to prepare a virus stock. When maximal syncytia and GFP is observed (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C[42-44,74].

***In vitro* characterization of rCedV-LayV-GFP**. The growth kinetics of rCedV-LayV-GFP compared to rCedV or rCedV-NiV/HeV chimeras will be assessed by infecting Vero cells with MOIs of 0.01, 0.1 and 1 and progeny virus recovered in 24hr intervals over a 72hr period and titered. In parallel experiments, infected cells will also be imaged for fluorescence and syncytia (HNV-CPE). **Figure 8** illustrates the syncytia (indicated by the yellow arrows) formed in Vero E6 cells infected with either rCedV-NiV-B-GFP or rCedV-HeV-GFP chimeras. The rCedV-LayV-GFP neutralization assays will be conducted by FRNT[44]. We have also already generated several murine mAbs to LayV F and G (3C4-LY and 4G5-LY to LayV F; and 2B2-LY and 6E5-LY to LayV F) and these will be used in neutralization assays. In addition, we will develop rabbit sera to LayV N, P and L proteins.

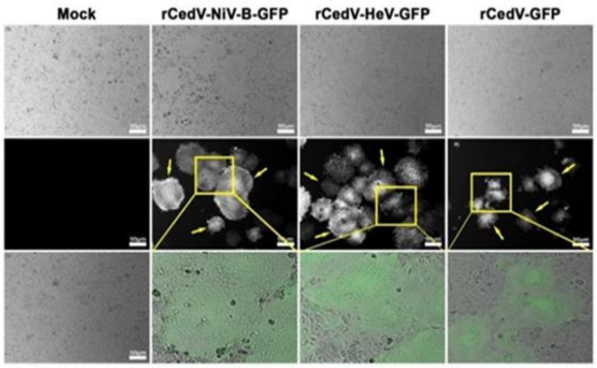

Figure 8. Syncytia induced by rCedV expressing NiV-B or HeV envelope glycoproteins. Vero E6 cells were uninfected (Mock) or infected with either rCedV-NiV-B-GFP, rCedV-HeV-GFP, or rCedV-GFP. All images are 24hrs post-infection. Zoomed-in fluorescence images (3rd row) are the yellow boxes. Arrows indicate giant multinucleated cells (syncytia). Representative images from three independent experiments are shown. Scale bar, 50 µm.

Aim 2.3: Construct, rescue and characterize recombinant reporter viruses encoding Angavokely virus envelope glycoproteins.

Generation of rCedV encoding AngV envelope glycoproteins. Figure 9 diagrams each of the proposed virus constructs that will be prepared. The genome designs, lengths and position of the *GFP* and *Luc* reporter genes are also shown. rCedV-AngV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the AngV F and G coding sequences. The AngV F and G coding sequences will be based on the GenBank: ON613535.1 sequence. The GenBank accession numbers for AngV F and AngV G are UVG43988.1 and UVG43989.1, respectively.

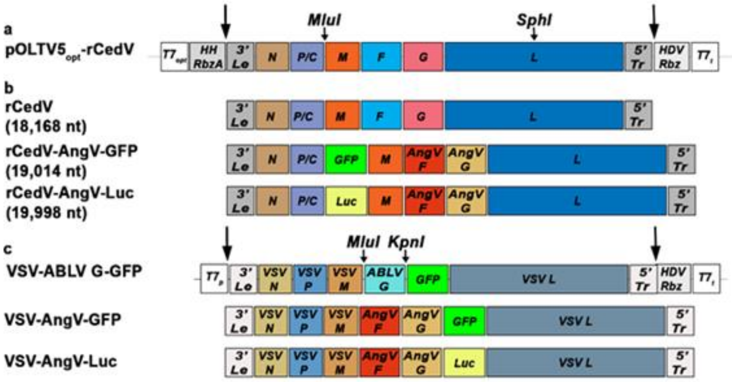

Figure 9. Schematic representation of the AngV chimeric reporter viruses. The pOLTV5$_{opt}$-rCedV plasmid (**a**). Shown are the unique restriction sites MluI and SphI that will be used to construct rCedV-AngV-GFP and rCedV-AngV-Luc. The rCedV-AngV-GFP and rCedV-AngV-Luc genome (**b**). Shown are the unique restriction sites MluI and KpnI that will be used to construct VSV-AngV-GFP and VSV-AngV-Luc (**c**). The long arrows indicate regions of self-cleavage.

CedV non-coding intergenic regions are retained to adhere to the genomic "rule of six". Unique restriction sites, will facilitate the insertion of the AngV F and G gene cassette into the rCedV antigenome plasmid (**Figure 9a**) generating rCedV-AngV-GFP (**Figure 9b**). The rCedV-AngV-Luc clone will be produced by swapping the reporter gene coding sequences. All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-AngV-GFP or pOLTV5$_{opt}$-rCedV-AngV-Luc antigenome plasmid. After 4 days cultures are examined for GFP expression and syncytia (HNV-CPE). BSR-T7/5 cells and supernatants from successful rescue are collected and passaged in Vero 76 cells (T-75 flasks) to prepare a virus stock. When maximal syncytia and GFP is observed (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C[42-44,74].

Generation of a VSV encoding AngV envelope glycoproteins. We will also construct reporter gene encoding versions of a replication competent VSV encoding the AngV F and G glycoproteins (GFP and Luc) (**Figure 9c)**. A large gene cassette comprising VSV untranslated intergenic regions flanking the AngV F and G coding sequences will be synthesized. Unique restriction enzyme sites, will facilitate the insertion of the AngV F and G gene cassette into the VSV backbone plasmid to generate VSV-AngV-GFP (**Figure 9c**). The VSV-AngV-Luc clone will be produced by swapping the reporter gene coding sequences. Cloning procedures are performed in *E. coli* Stbl2 cells and all plasmid clones verified by sequencing. Rescue of VSV-AngV-GFP and VSV-AngV-Luc, will be performed in BSR-T7/5 cells, in 12-well plates, transfected with helper plasmids, VSV-N, VSV-P, and VSV-L and the VSV-AngV-GFP or VSV-AngV-Luc antigenome plasmids. After 48hrs the cells and supernatants are collected and subjected to freeze-thawing and clarified by centrifugation. Amplification of rescued virus uses HEK293T cells (6-well plates) by inoculation with the supernatant from step 1. Typically, when GFP fluorescence and/or cytopathic effects (CPE) is observed, the cells and supernatants are harvested as above and the virus stocks stored at -80°C. Larger viral stocks are prepared in T-150 flasks in HEK293T cells, and harvested virus supernatants are purified by buffered sucrose cushion centrifugation and virus pellets resuspended in 10% sucrose/TNE buffer, and small volume single use aliquots stored at -80°C. All virus stocks are deep sequenced. Virus stocks (GFP) are titered (infectious units/ml (IU/ml)) by serial dilution on HEK293T cells in 96-well black walled plates. At 24hrs post-infection plates are fixed with 4% formaldehyde, washed 3x with diH_20 and imaged (fluorescence) with a CTL S6 analyzer. Luciferase encoding VSV stocks are titered by plaque assay[75].

Characterization of the recombinant reporter viruses in cell-based infection assays. Replication kinetics of rCedV-based and VSV-based AngV F/G viruses are assayed by Vero cell culture infection using MOIs of 0.01, 0.1 and 1, and progeny virus recovered in 24hr intervals and titered. rCedV-AngV-GFP virus replication can be compared to rCedV or rCedV NiV/HeV chimeras. Similarly, VSV-AngV F/G virus replication can be compared to expected virus production of wildtype VSV or VSV-ABLV G[71]. The rCedV-AngV-GFP and VSV-AngV-GFP assays will be conducted by FRNTs[44] and rCedV-AngV-Luc and VSV-AngV-Luc in luciferase assays[42].

Expected results, potential pitfalls and alternatives. We expect that rCedV-LayV-GFP and rCedV-AngV reporter viruses can be rescued. In addition, we expect that these chimeric viruses will induce syncytia and replicate to high titers. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9. In the event that the rescue of rCedV chimeric viruses are not viable, multiple strategies may be examined. 1) test different ratios of helper plasmids and antigenome plasmid; 2) perform rescue in different cell lines; 3) construct alternate versions of the LayV and/or AngV F and G genes within the antigenome plasmids, such as, fuse the LayV and/or AngV F and G ectodomains with the transmembrane and/or cytoplasmic tail domains of the corresponding CedV F and G elements which may facilitate virus particle formation and membrane fusion activity.

<u>Aim 3:</u> Evaluate HNV-specific antibodies and nanobodies developed by the Center's RPs and Core D.

Rationale and Preliminary Data. The rCedV chimeric system we established replaces the need for authentic NiV-B and HeV in neutralization assays. Neutralization values of well-characterized NiV/HeV cross-reactive neutralizing mAbs highly correlated between rCedV-NiV-B-GFP and rCedV-HeV-GFP and authentic NiV-B and HeV at BSL-4 when tested by conventional PRNT[44]. The Pearson correlation analysis between the rCedV chimeras BSL-2 PRNT and the NiV-B or HeV BSL-4 PRNT is shown in **Figure 10a**. We further developed the rCedV-NiV-B-GFP and rCedV-HeV-GFP neutralization assay into a high-throughput and quantitative assay that is based on the reduction of GFP foci, a FRNT[44]. The Pearson correlation analysis between the chimeras PRNT and FRNT is shown in **Figure 10b**. Taken together, these data demonstrate that rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeric viruses are an ideal set of suitable surrogate viruses for conducting a rapid FRNT-based assay for assessing NiV and HeV antibody neutralization.

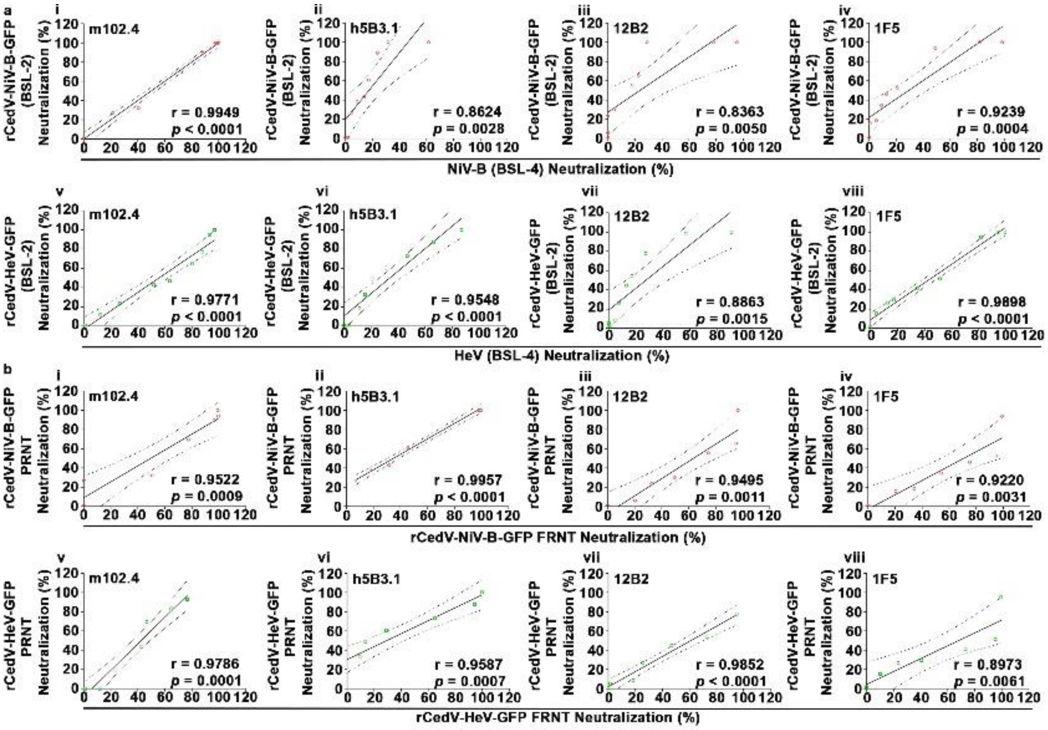

Figure 10. Pearson correlation analysis of rCedV chimeras. Pearson correlation analysis of PRNT neutralization (%) values of rCedV-NiV-B-GFP versus NiV-B (**a**, **i-iv**) and rCedV-HeV-GFP versus HeV (**a**, **v-viii**). Pearson correlation analysis from PRNTs (y-axes) and FRNTs (x-axes) of rCedV-NiV-B-GFP (**b**, **i-iv**) and rCedV-HeV-GFP (**b**, **v-viii**). Neutralization with mAbs m102.4, h5B3.1, 12B2 or 1F5 are shown. The Pearson correlation coefficient 'r,' p-value (two-tailed), linear regression line (solid lines), and 95% confidence intervals (dashed lines).

Experimental Design.

Here, using the new tools (rCedV-LayV-GFP, rCedV-AngV-GFP, rCedV-AngV-Luc, VSV-AngV-GFP and VSV-AngV-Luc) we will assess neutralizing activity, of HNV specific mAbs and/or sera from HNV immunized mice that will be generated by **Core D**. The FRNT is high throughput and performed in 96-well plates to establish a 7-point dose response. Serially diluted immune sera or mAbs are mixed with either rCedV-NiV-B-GFP or rCedV-HeV-GFP for 2hrs. The virus-mAb or virus-sera mixtures are then added in triplicate to confluent pre-seeded Vero 76 cells in black-walled clear bottom 96-well plates and incubated for an additional 24hrs. Plates are then fixed and imaged and fluorescent foci counted using the CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) will be determined as the mAb concentration or serum dilution at which there was a 50% reduction in fluorescent foci versus untreated control wells. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9.

Expected results, potential pitfalls and alternatives. We do not anticipate any unexpected limitations in assessing the neutralization potential of antibodies and sera generated from other research projects and/or cores as we have successfully demonstrated that the rCedV-GFP chimeric FRNT platform can serve as a surrogate BSL-2 neutralization assay that is high throughput with a fast turnaround time.

Aim 4: Validate PPZ-MNP platform with another paramyxovirus-specific antigen in Phase 2.

At completion of Phase I we will have i) a procedure to fabricate PPZ adjuvanted MNP using sG, sF or a combination of both viral glycoproteins; ii) generated rLayV with an associated animal model in collaboration with **Core E** with reporter virus construct (rCedV-LayV-GFP); and iii) generated reporter viruses AngV (rCedV-AngV-GFP, rCedV-AngV-Luc, VSV-AngV-GFP and VSV-AngV-Luc). Here, in Phase II we propose to test the hypothesis that the PPZ-MNP vaccine platform technology can be adapted and transferred as a 'plug and play' strategy for other paramyxoviruses, namely the divergent HNVs LayV and AngV. The major goal rests on the rescue of LayV and establishing an infection/disease model of this most recently discovered pathogenic, zoonotic, HNV. Nevertheless, if rescue of rLayV with an associated animal model is not achieved, we will still be able to test the MNP approach as proof-of-concept to the extent of generating robust immune responses in animals and testing neutralizing antibody responses using both LayV and AngV reporter virus systems.

PPZ-MNP manufacture. The fabrication of the MNPs by **Core C** will be prepared for both the F and G viral glycoproteins: LayV-sG, LayV-sF, AngV-sG and AngV-sF depending on the data and outcomes, and vaccine down-selection in Phase I we may also include a combination of sG and sF. Vaccine antigens will have been prepared by **Core D**. It may be important to evaluate both the attachment and fusion glycoprotein immunogens for LayV and AngV in Phase II. Although the preponderance of data to date for the pathogenic prototype HNVs (NiV/HeV) indicates that the attachment glycoprotein (G) alone can serve as an effective vaccine immunogen, this is presently unknown for these two divergent HNVs, so test both sF and sG for these HNVs is needed.

Immunogenicity. As in Aim 1, groups of 5 mice will be used for each immunogen(s) and a control of nonimmunized subjects. Sera will be drawn as scheduled in **Figure 3**. ELISA titers of sera to vaccine immunogens will be evaluated by **Core C** and sera will be evaluated for virus neutralization with newly developed reporter viruses. Cellular immune responses will be assessed as described in Aim 1.

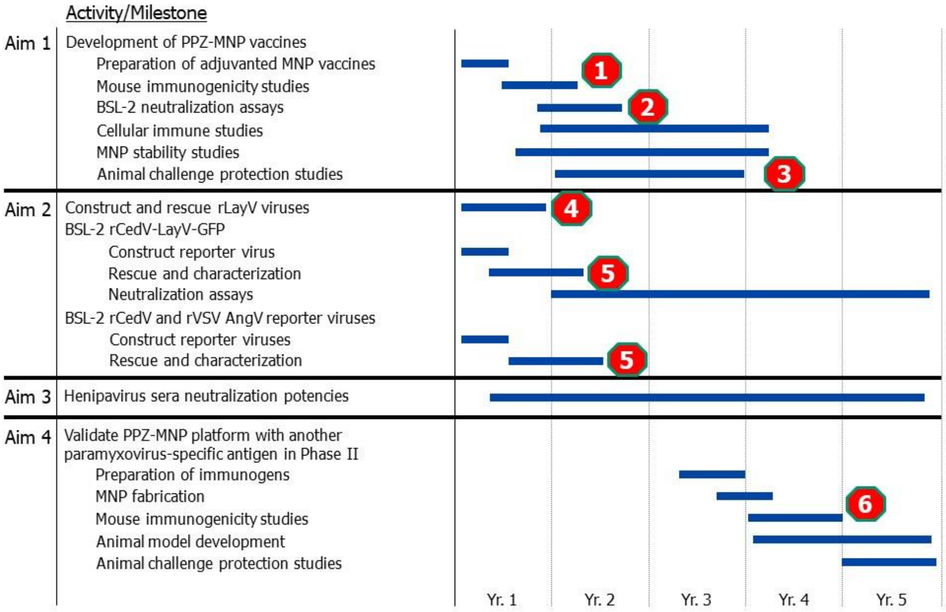
Animal challenge studies. The experimental design for these studies will be adjusted once the animal model has been developed. The basic design will follow those for ferrets and AGMs described in Aim 1. The immunogen will be chosen based on the results from the mouse sera neutralization tests.

Expected results, potential pitfalls and alternatives. We expect that LayV / AngV glycoproteins MNPs fabrication will be possible. Mouse immunization studies with MNPs are likely to be uncomplicated and we will be able to assess immune responses. These data will determine whether the sG or sF is the immunogen of choice for best virus neutralization antibody induction. If rescue of rLayV and establishing an animal model are not met, the ability to measure inhibition of virus in cell-based assays, using either the new reporter viruses or a cell-cell fusion surrogate assays will be done. The mouse immunogenicity studies, together with the virus neutralization assays will provide a foundation for potential anti-LayV and anti-AngV MNP vaccine approaches.

Project Milestones, Timelines, and Go/No-go decisions. The **RP2** Aims, milestones, and timeline with activities having periodic assessments by Center leaders, SAB, and NIAID staff as shown in the Gannt Chart.

Aim 1: Develop PPZ-MNP-based sG$_{tet}$ and sF$_{stb}$ prototype HNV subunit vaccines

Milestone 1: Adjuvanted MNP vaccines are successfully prepared: In year 1, the MNP vaccine fabrication by **Core C** will commence and formulation of recombinant antigens with PCEP adjuvant in the context of MNPs will be assessed. We are confident that this stage of the research plan will be achievable because we have already had success in MNP fabrication with the HeV-sG formulated with two different PPZ adjuvants (PCEP and PCPP) and the preliminary mouse immunization and cellular immune responses and induction of NiV/HeV cross-neutralizing antibody titers was excellent, with ID$_{50}$ titers significantly greater than previously measured pre-challenge ID$_{50}$ titers that provided complete protection across several prior studies in cats, ferrets, horses, and AGMs (preliminary data). We expect that the formulation of the remaining 3 prototype HNV immunogens (NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb}$ (and the combination test: HeV-sG+NiV-sFstb)) adjuvanted with PCEP and applied to the MNPs will be fully achievable. Analysis will also include antigen stability studies by re-release of sG$_{tet}$ and sF$_{stb}$ immunogens and recognition by select conformation dependent mAbs. A go/no-go decision may be made pending the results of MNP fabrication and antigen analysis of each MNP vaccine type, poor fabrication or loss of antigen integrity will trigger termination of those individual vaccines prior to immunogenicity studies.



Gannt chart outlining project milestones (left). Solid lines represent periods of activity to achieve milestones. ***Go/No-go*** decision points are indicated by red octagons as follows:

(1) Successful fabrication of vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity is a ***No-go*** for the respective individual vaccine MNP.

(2) An SNT <10 is a ***No-go*** for the tested immunogen. The highest SNT >10 is a ***Go*** for the respective immunogen.

(3) Successful protection is a ***Go*** to the project Phase II. No protection is a ***No-go*** for the MNP vaccine platform.

(4) Successful rescue of rLayV is a ***Go*** to the development animal models in Aim 4. Otherwise is a ***No-go*** for the animal models development and the challenge protection studies in Aim 4.

(5) Successful rescue of a reporter virus is a ***Go*** for neutralization assays development. Inability to rescue a reporter virus is a ***No-go*** to that reporter virus neutralization assay development.

(6) Successful fabrication of vaccine MNPs is a ***Go***. Poor fabrication, loss of antigen integrity is a ***No-go*** for the respective individual vaccine MNP.

Milestone 2: High immunogenicity and best in class immunogen(s) identified: **Core C** will conduct immunogenicity studies in mice as detailed in the preliminary data and experimental plan and the Core research plan; multi-parameter humoral and cellular immune responses will be assessed (antigen specific antibody induction, virus-neutralization, and polyfunctional T-cell responses by in vitro stimulation). As sera are made available from the mice MNP vaccine cohorts, we will assess the NiV/HeV-neutralizing antibody activities of each of the MNP vaccine formulations of the prototype HNV immunogens (NiV-sG$_{tet}$, NiV-sF$_{stb}$, HeV-sF$_{stb}$, HeV-sG, and HeV-sG+NiV-sF$_{stb}$). The criteria to judge success and go/no-go decisions will be levels of cross-neutralizing antibody responses (neutralization of both HeV and NiV-B) induced by each vaccine type. We expect to be able to down-select to 'best-in-class' vaccine as a single antigen or perhaps the combination antigen MNP vaccine formulation at this stage prior to progressing to the first-round ferret challenge models.

Milestone 3: MNP vaccination protection in animal challenge studies: Here, the determination of whether MNP vaccination affords protection in animal model challenge experiments will be made. For the NiV and HeV prototypes the animal models (ferret and AGM) are extremely well-developed and the PABVAX Center leadership and staff have extensive experience in this area, and outcomes at this stage should be readily assessable. If we are successful in developing and validating the PPZ adjuvanted MNP recombinant protein vaccine approach for the HNV prototypes (NiV/HeV) and demonstrate protection in the planned homologous and heterologous HNV challenge studies, this will be expected to be a 'go' decision point in year 3, and the proposed Specific Aim 4 tasks (below) will continue in preparation for Phase II of the PABVAX Center. If in the unlikely event that the MNP vaccine approach fails (no-go) then further consultation with industry and regulatory expertise within **Core D** and partners and the **SAB** will be geared towards using the previously identified 'best-in-class' immunogens with alternative vaccine platforms (IM formulations; virus vectored such as a VSV technology held by the PABVAX Center PI and RP1 PI at UTMB; or mRNA, Moderna Inc., has provided the Center a letter of support).

Aim 2: Rescue Langya virus and construct LayV and AngV glycoprotein bearing reporter virus tools.

Milestone 1: Successful rescue of recombinant Langya virus. Since the genetic data on LayV is derived from an actual human virus isolate, it suggests that rescue of rLayV will be possible. **RP2** staff have extensive experience in HNV reverse genetics with rCedV (and VSV) with unique newly developed reagents. Virus rescue is in collaboration with **Core E**, followed by virus characterization in cell-based assays. **Core E** will then initiate small animal model development studies such as the hamster and/or ferret, both successful for the prototype HNVs. If rescue and animal modeling is successful, it will be very significant advancement for this pandemic preparedness initiative and objectives, and the virus, reagents, tools and models supplied to the ReVAMPP network. If rescue is not possible a no-go decision is obvious for animal model development. However, even if a LayV isolate remains unavailable by other means, we can still test the MNP approach with LayV and also our alternative divergent HNV prototype (AngV) by characterizing G and/or F vaccine-induced neutralizing antibodies using alternative reporter viruses (Milestone 2 below) or cell-based (cell-cell fusion assays; **Figure 6B**).

<u>*Milestone 2: Construction of rCedV and rVSV reporter viruses encoding LayV and AngV F/G glycoproteins:*</u> Here, we have reasonable confidence that one or both alternate reporter virus platforms will be possible. Successful rescue of these reporter viruses will enable the determination of immune sera neutralization titers and is a 'go' for the development of the neutralization assays. An unsuccessful rescue of either of the LayV or AngV reporters will be a no-go for those assay developments. If neither reporter virus is rescued we will proceed to cell-cell fusion assays development to study the immune sera neutralization titers. We have already successfully generated recombinant sF_{stb} and sG_{tet} glycoproteins from AngV and LayV based on available sequence data (AngV, **RP2** in collaboration with **Dr. Cara Brook,** The University of Chicago, and letter of support included in the PABVAX Overall component; and LayV, in collaboration with **RP5** leaders and **Genovac, Inc.**). In our prior experience, success in making soluble and secreted oligomeric forms of virus glycoproteins strongly indicates that genetic sequences are correct which should also translate into functional proteins. Rescued viruses will be characterized in various cell-based assays. These new virus tools will be used in collaboration with **RP4**, **RP5** and **Core D**, in assessing newly developed mAbs and nabs against LayV and AngV, and also vaccine-induced neutralizing antibody responses in PABVAX Center activities in Phase II.

Aim 3: Is also shown which is the collaborative support provided by **RP2** in assessing specific antibody development activities to HNVs by **RP4** and **RP5** is also included.

<u>***Aim 4: Validate PPZ-MNP platform with another paramyxovirus-specific antigen in Phase 2***</u>. At this stage one or both of the divergent HNV prototypes (LayV and/or AngV) would be selected and the milestones for progress would include MNP vaccine manufacture; mouse immunogenicity studies; and virus challenge protection. These milestones will be similar as described for Specific Aim 1. We have obtained preliminary structural characterizations of sF_{stb} and sG_{tet} glycoproteins from AngV and LayV (native-like oligomeric and stabilized glycoproteins) in collaboration with **RP5** leaders, and have also determined (preliminary data) that the LayV sF_{stb} and sG_{tet} glycoproteins are recognized by 3 previously generated mAbs to MojV F/G from our lab (**RP2**). As discussed above, the primary HNV target of **RP2** is LayV, and the alternate is AngV, but the go/no-go decisions on the virus target will depend on the progress and outcomes of the earlier studies. Also, as discussed above, even in the absence of rLayV rescue or its availability from another source and its characterization in animal models by **Core E**; or the possible isolation of AngV and its work-up *in vivo* and pathogenesis studies by Core E; we expect to still be able to assess and validate the recombinant subunit protein MNP vaccine approach with our already prepared immunogens and the other virus tools we plan on developing.

Industry Expertise and Regulatory Considerations

Consultation with industry and regulatory expertise within **Cores A and D** and the **SAB** will be critical and occur with regularity as the project progresses by quarterly virtual meetings, written quarterly reports and data analysis, and annual meetings with Center participants. Relative to the major goal of **RP2** (MNP vaccines): Stability, manufacturability testing, and early process development of the MNP-based vaccines will be researched in collaboration with **Core C** and **Core D** industry experts, and interface with the **SAB**. As vaccines are regulated by The Center for Drug Evaluation and Research (CDER) of the U.S. Food and Drug Administration (FDA), performance of all activities will be as per regulatory expectations. Consultation and input from **Core D** vaccine industrial partners (Emergent Biosolutions, Inc., and Moderna, Inc.; letters of support provided) will be integrated into the translational development efforts of the MNP-based HNV vaccine platform. The expectation in the out years of Phase I of the PABVAX period, leaders of Center will hold a pre-IND (type B) meeting with the FDA to discuss the Chemistry Manufacturing and Controls (CMC) section (topics such as cleavage or tag removal strategies if an issue for any recombinant protein vaccine candidate(s) for Drug Substance and strategy for manufacturing and releasing Drug Product), along with the all efficacy data from **RP1/RP2/Core E** and future IND-enabling toxicology studies to be supported by other NIAID mechanisms. Feedback from such meetings will be valuable for the translational development of any PPZ-MNP vaccines toward future "plug and play" pandemic readiness efforts, including the PABVAX Phase II plans, and the overall goal of the NIAID, ReVAMPP Centers.

If new neutralizing mAbs to the F glycoprotein of NiV/HeV (cross-reactive) or to LayV or AngV or nabs or bi-specific nabs that show antiviral activities to NiV/HeV, from the collaborations of **RP2, RP3, RP4** and **RP5** are found, we will seek industry and regulatory expertise in **Core D** and the **SAB** in areas such as; identification of correlates of protection, lead optimization, stability and manufacturability testing. Antibodies may be engineered (such as altered N-glycans, Fc mutations for effector functions and extended half-life, multimeric formats) by **Core D** and further evaluated to correlate mechanisms of action with maximal efficacy by **Core E** (authentic HNVs) and **RP3** (rCedV chimera model). This work will identify lead prototypes to transition to early process development. Further details on antibody development, milestones, and go/no-go decisions are discussed in the relevant RPs and **Cores D** and **E**.

here is RP2 Res strategy, in case it gets late
Moushimi and Tony are looking at this final version from me

Brian and I have qual exams this PM

Are we supposed to remove the hyperlinks in the References also?

CENTER OVERVIEW: *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center (PABVAX)

RESEARCH STRATEGY

Introduction. Emerging and periodically reemerging pathogenic enveloped RNA viruses are continuous pandemic threats. Among viral taxon associated with human zoonoses, members of the family ***Paramyxoviridae*** and order ***Bunyavirales*** stand out for their capacity to cause debilitating and life-threatening disease**.** Humans can become infected via excreta from animal reservoir hosts such as rodents or bats, through intermediate amplifying hosts such as small or domestic animals, or by arthropod vectors such as mosquitos and ticks[1-4]. Humans often represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur. During this process, RNA viral pathogens may mutate and adapt to more efficiently replicate and shed in the host, posing an epidemic threat[5, 6]. The viral order ***Bunyavirales*** is composed of several viral families containing high priority human pathogens[7]. Notably, the ***Arenaviridae*** and ***Nairoviridae*** families contain viruses that cause severe hemorrhagic fever diseases in humans globally with mortality rates up to 60%[8] and significant, long-term sequelae in survivors[9]. Many bunyaviruses are included on the World Health Organization's (WHO) List of Priority Pathogens[10, 11]. Six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHAPV, GTOV, JUNV, MACV) and one nairovirus, Crimean-Congo hemorrhagic fever virus (CCHFV), are also identified as NIAID Category A pathogens[12] due to their 1) high associated morbidity and mortality rates, 2) ease of dissemination and/or ability to transmit from person-to-person, 3) potential to cause public panic and social disruption, and 4) requirement for special actions in the context of public health preparedness. The ***Paramyxoviridae*** also includes members in the WHO Priority Pathogens, namely Nipah virus (NiV) and Hendra virus (HeV). These henipaviruses (HNVs) are the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease[13]. The genus now includes nine additional reported HNVs, but only HeV and NiV are associated with severe and often fatal henipaviral disease in humans and a number of animal species[14]. Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illness in humans[15].

These collective factors plus the absence of approved vaccines or therapeutics make bunyaviruses and paramyxoviruses a significant threat to global public health. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for developing vaccine and monoclonal antibody (mAb) countermeasures to prototype bunyavirus and paramyxovirus pathogens (**Table 1**). In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old World) Machupo (New World)	Lujo (Old World) Chapare (New World)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Table 1. PABVAX selected prototype and test case viral agents

Arenaviridae: The *Arenaviridae* is composed of five genera: *Mammarenavirus*, *Reptarenavirus*, *Innmovirus*, *Antennavirus*, and *Hartmanivirus*[16]. The genus *Mammarenavirus* contains a large number of rodent-borne viruses, some of which cause severe hemorrhagic fever, neurological damage, death, and permanent sequelae; hearing loss, vision impairment, and balance issues in survivors[17]. While these genera exhibit a global distribution, two geographically distinct serogroups exist that diverged[18]. Old World complex mammarenaviruses (OWAV) in the Eastern Hemisphere include LASV, lymphocytic choriomeningitis virus (LCMV), and the newly discovered LUJV; New World complex mammarenaviruses (NWAV) in the Western Hemisphere include JUNV, MACV, Sabia Virus (SABV), and CHAPV. There are no FDA approved vaccines or therapeutics for mammarenaviruses, though the attenuated JUNV "Candid-1" vaccine is approved for use in Argentina.

Disease severity and case fatality rates (CFR) vary across mammarenaviruses even within the same clades and species. Up to 500,000 cases of LASV infection occur per year with CFRs sometimes approaching 70% in hospitalized cases[19]. Before the introduction of the Candid-1 vaccine, it is believed that an upwards of 60,000 cases of Argentine Hemorrhagic Fever (AHF) from infection with JUNV occurred per year with CFRs ranging from 15-30%. Convalescent plasma from JUNV survivors is still the primary means to treat acute AHF in Argentina[20]. Over 1000 cases were reported for the initial outbreak of MACV with CFRs ranging from 5-30%; enhanced rodent abatement practices and potentially cross-protective immunity in populations that have taken the JUNV Candid-1 vaccine may have reduced recent outbreak frequency[21]. All mammarenaviruses share a common genomic organization consisting of two ambisense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix) and L protein (polymerase), and the glycoprotein precursor (GPC) and nucleoprotein (NP)[17]. Despite general

similarity of their genomic architecture, mammarenaviruses exhibit marked differences in their replication life cycles including attachment factors, entry mechanisms, and immune evasion; nonetheless, the dominant antigens driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Despite the abundant genetic diversity of LASV, high levels of cross reactivity have been seen with antigen-based diagnostics across seven known lineages, suggesting the generation of cross-protective immunogens and antibodies against mammarenaviruses is achievable[22]. Monoclonal antibodies derived from human LASV survivors were shown to protect nonhuman primates (NHP) against lethal challenge[23]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[24]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, indicating this domain could serve as an antigenic target. Investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccines to test this approach and have demonstrated protection against lethal LASV lineage IV Josiah challenge. Specifically, a stabilized prefusion trimeric GPe, an immunogen containing a highly conserved NP NTD epitope, or a combination of these two approaches conferred protection in a lethal outbred guinea pig model. Nevertheless, even with the considerable molecular diversity in LASV strains, conservation at key antigenic sites within the GP and NP suggest a pan-LASV vaccine may be possible[22, 25, 26]. **RP1** and **Core E** investigators have demonstrated that a recombinant vesicular stomatitis virus (rVSV)-based vaccine expressing the LASV-Josiah GPC is protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[27], and against heterologous challenge with Lineage II[28], III, V[29], and VI viruses (Cross and Geisbert, unpublished data).

In **Phase I of RP1**, the ability of an optimized LASV GPe/NP subunit vaccine delivered intramuscularly (IM) will be assessed in guinea pig and NHP models across multiple viral lineages. We will also assess a microneedle skin patch (MNP) formulation optimized in **Core C** to determine if a needle-free vaccination route affords more potent vaccine-mediated responses and protection. Similarly, we have generated MACV GPe immunogens and will design a MACV NP-NTD subunit antigen to test the same approach across multiple MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing both OWAV (LUJV) and NWAV (CHAPV) complexes, for which there are no vaccines available. A unique advantage of the PABVAX Center is its access to Biosafety Level (BSL)-4 containment, allowing us to work with authentic versus surrogate arenaviruses. The BSL-4 facilities described in **Core E** are capable of evaluating countermeasures in small animal models and NHPs. The cynomolgus macaque is the current “gold standard” animal model for LASV, JUNV, and MACV research as disease recapitulates human infection and there are a multitude of immunological reagents available[30-32]. The evaluation of prototype OWAV and NWAV vaccines and therapies in the NHP model is likely pivotal for IND applications and for future licensure of medical countermeasures for human use.

<u>Nairoviridae:</u> Unique to most bunyaviruses, orthonairoviruses are transmitted primarily by ticks[2]. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[33], Issyk-Kul virus[34], Songling virus[35]), CCHFV is the most recognized public health threat. Outbreaks of CCHFV have occurred across Europe, Africa, the Middle East, and Asia. There is growing concern for expansion of the CCHFV endemic region due to increased range of its tick host (*Hyalomma* spp.) tied to bird migration changes, livestock trade, and global warming. For example, CCHFV cases have been reported in Spain[36], a previously non-endemic region, and *Hyalomma* ticks have been found in Sweden[37]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to a severe hemorrhagic fever and death in 30% of cases[38]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[39]. Ribavirin has been used to treat infections with limited success[40].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and GPC [38]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[38]. Conversely, the CCHFV GPC is considerably less conserved (< 75% amino acid identity)[38]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location. Thus, creating a pan-CCHFV vaccine or therapeutic based solely on one clade poses a challenge. Nevertheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a rVSV vectored vaccine expressing the full GPC of CCHFV[41].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP immunogens with the highest level of homology across clades. We will assess their capacity to protect against lethal challenge with isolates from multiple CCHFV clades in established mouse[41, 42] and NHP[43] models with **Core E**. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best formulation of CCHFV GP/NP MNP vaccine against the emerging test case nairovirus, Kasokero virus, for which there are no vaccines available.

Paramyxoviridae: The HNVs NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality[4, 44]. HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality[45]. NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs, which served as amplifying hosts[46]. NiV and HeV can infect at least 18 animal species across 6 orders of mammals, and among these they cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans[14,47]. The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission[5]. Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and Southeast Asia and Australia. Their broad host tropism and ability to infect livestock also causes increased risk of human infections. HNVs are single-stranded, negative sense, enveloped RNA viruses and their biology lends themselves to be synthetically produced. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS). The Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents[48] because the virus could be engineered for mass dissemination and it possesses the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the R&D Blueprint list of priority pathogens with epidemic potential[49].

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb exist. These postexposure treatments conferred protecion against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP)[50-53]. The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia[54]. In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs, and several vaccine platforms have clear potential for use in people[14]. The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies[14]. Such preventive vaccines would have utility for lab workers, first responders or individuals at high-risk exposure, and in mitigating the spread of an outbreak. In the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent[55]. It is widely considered that the African green monkey (AGM) is the current “gold standard” animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection[47, 56]. The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished data)[57]. The divergent LayV will be the focus of the test case studies. The choice is justifiable for several important reasons: 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; and 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including rescuing recombinant LayV (rLayV), exploring animal model development, constructing additional LayV and AngV reporter virus tools, and then translating and testing the MNP vaccine “plug-and-play” approach. Finally, we will evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME. A strength of the PABVAX is that a majority of the Center Research Project (RP) and Scientific Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center’s RPs and Core leaders currently have active and productive collaborative research programs in related areas, most spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

The pandemic preparedness research gaps addressed by PABVAX are diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **arenaviruses** and **nairoviruses**, and **RP2** will target the prototype **HNVs**. Both RP1 and RP2 will develop new prototype virus tools (recombinant prototype viruses) along with existing tools, to analyze vaccine responses and evaluate new mAbs and nabs from the other RPs. A third RP will develop a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant *Cedar henipavirus* (rCedV) *in vivo* and a bioluminescence detection method that can longitudinally trace the dynamics and anatomical progression of infection with a luciferase-encoding virus in individual animals (**RP3**). There will also be two RPs that focus on the development of broadly reactive human mAbs and nanobodies to the PABVAX selected viral prototypes. **RP4** will isolate human mAbs derived from NiV-infected survivors with a specific focus on F glycoprotein-targeting mAbs. Additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will engage in the manufacture, quality control, and testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**). Under the direction of the PD/PIs (Drs. Geisbert and Broder), the Administrative Core (**Core A**) will provide organizational and programmatic structure to promote research productivity and scientific interactions along with compliance with regulations concerning select agent, vertebrate animal, and any human subject use. **Core A** will coordinate all activities with the external Scientific Advisory Board (**SAB**) and make data available through the Data Management Core (**Core B**).

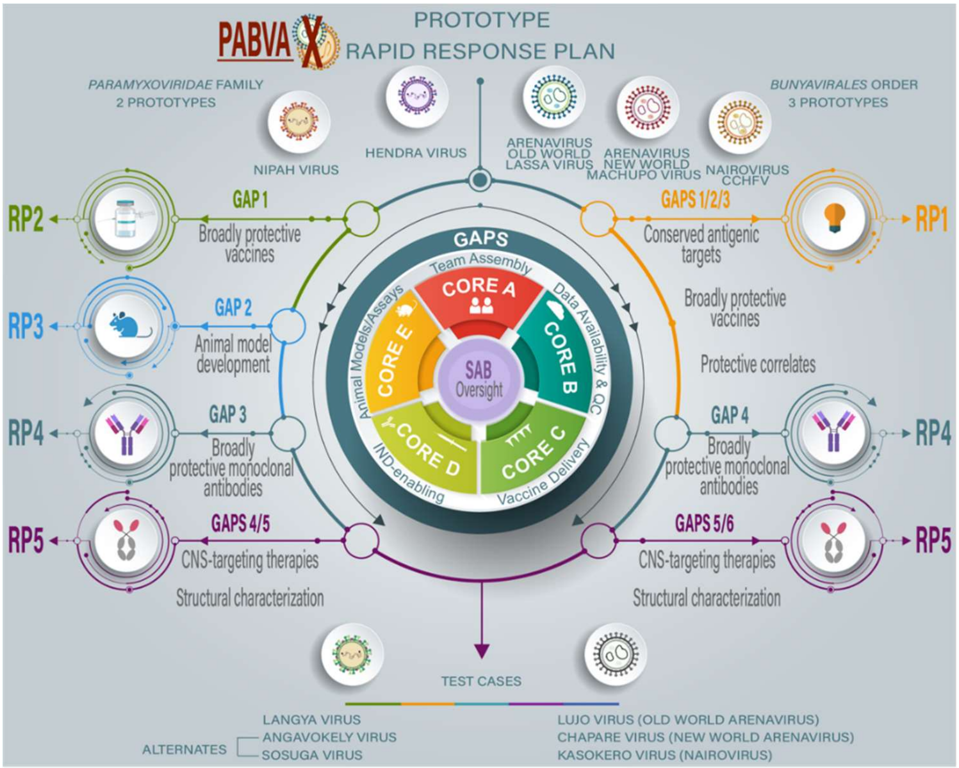

Figure 1: Research gaps addressed by the *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center- (PABVAX).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform. The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from the UPitt and IBBR/UMD (**Core C**). This project tested a dissolvable MNP-based vaccine technology ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine[58]. The MNP vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable microneedles that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants[59] to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as to facilitate improved vaccine storage and distribution due to their improved thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, Scientific **Core C** (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ)-adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (*Paramyxoviridae*). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity *in vitro*, along with analysis of polyfunctional T-cell responses by antigenic peptide stimulation, followed by intracellular cytokine staining (ICS) and flow cytometry.

Discover effective antibody-based prophylactics and therapies. Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah[60], Hendra[61], Ebola[62], Marburg[63] and Lassa[64]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, etc.), a feature to be exploited in **Core D** by Dr. Gunn. In addition to therapeutic applications, mAbs with Fc mutations dramatically extend serum half-life[65-67] and offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g*. rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization, and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures. Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the Animal Model Development and Preclinical Evaluation Scientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective efficacy of antivirals and vaccines, as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation, including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within

RP1. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they are generally less laborious and can be adapted to higher throughput platforms and/or integrated with other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput fluorescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic NiV and HeV vaccine-induced immune sera, mAbs (**RP4**), nbs (**RP5**), and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either HeV or NiV-B envelope GPs) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals to explore nab based therapeutics to CNS resident HNVs[68].

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the HNVs (*Paramyxoviridae*) and the *Bunyavirales* (*Arenaviridae* and *Nairoviridae*) that will bolster vaccine endurance to storage and transportation; we also anticipate improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

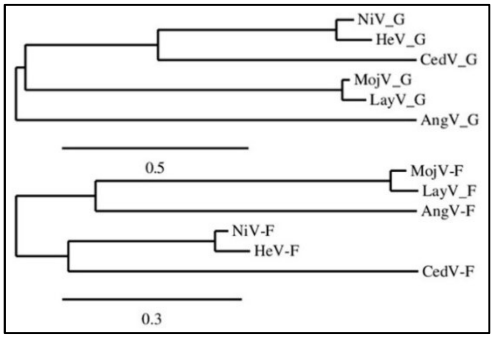
The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology, and mAb and vaccine translational drug development along with Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Paramyxoviruses: NiV and HeV are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis[4, 44]. HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals. These viruses are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of CedV, Gamak virus, Daeryong virus, and (LayV)[69] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[70-73]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and

Figure 2: Phylogenetic analysis of select HNV G and F glycoproteins. Trees were constructed for using the PhyML program's maximum likelihood method and aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.



AngV, are old world pteropid fruit bats[70, 74]. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province)[15]. The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**. Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal HNV disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters[47], and AGMs (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P). The P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists[75-79]. The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections[80, 81]. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature[82]. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2[83] and CedV is now recognized as a BSL-2 restricted agent[84]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore **LayV as part of the Center's Phase II "plug and play"** research plan (**RP2** and **PR5** with **Cores C, D,** and **E**).

Arenaviruses (old world): For **phase 1**, **RP1** will utilize **LASV as the prototype virus** due its significant public health burden throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[85]. LASV is the most imported viral hemorrhagic fever (VHF) next to Dengue virus and has been documented in several countries outside of Africa over 35 times[86]. CFRs approaching 70% in hospitalized cases and marked long term sequelae are the result of the lack of approved vaccines or therapeutics, although several live attenuated virus candidates are currently being evaluated with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI)[87]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize only LASV GP as the target immunogen.

Investigators in **RP1**, **Core D**, and **Core E** have already demonstrated protective efficacy against challenge with LASV in outbred guinea pigs vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These immunogens have been engineered to express homologous antigenic regions to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach suggests a similar strategy could be implemented against other arenaviruses. The **OWAV test pathogen, LUJV,** was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia, which quickly spread nosocomially[88]. The CFR for this infectious virus was 80% in this small outbreak of 5 people. There are currently no approved vaccines or therapeutics available for this virus and its genetic divergence from suggest current LASV countermeasures may be of limited use. LUJV will serve as an ideal "test case" to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Arenaviruses (new world): The live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[89], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[90, 91]. Furthermore, there is the potential for pathogenic reversion. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest exploring other JUNV countermeasures are warranted. Building on the success of the LASV GPe/NP-NTD, investigators in **RP1 and Cores D and E** will engineer broadly protective MACV GPe and NP-NTD antigens and perform efficacy testing in established guinea pig and NHP models. We will extend this plug-and-play approach to the **NWAV test case, CHAPV**. First reported in 2003 in Bolivia, CHAPV is a rodent-borne mammarenavirus associated with the development of severe hemorrhagic fever with case fatality rates up to 60%[92, 93]. Recent studies have demonstrated clear human-to-human transmission during the acute phase evidenced by several nosocomial infections; isolation of viable virus from semen at 86 days after symptom onset demonstrates a clear need to implement specialized management

and treatment [93]. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Nairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as it represents the largest global public health burden within the orthonairovirus family with outbreaks annually across Europe, Africa, and Asia. There are no FDA-approved vaccines for CCHFV; however, a suckling mouse brain-derived, adjuvanted whole virus vaccine for CCHFV has been approved for use in Bulgaria. This vaccine has numerous safety concerns and has limited demonstrated efficacy. Several experimental vaccine approaches have been evaluated ranging from viral vectored approaches to DNA-based vaccines with varying efficacy, advantages, and disadvantages[94]; however, only a Modified Vaccinia Ankara virus vaccine (MVA-CCHFV) has begun to advance towards clinical trials[95]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test these for protective efficacy from challenge with 6 different CCHFV lineages using established mouse and NHP models. Next, we will deploy the same approach to the **test case nairovirus, Kasokero virus (KASV),** for which no vaccine or treatment exists.

In 1977, KASV was first isolated from Ugandan bats and caused several cases of acute febrile illness of laboratory workers from the same lab that processed the infected bats[96]. Surveys of 109 laboratory workers from the same facility demonstrated 13% seropositivity and clinical symptoms in individuals 4 to 15 months after the virus was isolated. These findings suggest either continued laboratory-associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the tick reservoir, *Ornithodoros faini,* to participate in enzootic maintenance of KASV[97]. While most chiropteran ticks exhibit host specificity, humans entering caves these bats inhabit have reported bites from *O.faini* ticks. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics suggest investment in countermeasure development against this virus is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Management Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**; arenavirus and nairovirus projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine active and passive immunization approaches to further improve the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

An additional and outstanding advantage of the PABVAX Center is the **Animal Model Development and Preclinical Evaluation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL. Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for the Center RPs will be performed by the same BSL-4 staff under the

same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for members of the *Bunyavirales* and *Paramyxoviridae*.**
2. **Develop new tools and animal models for cell-based and *in vivo* therapeutic evaluation.**
3. **Develop antibodies and nanobodies to the selected prototype and test viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

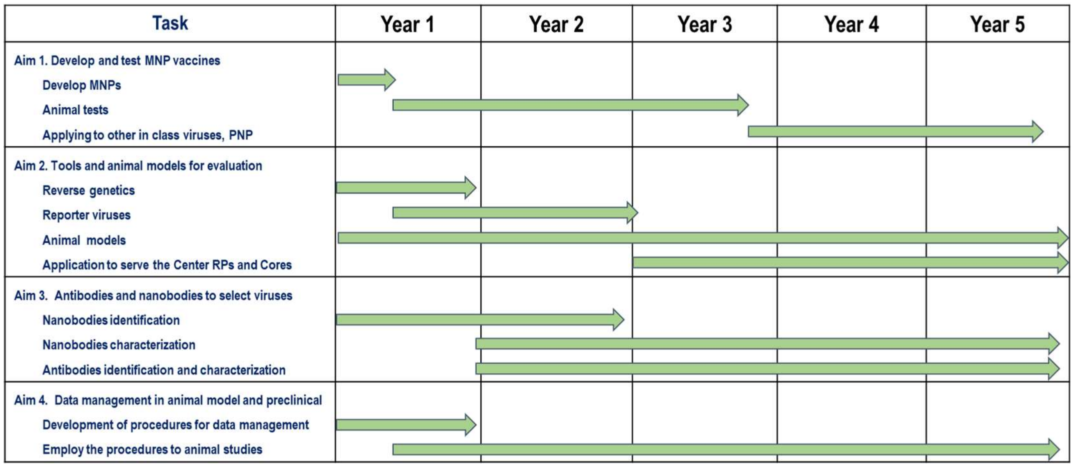


Figure 3: Projected PABVAX timeline to achieve the 4 overarching tasks.

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**. Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (details are specified within the Administration **Core A** Research Strategy). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommending new directions as appropriate, and providing Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

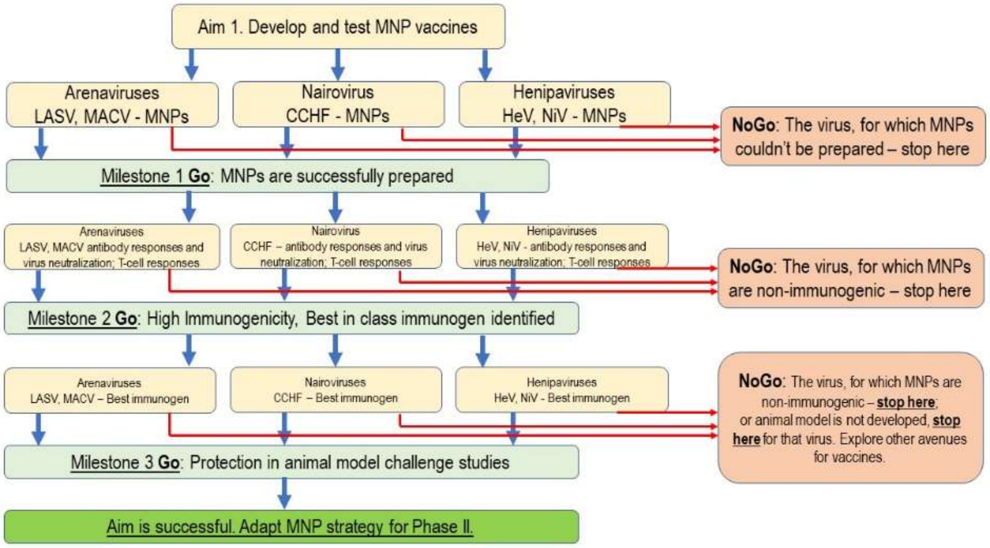

Figure 4. Milestones and criteria for **Aim 1** of the PABVAX Center's overall objectives.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

The first milestone will address whether formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made (**Figure 4**). The determination of MNP vaccine potential success will first be established using immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen-specific antibody induction, virus neutralization, and polyfunctional T-cell responses by *in vitro* stimulation of isolated cells). Go/no go decisions will be made based on outcomes of these first-tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as a success. Comparisons will also be made such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of the best-in-class immunogens, or immunogen combinations, will also be explored to down-select vaccines. The third milestone will determine whether MNP vaccination affords protection in animal model challenge experiments. In the case of NiV and HeV prototypes, the animal models chosen (ferrets and African green monkeys (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales*, there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASV, and guinea pig models exist for some but not all of these lineages. For MACV, there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is the limitations of cost and availability of rhesus and cynomolgus monkeys. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be developing and evaluating animal models within the PABVAX program, including further development of AGM models for arenaviruses and possibly CCHFV as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for cell-based and in vivo therapeutics evaluation.

The second overall objective of PABVAX is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation (**Figure 5**). These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed because genomic data is incomplete. rLayV pathogenesis and animal model development will be conducted by **Core E**. If successful, a large battery of new materials will be available to share with the ReVAMPP network and be key milestones for execution of Phase II of the PABVAX Center program.

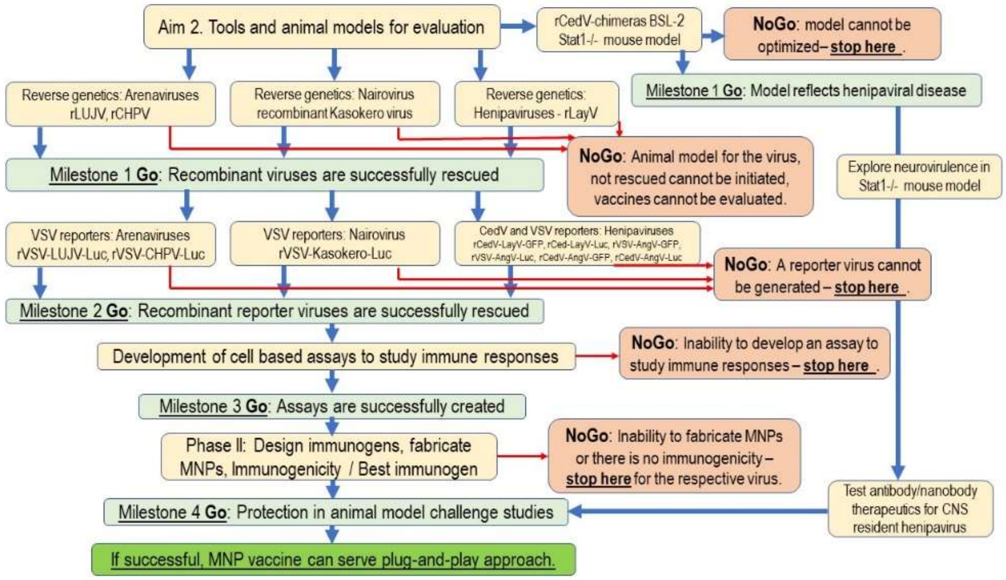

Figure 5. Milestones and criteria for **Aim 2** of the PABVAX Center's overall objectives.

The translation of the MNP vaccine plug-and-play approach will be in Phase II (**Table 1**). Milestones will be similar to those in **Figure 4**. New virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new *in vivo* bioluminescence-based immune deficient mouse model developed by the PIs of **PR2** and **RP3** that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease *in vivo* safely and expediently at BSL-2 containment. The model

will be deployed to test a critically important therapeutic need against CNS resident HNV infection, and **RP3** will collaborate with **RP5** in the testing of engineered nabs.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

New human mAbs and nbs as tools and potential therapeutics will be developed by **RP4** and **RP5** in collaboration with **RP2** and **Core D** (**Figure 6**). NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs, and in collaboration with **RP2**, neutralization potencies will be rapidly assessed (as well as evaluating synergistic cell-based mAb neutralization) that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

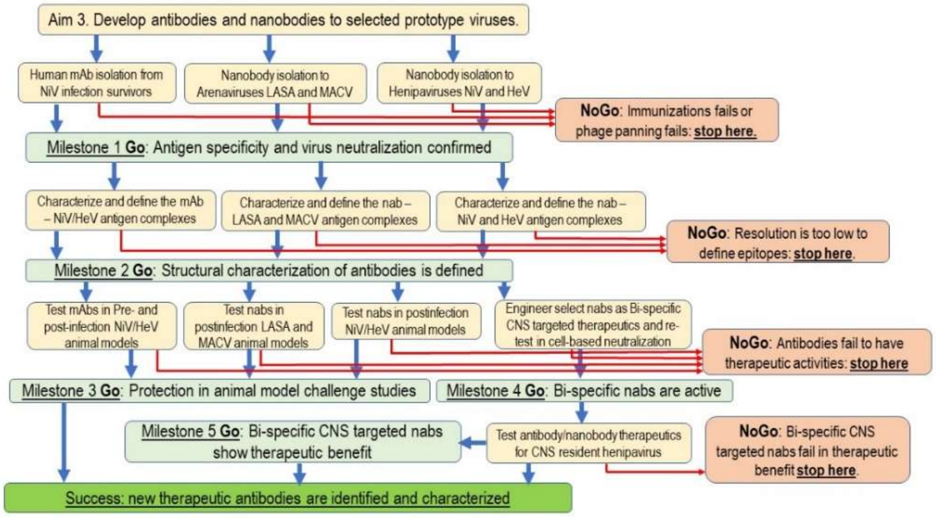

Figure 6. Milestones and criteria for **Aim 3** of the PABVAX Center's overall objectives.

Nbs, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nbs can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nbs targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus), and select animal models of LASV and MACV by **Core E**. Success will be measured by the 1) identification of potent virus-neutralizing nbs, 2) discovery of more broadly reactive nbs particularly to the multiple LASV clades, 3) evidence of therapeutic benefit in animal models, and 4) the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

Industry Partnerships.

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience in developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and

make an ideal partner for PABVAX. Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

SPECIAL FEATURES OF THE PABVAX

Galveston National Laboratory (GNL). The GNL is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics, and therapeutics. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370 NHP studies employing some 2,772 animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses have been performed. These studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder, and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP facility and a staff of full-time veterinarians. **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above, another special feature is the location of the WRCEVA virus collection within the GNL.

***Core E (Animal model development and preclinical evaluation)*. Core E** operations will be conducted at the GNL, and in conjunction with **Core A**, will also include a regulatory expert from the UTMB Institutional Office of Regulated Nonclinical Studies (ORNcS). The ORNcS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL, and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses, arenaviruses, and henipaviruses. He has published over 250 peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI), was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs). Mapp Biopharmaceutical has deep experience with antigens and mAbs against these antigens. Their early development and research group has expertise in immunology, infectious diseases, and the production of antigens, antibodies, and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [98] [99]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1[100]. Dr. Gunn and Genovac will join the team to analyze antibody Fc effector functions and to provide antigen/antibody discovery resources, respectively. Dr. Geisbert will contribute his experience with high containment animal models and vaccine development. As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

Subject: UTMB and USUHS ReVAMPP Overall Research Strategy Final
Date: Monday, June 5, 2023 12:01:01 PM
Attachments: Overall_Research-Strategy_PABVAX-12pages-Final.docx

---

Here is the final Research Strategy for the Overall for the UTMB and USUHS ReVAMPP Center. I think there is still one question from Larry that Chris needs to address for the Overall Aims.

CENTER OVERVIEW: *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction. Emerging and periodically reemerging pathogenic enveloped RNA viruses are continuous pandemic threats. Among viral taxon associated with human zoonoses, members of the family ***Paramyxoviridae*** and order ***Bunyavirales*** stand out for their capacity to cause debilitating and life-threatening disease**.** Humans can become infected via excreta from animal reservoir hosts such as rodents or bats, through intermediate amplifying hosts such as small or domestic animals, or by arthropod vectors such as mosquitos and ticks[1-4]. Humans often represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur. During this process, RNA viral pathogens may mutate and adapt to more efficiently replicate and shed in the host, posing an epidemic threat[5, 6]. The viral order ***Bunyavirales*** is composed of several viral families containing high priority human pathogens[7]. Notably, the ***Arenaviridae*** and ***Nairoviridae*** families contain viruses that cause severe hemorrhagic fever diseases in humans globally with mortality rates up to 60%[8] and significant, long-term sequelae in survivors[9]. Many bunyaviruses are included on the World Health Organization's (WHO) List of Priority Pathogens[10, 11]. Six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHAPV, GTOV, JUNV, MACV) and one nairovirus, Crimean-Congo Hemorrhagic Fever Virus (CCHFV), are also identified as NIAID Category A pathogens[12] due to their 1) high associated morbidity and mortality rates, 2) ease of dissemination and/or ability to transmit from person-to-person, 3) potential to cause public panic and social disruption, and 4) requirement for special actions in the context of public health preparedness. The ***Paramyxoviridae*** also includes members in the WHO Priority Pathogens, namely Nipah virus (NiV) and Hendra virus (HeV). These henipaviruses (HNVs) are the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease[13]. The genus now includes nine additional reported HNVs, but only HeV and NiV are associated with severe and often fatal henipaviral disease in humans and a number of animal species[14]. Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illness in humans[15].

These collective factors plus the absence of approved vaccines or therapeutics make bunyaviruses and paramyxoviruses a significant threat to global public health. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for developing vaccine and monoclonal antibody (mAb) countermeasures to prototype bunyavirus and paramyxovirus pathogens (**Table 1**). In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old World) Machupo (New World)	Lujo (Old World) Chapare (New World)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Table 1. PABVAX selected prototype and test case viral agents

Arenaviridae*:* The *Arenaviridae* is composed of five genera: *Mammarenavirus*, *Reptarenavirus*, *Innmovirus*, *Antennavirus*, and *Hartmanivirus*[16]. The genus *Mammarenavirus* contains a large number of rodent-borne viruses, some of which cause severe hemorrhagic fever, neurological damage, death, and permanent sequelae; hearing loss, vision impairment, and balance issues in survivors[17]. While these genera exhibit a global distribution, two geographically distinct serogroups exist that diverged[18]. Old World complex mammarenaviruses (OWAV) in the Eastern Hemisphere include LASV, Lymphocytic Choriomeningitis Virus (LCMV), and the newly discovered LUJV; New World complex mammarenaviruses (NWAV) in the Western Hemisphere include JUNV, MACV, Sabia Virus (SABV), and CHAPV. There are no FDA approved vaccines or therapeutics for mammarenaviruses, though the attenuated JUNV "Candid-1" vaccine is approved for use in Argentina.

Disease severity and case fatality rates (CFR) vary across mammarenaviruses even within the same clades and species. Up to 500,000 cases of LASV infection occur per year with CFRs sometimes approaching 70% in hospitalized cases[19]. Before the introduction of the Candid-1 vaccine, it is believed that an upwards of 60,000 cases of Argentine Hemorrhagic Fever (AHF) from infection with JUNV occurred per year with CFRs ranging from 15-30%. Convalescent plasma from JUNV survivors is still the primary means to treat acute AHF in Argentina[20]. Over 1000 cases were reported for the initial outbreak of MACV with CFRs ranging from 5-30%; enhanced rodent abatement practices and potentially cross-protective immunity in populations that have taken the JUNV Candid-1 vaccine may have reduced recent outbreak frequency[21]. All mammarenaviruses share a common genomic organization consisting of two ambisense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix) and L protein (polymerase), and the glycoprotein precursor (GPC) and nucleoprotein (NP)[17]. Despite general

similarity of their genomic architecture, mammarenaviruses exhibit marked differences in their replication life cycles including attachment factors, entry mechanisms, and immune evasion; nonetheless, the dominant antigens driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Despite the abundant genetic diversity of LASV, high levels of cross reactivity have been seen with antigen-based diagnostics across seven known lineages, suggesting the generation of cross-protective immunogens and antibodies against mammarenaviruses is achievable[22]. Monoclonal antibodies derived from human LASV survivors were shown to protect non-human primates (NHP) against lethal challenge[23]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[24]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, indicating this domain could serve as an antigenic target. Investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccines to test this approach and have demonstrated protection against lethal LASV lineage IV Josiah challenge. Specifically, a stabilized prefusion trimeric GPe, an immunogen containing a highly conserved NP NTD epitope, or a combination of these two approaches conferred protection in a lethal outbred guinea pig model. Nevertheless, even with the considerable molecular diversity in LASV strains, conservation at key antigenic sites within the GP and NP suggest a pan-LASV vaccine may be possible[22, 25, 26]. **RP1** and **Core E** investigators have demonstrated that a recombinant vesicular stomatitis virus (rVSV)-based vaccine expressing the LASV-Josiah GPC is protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[27], and against heterologous challenge with Lineage II[28], III, V[29], and VI viruses (Cross and Geisbert, unpublished data).

In **Phase I of RP1**, the ability of an optimized LASV GPe/NP subunit vaccine delivered intramuscularly (IM) will be assessed in guinea pig and NHP models across multiple viral lineages. We will also assess a microneedle skin patch (MNP) formulation optimized in **Core C** to determine if a needle-free vaccination route affords more potent vaccine-mediated responses and protection. Similarly, we have generated MACV GPe immunogens and will design a MACV NP-NTD subunit antigen to test the same approach across multiple MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing both OWAV (LUJV) and NWAV (CHAPV) complexes, for which there are no vaccines available. A unique advantage of the PABVAX Center is its access to biosafety level (BSL)-4 containment, allowing us to work with authentic versus surrogate arenaviruses. The BSL-4 facilities described in **Core E** are capable of evaluating countermeasures in small animal models and NHPs. The cynomolgus macaque is the current "gold standard" animal model for LASV, JUNV, and MACV research as disease recapitulates human infection and there are a multitude of immunological reagents available[30-32]. The evaluation of prototype OWAV and NWAV vaccines and therapies in the NHP model is likely pivotal for IND applications and for future licensure of medical countermeasures for human use.

<u>Nairoviridae:</u> Unique to most bunyaviruses, orthonairoviruses are transmitted primarily by ticks[2]. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[33], Issyk-Kul virus[34], Songling virus[35]), CCHFV is the most recognized public health threat. Outbreaks of CCHFV have occurred across Europe, Africa, the Middle East, and Asia. There is growing concern for expansion of the CCHFV endemic region due to increased range of its tick host (*Hyalomma* spp.) tied to bird migration changes, livestock trade, and global warming. For example, CCHFV cases have been reported in Spain[36], a previously non-endemic region, and *Hyalomma* ticks have been found in Sweden[37]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to a severe hemorrhagic fever and death in 30% of cases[38]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[39]. Ribavirin has been used to treat infections with limited success[40].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and GPC [38]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[38]. Conversely, the CCHFV GPC is considerably less conserved (< 75% amino acid identity)[38]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location. Thus, creating a pan-CCHFV vaccine or therapeutic based solely on one clade poses a challenge. Nevertheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a rVSV vectored vaccine expressing the full GPC of CCHFV[41].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP immunogens with the highest level of homology across clades. We will assess their capacity to protect against lethal challenge with isolates from multiple CCHFV clades in established mouse[41, 42] and NHP[43] models with **Core E**. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best formulation of CCHFV GP/NP MNP vaccine against the emerging test case nairovirus, Kasokero virus, for which there are no vaccines available.

Paramyxoviridae: The HNVs NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality[4, 44]. HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality[45]. NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs, which served as amplifying hosts[46]. NiV and HeV can infect at least 18 animal species across 6 orders of mammals, and among these they cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans[14,47]. The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission[5]. Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and Southeast Asia and Australia. Their broad host tropism and ability to infect livestock also causes increased risk of human infections. HNVs are single-stranded, negative sense, enveloped RNA viruses and their biology lends themselves to be synthetically produced. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS). The Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents[48] because the virus could be engineered for mass dissemination and it possesses the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the R&D Blueprint list of priority pathogens with epidemic potential[49].

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb exist. These postexposure treatments conferred protecion against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP)[50-53]. The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia[54]. In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs, and several vaccine platforms have clear potential for use in people[14]. The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies[14]. Such preventive vaccines would have utility for lab workers, first responders or individuals at high-risk exposure, and in mitigating the spread of an outbreak. In the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent[55]. It is widely considered that the African green monkey (AGM) is the current "gold standard" animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection[47, 56]. The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished)[57]. The divergent LayV will be the focus of the test case studies. The choice is justifiable for several important reasons: 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; and 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including rescuing recombinant LayV (rLayV), exploring animal model development, constructing additional LayV and AngV reporter virus tools, and then translating and testing the MNP vaccine "plug-and-play" approach. Finally, we will evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME. A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center's RPs and Core leaders currently have active and productive collaborative research programs in related areas, most spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

The pandemic preparedness research gaps addressed by PABVAX are diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **arenaviruses** and **nairoviruses**, and **RP2** will target the prototype **HNVs**. Both RP1 and RP2 will develop new prototype virus tools (recombinant prototype viruses) along with existing tools, to analyze vaccine responses and evaluate new mAbs and nabs from the other RPs. A third RP will develop a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant *Cedar henipavirus* (rCedV) *in vivo* and a bioluminescence detection method that can longitudinally trace the dynamics and anatomical progression of infection with a luciferase-encoding virus in individual animals (**RP3**). There will also be two RPs that focus on the development of broadly reactive human mAbs and nanobodies to the PABVAX selected viral prototypes. **RP4** will isolate human mAbs derived from NiV-infected survivors with a specific focus on F glycoprotein-targeting mAbs. Additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will engage in the manufacture, quality control, and testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**). Under the direction of the PD/PIs (Drs. Geisbert and Broder), the Administrative Core (**Core A**) will provide organizational and programmatic structure to promote research productivity and scientific interactions along with compliance with regulations concerning select agent, vertebrate animal, and human subject use. **Core A** will coordinate all activities with the Scientific Advisory Board (**SAB**) and make data available through the Data Management Core (**Core B**).

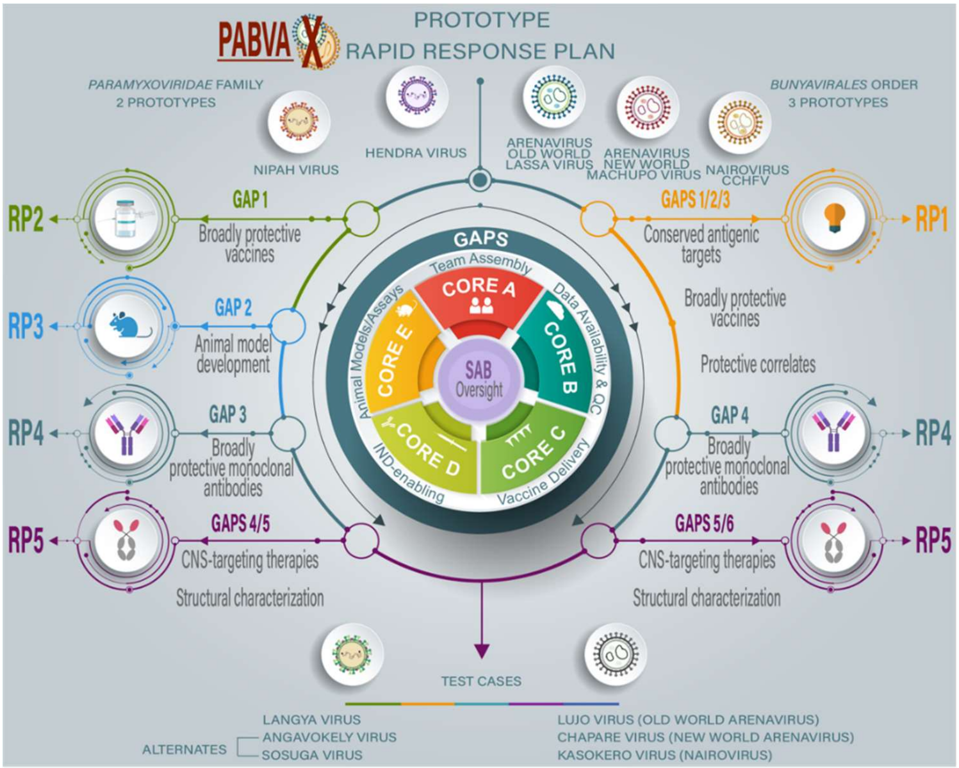

Figure 1: Research gaps addressed by the *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center- (PABVAX).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform. The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from the UPitt and IBBR/UMD (**Core C**). This project tested a dissolvable MNP-based vaccine technology ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine[58]. The MNP vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable microneedles that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants[59] to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as to facilitate improved vaccine storage and distribution due to their improved thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, Scientific **Core C** (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ)-adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (*Paramyxoviridae*). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity *in vitro*, along with analysis of polyfunctional T-cell responses by antigenic peptide stimulation, followed by intracellular cytokine staining (ICS) and flow cytometry.

Discover effective antibody-based prophylactics and therapies. Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah[60], Hendra[61], Ebola[62], Marburg[63] and Lassa[64]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, etc.), a feature to be exploited in **Core D** by Dr. Gunn. In addition to therapeutic applications, mAbs with Fc mutations dramatically extend serum half-life[65-67] and offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g*. rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization, and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures. Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the Animal Model Development and Preclinical Evaluation Scientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective efficacy of antivirals and vaccines, as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation, including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within

RP1. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they are generally less laborious and can be adapted to higher throughput platforms and/or integrated with other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput fluorescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic NiV and HeV vaccine-induced immune sera, mAbs (**RP4**), nbs (**RP5**), and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either HeV or NiV-B envelope GPs) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals to explore nab based therapeutics to CNS resident HNVs[68].

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the HNVs (*Paramyxoviridae*) and the *Bunyavirales* (*Arenaviridae* and *Nairoviridae*) that will bolster vaccine endurance to storage and transportation; we also anticipate improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

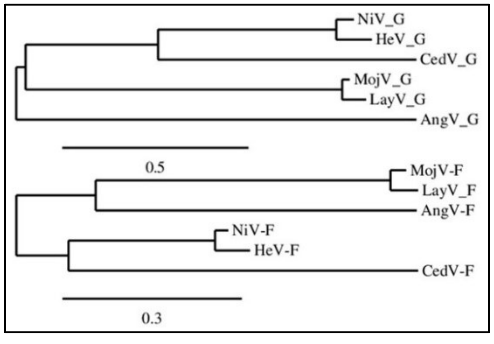
The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology, and mAb and vaccine translational drug development along with Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Paramyxoviruses: NiV and HeV are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis[4, 44]. HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals. These viruses are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of CedV, Gamak virus, Daeryong virus, and (LayV)[69] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[70-73]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and

Figure 2: Phylogenetic analysis of select HNV G and F glycoproteins. Trees were constructed for using the PhyML program's maximum likelihood method and aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.



AngV, are old world pteropid fruit bats[70, 74]. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province)[15]. The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**. Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal HNV disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters[47], and AGMs (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P). The P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists[75-79]. The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections[80, 81]. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature[82]. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2[83] and CedV is now recognized as a BSL-2 restricted agent[84]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II "plug and play" research plan (**RP2** and **PR5** with **Cores C, D,** and **E**).

Arenaviruses (old world): For **phase 1**, **RP1** will utilize **LASV as the prototype virus** due its significant public health burden throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[85]. LASV is the most imported viral hemorrhagic fever (VHF) next to Dengue virus and has been documented in several countries outside of Africa over 35 times[86]. CFRs approaching 70% in hospitalized cases and marked long term sequelae are the result of the lack of approved vaccines or therapeutics, although several live attenuated virus candidates are currently being evaluated with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI)[87]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize only LASV GP as the target immunogen.

Investigators in **RP1**, **Core D**, and **Core E** have already demonstrated protective efficacy against challenge with LASV in outbred guinea pigs vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These immunogens have been engineered to express homologous antigenic regions to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach suggests a similar strategy could be implemented against other arenaviruses. The **OWAV test pathogen, LUJV,** was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia, which quickly spread nosocomially[88]. The CFR for this infectious virus was 80% in this small outbreak of 5 people. There are currently no approved vaccines or therapeutics available for this virus and its genetic divergence from suggest current LASV countermeasures may be of limited use. LUJV will serve as an ideal "test case" to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Arenaviruses (new world): The live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[89], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[90, 91]. Furthermore, there is the potential for pathogenic reversion. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest exploring other JUNV countermeasures are warranted. Building on the success of the LASV GPe/NP-NTD, investigators in **RP1 and Cores D and E** will engineer broadly protective MACV GPe and NP-NTD antigens and perform efficacy testing in established guinea pig and NHP models. We will extend this plug-and-play approach to the **NWAV test case, CHAPV**. First reported in 2003 in Bolivia, CHAPV is a rodent-borne mammarenavirus associated with the development of severe hemorrhagic fever with case fatality rates up to 60%[92, 93]. Recent studies have demonstrated clear human-to-human transmission during the acute phase evidenced by several nosocomial infections; isolation of viable virus from semen at 86 days after symptom onset demonstrates a clear need to implement specialized management

and treatment [93]. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Nairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as it represents the largest global public health burden within the orthonairovirus family with outbreaks annually across Europe, Africa, and Asia. There are no FDA-approved vaccines for CCHFV; however, a suckling mouse brain-derived, adjuvanted whole virus vaccine for CCHFV has been approved for use in Bulgaria. This vaccine has numerous safety concerns and has limited demonstrated efficacy. Several experimental vaccine approaches have been evaluated ranging from viral vectored approaches to DNA-based vaccines with varying efficacy, advantages, and disadvantages[94]; however, only a Modified Vaccinia Ankara virus vaccine (MVA-CCHFV) has begun to advance towards clinical trials[95]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test these for protective efficacy from challenge with 6 different CCHFV lineages using established mouse and NHP models. Next, we will deploy the same approach to the **test case nairovirus, Kasokero virus (KASV),** for which no vaccine or treatment exists.

In 1977, KASV was first isolated from Ugandan bats and caused several cases of acute febrile illness of laboratory workers from the same lab that processed the infected bats[96]. Surveys of 109 laboratory workers from the same facility demonstrated 13% seropositivity and clinical symptoms in individuals 4 to 15 months after the virus was isolated. These findings suggest either continued laboratory-associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the tick reservoir, *Ornithodoros faini,* to participate in enzootic maintenance of KASV[97]. While most chiropteran ticks exhibit host specificity, humans entering caves these bats inhabit have reported bites from *O.faini* ticks. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics suggest investment in countermeasure development against this virus is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Management Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**; arenavirus and nairovirus projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine active and passive immunization approaches to further improve the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

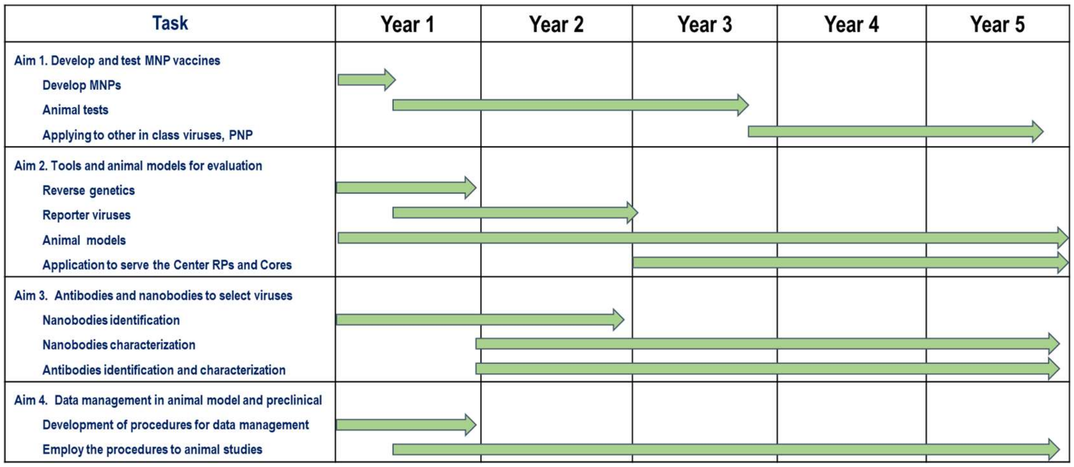
An additional and outstanding advantage of the PABVAX Center is the **Animal Model Development and Preclinical Evaluation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL . Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for the Center RPs will be performed by the same BSL-4 staff under the

same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for members of the *Bunyavirales* and *Paramyxoviridae*.**
2. **Develop new tools and animal models for cell-based and *in vivo* therapeutic evaluation.**
3. **Develop antibodies and nanobodies to the selected prototype and test viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**



Task	Year 1	Year 2	Year 3	Year 4	Year 5
Aim 1. Develop and test MNP vaccines					
Develop MNPs	→				
Animal tests	→	→	→		
Applying to other in class viruses, PNP				→	→
Aim 2. Tools and animal models for evaluation					
Reverse genetics	→				
Reporter viruses	→	→			
Animal models	→	→	→	→	→
Application to serve the Center RPs and Cores			→	→	→
Aim 3. Antibodies and nanobodies to select viruses					
Nanobodies identification	→	→			
Nanobodies characterization		→	→	→	→
Antibodies identification and characterization		→	→	→	→
Aim 4. Data management in animal model and preclinical					
Development of procedures for data management	→				
Employ the procedures to animal studies	→	→	→	→	→

Figure 3: Projected PABVAX timeline to achieve the 4 overarching tasks.

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**. Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (details are specified within the Administration **Core A** Research Strategy). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommending new directions as appropriate, and providing Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

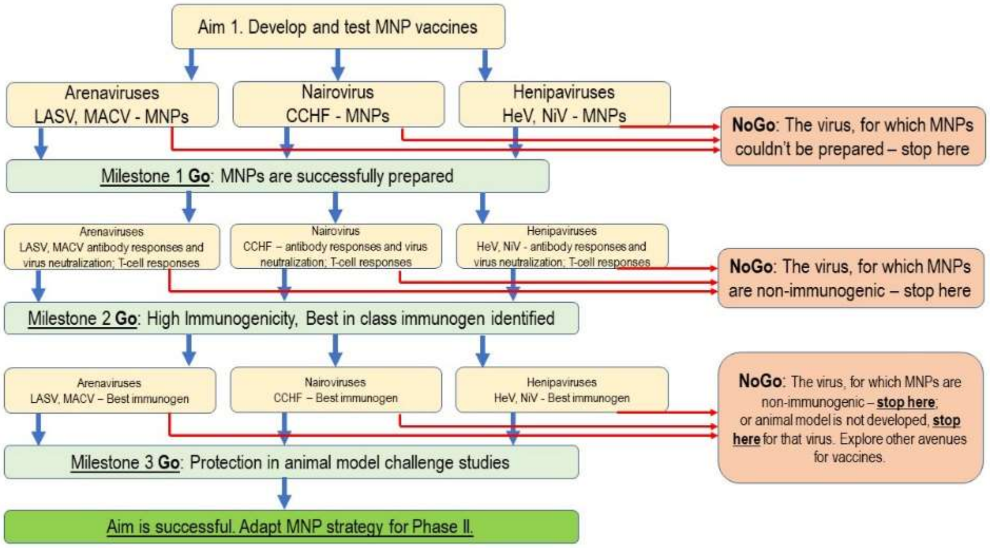


Figure 4. Milestones and criteria for **Aim 1** of the PABVAX Center's overall objectives.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

The first milestone will address whether formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made (**Figure 4**). The determination of MNP vaccine potential success will first be established using immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen-specific antibody induction, virus neutralization, and polyfunctional T-cell responses by *in vitro* stimulation of isolated cells). Go/no go decisions will be made based on outcomes of these first-tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as a success. Comparisons will also be made such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of the best-in-class immunogens, or immunogen combinations, will also be explored to down-select vaccines. The third milestone will determine whether MNP vaccination affords protection in animal model challenge experiments. In the case of NiV and HeV prototypes, the animal models chosen (ferrets and African green monkeys (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales*, there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASV, and guinea pig models exist for some but not all of these lineages. For MACV, there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is the limitations of cost and availability of rhesus and cynomolgus monkeys. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be developing and evaluating animal models within the PABVAX program, including further development of AGM models for arenaviruses and possibly CCHFV as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for cell-based and in vivo therapeutics evaluation.

The second overall objective of PABVAX is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation (**Figure 5**). These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed because genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If successful, a large battery of new materials will be available to share with the ReVAMPP network and be key milestones for execution of Phase II of the PABVAX Center program.

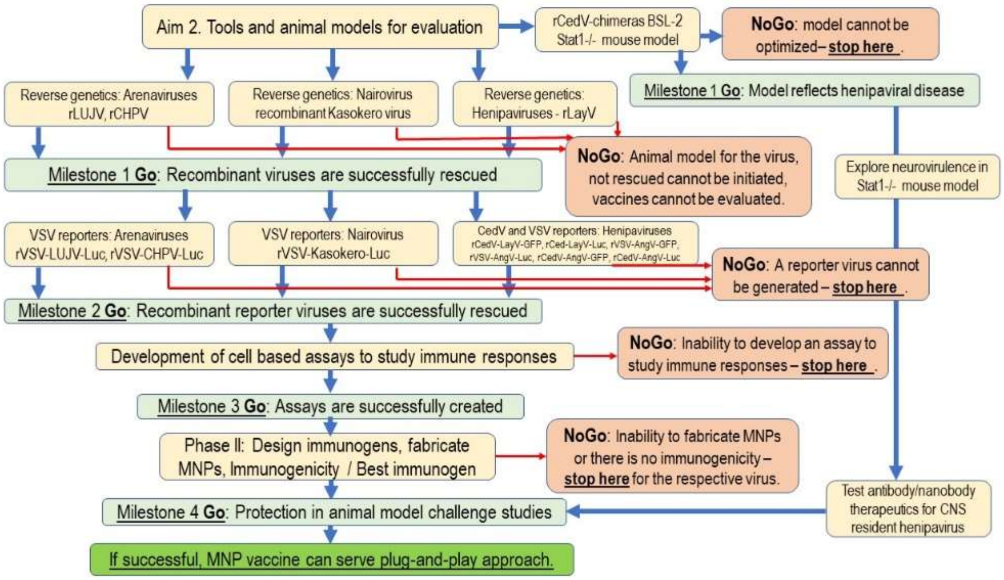

Figure 5. Milestones and criteria for **Aim 2** of the PABVAX Center's overall objectives.

The translation of the MNP vaccine plug-and-play approach will be in Phase II (**Table 1**). Milestones will be similar to those in **Figure 4**. New virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new *in vivo* bioluminescence-based immune deficient mouse model developed by the PIs of **PR2** and **RP3** that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease *in vivo* safely and expediently at BSL-2 containment. The model

will be deployed to test a critically important therapeutic need against CNS resident HNV infection, and **RP3** will collaborate with **RP5** in the testing of engineered nabs.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

New human mAbs and nbs as tools and potential therapeutics will be developed by **RP4** and **RP5** in collaboration with **RP2** and **Core D** (**Figure 6**). NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs, and in collaboration with **RP2**, neutralization potencies will be rapidly assessed (as well as evaluating synergistic cell-based mAb neutralization) that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

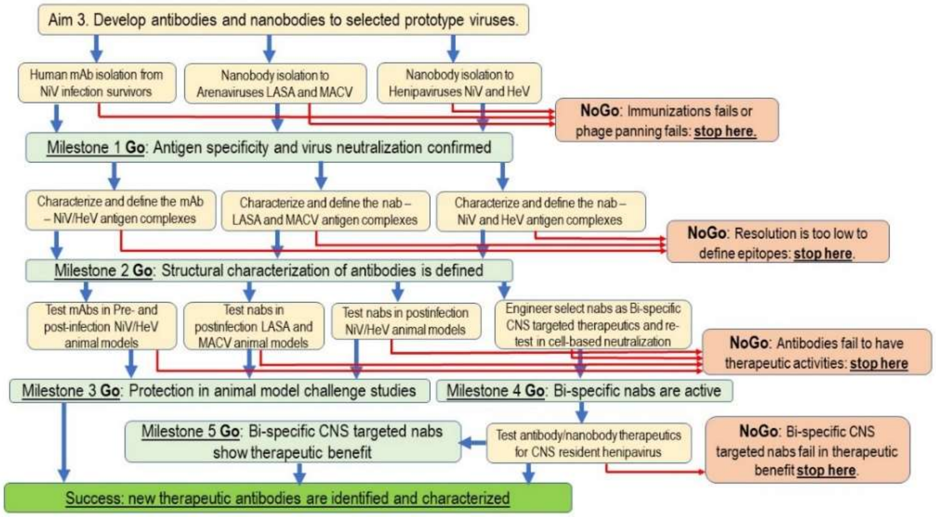

Figure 6. Milestones and criteria for **Aim 3** of the PABVAX Center's overall objectives.

Nbs, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nbs can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nbs targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus), and select animal models of LASV and MACV by **Core E**. Success will be measured by the 1) identification of potent virus-neutralizing nbs, 2) discovery of more broadly reactive nbs particularly to the multiple LASV clades, 3) evidence of therapeutic benefit in animal models, and 4) the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

Industry Partnerships.

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience in developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and

make an ideal partner for PABVAX. Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

SPECIAL FEATURES OF THE PABVAX

Galveston National Laboratory (GNL). The GNL is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics, and therapeutics. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370 NHP studies employing some 2,772 animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses have been performed. These studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder, and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP facility and a staff of full-time veterinarians. **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above, another special feature is the location of the WRCEVA virus collection within the GNL.

***Core E (Animal model development and preclinical evaluation)*. Core E** operations will be conducted at the GNL, and in conjunction with **Core A**, will also include a regulatory expert from the UTMB Institutional Office of Regulated Nonclinical Studies (ORNcS). The ORNcS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL, and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses, arenaviruses, and henipaviruses. He has published over 250 peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI), was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs). Mapp Biopharmaceutical has deep experience with antigens and mAbs against these antigens. Their early development and research group has expertise in immunology, infectious diseases, and the production of antigens, antibodies, and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [98] [99]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1[100]. Dr. Gunn and Genovac will join the team to analyze antibody Fc effector functions and to provide antigen/antibody discovery resources, respectively. Dr. Geisbert will contribute his experience with high containment animal models and vaccine development. As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

CENTER OVERVIEW: *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center – (PABVAX) RESEARCH STRATEGY

Introduction. Emerging and periodically reemerging pathogenic enveloped RNA viruses are continuous pandemic threats. Among viral taxon associated with human zoonoses, members of the family ***Paramyxoviridae*** and order ***Bunyavirales*** stand out for their capacity to cause debilitating and life-threatening disease**.** Humans can become infected via excreta from animal reservoir hosts such as rodents or bats, through intermediate amplifying hosts such as small or domestic animals, or by arthropod vectors such as mosquitos and ticks[1-4]. Humans often represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur. During this process, RNA viral pathogens may mutate and adapt to more efficiently replicate and shed in the host, posing an epidemic threat[5-8]. The viral order ***Bunyavirales*** is composed of several viral families containing high priority human pathogens[9]. Notably, the ***Arenaviridae*** and ***Nairoviridae*** families contain viruses that cause severe hemorrhagic fever diseases in humans globally with mortality rates up to 60%[10] and significant, long-term sequelae in survivors[11]. Many bunyaviruses are included on the World Health Organization's (WHO) List of Priority Pathogens[12,13]. Six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHAPV, GTOV, JUNV, MACV) and one nairovirus, Crimean-Congo Hemorrhagic Fever Virus (CCHFV), are also identified as NIAID Category A pathogens[14] due to their 1) high associated morbidity and mortality rates, 2) ease of dissemination and/or ability to transmit from person-to-person, 3) potential to cause public panic and social disruption, and 4) requirement for special actions in the context of public health preparedness. The ***Paramyxoviridae*** also includes members in the WHO Priority Pathogens, namely Nipah virus (NiV) and Hendra virus (HeV). These henipaviruses (HNVs) are the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease[15]. The genus now includes nine additional reported HNVs, but only HeV and NiV are associated with severe and often fatal henipaviral disease in humans and a number of animal species[16]. Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illness in humans[17].

These collective factors plus the absence of approved vaccines or therapeutics make bunyaviruses and paramyxoviruses a significant threat to global public health. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for developing vaccine and monoclonal antibody (mAb) countermeasures to prototype bunyavirus and paramyxovirus pathogens (**Table 1**). In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old World) Machupo (New World)	Lujo (Old World) Chapare (New World)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Table 1. PABVAX selected prototype and test case viral agents

Arenaviridae: The *Arenaviridae* is composed of five genera: *Mammarenavirus*, *Reptarenavirus*, *Innmovirus*, *Antennavirus*, and *Hartmanivirus*[18]. The genus *Mammarenavirus* contains a large number of rodent-borne viruses, some of which cause severe hemorrhagic fever, neurological damage, death, and permanent sequelae; hearing loss, vision impairment, and balance issues in survivors[19]. While these genera exhibit a global distribution, two geographically distinct serogroups exist that diverged[20]. Old World complex mammarenaviruses (OWAV) in the Eastern Hemisphere include LASV, Lymphocytic Choriomeningitis Virus (LCMV), and the newly discovered LUJV; New World complex mammarenaviruses (NWAV) in the Western Hemisphere include JUNV, MACV, Sabia Virus (SABV), and CHAPV. There are no FDA approved vaccines or therapeutics for mammarenaviruses, though the attenuated JUNV "Candid-1" vaccine is approved for use in Argentina.

Disease severity and case fatality rates (CFR) vary across mammarenaviruses even within the same clades and species. Up to 500,000 cases of LASV infection occur per year with CFRs sometimes approaching 70% in hospitalized cases[21]. Before the introduction of the Candid-1 vaccine, it is believed that an upwards of 60,000 cases of Argentine Hemorrhagic Fever (AHF) from infection with JUNV occurred per year with CFRs ranging from 15-30%. Convalescent plasma from JUNV survivors is still the primary means to treat acute AHF in Argentina[22]. Over 1000 cases were reported for the initial outbreak of MACV with CFRs ranging from 5-30%; enhanced rodent abatement practices and potentially cross-protective immunity in populations that have taken the JUNV Candid-1 vaccine may have reduced recent outbreak frequency[23]. All mammarenaviruses share a common genomic organization consisting of two ambisense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix) and L protein (polymerase), and the glycoprotein precursor (GPC) and nucleoprotein (NP)[19]. Despite general

similarity of their genomic architecture, mammarenaviruses exhibit marked differences in their replication life cycles including attachment factors, entry mechanisms, and immune evasion; nonetheless, the dominant antigens driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Despite the abundant genetic diversity of LASV, high levels of cross reactivity have been seen with antigen-based diagnostics across seven known lineages, suggesting the generation of cross-protective immunogens and antibodies against mammarenaviruses is achievable[24]. Monoclonal antibodies derived from human LASV survivors were shown to protect non-human primates (NHP) against lethal challenge[25]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[26]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, indicating this domain could serve as an antigenic target. Investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccines to test this approach and have demonstrated protection against lethal LASV lineage IV Josiah challenge. Specifically, a stabilized prefusion trimeric GPe, an immunogen containing a highly conserved NP NTD epitope, or a combination of these two approaches conferred protection in a lethal outbred guinea pig model. Nevertheless, even with the considerable molecular diversity in LASV strains, conservation at key antigenic sites within the GP and NP suggest a pan-LASV vaccine may be possible[24,27,28]. **RP1** and **Core E** investigators have demonstrated that a recombinant vesicular stomatitis virus (rVSV)-based vaccine expressing the LASV-Josiah GPC is protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[29], and against heterologous challenge with Lineage II[30], III, V[31], and VI viruses (Cross and Geisbert, unpublished data).

In **Phase I of RP1**, the ability of an optimized LASV GPe/NP subunit vaccine delivered intramuscularly (IM) will be assessed in guinea pig and NHP models across multiple viral lineages. We will also assess a microneedle skin patch (MNP) formulation optimized in **Core C** to determine if a needle-free vaccination route affords more potent vaccine-mediated responses and protection. Similarly, we have generated MACV GPe immunogens and will design a MACV NP-NTD subunit antigen to test the same approach across multiple MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing both OWAV (LUJV) and NWAV (CHAPV) complexes, for which there are no vaccines available. A unique advantage of the PABVAX Center is its access to biosafety level (BSL)-4 containment, allowing us to work with authentic versus surrogate arenaviruses. The BSL-4 facilities described in **Core E** are capable of evaluating countermeasures in small animal models and NHPs. The cynomolgus macaque is the current "gold standard" animal model for LASV, JUNV, and MACV research as disease recapitulates human infection and there are a multitude of immunological reagents available[32-34]. The evaluation of prototype OWAV and NWAV vaccines and therapies in the NHP model is likely pivotal for IND applications and for future licensure of medical countermeasures for human use.

<u>Nairoviridae:</u> Unique to most bunyaviruses, orthonairoviruses are transmitted primarily by ticks[2]. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[35], Issyk-Kul virus[36], Songling virus[37]), CCHFV is the most recognized public health threat. Outbreaks of CCHFV have occurred across Europe, Africa, the Middle East, and Asia. There is growing concern for expansion of the CCHFV endemic region due to increased range of its tick host (*Hyalomma* spp.) tied to bird migration changes, livestock trade, and global warming. For example, CCHFV cases have been reported in Spain[38] , a previously non-endemic region, and *Hyalomma* ticks have been found in Sweden[39]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to a severe hemorrhagic fever and death in 30% of cases[40]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[41]. Ribavirin has been used to treat infections with limited success[42].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and GPC [40]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[40]. Conversely, the CCHFV GPC is considerably less conserved (< 75% amino acid identity)[40]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location. Thus, creating a pan-CCHFV vaccine or therapeutic based solely on one clade poses a challenge. Nevertheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a rVSV vectored vaccine expressing the full GPC of CCHFV[43].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP immunogens with the highest level of homology across clades. We will assess their capacity to protect against lethal challenge with isolates from multiple CCHFV clades in established mouse[43,44] and NHP[45] models with **Core E**. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best formulation of CCHFV GP/NP MNP vaccine against the emerging test case nairovirus, Kasokero virus, for which there are no vaccines available.

Paramyxoviridae: The HNVs NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality[4,46]. HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality[47]. NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs, which served as amplifying hosts[48]. NiV and HeV can infect at least 18 animal species across 6 orders of mammals, and among these they cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans[16,49]. The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission[5]. Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and Southeast Asia and Australia. Their broad host tropism and ability to infect livestock also causes increased risk of human infections. HNVs are single-stranded, negative sense, enveloped RNA viruses and their biology lends themselves to be synthetically produced. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS). The Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents[50] because the virus could be engineered for mass dissemination and it possesses the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the R&D Blueprint list of priority pathogens with epidemic potential[51].

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb exist. These postexposure treatments conferred protecion against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP)[52-55]. The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia[56]. In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs, and several vaccine platforms have clear potential for use in people[16]. The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies[16]. Such preventive vaccines would have utility for lab workers, first responders or individuals at high-risk exposure, and in mitigating the spread of an outbreak. In the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent[57]. It is widely considered that the African green monkey (AGM) is the current “gold standard” animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection[49,58]. The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished)[59]. The divergent LayV will be the focus of the test case studies. The choice is justifiable for several important reasons: 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; and 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including rescuing recombinant LayV (rLayV), exploring animal model development, constructing additional LayV and AngV reporter virus tools, and then translating and testing the MNP vaccine "plug-and-play" approach. Finally, we will evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME. A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center's RPs and Core leaders currently have active and productive collaborative research programs in related areas, most spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

The pandemic preparedness research gaps addressed by PABVAX are diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **arenaviruses** and **nairoviruses**, and **RP2** will target the prototype **HNVs**. Both RP1 and RP2 will develop new prototype virus tools (recombinant prototype viruses) along with existing tools, to analyze vaccine responses and evaluate new mAbs and nabs from the other RPs. A third RP will develop a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant *Cedar henipavirus* (rCedV) *in vivo* and a bioluminescence detection method that can longitudinally trace the dynamics and anatomical progression of infection with a luciferase-encoding virus in individual animals (**RP3**). There will also be two RPs that focus on the development of broadly reactive human mAbs and nanobodies to the PABVAX selected viral prototypes. **RP4** will isolate human mAbs derived from NiV-infected survivors with a specific focus on F glycoprotein-targeting mAbs. Additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will engage in the manufacture, quality control, and testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**). Under the direction of the PD/PIs (Drs. Geisbert and Broder), the Administrative Core (**Core A**) will provide organizational and programmatic structure to promote research productivity and scientific interactions along with compliance with regulations concerning select agent, vertebrate animal, and human subject use. **Core A** will coordinate all activities with the Scientific Advisory Board (**SAB**) and make data available through the Data Management Core (**Core B**).

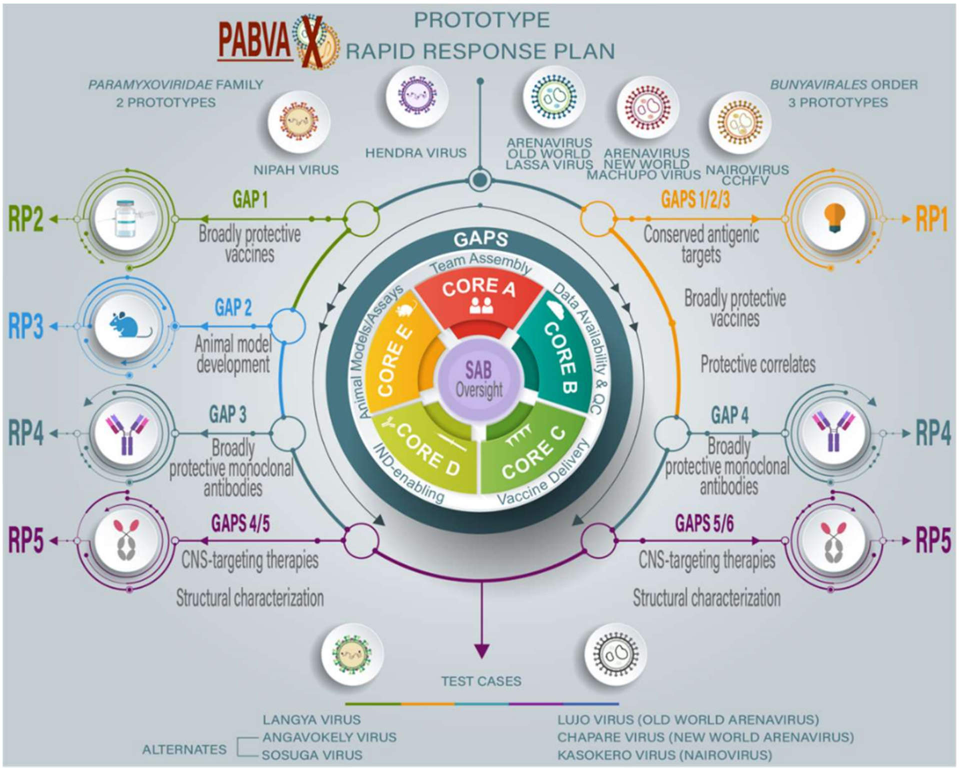

Figure 1: Research gaps addressed by the *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center- (PABVAX).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform. The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from the UPitt and IBBR/UMD (**Core C**). This project tested a dissolvable MNP-based vaccine technology ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine[60]. The MNP vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable microneedles that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants[61] to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as to facilitate improved vaccine storage and distribution due to their improved thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, Scientific **Core C** (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ)-adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (*Paramyxoviridae*). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity *in vitro*, along with analysis of polyfunctional T-cell responses by antigenic peptide stimulation, followed by intracellular cytokine staining (ICS) and flow cytometry.

Discover effective antibody-based prophylactics and therapies. Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah[62], Hendra[63], Ebola[64,65], Marburg[66] and Lassa[67]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc*.), a feature to be exploited in **Core D** by Dr. Gunn. In addition to therapeutic applications, mAbs with Fc mutations dramatically extend serum half-life[68-70] and offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g*. rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization, and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures. Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the Animal Model Development and Preclinical Evaluation Scientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective efficacy of antivirals and vaccines, as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation, including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within

RP1. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they are generally less laborious and can be adapted to higher throughput platforms and/or integrated with other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput fluorescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic NiV and HeV vaccine-induced immune sera, mAbs (**RP4**), nbs (**RP5**), and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either HeV or NiV-B envelope GPs) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals to explore nab based therapeutics to CNS resident HNVs[71].

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the HNVs (*Paramyxoviridae*) and the *Bunyavirales* (*Arenaviridae* and *Nairoviridae*) that will bolster vaccine endurance to storage and transportation; we also anticipate improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology, and mAb and vaccine translational drug development along with Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

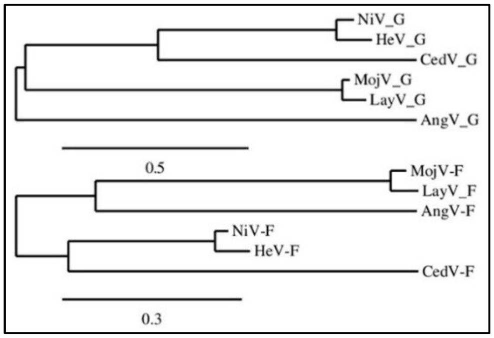

Figure 2: Phylogenetic analysis of select HNV G and F glycoproteins. Trees were constructed for using the PhyML program's maximum likelihood method and aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Paramyxoviruses: NiV and HeV are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis[4,46]. HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals. These viruses are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of CedV, Gamak virus, Daeryong virus, and (LayV)[72] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[73-76]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and

AngV, are old world pteropid fruit bats[73,77]. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province)[17]. The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**. Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal HNV disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters[49], and AGMs (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P). The P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists[78-82]. The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections[83,84]. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature[85]. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2[86] and CedV is now recognized as a BSL-2 restricted agent[87]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II "plug and play" research plan (**RP2** and **PR5** with **Cores C, D,** and **E**).

Arenaviruses (old world): For **phase 1**, **RP1** will utilize **LASV as the prototype virus** due its significant public health burden throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[88]. LASV is the most imported viral hemorrhagic fever (VHF) next to Dengue virus and has been documented in several countries outside of Africa over 35 times[89]. CFRs approaching 70% in hospitalized cases and marked long term sequelae are the result of the lack of approved vaccines or therapeutics, although several live attenuated virus candidates are currently being evaluated with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI)[90]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize only LASV GP as the target immunogen.

Investigators in **RP1**, **Core D**, and **Core E** have already demonstrated protective efficacy against challenge with LASV in outbred guinea pigs vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These immunogens have been engineered to express homologous antigenic regions to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach suggests a similar strategy could be implemented against other arenaviruses. The **OWAV test pathogen, LUJV,** was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia, which quickly spread nosocomially[91]. The CFR for this infectious virus was 80% in this small outbreak of 5 people. There are currently no approved vaccines or therapeutics available for this virus and its genetic divergence from suggest current LASV countermeasures may be of limited use. LUJV will serve as an ideal "test case" to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Arenaviruses (new world): The live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[92], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[93,94]. Furthermore, there is the potential for pathogenic reversion. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest exploring other JUNV countermeasures are warranted. Building on the success of the LASV GPe/NP-NTD, investigators in **RP1 and Cores D and E** will engineer broadly protective MACV GPe and NP-NTD antigens and perform efficacy testing in established guinea pig and NHP models. We will extend this plug-and-play approach to the **NWAV test case, CHAPV**. First reported in 2003 in Bolivia, CHAPV is a rodent-borne mammarenavirus associated with the development of severe hemorrhagic fever with case fatality rates up to 60%[95,96]. Recent studies have demonstrated clear human-to-human transmission during the acute phase evidenced by several nosocomial infections; isolation of viable virus from semen at 86 days after symptom onset demonstrates a clear need to implement specialized management

and treatment [96]. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Nairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as it represents the largest global public health burden within the orthonairovirus family with outbreaks annually across Europe, Africa, and Asia. There are no FDA-approved vaccines for CCHFV; however, a suckling mouse brain-derived, adjuvanted whole virus vaccine for CCHFV has been approved for use in Bulgaria. This vaccine has numerous safety concerns and has limited demonstrated efficacy. Several experimental vaccine approaches have been evaluated ranging from viral vectored approaches to DNA-based vaccines with varying efficacy, advantages, and disadvantages[97]; however, only a Modified Vaccinia Ankara virus vaccine (MVA-CCHFV) has begun to advance towards clinical trials[98]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test these for protective efficacy from challenge with 6 different CCHFV lineages using established mouse and NHP models. Next, we will deploy the same approach to the **test case nairovirus, Kasokero virus (KASV),** for which no vaccine or treatment exists.

In 1977, KASV was first isolated from Ugandan bats and caused several cases of acute febrile illness of laboratory workers from the same lab that processed the infected bats[99]. Surveys of 109 laboratory workers from the same facility demonstrated 13% seropositivity and clinical symptoms in individuals 4 to 15 months after the virus was isolated. These findings suggest either continued laboratory-associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the tick reservoir, *Ornithodoros faini,* to participate in enzootic maintenance of KASV[100]. While most chiropteran ticks exhibit host specificity, humans entering caves these bats inhabit have reported bites from *O.faini* ticks. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics suggest investment in countermeasure development against this virus is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Management Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**; arenavirus and nairovirus projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine active and passive immunization approaches to further improve the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

An additional and outstanding advantage of the PABVAX Center is the **Animal Model Development and Preclinical Evaluation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL . Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for the Center RPs will be performed by the same BSL-4 staff under the

same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for members of the *Bunyavirales* and *Paramyxoviridae*.**
2. **Develop new tools and animal models for cell-based and *in vivo* therapeutic evaluation.**
3. **Develop antibodies and nanobodies to the selected prototype and test viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

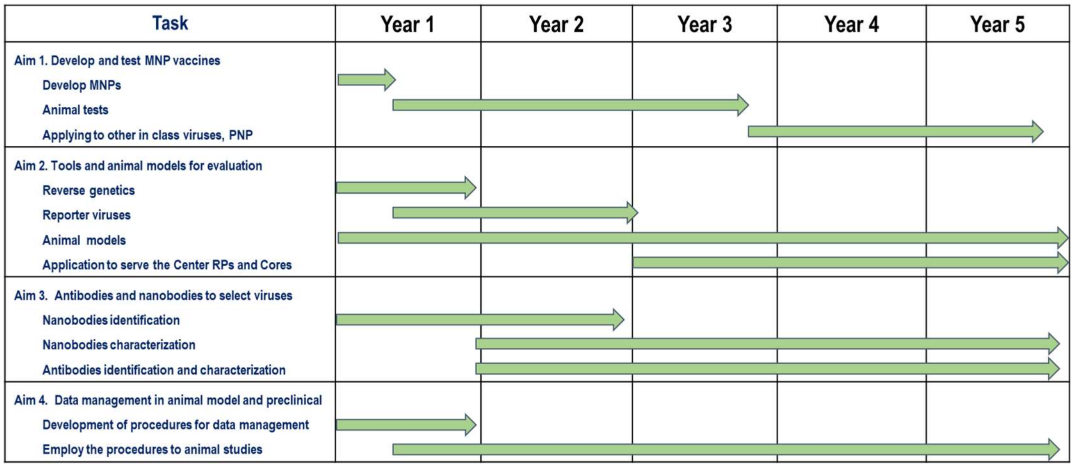

Figure 3: Projected PABVAX timeline to achieve the 4 overarching tasks.

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**. Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (details are specified within the Administration **Core A** Research Strategy). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommending new directions as appropriate, and providing Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

<u>**Overall Objectives**</u>

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

The first milestone will address whether formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made (**Figure 4**). The determination of MNP vaccine potential success will first be established using immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune

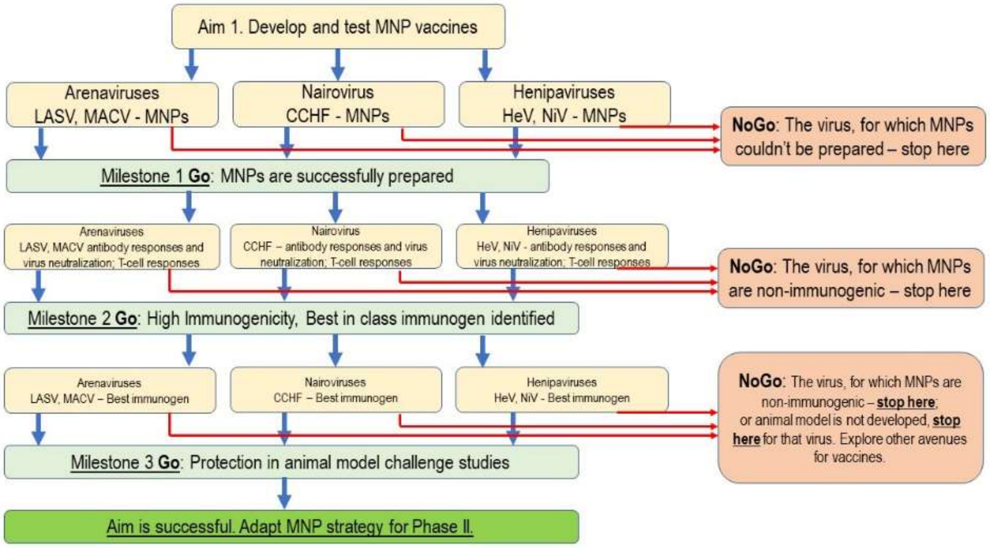

Figure 4. Milestones and criteria for **Aim 1** of the PABVAX Center's overall objectives.

responses will be assessed (antigen-specific antibody induction, virus neutralization, and polyfunctional T-cell responses by *in vitro* stimulation of isolated cells). Go/no go decisions will be made based on outcomes of these first-tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as a success. Comparisons will also be made such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of the best-in-class immunogens, or immunogen combinations, will also be explored to down-select vaccines. The third milestone will determine whether MNP vaccination affords protection in animal model challenge experiments. In the case of NiV and HeV prototypes, the animal models chosen (ferrets and African green monkeys (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales*, there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASV, and guinea pig models exist for some but not all of these lineages. For MACV, there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is the limitations of cost and availability of rhesus and cynomolgus monkeys. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be developing and evaluating animal models within the PABVAX program, including further development of AGM models for arenaviruses and possibly CCHFV as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for cell-based and in vivo therapeutics evaluation.

The second overall objective of PABVAX is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation (**Figure 5**). These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed because genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If successful, a large battery of new materials will be available to share with the ReVAMPP network and be key milestones for execution of Phase II of the PABVAX Center program.

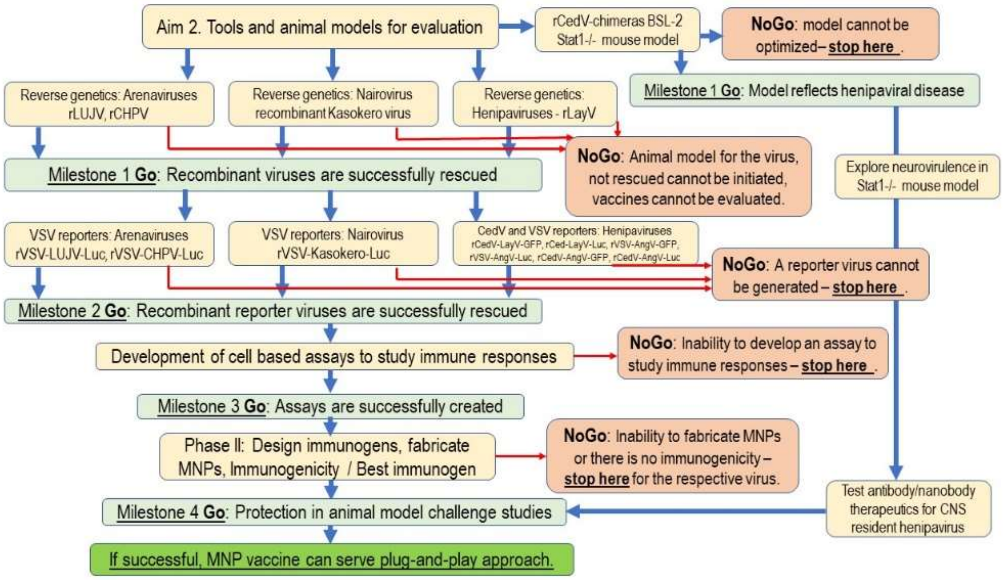

Figure 5. Milestones and criteria for **Aim 2** of the PABVAX Center's overall objectives.

The translation of the MNP vaccine plug-and-play approach will be in Phase II (**Table 1**). Milestones will be similar to those in **Figure 4**. New virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new *in vivo* bioluminescence-based immune deficient mouse model developed by the PIs of **PR2** and **RP3** that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease *in vivo* safely and expediently at BSL-2 containment. The model

will be deployed to test a critically important therapeutic need against CNS resident HNV infection, and **RP3** will collaborate with **RP5** in the testing of engineered nabs.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

New human mAbs and nbs as tools and potential therapeutics will be developed by **RP4** and **RP5** in collaboration with **RP2** and **Core D** (**Figure 6**). NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs, and in collaboration with **RP2**, neutralization potencies will be rapidly assessed (as well as evaluating synergistic cell-based mAb neutralization) that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

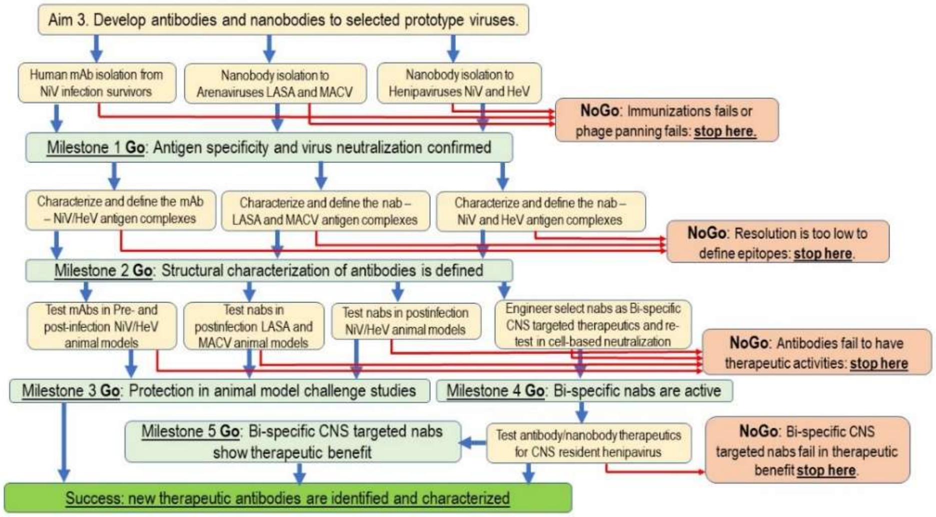

Figure 6. Milestones and criteria for **Aim 3** of the PABVAX Center's overall objectives.

Nbs, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nbs can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nbs targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus), and select animal models of LASV and MACV by **Core E**. Success will be measured by the 1) identification of potent virus-neutralizing nbs, 2) discovery of more broadly reactive nbs particularly to the multiple LASV clades, 3) evidence of therapeutic benefit in animal models, and 4) the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

***Industry Partnerships**.*

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience in developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and

make an ideal partner for PABVAX. Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

SPECIAL FEATURES OF THE PABVAX

Galveston National Laboratory (GNL). The GNL is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics, and therapeutics. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370 NHP studies employing some 2,772 animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses have been performed. These studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder, and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP facility and a staff of full-time veterinarians. **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above, another special feature is the location of the WRCEVA virus collection within the GNL.

Core E (Animal model development and preclinical evaluation). **Core E** operations will be conducted at the GNL, and in conjunction with **Core A**, will also include a regulatory expert from the UTMB Institutional Office of Regulated Nonclinical Studies (ORNcS). The ORNcS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL, and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses, arenaviruses, and henipaviruses. He has published over 250 peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI), was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs). Mapp Biopharmaceutical has deep experience with antigens and mAbs against these antigens. Their early development and research group has expertise in immunology, infectious diseases, and the production of antigens, antibodies, and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [101] [102]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1[103]. Dr. Gunn and Genovac will join the team to analyze antibody Fc effector functions and to provide antigen/antibody discovery resources, respectively. Dr. Geisbert will contribute his experience with high containment animal models and vaccine development. As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

CENTER OVERVIEW: *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction. Emerging and periodically reemerging pathogenic enveloped RNA viruses are continuous pandemic threats. Among viral taxon associated with human zoonoses, members of the family ***Paramyxoviridae*** and order ***Bunyavirales*** stand out for their capacity to cause debilitating and life-threatening disease**.** Humans can become infected via excreta from animal reservoir hosts such as rodents or bats, through intermediate amplifying hosts such as small or domestic animals, or by arthropod vectors such as mosquitos and ticks[1-4]. Humans often represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur. During this process, RNA viral pathogens may mutate and adapt to more efficiently replicate and shed in the host, posing an epidemic threat[5-8]. The viral order *Bunyavirales* is composed of several viral families containing high priority human pathogens[9]. Notably, the ***Arenaviridae*** and ***Nairoviridae*** families contain viruses that cause severe hemorrhagic fever diseases in humans globally with mortality rates up to 60%[10] and significant, long-term sequelae in survivors[11]. Many bunyaviruses are included on the World Health Organization's (WHO) List of Priority Pathogens[12,13]. Six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHAPV, GTOV, JUNV, MACV) and one nairovirus, Crimean-Congo Hemorrhagic Fever Virus (CCHFV), are also identified as NIAID Category A pathogens[14] due to their 1) high associated morbidity and mortality rates, 2) ease of dissemination and/or ability to transmit from person-to-person, 3) potential to cause public panic and social disruption, and 4) requirement for special actions in the context of public health preparedness. The ***Paramyxoviridae*** also includes members in the WHO Priority Pathogens, namely Nipah virus (NiV) and Hendra virus (HeV). These henipaviruses (HNVs) are the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease[15]. The genus now includes nine additional reported HNVs, but only HeV and NiV are associated with severe and often fatal henipaviral disease in humans and a number of animal species[16]. Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illness in humans[17].

These collective factors plus the absence of approved vaccines or therapeutics make bunyaviruses and paramyxoviruses a significant threat to global public health. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for developing vaccine and monoclonal antibody (mAb) countermeasures to prototype bunyavirus and paramyxovirus pathogens (**Table 1**). In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old World) Machupo (New World)	Lujo (Old World) Chapare (New World)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Table 1. PABVAX selected prototype and test case viral agents

***Arenaviridae**:* The *Arenaviridae* is composed of five genera: *Mammarenavirus*, *Reptarenavirus*, *Innmovirus*, *Antennavirus*, and *Hartmanivirus*[18]. The genus *Mammarenavirus* contains a large number of rodent-borne viruses, some of which cause severe hemorrhagic fever, neurological damage, death, and permanent sequelae; hearing loss, vision impairment, and balance issues in survivors[19]. While these genera exhibit a global distribution, two geographically distinct serogroups exist that diverged[20]. Old World complex mammarenaviruses (OWAV) in the Eastern Hemisphere include LASV, Lymphocytic Choriomeningitis Virus (LCMV), and the newly discovered LUJV; New World complex mammarenaviruses (NWAV) in the Western Hemisphere include JUNV, MACV, Sabia Virus (SABV), and CHAPV. There are no FDA approved vaccines or therapeutics for mammarenaviruses, though the attenuated JUNV "Candid-1" vaccine is approved for use in Argentina.

Disease severity and case fatality rates (CFR) vary across mammarenaviruses even within the same clades and species. Up to 500,000 cases of LASV infection occur per year with CFRs sometimes approaching 70% in hospitalized cases[21]. Before the introduction of the Candid-1 vaccine, it is believed that an upwards of 60,000 cases of Argentine Hemorrhagic Fever (AHF) from infection with JUNV occurred per year with CFRs ranging from 15-30%. Convalescent plasma from JUNV survivors is still the primary means to treat acute AHF in Argentina[22]. Over 1000 cases were reported for the initial outbreak of MACV with CFRs ranging from 5-30%; enhanced rodent abatement practices and potentially cross-protective immunity in populations that have taken the JUNV Candid-1 vaccine may have reduced recent outbreak frequency[23]. All mammarenaviruses share a common genomic organization consisting of two ambisense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix) and L protein (polymerase), and the glycoprotein precursor (GPC) and nucleoprotein (NP)[19]. Despite general similarity of their genomic architecture, mammarenaviruses exhibit marked differences in their replication life cycles including attachment factors, entry mechanisms, and immune evasion; nonetheless, the dominant antigens driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Despite the abundant genetic diversity of LASV, high levels of cross reactivity have been seen with antigen-based diagnostics across seven known lineages, suggesting the generation of cross-protective immunogens and antibodies against mammarenaviruses is achievable[24]. Monoclonal antibodies derived from human LASV survivors were shown to protect non-human primates (NHP) against lethal challenge[25]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[26]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, indicating this domain could serve as an antigenic target. Investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccines to test this approach and have demonstrated protection against lethal LASV-Josiah challenge. Specifically, a stabilized prefusion trimeric GPe, an immunogen containing a highly conserved NP NTD epitope, or a combination of these two approaches conferred protection in a lethal outbred guinea pig model. Nevertheless, even with the considerable molecular diversity in LASV strains, conservation at key antigenic sites within the GP and NP suggest a pan-LASV vaccine may be possible[24,27,28]. **RP1** and **Core E** investigators have demonstrated that a Vesicular stomatitis virus (rVSV)-based vaccine expressing the LASV-Josiah GPC is protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[29], and against heterologous challenge with Lineage II[30], III, V[31], and VI viruses (Cross and Geisbert Unpublished).

In **Phase I of RP1**, the ability of an optimized LASV GPe/NP subunit vaccine delivered intramuscularly (IM) will be assessed in guinea pig and NHP models across multiple viral lineages. We will also assess a microneedle skin patch (MNP) formulation optimized in **Core C** to determine if a needle-free vaccination route affords more potent vaccine-mediated responses and protection. Similarly, we have generated MACV GPe immunogens and will design a MACV NP-NTD subunit antigen to test the same approach across multiple MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing both OWAV (LUJV) and NWAV (CHAPV) complexes, for which there are no vaccines available. A unique advantage of the PABVAX Center is its access to biosafety level (BSL)-4 containment, allowing us to work with authentic versus surrogate arenaviruses. The BSL4 facilities described in **Core E** are capable of evaluating countermeasures in small animal models and NHPs. The cynomolgus macaque is the current “gold standard” animal model for LASV, JUNV, and MACV research as disease recapitulates human infection and there are a multitude of immunological reagents available[32-34]. The evaluation of prototype OWAV and NWAV vaccines and therapies in the NHP model is likely pivotal for IND applications and for future licensure of medical countermeasures for human use.

<u>Nairoviridae:</u> Unique to most bunyaviruses, orthonairoviruses are transmitted primarily by ticks[2]. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[35], Issyk-Kul virus[36], Songling virus[37]), CCHFV is the most recognized public health threat. Outbreaks of CCHFV have occurred across Europe, Africa, the Middle East, and Asia. There is growing concern for expansion of the CCHFV endemic region due to increased range of its tick host (*Hyalomma* spp.) tied to bird migration changes, livestock trade, and global warming. For example, CCHFV cases have been reported in Spain[38] , a previously non-endemic region, and *Hyalomma* ticks have been found in Sweden[39]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to a severe hemorrhagic fever and death in 30% of cases[40]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[41]. Ribavirin has been used to treat infections with limited success[42].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and GPC [40]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[40]. Conversely, the CCHFV GPC is considerably less conserved (< 75% amino acid identity)[40]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location. Thus, creating a pan-CCHFV vaccine or therapeutic based solely on one clade poses a challenge. Nevertheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a rVSV vectored vaccine expressing the full GPC of CCHFV[43].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP immunogens with the highest level of homology across clades. We will assess their capacity to protect against lethal challenge with isolates from multiple CCHFV clades in established mouse[43,44] and NHP[45] models with **Core E**. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best formulation of CCHFV GP/NP MNP vaccine against the emerging test case nairovirus, Kasokero virus, for which there are no vaccines available.

Paramyxoviridae: The HNVs NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality[4,46]. HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality[47]. NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs, which served as amplifying hosts[48]. NiV and HeV can infect at least 18 animal species across 6 orders of mammals, and among these they cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans[16,49]. The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission[5]. Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and Southeast Asia and Australia. Their broad host tropism and ability to infect livestock also causes increased risk of human infections. HNVs are single-stranded, negative sense, enveloped RNA viruses and their biology lends themselves to be synthetically produced. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS). The Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents[50] because the virus could be engineered for mass dissemination and it possesses the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the R&D Blueprint list of priority pathogens with epidemic potential[51].

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb exist. These postexposure treatments conferred protecion against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP)[52-55]. The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia[56]. In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs, and several vaccine platforms have clear potential for use in people[16]. The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies[16]. Such preventive vaccines would have utility for lab workers, first responders or individuals at high-risk exposure, and in mitigating the spread of an outbreak. In the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent[57]. It is widely considered that the African green monkey (AGM) is the current “gold standard” animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection[49,58]. The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished)[59]. The divergent LayV will be the focus of the test case studies. The choice is justifiable for several important reasons: 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; and 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including rescuing recombinant LayV (rLayV), exploring animal model development, constructing additional LayV and AngV reporter virus tools, and then translating and testing the MNP vaccine 'plug-and-play' approach. Finally, we will evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME. A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center's RPs and Core leaders currently have active and productive collaborative research programs in related areas, most spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

The pandemic preparedness research gaps addressed by PABVAX are diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **arenaviruses** and **nairoviruses**, and **RP2** will target the prototype **HNVs**. Both RP1 and RP2 will develop new prototype virus tools (recombinant prototype viruses) along with existing tools, to analyze vaccine responses and evaluate new mAbs and nabs from the other RPs. A third RP will develop a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant *Cedar henipavirus* (rCedV) in vivo and a bioluminescence detection method that can longitudinally trace the dynamics and anatomical progression of infection with a luciferase-encoding virus in individual animals (**RP3**). There will also be two RPs that focus on the development of broadly reactive human mAbs and nanobodies to the PABVAX selected viral prototypes. **RP4** will isolate human mAbs derived from NiV-infected survivors with a specific focus on F glycoprotein-targeting mAbs. Additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will engage in the manufacture, quality control, and testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**). Under the direction of the PD/PIs (Drs. Geisbert and Broder), the Administrative Core (**Core A**) will provide organizational and programmatic structure to promote research productivity and scientific interactions along with compliance with regulations concerning select agent, vertebrate animal, and human subject use. **Core A** will coordinate all activities with the Scientific Advisory Board (**SAB**) and make data available through the Data Management Core (**Core B**).

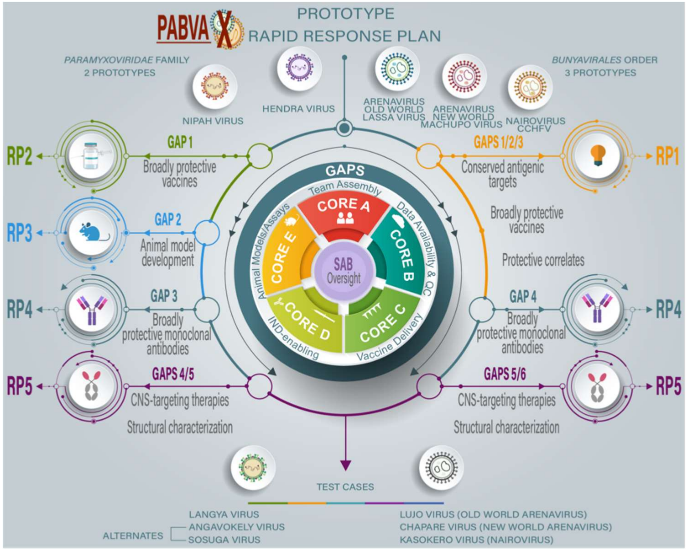

Figure 1: Research gaps addressed by the *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center- (PABVAX).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform. The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from the UPitt and IBBR/UMD (**Core C**). This project tested a dissolvable MNP-based vaccine technology ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine[60]. The MNP vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable microneedles that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants[61] to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as to facilitate improved vaccine storage and distribution due to their improved thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, Scientific **Core C** (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ)-adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (*Paramyxoviridae*). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity *in vitro*, along with analysis of polyfunctional T-cell responses by antigenic peptide stimulation, followed by intracellular cytokine staining (ICS) and flow cytometry.

Discover effective antibody-based prophylactics and therapies. Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah[62], Hendra[63], Ebola[64,65], Marburg[66] and Lassa[67]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc*.), a feature to be exploited in **Core D** by Dr. Gunn. In addition to therapeutic applications, mAbs with Fc mutations dramatically extend serum half-life[68-70] and offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g*. rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization, and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures. Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the Animal Model Development and Preclinical Evaluation Scientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective efficacy of antivirals and vaccines, as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation, including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within

RP1. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they are generally less laborious and can be adapted to higher throughput platforms and/or integrated with other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput fluorescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic NiV and HeV vaccine-induced immune sera, mAbs (**RP4**), nbs (**RP5**), and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either HeV or NiV-B envelope GPs) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals to explore nab based therapeutics to CNS resident HNVs[71].

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the HNVs (*Paramyxoviridae*) and the *Bunyavirales* (*Arenaviridae* and *Nairoviridae*) that will bolster vaccine endurance to storage and transportation; we also anticipate improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology, and mAb and vaccine translational drug development along with Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Paramyxoviruses: NiV and HeV are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis[4,46]. HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals. These viruses are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of CedV, Gamak virus, Daeryong virus, and (LayV)[72] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[73,74]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV, are old world pteropid fruit bats[73,75]. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of

apparent rodent origin from Southeast China (Yunnan province)[17]. The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**. Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal HNV disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters[49], and AGMs (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P). The P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists[76-80]. The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections[81,82]. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature[83]. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2[84] and CedV is now recognized as a BSL-2 restricted agent[85]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D,** and **E**).

Figure 2: Phylogenetic analysis of select HNV G and F glycoproteins. Trees were constructed for using the PhyML program's maximum likelihood method and aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Arenaviruses (old world): For **phase 1**, **RP1** will utilize **LASV as the prototype virus** due its significant public health burden throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[86]. LASV is the most imported viral hemorrhagic fever (VHF) next to Dengue virus and has been documented in several countries outside of Africa over 35 times[87]. CFRs approaching 70% in hospitalized cases and marked long term sequelae are the result of the lack of approved vaccines or therapeutics, although several live attenuated virus candidates are currently being evaluated with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI)[88]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize only LASV GP as the target immunogen.

Investigators in **RP1**, **Core D**, and **Core E** have already demonstrated protective efficacy against challenge with LASV in outbred guinea pigs vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These immunogens have been engineered to express homologous antigenic regions to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach suggests a similar strategy could be implemented against other arenaviruses. The **OWAV test pathogen, LUJV,** was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia, which quickly spread nosocomially[89]. The CFR for this infectious virus was 80% in this small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from suggest current LASV countermeasures may be of limited use. LUJV will serve as an ideal "test case" to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Arenaviruses (new world): The live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[90], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[91,92]. Furthermore, there is the potential for pathogenic reversion. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest exploring other JUNV countermeasures are warranted. Building on the success of the LASV GPe/NP-NTD, investigators in **RP1 and Cores D and E** will engineer broadly protective MACV GPe and NP-NTD antigens and perform efficacy testing in established guinea pig and NHP models. We will extend this plug-and-play approach to the **NWAV test case, CHAPV**. First reported in 2003 in Bolivia, CHAPV is a rodent-borne mammarenavirus associated with the development of severe hemorrhagic fever with case fatality rates up to 60%[93,94]. Recent studies have demonstrated clear human-to-human transmission during the acute phase evidenced by several nosocomial infections; isolation of viable virus from semen at 86 days after symptom onset demonstrates a clear need to implement specialized management and treatment [94]. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Nairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as it represents the largest global public health burden within the orthonairovirus family with outbreaks annually across Europe, Africa, and Asia. There are no FDA-approved vaccines for CCHFV; however, a suckling mouse brain-derived, adjuvanted whole virus vaccine for CCHFV has been approved for use in Bulgaria. This vaccine has numerous safety concerns and has limited demonstrated efficacy. Several experimental vaccine approaches have been evaluated ranging from viral vectored approaches to DNA-based vaccines with varying efficacy, advantages, and disadvantages[95]; however, only a Modified Vaccinia Ankara virus vaccine (MVA-CCHFV) has begun to advance towards clinical trials[96]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test these for protective efficacy from challenge with 6 different CCHFV lineages using established mouse and NHP models. Next, we will deploy the same approach to the **test case nairovirus, Kasokero virus (KASV),** for which no vaccine exists.

In 1977, KASV was first isolated from Ugandan bats and caused several cases of acute febrile illness of laboratory workers from the same lab that processed the infected bats[97]. Surveys of 109 laboratory workers from the same facility demonstrated 13% seropositivity and clinical symptoms in individuals 4 to 15 months after the virus was isolated. These findings suggest either continued laboratory-associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the tick reservoir, *Ornithodoros faini,* to participate in enzootic maintenance of KASV[98]. While most chiropteran ticks exhibit host specificity, humans entering caves these bats inhabit have reported bites from *O.faini* ticks. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics suggest investment in countermeasure development against this virus is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**; arenavirus and nairovirus projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine active and passive immunization approaches to further improve the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

An additional and outstanding advantage of the PABVAX Center is the **Animal Model Development and Preclinical Evaluation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for members of the *Bunyavirales* and *Paramyxoviridae*.**
2. **Develop new tools and animal models for cell-based and *in vivo* therapeutic evaluation.**
3. **Develop antibodies and nanobodies to the selected prototype and test viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

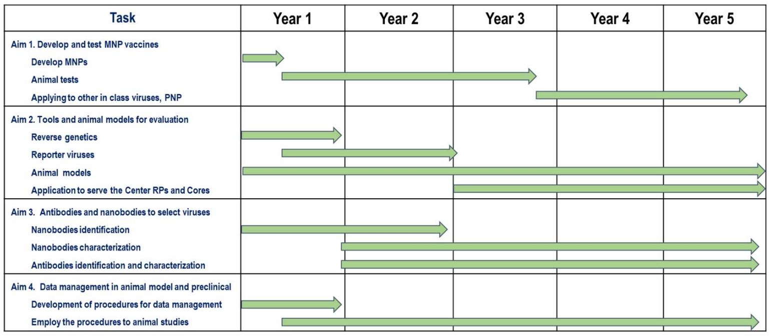

Figure 3: Projected PABVAX timeline to achieve the 4 overarching tasks.

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**. Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (details are specified within the Administration **Core A** Research Strategy). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommending new directions as appropriate, and providing Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

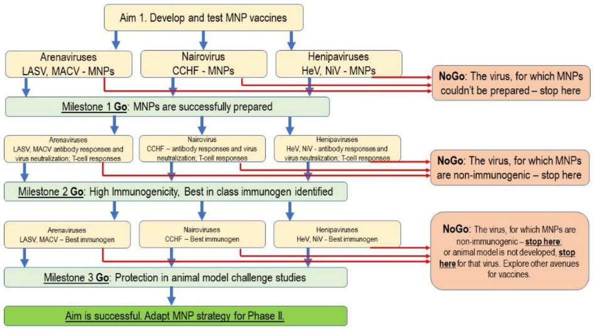

Figure 4. Milestones and criteria for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will address whether formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be established using immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen-specific antibody induction, virus neutralization, and polyfunctional T-cell responses by *in vitro* stimulation of isolated cells). Go/no go decisions will be made based on outcomes of these first-tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as a success. Comparisons will also be made such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of the best-in-class immunogens, or immunogen combinations, will also be explored to down-select vaccines. The third milestone will determine whether MNP vaccination affords protection in animal model challenge experiments. In the case of NiV and HeV prototypes, the animal models chosen (ferrets and AGMs) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales*, there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASV and guinea pig models exist for some but not all of these lineages. For MACV, there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is the limitations of cost and availability of rhesus and cynomolgus monkeys. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be developing and evaluating animal models within the PABVAX program, including further development of AGM models for arenaviruses and possibly CCHFV as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for cell-based and in vivo therapeutics evaluation.

The second overall objective of PABVAX is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed because genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If successful, a large battery of new materials will be available to share with the ReVAMPP network, and be key milestones for execution of Phase II of the PABVAX Center program.

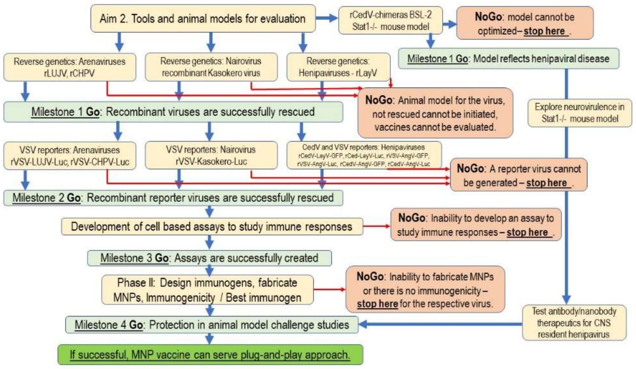

Figure 5. Milestones and criteria for **Aim 2** of the PABVAX Center's overall objectives.

The translation of the MNP vaccine plug-and-play approach will be in Phase II (**Table 1**). Milestones will be similar to those in **Figure 4**. New virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new *in vivo* bioluminescence-based immune deficient mouse model developed by the PIs of **PR2** and **RP3** that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease *in vivo* safely and expediently at BSL-2 containment. The model will be deployed to test a critically important therapeutic need against CNS resident HNV infection, and **RP3** will collaborate with **RP5** in the testing of engineered nabs.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

New human mAbs and nbs as tools and potential therapeutics will be developed by **RP4** and **RP5** in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs, and in collaboration with **RP2**, neutralization potencies will be rapidly assessed (as well as evaluating synergistic cell-based mAb neutralization) that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

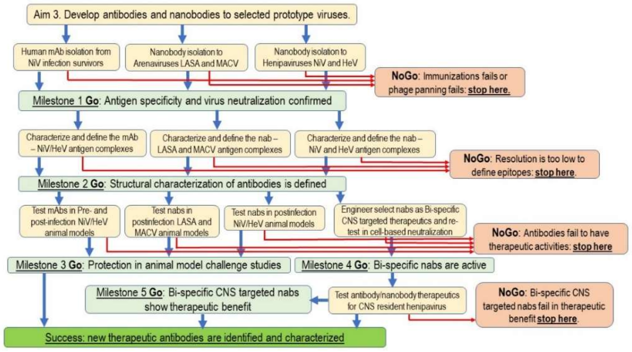

Figure 5. Milestones and criteria for **Aim 3** of the PABVAX Center's overall objectives.

Nbs, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nbs can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nbs targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus), and select animal models of LASV and MACV by **Core E**. Success will be measured by the 1) identification of potent virus-neutralizing nbs, 2) discovery of more broadly reactive nbs particularly to the multiple LASV clades, 3) evidence of therapeutic benefit in animal models, and 4) the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

Industry Partnerships. ~~*Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner that will provide access to vaccine expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.*~~

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience in developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX. Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

SPECIAL FEATURES OF THE PABVAX

Galveston National Laboratory (GNL). The GNL is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The

GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics, and therapeutics. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370 NHP studies employing some 2,772 animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses have been performed. These studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder, and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP facility and a staff of full-time veterinarians. **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above another special feature is the location of the WRCEVA virus collection within the GNL.

***Core E (Animal model development and preclinical evaluation)*. Core E** operations will be conducted at the GNL, and in conjunction with **Core A**, will also include the UTMB Institutional Office of Regulated Nonclinical Studies (ORNcS). The ORNcS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a “well documented” quality system program. Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL, and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses, arenaviruses, and henipaviruses. He has published over 250 peer-reviewed articles in these areas. Dr. Geisbert’s research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI), was the first to develop a NHP model of NiV/HeV infection and disease, and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs). Mapp Biopharmaceutical has deep experience with antigens and mAbs against these antigens. Their early development and research group has expertise in immunology, infectious diseases, and the production of antigens, antibodies, and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [99] [100]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1[101]. Dr. Gunn and Genovac will join the team to analyze antibody Fc effector functions and to provide antigen/antibody discovery resources, respectively. Dr. Geisbert will contribute his experience with high containment animal models and vaccine development.

As per NIAID’s expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID’s preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID’s preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

CENTER OVERVIEW: *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction. Emerging and periodically reemerging pathogenic enveloped RNA viruses are continuous pandemic threats. Among viral taxon associated with human zoonoses, members of the family ***Paramyxoviridae*** and order ***Bunyavirales*** stand out for their capacity to cause debilitating and life-threatening disease**.** Humans can become infected via excreta from animal reservoir hosts such as rodents or bats, through intermediate amplifying hosts such as small or domestic animals, or by arthropod vectors such as mosquitos and ticks[1-4]. Humans often represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur. During this process, RNA viral pathogens may mutate and adapt to more efficiently replicate and shed in the host, posing an epidemic threat[5-8]. The viral order *Bunyavirales* is composed of several viral families containing high priority human pathogens[9]. Notably, the ***Arenaviridae*** and ***Nairoviridae*** families contain viruses that cause severe hemorrhagic fever diseases in humans globally with mortality rates up to 60%[10] and significant, long-term sequelae in survivors[11]. Many bunyaviruses are included on the World Health Organization's (WHO) List of Priority Pathogens[12,13]. Six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHAPV, GTOV, JUNV, MACV) and one nairovirus, Crimean-Congo Hemorrhagic Fever Virus (CCHFV), are also identified as NIAID Category A pathogens[14] due to their 1) high associated morbidity and mortality rates, 2) ease of dissemination and/or ability to transmit from person-to-person, 3) potential to cause public panic and social disruption, and 4) requirement for special actions in the context of public health preparedness. The ***Paramyxoviridae*** also includes members in the WHO Priority Pathogens, namely Nipah virus (NiV) and Hendra virus (HeV). These henipaviruses (HNVs) are the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease[15]. The genus now includes nine additional reported HNVs, but only HeV and NiV are associated with severe and often fatal henipaviral disease in humans and a number of animal species[16]. Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illness in humans[17].

These collective factors plus the absence of approved vaccines or therapeutics make bunyaviruses and paramyxoviruses a significant threat to global public health. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for developing vaccine and monoclonal antibody (mAb) countermeasures to prototype bunyavirus and paramyxovirus pathogens (**Table 1**). In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old World) Machupo (New World)	Lujo (Old World) Chapare (New World)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Table 1. PABVAX selected prototype and test case viral agents

Arenaviridae*:* The *Arenaviridae* is composed of five genera: *Mammarenavirus*, *Reptarenavirus*, *Innmovirus*, *Antennavirus*, and *Hartmanivirus*[18]. The genus *Mammarenavirus* contains a large number of rodent-borne viruses, some of which cause severe hemorrhagic fever, neurological damage, death, and permanent sequelae; hearing loss, vision impairment, and balance issues in survivors[19]. While these genera exhibit a global distribution, two geographically distinct serogroups exist that diverged[20]. Old World complex mammarenaviruses (OWAV) in the Eastern Hemisphere include LASV, Lymphocytic Choriomeningitis Virus (LCMV), and the newly discovered LUJV; New World complex mammarenaviruses (NWAV) in the Western Hemisphere include JUNV, MACV, Sabia Virus (SABV), and CHAPV. There are no FDA approved vaccines or therapeutics for mammarenaviruses, though the attenuated JUNV "Candid-1" vaccine is approved for use in Argentina.

Disease severity and case fatality rates (CFR) vary across mammarenaviruses even within the same clades and species. Up to 500,000 cases of LASV infection occur per year with CFRs sometimes approaching 70% in hospitalized cases[21]. Before the introduction of the Candid-1 vaccine, it is believed that an upwards of 60,000 cases of Argentine Hemorrhagic Fever (AHF) from infection with JUNV occurred per year with CFRs ranging from 15-30%. Convalescent plasma from JUNV survivors is still the primary means to treat acute AHF in Argentina[22]. Over 1000 cases were reported for the initial outbreak of MACV with CFRs ranging from 5-30%; enhanced rodent abatement practices and potentially cross-protective immunity in populations that have taken the JUNV Candid-1 vaccine may have reduced recent outbreak frequency[23]. All mammarenaviruses share a common genomic organization consisting of two ambisense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix) and L protein (polymerase), and the glycoprotein precursor (GPC) and nucleoprotein (NP)[19]. Despite general similarity of their genomic architecture, mammarenaviruses exhibit marked differences in their replication life cycles including attachment factors, entry mechanisms, and immune evasion; nonetheless, the dominant antigens driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Despite the abundant genetic diversity of LASV, high levels of cross reactivity have been seen with antigen-based diagnostics across seven known lineages, suggesting the generation of cross-protective immunogens and antibodies against mammarenaviruses is achievable[24]. Monoclonal antibodies derived from human LASV survivors were shown to protect non-human primates (NHP) against lethal challenge[25]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[26]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, indicating this domain could serve as an antigenic target. Investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccines to test this approach and have demonstrated protection against lethal LASV-Josiah challenge. Specifically, a stabilized prefusion trimeric GPe, an immunogen containing a highly conserved NP NTD epitope, or a combination of these two approaches conferred protection in a lethal outbred guinea pig model. Nevertheless, even with the considerable molecular diversity in LASV strains, conservation at key antigenic sites within the GP and NP suggest a pan-LASV vaccine may be possible[24,27,28]. **RP1** and **Core E** investigators have demonstrated that a Vesicular stomatitis virus (rVSV)-based vaccine expressing the LASV-Josiah GPC is protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[29], and against heterologous challenge with Lineage II[30], III, V[31], and VI viruses (Cross and Geisbert Unpublished).

In **Phase I of RP1**, the ability of an optimized LASV GPe/NP subunit vaccine delivered intramuscularly (IM) will be assessed in guinea pig and NHP models across multiple viral lineages. We will also assess a microneedle skin patch (MNP) formulation optimized in **Core C** to determine if a needle-free vaccination route affords more potent vaccine-mediated responses and protection. Similarly, we have generated MACV GPe immunogens and will design a MACV NP-NTD subunit antigen to test the same approach across multiple MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing both OWAV (LUJV) and NWAV (CHAPV) complexes, for which there are no vaccines available. A unique advantage of the PABVAX Center is its access to biosafety level (BSL)-4 containment, allowing us to work with authentic versus surrogate arenaviruses. The BSL4 facilities described in **Core E** are capable of evaluating countermeasures in small animal models and NHPs. The cynomolgus macaque is the current "gold standard" animal model for LASV, JUNV, and MACV research as disease recapitulates human infection and there are a multitude of immunological reagents available[32-34]. The evaluation of prototype OWAV and NWAV vaccines and therapies in the NHP model is likely pivotal for IND applications and for future licensure of medical countermeasures for human use.

__Nairoviridae:__ Unique to most bunyaviruses, orthonairoviruses are transmitted primarily by ticks[2]. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[35], Issyk-Kul virus[36], Songling virus[37]), CCHFV is the most recognized public health threat. Outbreaks of CCHFV have occurred across Europe, Africa, the Middle East, and Asia. There is growing concern for expansion of the CCHFV endemic region due to increased range of its tick host (*Hyalomma* spp.) tied to bird migration changes, livestock trade, and global warming. For example, CCHFV cases have been reported in Spain[38] , a previously non-endemic region, and *Hyalomma* ticks have been found in Sweden[39]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to a severe hemorrhagic fever and death in 30% of cases[40]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[41]. Ribavirin has been used to treat infections with limited success[42].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and GPC [40]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[40]. Conversely, the CCHFV GPC is considerably less conserved (< 75% amino acid identity)[40]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location. Thus, creating a pan-CCHFV vaccine or therapeutic based solely on one clade poses a challenge. Nevertheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a rVSV vectored vaccine expressing the full GPC of CCHFV[43].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP immunogens with the highest level of homology across clades. We will assess their capacity to protect against lethal challenge with isolates from multiple CCHFV clades in established mouse[43,44] and NHP[45] models with **Core E**. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best formulation of CCHFV GP/NP MNP vaccine against the emerging test case nairovirus, Kasokero virus, for which there are no vaccines available.

<u>Paramyxoviridae:</u> The HNVs NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality[4,46]. HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality[47]. NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs, which served as amplifying hosts[48]. NiV and HeV can infect at least 18 animal species across 6 orders of mammals, and among these they cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans[16,49]. The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission[5]. Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and Southeast Asia and Australia. Their broad host tropism and ability to infect livestock also causes increased risk of human infections. HNVs are single-stranded, negative sense, enveloped RNA viruses and their biology lends themselves to be synthetically produced. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS). The Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents[50] because the virus could be engineered for mass dissemination and it possesses the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the R&D Blueprint list of priority pathogens with epidemic potential[51].

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb exist. These postexposure treatments conferred protecion against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP)[52-55]. The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia[56]. In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs, and several vaccine platforms have clear potential for use in people[16]. The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies[16]. Such preventive vaccines would have utility for lab workers, first responders or individuals at high-risk exposure, and in mitigating the spread of an outbreak. In the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent[57]. It is widely considered that the African green monkey (AGM) is the current “gold standard” animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection[49,58]. The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished)[59]. The divergent LayV will be the focus of the test case studies. The choice is justifiable for several important reasons: 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; and 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including rescuing recombinant LayV (rLayV), exploring animal model development, constructing additional LayV and AngV reporter virus tools, and then translating and testing the MNP vaccine 'plug-and-play' approach. Finally, we will evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME. A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center's RPs and Core leaders currently have active and productive collaborative research programs in related areas, most spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

The pandemic preparedness research gaps addressed by PABVAX are diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **arenaviruses** and **nairoviruses**, and **RP2** will target the prototype **HNVs**. Both RP1 and RP2 will develop new prototype virus tools (recombinant prototype viruses) along with existing tools, to analyze vaccine responses and evaluate new mAbs and nabs from the other RPs. A third RP will develop a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant *Cedar henipavirus* (rCedV) in vivo and a bioluminescence detection method that can longitudinally trace the dynamics and anatomical progression of infection with a luciferase-encoding virus in individual animals (**RP3**). There will also be two RPs that focus on the development of broadly reactive human mAbs and nanobodies to the PABVAX selected viral prototypes. **RP4** will isolate human mAbs derived from NiV-infected survivors with a specific focus on F glycoprotein-targeting mAbs. Additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will engage in the manufacture, quality control, and testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**). Under the direction of the PD/PIs (Drs. Geisbert and Broder), the Administrative Core (**Core A**) will provide organizational and programmatic structure

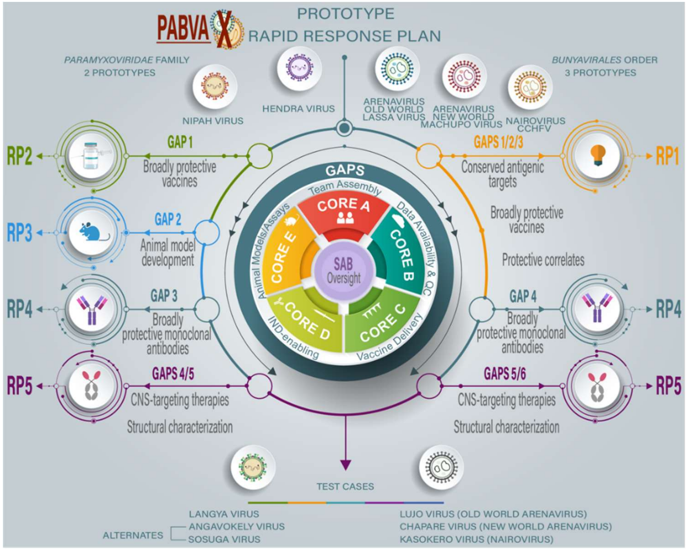

Figure 1: Research gaps addressed by the *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center- (PABVAX).

to promote research productivity and scientific interactions along with compliance with regulations concerning select agent, vertebrate animal, and human subject use. **Core A** will coordinate all activities with the Scientific Advisory Board (**SAB**) and make data available through the Data Management Core (**Core B**).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform. The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from the UPitt and IBBR/UMD (**Core C**). This project tested a dissolvable MNP-based vaccine technology ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine[60]. The MNP vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable microneedles that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants[61] to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as to facilitate improved vaccine storage and distribution due to their improved thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, Scientific **Core C** (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ)-adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (*Paramyxoviridae*). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity *in vitro*, along with analysis of polyfunctional T-cell responses by antigenic peptide stimulation, followed by intracellular cytokine staining (ICS) and flow cytometry.

Discover effective antibody-based prophylactics and therapies. Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah[62], Hendra[63], Ebola[64,65], Marburg[66] and Lassa[67]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc*.), a feature to be exploited in **Core D** by Dr. Gunn. In addition to therapeutic applications, mAbs with Fc mutations dramatically extend serum half-life[68-70] and offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g*. rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization, and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures. Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the Animal Model Development and Preclinical Evaluation Scientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective efficacy of antivirals and vaccines, as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation, including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they are generally less laborious and can be adapted to higher throughput platforms and/or integrated with other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput fluorescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic NiV and HeV vaccine-induced immune sera, mAbs (**RP4**), nbs (**RP5**), and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either HeV or NiV-B envelope GPs) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals to explore nab based therapeutics to CNS resident HNVs[71].

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the HNVs (*Paramyxoviridae*) and the *Bunyavirales* (*Arenaviridae* and *Nairoviridae*) that will bolster vaccine endurance to storage and transportation; we also anticipate improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology, and mAb and vaccine translational drug development along with Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Paramyxoviruses: NiV and HeV are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis[4,46]. HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals. These viruses are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of CedV, Gamak virus, Daeryong virus, and (LayV)[72] and five additional species known only from nucleic acid sequence information;

Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[73,74]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV, are old world pteropid fruit bats[73,75]. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province)[17]. The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**. Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal HNV disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters[49], and AGMs (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P). The P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists[76-80]. The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections[81,82]. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature[83]. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2[84] and CedV is now recognized as a BSL-2 restricted agent[85]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D,** and **E**).

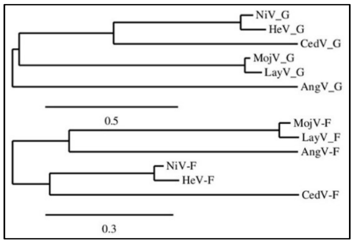

Figure 2: Phylogenetic analysis of select HNV G and F glycoproteins. Trees were constructed for using the PhyML program's maximum likelihood method and aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Arenaviruses (old world): For **phase 1**, **RP1** will utilize **LASV as the prototype virus** due its significant public health burden throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[86]. LASV is the most imported viral hemorrhagic fever (VHF) next to Dengue virus and has been documented in several countries outside of Africa over 35 times[87]. CFRs approaching 70% in hospitalized cases and marked long term sequelae are the result of the lack of approved vaccines or therapeutics, although several live attenuated virus candidates are currently being evaluated with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI)[88]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize only LASV GP as the target immunogen.

Investigators in **RP1**, **Core D**, and **Core E** have already demonstrated protective efficacy against challenge with LASV in outbred guinea pigs vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These immunogens have been engineered to express homologous antigenic regions to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach suggests a similar strategy could be implemented against other arenaviruses. The **OWAV test pathogen, LUJV,** was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia, which quickly spread nosocomially[89]. The CFR for this infectious virus was 80% in this small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from suggest current LASV countermeasures may be of limited use. LUJV will serve as an ideal "test case" to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Arenaviruses (new world): The live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[90], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[91,92]. Furthermore, there is the potential for pathogenic reversion. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest exploring other JUNV countermeasures are warranted.

Building on the success of the LASV GPe/NP-NTD, investigators in **RP1 and Cores D and E** will engineer broadly protective MACV GPe and NP-NTD antigens and perform efficacy testing in established guinea pig and NHP models. We will extend this plug-and-play approach to the **NWAV test case, CHAPV**. First reported in 2003 in Bolivia, CHAPV is a rodent-borne mammarenavirus associated with the development of severe hemorrhagic fever with case fatality rates up to 60%[93,94]. Recent studies have demonstrated clear human-to-human transmission during the acute phase evidenced by several nosocomial infections; isolation of viable virus from semen at 86 days after symptom onset demonstrates a clear need to implement specialized management and treatment [94]. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Nairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as it represents the largest global public health burden within the orthonairovirus family with outbreaks annually across Europe, Africa, and Asia. There are no FDA-approved vaccines for CCHFV; however, a suckling mouse brain-derived, adjuvanted whole virus vaccine for CCHFV has been approved for use in Bulgaria. This vaccine has numerous safety concerns and has limited demonstrated efficacy. Several experimental vaccine approaches have been evaluated ranging from viral vectored approaches to DNA-based vaccines with varying efficacy, advantages, and disadvantages[95]; however, only a Modified Vaccinia Ankara virus vaccine (MVA-CCHFV) has begun to advance towards clinical trials[96]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test these for protective efficacy from challenge with 6 different CCHFV lineages using established mouse and NHP models. Next, we will deploy the same approach to the **test case nairovirus, Kasokero virus (KASV),** for which no vaccine exists.

In 1977, KASV was first isolated from Ugandan bats and caused several cases of acute febrile illness of laboratory workers from the same lab that processed the infected bats[97]. Surveys of 109 laboratory workers from the same facility demonstrated 13% seropositivity and clinical symptoms in individuals 4 to 15 months after the virus was isolated. These findings suggest either continued laboratory-associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the tick reservoir, *Ornithodoros faini,* to participate in enzootic maintenance of KASV[98]. While most chiropteran ticks exhibit host specificity, humans entering caves these bats inhabit have reported bites from *O.faini* ticks. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics suggest investment in countermeasure development against this virus is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**; arenavirus and nairovirus projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine active and passive immunization approaches to further improve the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

An additional and outstanding advantage of the PABVAX Center is the **Animal Model Development and Preclinical Evaluation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for members of the *Bunyavirales* and *Paramyxoviridae*.**
2. **Develop new tools and animal models for cell-based and *in vivo* therapeutic evaluation.**
3. **Develop antibodies and nanobodies to the selected prototype and test viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

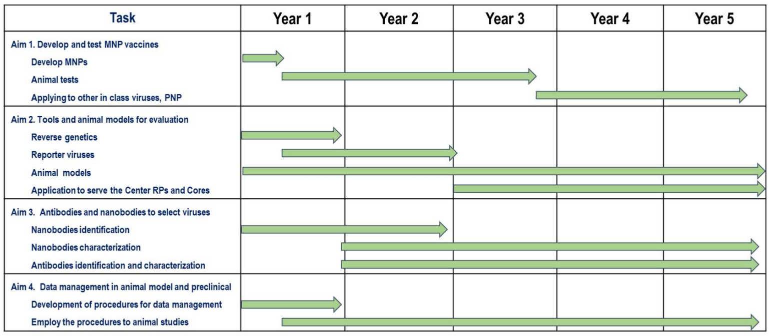

Figure 3: Projected PABVAX timeline to achieve the 4 overarching tasks.

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**. Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (details are specified within the Administration **Core A** Research Strategy). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommending new directions as appropriate, and providing Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

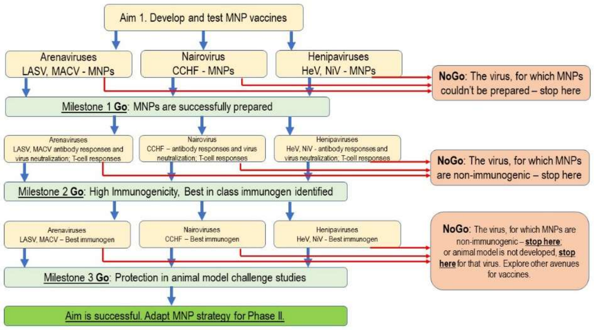

Figure 4. Milestones and criteria for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will address whether formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be established using immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen-specific antibody induction, virus neutralization, and polyfunctional T-cell responses by *in vitro* stimulation of isolated cells). Go/no go decisions will be made based on outcomes of these first-tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as a success. Comparisons will also be made such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of the best-in-class immunogens, or immunogen combinations, will also be explored to down-select vaccines. The third milestone will determine whether MNP vaccination affords protection in animal model challenge experiments. In the case of NiV and HeV prototypes, the animal models chosen (ferrets and AGMs) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales*, there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASV and guinea pig models exist for some but not all of these lineages. For MACV, there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is the limitations of cost and availability of rhesus and cynomolgus monkeys. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be developing and evaluating animal models within the PABVAX program, including further development of AGM models for arenaviruses and possibly CCHFV as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for cell-based and in vivo therapeutics evaluation.

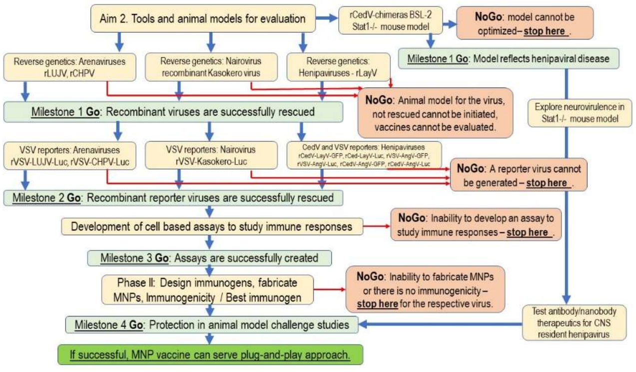

Figure 5. Milestones and criteria for **Aim 2** of the PABVAX Center's overall objectives.

The second overall objective of PABVAX is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed because genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If successful, a large battery of new materials will be available to share with the ReVAMPP network, and be key milestones for execution of Phase II of the PABVAX Center program.

The translation of the MNP vaccine plug-and-play approach will be in Phase II (**Table 1**). Milestones will be similar to those in **Figure 4**. New virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new *in vivo* bioluminescence-based immune deficient mouse model developed by the PIs of **PR2** and **RP3** that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease *in vivo* safely and expediently at BSL-2 containment. The model will be deployed to test a critically important therapeutic need against CNS resident HNV infection, and **RP3** will collaborate with **RP5** in the testing of engineered nabs.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

New human mAbs and nbs as tools and potential therapeutics will be developed by **RP4** and **RP5** in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs, and in collaboration with **RP2**, neutralization potencies will be rapidly assessed (as well as evaluating synergistic cell-based mAb neutralization) that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

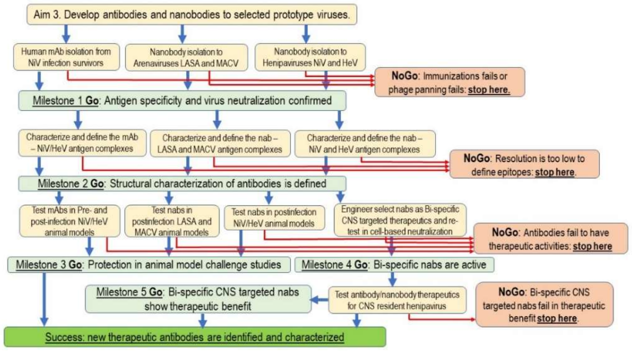

Figure 5. Milestones and Criteria for **Aim 3** of the PABVAX Center's overall objectives.

Nbs, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nbs can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nbs targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus), and select animal models of LASV and MACV by **Core E**. Success will be measured by the 1) identification of potent virus-neutralizing nbs, 2) discovery of more broadly reactive nbs particularly to the multiple LASV clades, 3) evidence of therapeutic benefit in animal models, and 4) the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

Industry Partnerships*. Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner that will provide access to vaccine expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.*

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience in developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX. Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Commented [LZ2]: I can expand on this if needed.

SPECIAL FEATURES OF THE PABVAX

Galveston National Laboratory (GNL). The GNL is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics, and therapeutics. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370 NHP studies employing some 2,772 animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses have been performed. These studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder, and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP facility and a staff of full-time veterinarians. **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above another special feature is the location of the WRCEVA virus collection within the GNL.

***Core E (Animal model development and preclinical evaluation)*. Core E** operations will be conducted at the GNL, and in conjunction with **Core A**, will also include the UTMB Institutional Office of Regulated Nonclinical Studies (ORNcS). The ORNcS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL, and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses, arenaviruses, and henipaviruses. He has published over 250 peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI), was the first to develop a NHP model of NiV/HeV infection and disease, and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs). Mapp Biopharmaceutical has deep experience with antigens and mAbs against these antigens. Their early development and research group has expertise in immunology, infectious diseases, and the production of antigens, antibodies, and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [99] [100]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-

Ebolavirus therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1[101]. Dr. Gunn and Genovac will join the team to analyze antibody Fc effector functions and to provide antigen/antibody discovery resources, respectively.

As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

Commented [LZ3]: Chris…not sure where this fits best, but its something the RFA mentions we should address…

CENTER OVERVIEW: *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction. Emerging and periodically reemerging pathogenic enveloped RNA viruses are continuous pandemic threats. Among viral taxon associated with human zoonoses, members of the family ***Paramyxoviridae*** and order ***Bunyavirales*** stand out for their capacity to cause debilitating and life-threatening disease**.** Humans can become infected via excreta from animal reservoir hosts such as rodents or bats, through intermediate amplifying hosts such as small or domestic animals, or by arthropod vectors such as mosquitos and ticks[1-4]. Humans often represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur. During this process, RNA viral pathogens may mutate and adapt to more efficiently replicate and shed in the host, posing an epidemic threat[5-8]. The viral order *Bunyavirales* is composed of several viral families containing high priority human pathogens[9]. Notably, the ***Arenaviridae*** and ***Nairoviridae*** families contain viruses that cause severe hemorrhagic fever diseases in humans globally with mortality rates up to 60%[10] and significant, long-term sequelae in survivors[11]. Many bunyaviruses are included on the World Health Organization's (WHO) List of Priority Pathogens[12,13]. Six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHAPV, GTOV, JUNV, MACV) and one nairovirus, Crimean-Congo Hemorrhagic Fever Virus (CCHFV), are also identified as NIAID Category A pathogens[14] due to their 1) high associated morbidity and mortality rates, 2) ease of dissemination and/or ability to transmit from person-to-person, 3) potential to cause public panic and social disruption, and 4) requirement for special actions in the context of public health preparedness. The family ***Paramyxoviridae*** also includes members that are WHO Priority Pathogens, namely Nipah virus (NiV) and Hendra virus (HeV). These zoonotic henipaviruses (HNVs) are considered prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease[15]. The genus now includes nine additional reported HNVs, but only HeV and NiV are associated with severe and often fatal henipaviral disease in humans and a number of animal species[16]. Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illness in humans[17].

Commented [CB1]: I think as you review this doc, perhaps specifically name the PIs and PLs in certain areas?

These collective factors plus the absence of approved vaccines or therapeutics make bunyaviruses and paramyxoviruses a significant threat to global public health. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for developing vaccine and monoclonal antibody (mAb) countermeasures to prototype bunyavirus and paramyxovirus pathogens (**Table 1**). In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old World) Machupo (New World)	Lujo (Old World) Chapare (New World)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Table 1. PABVAX selected prototype and test case viral agents

Arenaviridae*:* The family *Arenaviridae* is composed of five genera: *Mammarenavirus*, *Reptarenavirus*, *Innmovirus*, *Antennavirus*, and *Hartmanivirus*[18]. The genus *Mammarenavirus* contains a large number of rodent-borne viruses, some of which cause severe hemorrhagic fever, neurological damage, death, and permanent sequelae such as hearing loss, vision impairment, and balance issues in survivors[19]. While these genera exhibit a global distribution, two geographically distinct serogroups exist that diverged ~45,000 years ago[20]. Old World complex mammarenaviruses (OWAV) in the Eastern Hemisphere include LASV, Lymphocytic Choriomeningitis Virus (LCMV), and the newly discovered LUJV; New World complex mammarenaviruses (NWAV) in the Western Hemisphere include JUNV, MACV, Sabia Virus (SABV), and CHAPV. There are currently no US FDA approved vaccines or therapeutics for mammarenaviruses, though the attenuated JUNV "Candid-1" vaccine is approved for use in Argentina.

Disease severity and case fatality rates (CFR) vary across mammarenaviruses even within the same clades and species. Up to 500,000 cases of LASV infection occur per year with CFRs sometimes approaching 70% in hospitalized cases[21]. Before the introduction of the Candid-1 vaccine, it is believed that an upwards of 60,000 cases of Argentine Hemorrhagic Fever (AHF) from infection with JUNV occurred per year with CFRs ranging from 15-30%. Convalescent plasma from JUNV survivors is still the primary means to treat acute AHF in Argentina[22]. Over 1000 cases were reported for the initial outbreak of MACV with CFRs ranging from 5-30%;

enhanced rodent abatement practices and potentially cross-protective immunity in populations that have taken the JUNV Candid-1 vaccine may have reduced recent outbreak frequency[23].

All mammarenaviruses share a common genomic organization consisting of two ambisense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix) and L protein (polymerase), and the glycoprotein precursor (GPC) and nucleoprotein (NP)[19]. Despite general similarity of their genomic architecture, mammarenaviruses exhibit marked differences in their replication life cycles including attachment factors, entry mechanisms, and immune evasion; nonetheless, the dominant antigens driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Despite the abundant genetic diversity of LASV, high levels of cross reactivity have been seen with antigen-based diagnostics across seven known lineages, suggesting the generation of cross-protective immunogens and antibodies against mammarenaviruses is achievable[24]. Monoclonal antibodies derived from human LASV survivors were shown to protect non-human primates (NHP) against lethal challenge[25]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[26]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, indicating this domain could serve as an antigenic target. Investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccines to test this approach and have demonstrated protection against lethal LASV-Josiah challenge. Specifically, a stabilized prefusion trimeric GPe, an immunogen containing a highly conserved NP NTD epitope, or a combination of these two approaches conferred protection in a lethal outbred guinea pig model.

Despite the considerable molecular diversity in LASV strains, conservation at key antigenic sites within the GP and NP suggest the feasibility of generating a pan-LASV vaccine[24,27,28]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a recombinant Vesicular stomatitis virus (rVSV)-based vector expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[29], but also protects against heterologous challenge with Lineage II[30], III (Cross, Geisbert unpublished), V[31], and VI viruses (Cross and Geisbert Unpublished).

In **Phase I of RP1**, the ability of an optimized LASV GPe/NP subunit vaccine delivered intramuscularly (IM) will be assessed in guinea pig and NHP models across multiple viral lineages. We will also assess a microneedle skin patch (MNP) formulation optimized in **Core C** to determine if a needle-free vaccination route affords more potent vaccine-mediated responses and protection. Similarly, we have generated MACV GPe immunogens and will design a MACV NP-NTD subunit antigen to test the same approach across multiple MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing both OWAV (LUJV) and NWAV (CHAPV) complexes, for which there are no vaccines available. A unique advantage of the PABVAX Center is its access to biosafety level (BSL)-4 containment, allowing us to work with authentic versus surrogate arenaviruses. The BSL4 facilities described in **Core E** are capable of evaluating countermeasures in small animal models and NHPs. The cynomolgus macaque is the current "gold standard" animal model for LASV, JUNV, and MACV research as disease recapitulates human infection and there are a multitude of immunological reagents available[32-34]. The evaluation of prototype OWAV and NWAV vaccines and therapies in the NHP model is likely pivotal for IND applications and for future licensure of medical countermeasures for human use.

<u>Nairoviridae:</u> Unique to most other bunyaviruses, orthonairoviruses are transmitted primarily by ticks[2]. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[35], Issyk-Kul virus[36], Songling virus[37]), CCHFV is by far the most recognized public health threat. Outbreaks of CCHFV have occurred across Europe, Africa, the Middle East, and Asia. There is growing concern for expansion of the CCHFV endemic region due to increased range of its tick reservoir host (*Hyalomma* spp.) tied to bird migration changes, livestock trade, and global warming. For example, CCHFV cases have been reported in Spain[38] , a previously non-endemic region, and *Hyalomma* ticks have been found as north as Sweden[39]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to a severe hemorrhagic fever progressing to death in 30% of cases in some regions[40]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[41]. Ribavirin has been used to treat infections with limited success[42].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and GPC [40]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[40]. Conversely, the CCHFV GPC is considerably less conserved (< 75% amino acid identity)[40]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location. Thus, creating a pan-CCHFV vaccine or therapeutic based solely on one clade poses a challenge. Nevertheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a rVSV vectored vaccine expressing the full GPC of CCHFV[43].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP immunogens with the highest level of homology across clades. We will assess their capacity to protect against lethal challenge with isolates from multiple CCHFV clades in established mouse[43,44] and NHP[45] models with **Core E**. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best formulation of CCHFV GP/NP MNP vaccine against the emerging test case nairovirus, Kasokero virus, for which there are no vaccines available.

Paramyxoviridae: The HNVs NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality[4,46]. HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality[47]. NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs, which served as amplifying hosts[48]. NiV and HeV can infect at least 18 animal species across 6 orders of mammals, and among these they cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans[16,49]. The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission[5]. Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and Southeast Asia and Australia. Their broad host tropism and ability to infect livestock offers an amplification opportunity for increased risk of human spillover. The HNVs are single-stranded, negative sense, enveloped RNA viruses and their biology lends themselves to be synthetically produced as agents of potential and deliberate misuse. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS). The Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents[50] because the virus could be engineered for mass dissemination and it possesses the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the R&D Blueprint list of priority pathogens with epidemic potential[51].

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb exist. These postexposure treatments conferred protecion against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP)[52-55]. The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia[56]. In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs, and several vaccine platforms have clear potential for use in people[16]. The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies[16]. Such preventive vaccines would have utility for lab workers, first responders or individuals at high-risk exposure, and in mitigating the spread of an outbreak. In the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent[57]. It is widely considered that the African green monkey (AGM) is the current “gold standard” animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection[49,58]. The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished)[59]. The PABVAX Center has chosen to initiate studies on the divergent LayV as the Phase II test case scenario. The choice is justifiable for several important reasons: 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; and 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including rescuing recombinant LayV (rLayV), exploring animal model development, constructing additional LayV and AngV reporter virus tools, and then translating and testing the MNP vaccine ‘plug-and-play’ approach. Finally, we will evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

Commented [CRW2]: Reviewer may be looking for description of Phase I. Not mentioned in this section.

PABVAX THEME. A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center’s RPs and Core leaders currently have active and productive collaborative research programs in related areas, most spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

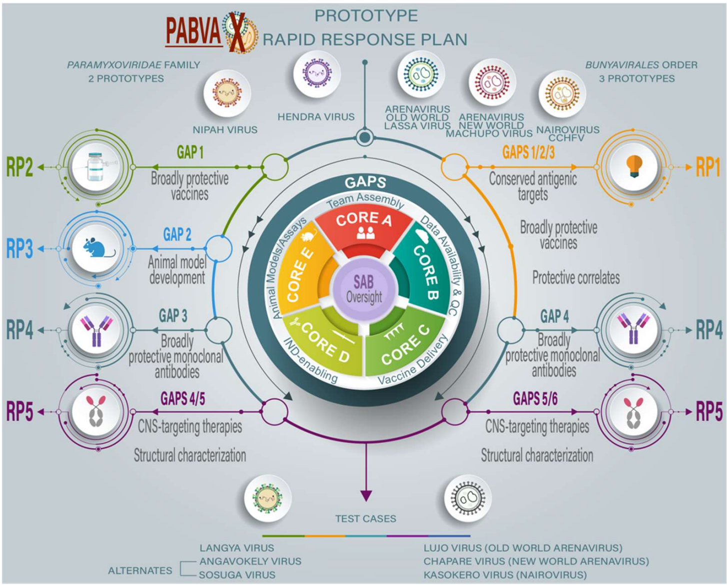

Figure 1: Research gaps addressed by the *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center (PABVAX).

The pandemic preparedness research gaps addressed by PABVAX are diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **arenaviruses** and **nairoviruses**, and **RP2** will target the prototype **HNVs**. Both RP1 and RP2 will develop new prototype virus tools (recombinant prototype viruses) along with existing tools, to analyze vaccine responses and evaluate new mAbs and nabs from the other RPs. A third RP will develop a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant *Cedar henipavirus* (rCedV) in vivo and a bioluminescence detection method that can longitudinally trace the dynamics and anatomical progression of infection with a luciferase-encoding virus in individual animals (**RP3**). There will also be two RPs that focus on the development of broadly reactive human mAbs and nanobodies to the PABVAX selected viral prototypes. **RP4** will isolate human mAbs derived from NiV-infected survivors with a specific focus on F glycoprotein-targeting mAbs. Additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will engage in the manufacture, quality control, and testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**). Under the direction of the PD/PIs (Drs. Geisbert and Broder), the Administrative Core (**Core A**) will provide organizational and programmatic structure to promote research productivity and scientific interactions along with compliance with regulations concerning select agent, vertebrate animal, and human subject use. **Core A** will coordinate all activities with the Scientific Advisory Board (**SAB**) and make data available through the Data Management Core (**Core B**).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform. The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from the UPitt and IBBR/UMD (**Core C**). This project tested a dissolvable MNP-based vaccine technology ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine[60]. The MNP vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable microneedles that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants[61] to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as to facilitate improved vaccine storage and distribution due to their improved thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, Scientific **Core C** (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ)-adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (*Paramyxoviridae*). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity *in vitro*, along with analysis of polyfunctional T-cell responses by antigenic peptide stimulation, followed by intracellular cytokine staining (ICS) and flow cytometry.

Discover effective antibody-based prophylactics and therapies. Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah[62], Hendra[63], Ebola[64,65], Marburg[66] and Lassa[67]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc*.), a feature to be exploited in **Core D** by Dr. Gunn. In addition to therapeutic applications, mAbs with Fc mutations dramatically extend serum half-life[68-70] and offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g*. rapid response personnel). Members of

PABVAX have extensive experience with the discovery, characterization, and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures. Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the Animal Model Development and Preclinical Evaluation Scientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective efficacy of antivirals and vaccines, as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation, including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they are generally less laborious and can be adapted to higher throughput platforms and/or integrated with other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput fluorescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic NiV and HeV vaccine-induced immune sera, mAbs (**RP4**), nbs (**RP5**), and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either HeV or NiV-B envelope GPs) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals to explore nab based therapeutics to CNS resident HNVs[71].

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the HNVs (*Paramyxoviridae*) and the *Bunyavirales* (*Arenaviridae* and *Nairoviridae*) that will bolster vaccine endurance to storage and transportation; we also anticipate improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology, and mAb and vaccine translational drug development along with Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Paramyxoviruses: NiV and HeV are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis[4,46]. HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals. These viruses are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of CedV, Gamak virus, Daeryong virus, and (LayV)[72] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[73,74]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV, are old world pteropid fruit bats[73,75]. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province)[17]. The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**. Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal HNV disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters[49], and AGMs (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P). The P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists[76-80]. The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections[81,82]. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature[83]. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2[84] and CedV is now recognized as a BSL-2 restricted agent[85]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D,** and **E**).

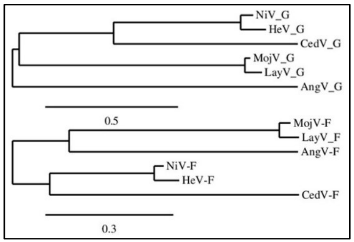

Figure 2: Phylogenetic analysis of select HNV G and F glycoproteins. Trees were constructed for using the PhyML program's maximum likelihood method and aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Arenaviruses (old world): For **phase 1**, **RP1** will utilize **LASV as the prototype virus** due its significant public health burden throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[86]. LASV is the most imported viral hemorrhagic fever (VHF) next to Dengue virus and has been documented in several countries outside of Africa over 35 times[87]. CFRs approaching 70% in hospitalized cases and marked long term sequelae are the result of the lack of approved vaccines or therapeutics, although several live attenuated virus candidates are currently being evaluated with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI)[88]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize only LASV GP as the target immunogen.

Investigators in **RP1**, **Core D**, and **Core E** have already demonstrated protective efficacy against challenge with LASV in outbred guinea pigs vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These immunogens have been engineered to express homologous antigenic regions to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach suggests a similar strategy could be implemented against other arenaviruses. The **OWAV test pathogen, LUJV,** was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia, which quickly spread nosocomially[89]. The CFR for this infectious virus was 80% in this small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from suggest current LASV countermeasures may be of limited use. LUJV will serve as an ideal "test case" to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Arenaviruses (new world): The live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[90], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[91,92]. Furthermore, there is the potential for pathogenic reversion. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest exploring other JUNV countermeasures are warranted. Building on the success of the LASV GPe/NP-NTD, investigators in **RP1 and Cores D and E** will engineer broadly protective MACV GPe and NP-NTD antigens and perform efficacy testing in established guinea pig and NHP models. We will extend this plug-and-play approach to the **NWAV test case, CHAPV**. First reported in 2003 in Bolivia, CHAPV is a rodent-borne mammarenavirus associated with the development of severe hemorrhagic fever with case fatality rates up to 60%[93,94]. Recent studies have demonstrated clear human-to-human transmission during the acute phase evidenced by several nosocomial infections; isolation of viable virus from semen at 86 days after symptom onset demonstrates a clear need to implement specialized management and treatment [94]. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Nairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as it represents the largest global public health burden within the orthonairovirus family with outbreaks annually across Europe, Africa, and Asia. There are no FDA-approved vaccines for CCHFV; however, a suckling mouse brain-derived, adjuvanted whole virus vaccine for CCHFV has been approved for use in Bulgaria. This vaccine has numerous safety concerns and has limited demonstrated efficacy. Several experimental vaccine approaches have been evaluated ranging from viral vectored approaches to DNA-based vaccines with varying efficacy, advantages, and disadvantages[95]; however, only a Modified Vaccinia Ankara virus vaccine (MVA-CCHFV) has begun to advance towards clinical trials[96]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test these for protective efficacy from challenge with 6 different CCHFV lineages using established mouse and NHP models. Next, we will deploy the same approach to the **test case nairovirus, Kasokero virus (KASV),** for which no vaccine exists.

In 1977, KASV was first isolated from Ugandan bats and caused several cases of acute febrile illness of laboratory workers from the same lab that processed the infected bats[97]. Surveys of 109 laboratory workers from the same facility demonstrated 13% seropositivity and clinical symptoms in individuals 4 to 15 months after the virus was isolated. These findings suggest either continued laboratory-associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the tick reservoir, *Ornithodoros faini,* to participate in enzootic maintenance of KASV[98]. While most chiropteran ticks exhibit host specificity, humans entering caves these bats inhabit have reported bites from *O.faini* ticks. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics suggest investment in countermeasure development against this virus is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**; arenavirus and nairovirus projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine active and passive immunization approaches to further improve the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

An additional and outstanding advantage of the PABVAX Center is the **Animal Model Development and Preclinical Evaluation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for members of the *Bunyavirales* and *Paramyxoviridae*.**
2. **Develop new tools and animal models for the conduct of cell-based and *in vivo* therapeutic evaluation.**
3. **Develop antibodies and nanobodies to the selected prototype and test viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

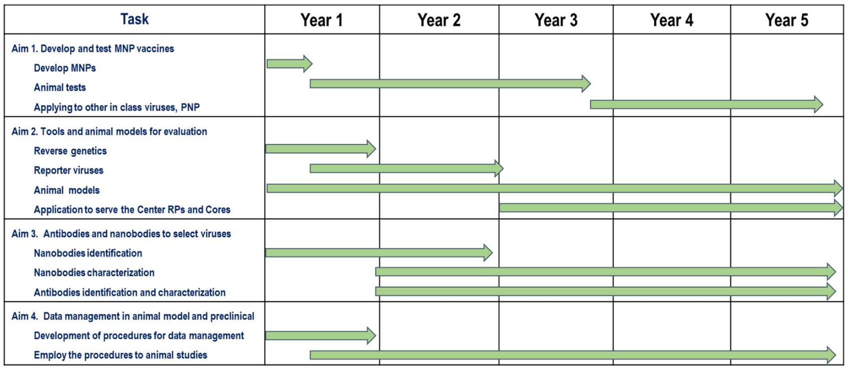

Figure 3: Projected PABVAX timeline to achieve the 4 overarching tasks.

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**. Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (details are specified within the Administration **Core A** Research Strategy). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommending new directions as appropriate, and providing Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

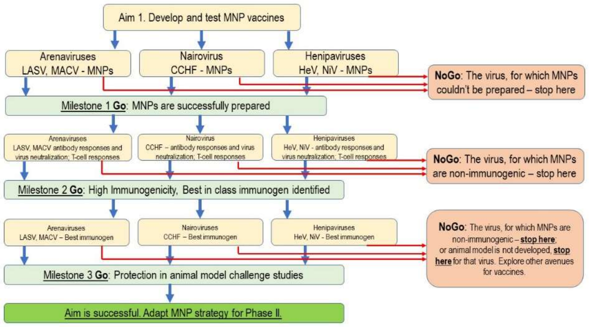

Figure 4. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will address whether formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be established using immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen-specific antibody induction, virus neutralization, and polyfunctional T-cell responses by *in vitro* stimulation of isolated cells). Go/no go decisions will be made based on outcomes of these first-tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as a success. Comparisons will also be made such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of the best-in-class immunogens, or immunogen combinations, will also be explored to down-select vaccines. The third milestone will determine whether MNP vaccination affords protection in animal model challenge experiments. In the case of NiV and HeV prototypes, the animal models chosen (ferrets and AGMs) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales*, there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASV and guinea pig models exist for some but not all of these lineages. For MACV, there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is that rhesus macaques are nearly unavailable and cynomolgus monkeys now exceed costs of $35K each. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be further developing and evaluating animal model systems, including new models, within the PABVAX program, including further development of AGM models for arenaviruses and possibly CCHFV as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.

The second overall objective of PABVAX is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will

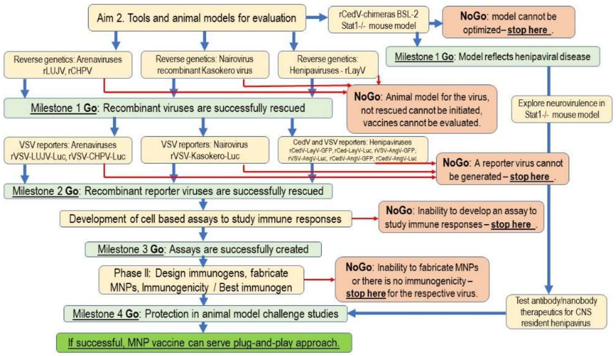

Figure 5. Milestones and criteria for progress for **Aim 2** of the PABVAX Center's overall objectives.

be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed as the complete genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If these objectives are successful, a large battery of new reagents and tools will be available to share with the ReVAMPP network, as well as serving as key components for initiation and execution of Phase II of the PABVAX Center program.

The translation and testing of the MNP vaccine plug-and-play approach will be initiated in the Phase II prototype viruses (**Table 1**). The milestones here will be similar to those outlined in **Figure 4**. The new virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the new divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new *in vivo* bioluminescence-based immune deficient mouse model (newly developed for Lyssavirus infection by the PIs of **PR2** and **RP3**) that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease *in vivo* safely and expediently at BSL-2 containment. If the model can be optimized (**Figure 5**), it will be deployed to test a critically important therapeutic need, the use of antivirals against CNS resident HNV infection, and **RP3** will collaborate with **RP5** in the testing of engineered nabs specific for the prototype HNVs NiV and HeV.

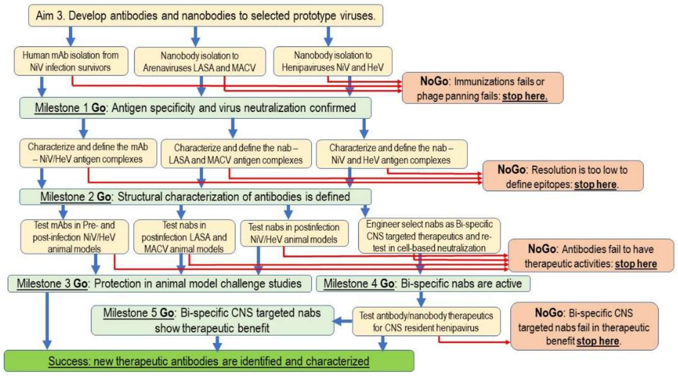

Figure 5. Milestones and criteria for progress for **Aim 3** of the PABVAX Center's overall objectives.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

New human mAbs and nbs as tools and potential therapeutics will be developed by **RP4** and **RP5** in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs, and in collaboration with **RP2**, neutralization potencies will be rapidly assessed (as well as evaluating synergistic cell-based mAb neutralization) that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

Nbs, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nbs can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nbs targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus), and select animal models of LASV and MACV by **Core E**. Success will be measured by the 1) identification of potent virus-neutralizing nbs, 2) discovery of more broadly reactive nbs particularly to the multiple LASV clades, 3) evidence of therapeutic benefit in animal models, and 4) the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

Industry Partnerships*. Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner that will provide access to vaccine expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.*

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience in developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX. Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Commented [LZ4]: I can expand on this if needed.

Galveston National Laboratory (GNL). The GNL is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics, and therapeutics. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370 separate NHP studies employing a total of 2,772 animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses have been successfully performed at the GNL. These NHP studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder, and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP facility and a staff of full-time veterinarians. In addition, **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above another special feature is the location of the WRCEVA virus collection within the GNL.

Core E (Animal model development and preclinical evaluation)**. Core E** operations will be conducted at the GNL, and in conjunction with **Core A**, will also include the UTMB Institutional Office of Regulated Nonclinical Studies (ORNcS). The ORNcS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL, and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses, arenaviruses, and henipaviruses. He has published over 250 peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI), was the first to develop a NHP model of NiV/HeV infection and disease, and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs). Mapp Biopharmaceutical has deep experience with antigens and mAbs against these antigens. Their early development and research group has expertise in immunology, infectious diseases, and the production of antigens, antibodies, and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [99] [100]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1[101]. Dr. Gunn and Genovac will join the team to analyze antibody Fc effector functions and to provide antigen/antibody discovery resources, respectively.

Core A (Administrative Core)

The investigators at USU, led by Dr. Broder have an extensive history in henipavirus research which he established in 1999, and he has published more than 75 articles, reviews, and chapters in this area. His group has also made significant translational research accomplishments in the area of henipavirus countermeasure developments including Equivac® HeV (Zoetis, Inc.) for use in horses in Australia, and the human mAb (m102.4) having a Phase I clinical trial completed (2016) in Australia, in partnership with the Queensland Government and NIAID. Dr. Broder was the recipient of the Federal Laboratory Consortium for Technology Transfer, Excellence Award in 2013. His administrative experience and skills, and his experience in translational research activities, qualify him to serve as the director of the PABVAX Center and Administrative Core.

Dr. Crowe's (**RP4**) research focuses on the molecular basis for the development of effective B cell responses to viruses in humans. He has published over 200 peer-reviewed research articles in this area. The Crowe laboratory is one of the leading groups in the development of innovative technologies for isolation and study of human mAbs. Dr. Crowe's group has isolated human mAbs that neutralize HIV, influenza, dengue, chikungunya, respiratory syncytial virus, human metapneumovirus, rotavirus, norovirus, and recently HNVs NiV and HeV (owing to the collaboration between the Crowe, Broder and Geisbert laboratories). Perhaps of greatest import, the SARS-CoV-2 mAbs generated by Dr. Crowe's laboratory were used in thousands of people during the COVID-19 pandemic. RP4 will work closely with Cores D and E in advancing mAb prototypes.

As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

Commented [LZ5]: Chris…not sure where this fits best, but its something the RFA mentions we should address…

CENTER OVERVIEW: *Paramyxoviridae* and *Bunyavirales* Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction

Emerging and periodically reemerging pathogenic enveloped RNA viruses are ~~a~~ continuous ~~infectious disease and potentially~~ pandemic threats ~~to global public health~~. Among ~~the many groups of these types of pathogens are viral~~viral taxon associated with human zoonoses ~~within~~ , members of the family ***Paramyxoviridae*** and order ***Bunyavirales*** stand out for their capacity to cause debilitating and life-threatening disease. Humans can become infected ~~where humans can acquire infections directly from~~via excreta from animal reservoir hosts such as rodents~~s~~ or ~~or~~ bats~~s,~~ through ~~through an~~ intermediate amplifying hosts such as ~~livestock~~small or domestic animals, or by ~~from~~ arthropod vectors such as mosquitos and ticks[1-4] ~~(Fields virology)~~. ~~More often than not,~~ H~~h~~umans often ~~-~~represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur~~, and should~~. During this process, RNA viral pathogens may mutate and adapt to more efficiently replicate~~ion~~ and shed~~ding~~ in the ~~human~~ host, posing an~~the~~ epidemic ~~potential of these viruses could~~threat ~~manifest~~[5-8] ~~(PMID: 23911335 -Nipah / others?)~~. The viral order *Bunyavirales* is composed of several viral families ~~known to contain~~ containing ~~multiple~~ high priority human pathogens[9]. Notably, the ***Arenaviridae*** and ***Nairoviridae*** families contain viruses ~~which~~ that cause severe hemorrhagic fever diseases in humans ~~across the world~~globally with mortality rates up to 60%[10] ~~XX~~ and significant, long-term sequelae in survivors[11]. Many bunya~~These~~ viruses are included on the World Health Organization's (WHO) List of Priority Pathogens[12,13] ~~where~~. S~~s~~ix arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHAPV, GTOV, JUNV, MACV) and one n~~N~~airovirus, ~~-~~Crimean-Congo Hemorrhagic Fever Virus (CCHFV), ~~and~~ are also identified as NIAID Category A pathogens[14] due to their 1) high associated morbidity and mortality rates, 2) ease of dissemination and/or ~~abilities~~ ability to transmit from person-to-person, 3) ~~, produce significant morbidity and mortality, have~~ potential ~~for~~ to cause public panic and social disruption~~major public health impact~~, and 4)~~,~~ requirement for ~~and require~~ special actions ~~for~~ in the context of public health preparedness. ~~-~~The family ***Paramyxoviridae*** also includes members that are ~~Also, within the~~ WHO Priority Pathogens, namely ~~s list is~~ Nipah virus (NiV) and ~~henipaviral disease which includes~~ Hendra virus (HeV). These ~~which are~~ zoonotic henipaviruses (HNVs) ~~in the family **Paramyxoviridae**. NiV and HeV have long been~~are considered ~~the~~ prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease[15] ~~(PMID: 16357858)~~. The genus now includes nine additional reported HNVs, but only HeV and NiV are ~~known to be~~ associated with severe and often fatal henipaviral disease in humans and a number of animal species[16] ~~(PMID: 32991264)~~. Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illness~~es~~ in humans[17] ~~[PMID: 35921459]~~.

~~Taken together, t~~These collective factors plus the absence of approved vaccines or therapeutics make bunyaviruses and paramyxoviruses ~~viral threats~~ a significant threat to global public health ~~are heightened due to the absence of approved vaccines or therapeutics~~. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for developing vaccine and monoclonal antibody (mAb) countermeasures ~~in developing~~to prototype ~~candidates~~ bunyavirus and paramyxovirus pathogens (**Table 1**) ~~against a selection of these viruses~~. In the out years of the Center effort, PABVAX will exploit these learned key principles in a “plug and play” demonstration against related viruses.

~~**Bunyavirales:**~~

Arenaviridae: The family *Arenaviridae* is composed of ~~three~~five genera: *Mammarenavirus~~idae~~*, *Reptarenavirus*, *Innmovirus*, *Antennavirus*, and *Hartmanivirus*[18~~9~~]. The genus *Mammarenavirus*idae ~~are~~contains ~~composed of~~ a large number of rodent-~~-~~borne viruses, some of which ~~are demonstrated human pathogens responsible for~~ caus~~e~~ing severe hemorrhagic fever, neurological damage, death, and ~~if not fatal can result~~ permanent ~~neurological~~ sequelae ~~including~~such as hearing loss, vision impairment, and balance issues in survivors[19]~~derangement~~. While these genera exhibit a global distribution, two geographically distinct ~~sub-genera~~serogroups exist ~~have formed due to the separation across continents by the Atlantic and Pacific Ocean~~that diverged ~45,000 years ago[20]. ~~–~~Old World complex ~~m~~Mammarenaviruses (OWAV) in the Eastern Hemisphere include ~~(Lassa Virus (~~LASV~~)~~, Lymphocytic Choriomeningitis Virus (LCMV), and ~~and~~ the newly discovered ~~Lujo Virus (~~LUJV~~);)~~ ~~and the~~ New World complex mamma~~A~~renaviruses (NWAV) in the Western Hemisphere include ~~(Junin Virus (~~JUNV~~)~~, ~~Machupo Virus (~~MACV~~)~~, Sabia Virus (SABV), and ~~the newly emerging Chapare Virus (~~CHAPV~~))~~. ~~Many of these viruses are identified as NIAID Category A pathogens requiring biosafety level 4 (BSL4) containment[14,19]. This classification is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness. While several promising medical countermeasures are in development,~~T~~t~~here are currently no US FDA approved vaccines or therapeutics for ~~any~~ mammarenaviruses, though the attenuated JUNV “Candid-1” vaccine is approved for use in Argentina.

~~Infection in humans is often the result of exposure to rodent excreta from infected animals~~ D~~where d~~isease severity and case fatality rates (CFR) ~~can~~ vary across ~~the~~ mammarenaviruses ~~genera and~~ even within ~~genetic lineages as~~the same clades and species. Up to 500,000 cases of LASV infection occur per year with CFRs sometimes approaching 70% in hospitalized cases[21]. ~~can be the case for infections with LASV where genetic diversity can be high, even within clades. While this genetic variability creates significant challenges for LASV molecular diagnostics, antigen-based diagnostics have seen high levels of cross reactivity across the seven known lineages of LASV suggesting cross protective antigens may be possible[21]. Lassa virus, the causative agent of Lassa fever (LF), likely causes the largest number of annual cases per year of LF, where its understood up to 500,000 cases per year can occur where the CFR can approach 70% in hospitalized cases[22]. Ribivirin has been used to treat infections with uncertain success[23].~~ Before the introduction of the ~~JUNV~~ Candid-1 vaccine, it is believed that an upwards of 60,000 cases of ~~JUNV infection, also known as~~ Argentine Hemorrhagic Fever (AHF) from infection with JUNV occurred per year ~~occurred where~~ with CFRs rang~~ed~~ing from 15-30%. Convalescent plasma from JUNV survivors is still the primary means to treat acute ~~JUNV infections~~AHF in Argentina[22]. Over 1000 cases were reported for t~~T~~he initial outbreak of MACV ~~Machupo virus had over 1000 cases and~~with CFRs ~~have ranged from~~ranging from 5-30%~~; with a CFR~~ , ~~where outbreak frequency is thought to have been reduced through~~ enhanced rodent abatement practices and potentially cross-protective immunity in populations ~~who~~that have taken the JUNV Candid-1 vaccine may have reduced recent outbreak frequency[23].

All mammarenaviruses share a common genomic organization consisting of two ambi-sense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix)~~,~~ and ~~the~~ L protein (polymerase), and the glycoprotein precursor (GPC)~~,~~ and ~~the~~ nucleoprotein (NP)[19]. ~~–~~Despite general similarity of their genomic architecture, ~~these groups~~mammarenaviruses exhibit marked differences in their replication life cycles~~. This includes differences in~~ including attachment factors, entry mechanisms, and immune evasion; nonetheless, the dominant antigen~~ic protein~~s driving immune responses for both ~~OWAV and NWAV~~OWAV and NWAV are the glycoprotein (GP) and NP.

Despite the abundant genetic diversity of LASV, high levels of cross reactivity have been seen with antigen-based diagnostics across seven known lineages, suggesting the generation of cross-protective immunogens and antibodies against mammarenaviruses is achievable[24]. Monoclonal antibodies derived from human LASV survivors ~~have been demonstrated~~were shown to protect non-human primates (NHP)~~,~~ against lethal challenge[25]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe)[26]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, ~~suggesting~~indicating ~~using~~ this domain ~~as a vaccine antigen may also be possible~~could serve as an antigenic target. ~~To test these notions, i~~Investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccines ~~approaches~~ to test this ~~idea~~approach.

Formatted ... [17]

Formatted ... [18]

Formatted ... [19]

Formatted ... [20]

and have demonstrated protection against lethal LASV-Josiah challenge. Specifically, ~~using~~ a stabilized prefusion~~,~~ trimeric GPe, an immunogen containing a highly conserved NP NTD epitope, or a combination of these two ~~antigen~~approaches conferred protection in ~~s using~~ a lethal outbred guinea pig model.

Formatted ... [21]

Despite the considerable molecular diversity in LASV strains, ~~there is understood that there is some~~ conservation at~~in~~ key antigenic sites within ~~both~~ the GPe and ~~the~~ NP~~, suggesting~~ suggest the feasibility of generating ~~, that~~ a pan~~PAN~~-LASV vaccine ~~may be possible~~[24,27,28]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a recombinant Vesicular s~~S~~tomatitis v~~V~~irus (rVSV)-based vector expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[29], but also ~~that live attenuated vaccines expressing this same GPC can protect NHP~~protects against heterologous challenge with ~~viruses from:~~ Lineage II[30], ~~Lineage~~ III (Cross, Geisbert unpublished), ~~Lineage~~ V[31], and ~~Lineage~~ VI viruses (Cross and Geisbert Unpublished).

Formatted ... [22]

In **Phase I of RP1**, the ability ~~for~~of an optimized ~~intramuscular (IM)~~ LASV GPe/NP subunit vaccine delivered intramuscularly (IM) ~~to protect against disease after challenge multiple LASV lineages~~ will be assessed in guinea pig and NHP models across multiple viral lineages. We will also assess ~~This~~a ~~formulation will also be assessed using a~~ microneedle skin patch (MNP) formulation optimized in **Core C** to determine if a needle-free vaccination route affords more potent vaccine~~-~~-mediated responses and protection. Similarly, we have ~~already~~ generated MACV GPe immunogens and will design a MACV NP-NTD subunit antigen to test ~~following~~ the same approach ~~approach followed with LASV against both homologous lineage challenge and heterologous challenge of~~ across multiple MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing both ~~emerging~~ OWAV (LUJV) and NWAV (CHAPV) complexes, for which there are no vaccines available. A unique ~~feature of this proposal~~advantage of the PABVAX Center is its access to biosafety level (BSL)-4 containment, allowing us to work with authentic versus surrogate arenaviruses. The BSL4 facilities described in **Core E** are capable of evaluating countermeasures in small animal models and NHPs. ~~It is widely considered that T~~the cynomolgus macaque is the current "gold standard" animal model for LASV, JUNV, and MACV research as ~~as there are a multitude of immunological reagents available and the~~ disease ~~pathogenesis appears to mirror~~recapitulates ~~that of~~ human infection and there are a multitude of immunological reagents available[32-34]. The evaluation of ~~successful countermeasures for the~~ prototype OWAV ~~AND~~and NWAV vaccines and therapies in the NHP model ~~will likely be~~is likely pivotal for IND applications and for future licensure of ~~select~~medical countermeasures for human use.

Formatted ... [23]

Nairoviridae: Unique ~~from~~to most other bunyaviruses, orthonairoviruses are transmitted primarily by ticks[2] ~~in nature (REF)~~. While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[35], Issyk-Kul virus[36], Songling virus[37]), ~~Crimean-Congo Hemorrhagic fever virus (~~CCHFV~~)~~ is by far the most recognized public health threat. Outbreaks of CCHFV have occurred ~~to humans as it responsible for annual outbreaks~~ across Europe, Africa, the Middle East, and Asia. There ~~are~~is growing concern~~s~~ for expansion of the CCHFV endemic r~~ange~~egion ~~expansion~~ due to ~~ongoing range expansion~~increased range of its tick reservoir host~~s~~ (*Hyalomma* spp.) tied to bird migration changes, livestock trade, and ~~even~~ global warming. For example, CCHFV ~~are contributing to increasing numbers of infections in humans in areas otherwise not known to be~~cases have been reported in ~~endemic including central~~ Spain[38], a previously non-endemic region, and ~~*most recently the reservoir*~~*Hyalomma* ~~Hyalomma~~ ticks have been found as north as Sweden[39]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to a ~~cause a~~ severe hemorrhagic fever ~~which may~~ progressing to death in 30% of cases in some regions[40]. ~~CCHFV is listed on the WHO priority pathogen list[13] and is also a NIH-NIAID category A pathogen[41].~~ There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[41] ~~(REF)~~. ~~Ribivirin~~Ribavirin has been used to treat infections with limited success[42].

Formatted ... [24]

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and ~~a~~ GPC [40]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[40]. Conversely, the CCHFV GPC is considerably less conserved~~, where less than~~ (< 75% amino acid ~~conservation is present~~identity)[40]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location. Thus, creating ~~which creates a challenge in terms of creating~~ a pan-CCHFV vaccine or therapeutic based solely on one clade poses a challenge. N~~one~~evertheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a rVSV vectored vaccine expressing the full GPC of CCHFV[43].

Formatted ... [25]

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP ~~subunits~~immunogens with the highest level of homology across clades. We will ~~and~~ assess their capacity to protect against ~~disease after~~lethal challenge with isolates from multiple CCHFV clades in established mouse[43,44] and NHP[45] models with **Core E**. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best ~~performing~~ formulation of CCHFV GP/NP MNP vaccine ~~approach~~ against the emerging test case ~~mammarenaviruses representing emerging~~nairo ~~bat~~ virus, Kasokero virus, for which there are no vaccines available.

Paramyxoviridae: ~~*The henipavirus paramyxoviruses.*~~ The ~~recognized, highly pathogenic~~ HNVs ~~,~~ NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality ~~(~~[4,46]~~; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia)~~. HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality[47] ~~(Murray, PMID: 7701348)~~. NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs, which served as amplifying hosts ~~(~~[48]~~)~~. NiV and HeV can infect at least 18 animal species across 6 orders of mammals, and among these they ~~will~~ cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans ~~(~~[16,49]~~)~~. The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission ~~(~~[5]~~)~~. Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and ~~South East~~Southeast Asia and Australia. Their broad host tropism and ability ~~of these viruses~~ to infect livestock offers an amplification opportunity ~~and~~ for increased risk of ~~subsequent~~ human ~~infections~~spillover. The ~~henipaviruses~~ HNVs are single-stranded, negative sense, enveloped RNA viruses and their biology ~~also~~ lends themselves to be synthetically produced ~~and~~ as agents of potential and deliberate misuse. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS). ~~and~~ The Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents ~~[~~[50]~~]~~, because ~~they~~ the virus could be engineered for mass dissemination and it possesses the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the ~~WHO~~ R&D Blueprint list of priority pathogens with epidemic potential ~~(Sweileh, W. M.~~[51]~~)~~.

Formatted ... [27]

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb exist. ~~-~~ These p~~p~~ostexposure treatments ~~have been demonstrated to be effective therapies~~conferred protecion against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP) ~~(~~[52-55]~~, 53, 54, 55)~~. The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia ~~(~~[56]~~)~~. In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs, and several vaccine platforms have clear potential for use in people[16] ~~(PMC8782152)~~. The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies[16] ~~(PMC8782152)~~. Such preventive vaccines would have utility for lab workers, first responders or individuals at ~~high risk~~high-risk exposure, and in mitigating the spread of an outbreak ~~; whereas~~ . I~~i~~n the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete

Formatted ... [28]

protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent ~~(Middleton, 2014~~[57]~~)~~. It is widely considered that the African green monkey (AGM) is the current "gold standard" animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection[49,58] ~~(Geisbert, 2012;Geisbert, 2010)~~. The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished) ~~(~~[59]~~)~~. The PABVAX Center has chosen to initiate studies on the divergent LayV as the Phase II test case scenario. The choice is justifiable for several important reasons~~,~~: 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; and 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. A~~lso, a~~nother divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including ~~the rescue of~~rescuing recombinant LayV (rLayV), ~~explore~~ exploring animal model development, constructing additional LayV and AngV reporter virus tools, and then ~~translate~~ translating and testing the MNP vaccine 'plug-and-play' approach. Finally, we will~~, and also~~ evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME.

A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center's RPs and Core leaders currently have active and productive collaborative research programs in related areas, ~~some~~ most spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

based therapeutics targeting henipaviruses and arenaviruses ~~along ~~with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will e~~be e~~ngage~~d~~ ~~in~~in the manufacture~~ and ~~, quality control, and ~~& ~~testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**). Under the direction of the PD/PIs (Drs. Geisbert and Broder), the Administrative Core (**Core A**) will provide organizational and programmatic structure to promote research productivity and scientific interactions along with compliance with regulations concerning select agent, vertebrate animal, and human subject use. **Core A** will coordinate all activities with the Scientific Advisory Board (**SAB**) and make data available through the Data Management Core (**Core B**).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform.
The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from the UPitt and IBBR/UMD (**Core C**). This project ~~that has ~~tested a dissolvable MNP-based vaccine technology ~~that is ~~ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine~~ approach (~~[60]~~)~~. ~~This ~~The MNP vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable ~~MNPs ~~microneedles that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants~~ (~~[61]~~)~~ to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as to facilitate ~~the ~~improved vaccine storage and distribution due to their improved thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, ~~a ~~Scientific **Core C**~~:~~ (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ)-adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (*Paramyxoviridae*). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity *in vitro*, along with ~~and ~~analysis of polyfunctional T-cell responses by ~~in vitro stimulation of isolated cells with ~~antigenic peptide stimulation~~s~~, followed by intracellular cytokine staining (ICS) and flow cytometry~~) responses~~.

Discover effective antibody-based prophylactics and therapies. M
~~PREP can be critical in the absence of available vaccines or cases in which vaccination is not possible.~~
~~HELP~~

~~M~~onoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah[62], Hendra~~-~~[63], Ebola~~-~~[64,65], Marburg~~-~~[66] and Lassa~~-~~[67]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc.*), a feature to be

exploited in **Core D** by Dr. Gunn. In addition to therapeutic applications, mAbs with Fc mutations ~~to~~ dramatically extend serum half-life~~.~~[68-70] and offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g.* rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization, and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures.

Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. ~~-~~The investigators within the A~~A~~nimal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation S~~s~~cientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including ~~……..~~ animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective ~~therapeutic~~ efficacy of antivirals and vaccines, as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation,~~;~~ including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they are generally less laborious and can be adapted to ~~greater~~ higher ~~-~~throughput platforms~~, are often less laborious, and they can make use of other~~ and/or integrated with other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput fluorescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic NiV~~pah~~ and ~~Hendra~~ HeV ~~virus~~ vaccine~~-~~ induced immune sera, mAbs (**RP4**) ~~and~~, nbs (**RP5**), and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either ~~the~~ HeV or NiV-B envelope GPs~~glycoproteins~~) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals~~, ideally suited~~ to explore nab based therapeutics to CNS resident ~~henipavirus~~HNVs~~(~~[71]~~)~~.

Formatted ... [80]

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. ~~Data generated to support of possible future regulatory submissions to the Food and Drug Administration (FDA) must be collected in accordance with quality systems, like good laboratory practice (GLP) regulations, to be useful and reliable, and to facilitate FDA review to ensure safety and efficacy.~~ The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the ~~henipaviruses~~ HNVs (*Paramyxoviridae*) and the *Bunyavirales* (*Arenaviridae* and *Nairoviridae*) that will bolster vaccine endurance to storage and transportation; ~~and~~ we also anticipate improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

Formatted ... [81]

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology, and mAb and vaccine translational drug development along with ~~and includes~~ Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

Formatted ... [82]

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

***~~Henipaviruses~~Paramyxoviruses*:** ~~Nipah virus (~~NiV ~~)~~ and ~~Hendra virus (~~HeV~~)~~ are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis[4,46] ~~(Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia)~~. HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals. T~~, and~~ hese viruses are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of ~~Cedar virus (~~CedV~~)~~, Gamak virus, Daeryong virus, and ~~Langya virus~~ (LayV)[72] a ~~[xxx] a~~nd five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[73,74] ~~[xxx]~~. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV, are old world pteropid fruit bats[73,75]. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province)[17]. The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**.

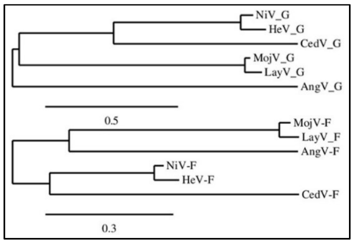

Figure 2: Phylogenetic analysis of select HNV G and F glycoproteins. Trees were constructed for using the PhyML program's maximum likelihood method and aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

~~**Figure 2. Phylogenetic analysis of select HNV G and F glycoproteins**. Phylogenetic trees were constructed for the HNV F and G glycoproteins using the PhyML program's maximum likelihood method. The trees were generated by aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.~~

Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal ~~henipaviral~~ HNV disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters[49] ~~(Geisbert 2012)~~, and ~~African green monkeys~~AGMs (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P)~~, and T~~. The P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists[76-80] ~~(xx).~~ . The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections[81,82]. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature[83]. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2[84] ~~(XXX)~~ and CedV is now recognized as a BSL-2 restricted agent[85] ~~[CDC manual]~~. Because the HNV, LayV, is known

to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D,** and **E**).

Arenaviruses (old world)~~Old Word Mammarenaviruses (OWAV)~~: For **phase 1**, **RP1** will utilize **LASV as the prototype ~~OWAV~~virus**, due ~~to the~~its significant public health burden ~~it creates~~ throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[86]. LASV ~~has~~ is the most imported viral hemorrhagic fever (VHF) next to D~~d~~engue virus and has been ~~imported to~~documented in several countries outside of Africa over 35 ~~documented~~ times[87]. –C~~ase fatality rates (C~~FR~~s)~~ approaching 70% in hospitalized cases and marked long term sequelae are the result of ~~no~~the lack of approved vaccines or therapeutics, although several live attenuated virus candidates are ~~approaching clinical evaluation~~currently being evaluated with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI)[88]. –Of the vaccines supported by CEPI, 4/5 of these vaccines utilize ~~the~~ only ~~the~~ LASV GP as the target immunogen ~~despite~~.

Investigators in **RP1**, **Core D**, and **Core E** have already demonstrated protective efficacy ~~of~~ against ~~disease after~~ challenge with LASV in outbred guinea pigs ~~in animals~~ vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. –These ~~antigens~~immunogens have been engineered to ~~harness~~express ~~the~~ homologous antigenic regions ~~of both antigens~~ to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach~~,~~ suggests a similar strategy ~~of using a subunit vaccine might also be effective against~~could be implemented against other arenaviruses. T~~While LASV is the most common pathogenic arenavirus in Africa in terms of human infections, t~~he **OWAV test pathogen, ~~Lujo virus~~LUJV,** was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia ~~but~~, which quickly ~~causing~~spread nosocomially~~ infections in care givers after the index case's medical evacuation to South Africa~~[89]. The ~~case fatality rate~~CFR for this ~~incredibly~~ infectious virus was 80% in thi~~s~~e small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from ~~LASV~~ suggest current LASV countermeasures ~~with antigenic targets~~ may be of limited use~~, implying~~. LUJV will ~~be~~serve as an ideal "test case" ~~OWAV~~ to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. -The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

~~New World Mamarenaviruses (NWAV~~Arenaviruses (new world)~~)~~: The~~A~~ live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina[90], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine[91,92]. Furthermore, there ~~are safety concerns related to~~ is the potential for pathogenic reversion ~~to pathogenic versions~~. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest exploring other ~~approaches~~ JUNV countermeasures are warranted. Building on the success of the LASV GPe/NP-NTD~~,~~ -~~i~~Investigators in **RP1 and Cores D and E** will engineer broadly protective MACV GPe and NP-NTD antigens and ~~test for~~perform efficacy testing in established guinea pig and NHP models ~~using MACV from multiple lineages to asses how broadly protective the approach is across MACV lineages~~. We will ~~then~~ extend this plug-and-play approach to ~~other~~ the **NWAV test case, CHAPV**. First reported in 2003 in Bolivia, ~~Chapare virus (~~CHAPV~~)~~ is a rodent-~~-~~borne mammarenavirus associated with the development of severe hemorrhagic fever with case fatality rates up to 60%[93,94]. Recent studies have demonstrated clear human-to-human transmission ~~risk~~ during the acute phase evidenced by several nosocomial infections~~ but also ~~; ~~detection~~isolation of viable virus from semen at 86 days after symptom onset ~~demonstrating~~demonstrates a clear need to implement specialized management and treatment[94]. ~~It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus.~~ The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

N~~Orthon~~airoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as it represents ~~is responsible for~~ the largest global public health burden within the orthonairovirus family ~~responsible for often large~~ with outbreaks ~~of human disease~~ annually across Europe, Africa, and Asia. There are no FDA-~~-~~approved vaccines for CCHFV; however, a suckling mouse brain-~~-~~derived, ~~CHCl2/heat-inactivated aluminum hydroxide adsorbed~~adjuvanted whole virus vaccine for CCHFV has been approved for use ~~only~~ in Bulgaria. This vaccine has ~~since 1974 but has~~ numerous safety concerns and has limited demonstrated efficacy. ~~Since then,~~S~~s~~everal

experimental vaccine approaches have been e~~xamined~~valuated ranging from viral vectored approaches to DNA-based vaccines with varying efficacy, advantages, and disadvantages[95]; however, only a Modified Vaccinia Ankara virus vaccine (~~n~~ MVA-CCHFV ~~vaccine~~) has begun to advance towards clinical trials[96]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test these for protective efficacy from ~~disease after~~ challenge with 6 different ~~lineages of~~ CCHFV ~~clades~~lineages using ~~in~~ established mouse and NHP models. Next, we will deploy the same approach to ~~a known human pathogen~~the **"test case"** ~~ortho~~nairovirus, **Kasokero virus (KASV)**, for which no vaccine exists.

In 1977, ~~Kasokero virus (KASV), a bat borne Orthonairovirus,~~KASV was first isolated from Ugandan bats and ~~responsible for~~ caus~~ing~~ed several cases of acute febrile illness of laboratory workers from the same lab that processed the infected bats[97]. ~~Sero~~S~~s~~urveys of 109 laboratory workers from the same facility ~~the virus was isolated and worked with~~ demonstrated ~~a~~ 13% seropositivity and ~~where medical surveys revealed~~ clinical symptoms in individuals 4 to 15 months after the virus was isolated. These findings~~,~~ suggest~~ting~~ either continued laboratory-associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the tick reservoir, *Ornithodoros faini*, ~~ticks~~ to participate in enzootic maintenance of KASV[98]. While most chiropteran ticks exhibit host specificity, humans entering caves ~~where~~ these bats inhabit ~~are~~ have reported bites from *O.faini* ticks ~~as well~~. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics ~~make~~ suggest investment in countermeasure development against this virus is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs~~;~~ such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**~~), (~~; ~~a~~arenavirus and nairovirus~~renaviridae and nairoviridae~~ projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine ~~the~~ active and passive immunization approaches to further improve~~d~~ the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

An additional and outstanding advantage of the PABVAX Center is the **Animal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL~~.~~ (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies.

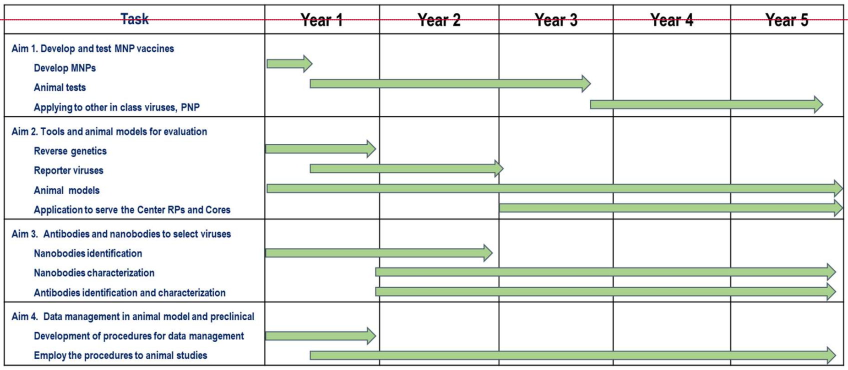
All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for ~~all~~ the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for members of the *Bunyavirales* and *Paramyxoviridae*.**
2. **Develop new tools and animal models for the conduct of cell-based and *in vivo* therapeutic~~s~~ evaluation.**
3. **Develop antibodies and nanobodies to the selected prototype and test viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

~~The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**.~~



~~**Figure 3**: Projected PABVAX timeline to achieve the 4 overarching tasks.~~

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**.

Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. ~~This is in addition to each PR's individual Milestone plan.~~ The oversight and evaluation of progress will be in concert with quarterly reports to the PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (d~~D~~etails are specified within the Administration **Core A** Research Strategy). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommending new directions as appropriate, and providing~~e~~ Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

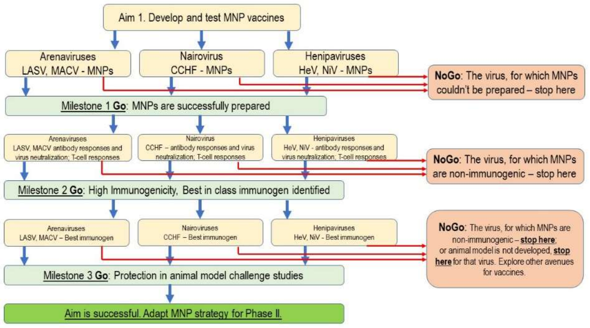

Figure 4. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

~~**Figure 4.** Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.~~

The first milestone will ~~be~~ address whether ~~proper~~ formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be ~~made based~~established ~~on~~ using immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen~~-~~ specific antibody induction ~~and~~ , virus ~~-~~neutralization, and polyfunctional T-cell responses by *in vitro* stimulation of isolated cells). Go/no go decisions will be made based on ~~the~~ outcomes of these ~~first tier~~first-tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as a success. Comparisons will also be made~~,~~ such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of the best-in-class immunogens, or ~~best~~ immunogen combination~~n immunogen~~s, ~~which~~ will also be explored~~, will be performed in order~~ to down-select vaccine~~-s~~choice. The third milestone will ~~be the determination~~determine ~~of~~ whether MNP vaccination affords protection in animal model challenge experiments. In the case of ~~the~~ NiV and HeV prototypes, the animal models chosen (ferrets and ~~the African green monkey (AGM)~~AGMs) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales*, there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASV~~A~~ and ~~there are~~ guinea pig models exist for some but not all of ~~those~~ these lineages. For MACV, there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is that rhesus macaques are nearly unavailable and cynomolgus monkeys ~~are~~ now ~~each greater than~~exceed costs of $35K each. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be further developing and evaluating animal model systems, including new models, within the PABVAX program, including further development of ~~the~~ AGM models for ~~the~~ arenaviruses and possibly ~~also for~~ CCHFV, as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.~~-~~

~~**Figure 5.** Milestones and criteria for progress for **Aim 2** of the PABVAX Center overall objectives.~~

The ~~PABVAX~~ second overall objective of PABVAX is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined *in vivo* (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by

reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed as the complete genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If these objectives are successful, ~~a~~ a large battery of new reagents and tools will be available to share with the ReVAMPP network, as well as serving as key components for initiation and execution of Phase II of the PABVAX Center program.

The translation and testing of the MNP vaccine plug-and-play approach will be initiated in the Phase II prototype viruses (**Table 1**). T~~t~~he milestones here will be similar to those outlined in **Figure 4**. The new virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the new divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new *in vivo* bioluminescence-based immune deficient mouse model (newly developed for Lyssavirus infection by the PIs of **PR2** and **RP3**) that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease *in vivo* safely and expediently at BSL-2 containment. If the model can be optimized (**Figure 5**), it will be deployed to test a critically important therapeutic need, the use of antivirals against CNS resident HNV infection, and **RP3** will collaborate with **RP5** in the testing of engineered nabs specific for the prototype HNVs NiV and HeV.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

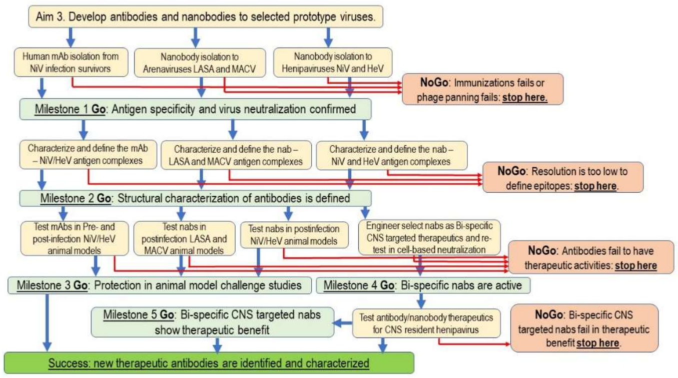

Figure 5. Milestones and criteria for progress for **Aim 3** of the PABVAX Center's overall objectives.

~~**Figure 6.** Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.~~

New human mAbs and ~~nanobodies~~ ~~(~~nbs~~)~~ as tools and potential therapeutics will be developed by **RP4** and **RP5** in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); ~~and~~ transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on ~~the~~ mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs, and in collaboration with **RP2**, neutralization potencies will be rapidly assessed (as well as evaluating synergistic cell-based mAb neutralization) that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, ~~-~~and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

~~Nanobodies~~Nbs, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, ~~nanobodies~~ nbs can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of ~~nanobodies~~ nbs targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), ~~and also for~~ therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus), and select animal models of LASV and MACV by **Core E**. Success will be measured by the 1) identification of potent virus-neutralizing nbs, 2) ~~potential~~ discovery of more broadly reactive nbs~~,~~ particularly to the multiple LASV~~A~~ clades, 3) ~~the~~ evidence of therapeutic benefit in animal models, and 4) the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.~~-~~

I~~NDUSTRY~~ndustry ~~PARTNERSHIPS~~Partnerships

~~Industry Partnership~~

. Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner ~~which~~ that will provide access to vaccine

expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience in developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX.

~~SPECIAL FEATURES OF THE PABVAX CENTER ENVIRONMENT AND OTHER RESOURCES~~ ??

Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Galveston National Laboratory (GNL).

The GNL~~,~~ is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics, and therapeutics ~~against them~~. The 7-story GNL offers over

12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370~~187~~ separate NHP studies employing a total of 2,772~~1,318~~ animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses ~~Ebola and Marburg viruses and also Nipah and Hendra~~ have been successfully performed at the GNL. ~~-~~These NHP studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder, and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP~~nonhuman primate~~ facility and a staff of full-time veterinarians. ~~-~~In addition, **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above another special feature is the location of the WRCEVA virus collection within the GNL.

Core E (Animal model development and preclinical evaluation).

Core E operations will be conducted at the GNL, and in conjunction with **Core A**~~-~~, will also include~~s~~ the UTMB Institutional Office of Regulated Nonclinical Studies (~~ONcRS~~ORNcS). The ORNcS~~ONcRS~~'s primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, ~~to meet regulatory requirements by assuring regulatory compliance,~~ quality assurance, and data management. ~~-~~NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. ~~Quality system and regulatory science processes for NHP studies performed at UTMB will be implemented and executed in conjunction with the ORNcS.~~ Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL, and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses, arenaviruses, and ~~the~~ henipaviruses~~ and~~. H~~h~~e has published over 250~~XXX~~ peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI), was the first to develop a NHP model of NiV/HeV infection and disease, and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs).

Mapp Biopharmaceutical has deep experience with antigens and ~~monoclonal antibodies (~~mAbs~~)~~ against these antigens. ~~'s product development team has grown significantly in the last two years in response to the development efforts on its anti-Ebola therapeutic, ZMapp™ which is being advanced to licensure as part of Project Bioshield. OTHER MAbs~~ Their early development and research group has expertise in immunology, infectious diseases, and the production of antigens, antibodies, and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [99] [100]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1~~-~~[101]. ~~-~~Dr. Gunn and Genovac will join the team to analyze antibody Fc effector functions and to provide antigen/antibody discovery resources, respectively. ~~developed multiple products, including a licensed biodefense biologic. As with Profectus, Mapp Bio's expertise and experience will be a very important and valuable asset to the Center.~~

~~Bonnie – Genovac~~

The investigators at USU, led by Dr. Broder have an extensive history in henipavirus research which he established in 1999, and he has published more than 75 articles, reviews, and chapters in this area. His group has also made significant translational research accomplishments in the area of henipavirus countermeasure developments including Equivac® HeV (Zoetis, Inc.) for use in horses in Australia, and the human mAb (m102.4) having a Phase I clinical trial completed (2016) in Australia, in partnership with the Queensland Government and NIAID. Dr. Broder was the recipient of the Federal Laboratory Consortium for Technology Transfer, Excellence Award in 2013. His administrative experience and skills, and his experience in translational research activities, qualify him to serve as the director of the PABVAX Center and Administrative Core.

Dr. Crowe's (**RP4**) research focuses on the molecular basis for the development of effective B cell responses to viruses in humans~~ and~~. H~~h~~e has published over 200 peer-reviewed research articles in this area. The Crowe laboratory is one of the leading groups in the development of innovative technologies for isolation and study of human mAbs. Dr. Crowe's group has isolated human mAbs that neutralize HIV, influenza, dengue, chikungunya, respiratory syncytial virus, human metapneumovirus, rotavirus, norovirus, and recently ~~henipaviruses~~ HNVs NiV and HeV (owing to the collaboration between the Crowe, Broder and Geisbert laboratories). Perhaps of greatest import, the SARS-CoV-2 mAbs generated by Dr. Crowe's laboratory were used in ~~xxx,000~~thousands of people during the COVID-19 pandemic. RP4 will work closely with Cores D and E in advancing mAb prototypes. ~~The Core B of the Center will work together with RP2 and RP3 along with the Core C to develop the first cocktail human mAb immunotherapeutics, and facilitate the transition products suitable for IND filing and human testing including design, construction, assessment, and optimization of these antibody-based therapies.~~

As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

Tom asked me to insert this to see how it would look so we can see what changes are needed to ensure legibility since the figure needed to get shrunk to fit. Some of the graphics dead center might be a little too small, not sure anything can be done there…

Maybe be good to have the whole title per RP listed instead of abbreviated form?

May need to identify what is meant by Gaps as its not identified in this document, I think maybe it is spelled out in Core E document?. Assuming maybe these are Gaps identified in the main RFA?

Just an idea…. having RP4 and RP5 bubbles duplicated to demonstrate different GAPs addressed is a little confusing to me, maybe if we do end up enumerating the gaps somewhere in the text, it might simplify things by identify what gaps are addressed by each RP so that each RP only has one bubble? EG:

- RP1=gap 1
- RP2=gap 1
- RP3=gap 2
- RP4=gap 2,3
- RP5= gap 3,4,5

CENTER OVERVIEW: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction

Commented [CB1]: I think as you review this doc, perhaps specifically name the PIs and PLs in certain areas?

Emerging and periodically reemerging pathogenic enveloped RNA viruses are ~~a~~ continuous ~~infectious disease and potentially~~ pandemic threats to global public health. Among the many groups of these types of pathogens are viral zoonoses within the family **Paramyxoviridae** and order ***Bunyavirales*** where humans can acquire infections directly from animal reservoir hosts such as rodents or bats~~,~~ through an intermediate amplifying host such as livestock, or from arthropod vectors such as mosquitos and ticks (Fields virology). More often than not, humans represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur, and should RNA viral pathogens mutate and adapt to more efficient replication and shedding in the human host, the epidemic potential of these viruses could manifest (PMID: 23911335 -Nipah / others?). The viral order *Bunyavirales* is composed of several viral families known to contain multiple high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic fever diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) and are also identified as NIAID Category A pathogens due to their ease of dissemination and/or abilities to transmit person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special actions for public health preparedness. Also, within the WHO Priority Pathogens list is Nipah virus (NiV) and henipaviral disease which includes Hendra virus (HeV) which are zoonotic henipaviruses (HNVs) in the family **Paramyxoviridae**. NiV and HeV have long been considered the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease (PMID: 16357858). The genus now includes nine additional reported HNVs but only HeV and NiV are known to be associated with severe and often fatal henipaviral disease in humans and a number of animal species (PMID: 32991264). Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illnesses in humans [PMID: 35921459].

Taken together, these viral threats to global public health are heightened due to the absence of approved vaccines or therapeutics. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for vaccine and monoclonal antibody (mAb) countermeasures in developing prototype candidates (**Table 1**) against a selection of these viruses. In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Table 1. PABVAX selected prototype and test case viral agents.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old world), Machupo (New world)	Lujo (Old world), Chapare (New world)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Bunyavirales:

Arenaviridae: The family Arenaviridae is composed of three genera: Mammarenaviridae, Reptarenavirus, and Hartmanivirus. The Mammarenaviridae are composed of a large number rodent borne viruses, some of which are demonstrated human pathogens responsible for causing severe hemorrhagic fever, neurological damage, and if not fatal can result permanent neurological sequelae including hearing loss, vision impairment, and balance [1]derangement. While these genera exhibit a global distribution, two geographically distinct sub-genera have formed due to the separation across continents by the Atlantic and Pacific Ocean. Old World Mammarenaviruses (Lassa Virus (LASV), Lymphocytic Choriomeningitis Virus (LCMV), and the newly discovered Lujo Virus (LUJV)) and the New World Arenaviruses (Junin Virus (JUNV), Machupo Virus (MACV), Sabia Virus (SABV), and the newly emerging Chapare Virus (CHAPV)). Many of these viruses are identified as NIAID Category A pathogens requiring biosafety level 4 (BSL4) containment [2]. This classification is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness. While several

promising medical countermeasures are in development, there are currently no US FDA approved vaccines or therapeutics for any mammarenaviruses, though the attenuated JUNV “Candid-1” vaccine is approved for use in Argentina.

Infection in humans is often the result of exposure to rodent excreta from infected animals where disease severity and case fatality rates (CFR) can vary across the genera and even within genetic lineages as can be the case for infections with LASV where genetic diversity can be high, even within clades. While this genetic variability creates significant challenges for LASV molecular diagnostics, antigen-based diagnostics have seen high levels of cross reactivity across the seven known lineages of LASV suggesting cross protective antigens may be possible[3]. Lassa virus, the causative agent of Lassa fever (LF), likely causes the largest number of annual cases per year of LF, where its understood up to 500,000 cases per year can occur where the CFR can approach 70% in hospitalized cases [4]. Ribivirin has been used to treat infections with uncertain success [5]. Before the introduction of the JUNV Candid-1 vaccine, its believed that upwards of 60,000 cases of JUNV infection, also known as Argentine Hemorrhagic Fever (AHF) per year occurred where CFRs ranged from 15-30 %. Convalescent plasma from JUNV survivors is still the primary means to treat acute JUNV infections in Argentina [6]. The initial outbreak of Machupo virus had over 1000 cases and CFRs have ranged from 5-30%; ~~with a CFR~~, ~~where~~ outbreak frequency is thought to have been reduced through enhanced rodent abatement practices and potentially cross-protective immunity in populations who have taken the JUNV Candid-1 vaccine [7].

All mammarenaviruses share a common genomic organization consisting of two ambi-sense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP) [1]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge [8]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe) [9]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. To test these notions, investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccine approaches to test this idea and have demonstrated protection against lethal LASV-Josiah challenge using a stabilized prefusion, trimeric GPe, a highly conserved NP NTD epitope, or a combination of the two antigens using a lethal outbred guinea pig model.

Despite the considerable molecular diversity in LASV strains, there is understood that there is some conservation in key antigenic sites within both the GPe and the NP, suggesting that a PAN-LASV vaccine may be possible[3, 10, 11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

In **Phase I of RP1**, the ability for an optimized intramuscular (IM) LASV GPe/NP subunit vaccine to protect against disease after challenge multiple LASV lineages will be assessed in guinea pig and NHP models. This formulation will also be assessed using a microneedle skin patch (MNP) formulation optimized in Core C to determine if a needle-free vaccination route affords more potent vaccine mediated responses and protection. Similarly, we have already generated MACV GPe and will design a MACV NP-NTD subunit antigen to test following the same approach followed with LASV against both homologous lineage challenge and heterologous challenge of MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing

emerging OWAV (LUJV) and NWAV (CHAPV) for which there are no vaccines available. A unique feature of this proposal is its access to BSL4 facilities described in **Core E** capable of evaluating countermeasures in NHP. It is widely considered that the cynomolgus macaque is the current "gold standard" animal model for LASV, JUNV, and MACV research as there are a multitude of immunological reagents available and the disease pathogenesis appears to mirror that of human infection[15-17]. The evaluation of successful countermeasures for the prototype OWAV AND NWAV in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

Unique from most other bunyaviruses, orthonairoviruses are transmitted primarily by ticks in nature (REF). While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[18], Issyk-Kul virus[19], Songling virus[20]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[21] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[22]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[23]. CCHFV is listed on the WHO priority pathogen list[24] and is also a NIH-NIAID category A pathogen[2]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[25] (REF). Ribivirin has been used to treat infections with limited success[26].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [23]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[23]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[23]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[27].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP subunits with the highest level of homology across clades and assess their capacity to protect against disease after challenge with multiple CCHFV clades in established mouse[27, 28] and NHP[29] models with Core E. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best performing formulation of CCHFV GP/NP MNP vaccine approach against emerging test case mammarenaviruses representing emerging bat virus, Kasokero virus for which there are no vaccines available.

~~The *Bunyavirales*.~~

~~Fill out~~

The henipavirus paramyxoviruses. The recognized, highly pathogenic HNVs, NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality (Murray, PMID: 7701348). NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs which served as amplifying hosts (Chua, PMID: 10827955). NiV and HeV

can infect at least 18 animal species across 6 orders of mammals, and among these they will cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans (PMID: 32991264; PMID: 22476556). The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission (PMID: 23911335). Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and South East Asia and Australia. Their broad host tropism and ability of these viruses to infect livestock offers an amplification opportunity and increased risk of subsequent human infections. The henipaviruses are single-stranded, negative sense, enveloped RNA viruses and their biology also lends themselves to be synthetically produced and agents of potential and deliberate misuse. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS) and Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents [Possession, Use, and Transfer of Select Agents and Toxins; Biennial Review; Department of Health and Human Services (Ed.) United States Government, Federal Register: Washington, DC, USA, 2020; Volume 85, FR 15087]. because they could be engineered for mass dissemination and possess the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the WHO R&D Blueprint list of priority pathogens with epidemic potential (Sweileh, W. M. PMC5299748).

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb, postexposure treatments have been demonstrated to be effective therapies against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP) (PMID: 22013123, PMID: 24964990, PMID: 27484128, PMID: 31686101). The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia (PMID: 32027842). In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs and several vaccine platforms have clear potential for use in people (PMC8782152). The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies (PMC8782152). Such preventive vaccines would have utility for lab workers, first responders or individuals at high risk exposure and in mitigating the spread of an outbreak; whereas in the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent (Middleton, 2014 PMID: 24572697). It is widely considered that the African green monkey (AGM) is the current "gold standard" animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection (Geisbert, 2012;Geisbert, 2010). The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished) (PMID: 33809833). The PABVAX Center has chosen to initiate studies on the divergent LayV as the Phase II test case scenario. The choice is justifiable for several important reasons; 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Also, another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including the rescue of recombinant LayV (rLayV), explore animal model development, construct additional LayV and AngV reporter virus tools, and then translate and test the MNP

Commented [CRW2]: Reviewer may be looking for description of Phase I. Not mentioned in this section.

vaccine ‘plug-and-play’ approach, and also evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME

A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center’s RPs and Core leaders currently have active and productive collaborative research programs in related areas, some spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

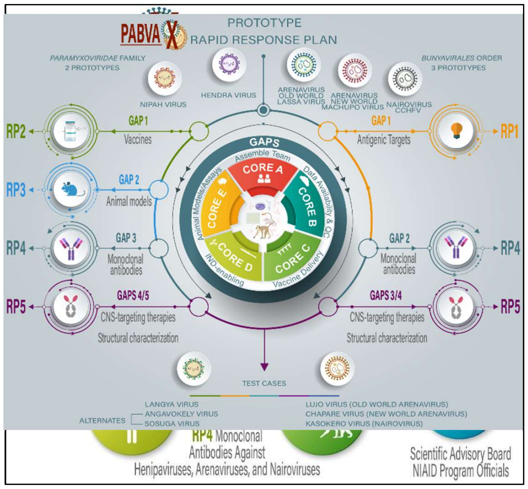

Figure 1: Organizational chart of the Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center-(PABVAX). **(connecting arrows are needed between elements and the SAB)**

The organizational structure of the PABVAX is diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **Arenaviridae** and **Nairoviridae** viruses, and **RP2** will target the prototype **henipaviruses** (HNVs). Both RP1 and RP2 will also be developing new prototype virus tools (recombinantly generated prototype viruses) along with existing tools, to be used in the analysis of vaccine responses as well as in the evaluation of new mAbs and nabs from the other RPs. A third RP will be engaged in the development of a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant Cedar henipavirus (rCedV) in vivo and a bioluminescence methodology that can longitudinally trace the dynamics and anatomical progression of luciferase encoding virus infection in individual animals (**RP3**). There will also be two RPs that will target the development of human mAbs and nanobodies to the PABVAX select viral prototypes. **RP4** will isolate human mAbs derived from NiV infected survivors with a specific focus on the F glycoprotein targeted mAbs, and additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses along with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will be engaged in manufacture and quality control & testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform.
The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from

Commented [CRW3]: Tom asked me to insert this to see how it would look so we can see what changes are needed to ensure legibility since the figure needed to get shrunk to fit. Some of the graphics dead center might be a little too small, not sure anything can be done there…

Maybe be good to have the whole title per RP listed instead of abbreviated form?

May need to identify what is meant by Gaps as its not identified in this document, I think maybe it is spelled out in Core E document?. Assuming maybe these are Gaps identified in the main RFA?

Just an idea…. having RP4 and RP5 bubbles duplicated to demonstrate different GAPs addressed is a little confusing to me, maybe if we do end up enumerating the gaps somewhere in the text, it might simplify things by identify what gaps are addressed by each RP so that each RP only has one bubble? EG:

- RP1=gap 1
- RP2=gap 1
- RP3=gap 2
- RP4=gap 2,3
- RP5= gap 3,4,5

Commented [LZ4R3]: It would be nice if the emergent/moderna logos can be squeezed in somewhere…

the UPitt and IBBR/UMD (**Core C**) that has tested a dissolvable MNP-based vaccine technology that is ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine approach (PMID: 32924651). This vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable MNPs that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants (PMID: 19864632) to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as facilitate the improved vaccine storage and distribution due to their thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, a Scientific **Core C**: (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ) adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (Paramyxoviridae). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity in vitro and polyfunctional T-cell responses by in vitro stimulation of isolated cells with antigenic peptides, intracellular cytokine staining (ICS) and flow cytometry) responses.

Discover effective antibody-based ~~prophylactics and~~ therapies.

~~PREP can be critical in the absence of available vaccines or cases in which vaccination is not possible.~~

HELP

Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah [30], Hendra [31], Ebola [32, 33], Marburg [34] and Lassa [35]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc.*), a feature to be exploited in **Core D**. In addition to therapeutic applications, mAbs with Fc mutations to dramatically extend serum half-life [36-38] offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g.* rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures.

Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the A~~A~~nimal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation S~~s~~cientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including ~~……..~~ animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective ~~therapeutic~~ efficacy of antivirals and vaccines as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation; including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera

Commented [CB5]: Larry/Dafna you are needed for this.

Commented [LZ6R5]: Here is something though we probably need a few sentences on nanobodies…

or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they can be adapted to greater high-throughput platforms, are often less laborious, and they can make use of other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput florescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic Nipah and Hendra virus vaccine induced immune sera, mAbs (**RP4**) and nbs (**RP5**) and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either the HeV or NiV-B envelope glycoproteins) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals, ideally suited to explore nab based therapeutics to CNS resident henipavirus (PMID: 35821488).

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. ~~Data generated to support of possible future regulatory submissions to the Food and Drug Administration (FDA) must be collected in accordance with quality systems, like good laboratory practice (GLP) regulations, to be useful and reliable, and to facilitate FDA review to ensure safety and efficacy.~~ The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the henipaviruses (Paramyxoviridae) and the Bunyavirales (Arenaviridae and Nairoviridae) that will bolster vaccine endurance to storage and transportation; and also improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology and mAb and vaccine translational drug development and includes Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Henipaviruses: Nipah virus (NiV) and Hendra virus (HeV) are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals and are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of Cedar virus (CedV), Gamak virus, Daeryong virus, and Langya virus (LayV) [xxx] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV) [xxx]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV,

are old world pteropid fruit bats. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province). The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**.

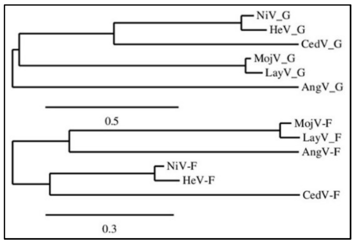

Figure 2. Phylogenetic analysis of select HNV G and F glycoproteins. Phylogenetic trees were constructed for the HNV F and G glycoproteins using the PhyML program's maximum likelihood method. The trees were generated by aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal henipaviral disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters (Geisbert 2012), and African green monkeys (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P), and the P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists (xx). The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2 (XXX) and CedV is now recognized as a BSL-2 restricted agent [CDC manual]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D, and E**).

Old Word Mammarenaviruses (OWAV): For **phase 1**, **RP1** will utilize **LASV as the prototype OWAV** due to the significant public health burden it creates throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[39]. LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to several countries outside of Africa over 35 documented times [40]. Case fatality rates (CFR) approaching 70% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) [41]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize the only the LASV GP as the target immunogen despite

Investigators in RP1, Core D, and Core E have already demonstrated protective efficacy of against disease after challenge with LASV in outbred guinea pigs in animals vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These antigens have been engineered to harness the homologous antigenic regions of both antigens to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach, suggest a similar strategy of using a subunit vaccine might also be effective against other arenaviruses. While LASV is the most common pathogenic arenavirus in Africa in terms of human infections, Lujo virus was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [42]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

New World Mamarenaviruses (NWAV): A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina [43], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine [44, 45]. Further, there are safety concerns related to potential for reversion to pathogenic versions. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted. Building on the success of the LASV GPe/NP-NTD. Investigators in **RP1 and Cores D and E** will engineer MACV GPe and NP-NTD antigens and test for efficacy in established guinea pig and NHP models using MACV from multiple lineages to asses how broadly protective the approach is across MACV lineages. We will then extend this plug-and-play approach to other NWAV. First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [46, 47]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [47]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Orthonairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family responsible for often large outbreaks of human disease annually across Europe, Africa, and Asia. There are no FDA approved vaccines for CCHFV; however, a suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974 but has numerous safety concerns and limited demonstrated efficacy. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[48]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[49]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test for protective efficacy from disease after challenge with 6 different lineages of CCHFV clades using in established mouse and NHP models. Next we will deploy the same approach to a known human pathogen "test case" orthonairovirus for which no vaccine exists.

In 1977, **Kasokero virus (KASV),** a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [50]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV [51]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Formatted: Indent: First line: 0.5"

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as

for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs; such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**), (aarenavirus and nairovirus~~renaviridae and nairoviridae~~ projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine the active and passive immunization approaches to further improved the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

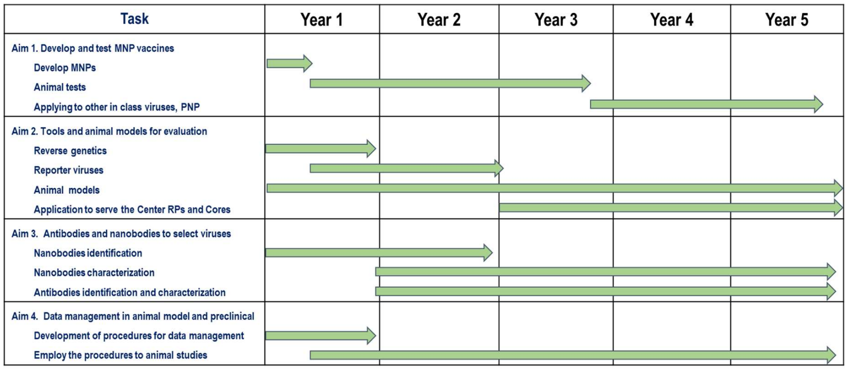
An additional and outstanding advantage of the PABVAX Center is the **Animal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL. (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for all the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.**
2. **Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.**
3. **Develop antibodies and nanobodies to selected prototype viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**.



Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. This is in addition to each PR's individual Milestone plan. The oversight and evaluation of progress will be in concert with quarterly reports to the

PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (Details are within the Administration **Core A**). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommend new directions as appropriate and provide Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

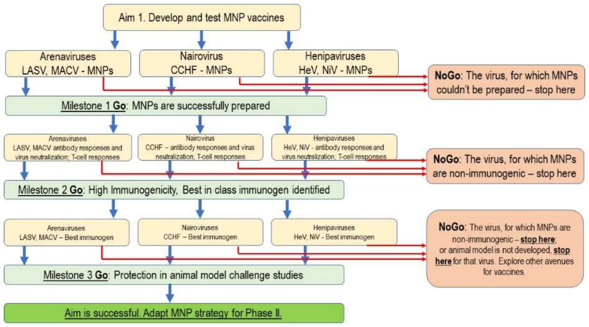


Figure 4. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will be whether proper formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be made based on immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen specific antibody induction and virus-neutralization and polyfunctional T-cell responses by in vitro stimulation of isolated cells). Go/no go decisions will be made based on the outcomes of these first tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as success. Comparisons will also be made, such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of best-in-class immunogens, or best combination immunogens which will also be explored, will be performed in order to down-select vaccine choice. The third milestone will be the determination of whether MNP vaccination affords protection in animal model challenge experiments. In the case of the NiV and HeV prototypes the animal models chosen (ferret and the African green monkey (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales* there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASA and there are guinea pig models for some but not all of those lineages. For MACV there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is that rhesus macaques are nearly unavailable and cynomolgus monkeys are now each greater than 35K. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be further developing and evaluating animal model systems, including new models, within the PABVAX program, including further development of the AGM for the arenaviruses and possibly also for CCHF as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Commented [LZ12]: Rather than a STOP if there is an issue with MNPs, should we shunt that into a subunit vaccine approach and/or other formulation determined in conjunction with Industrial Partners?

Aim 2. Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.

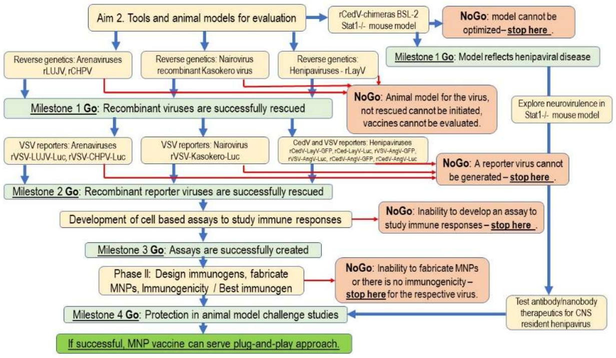

Figure 5. Milestones and criteria for progress for **Aim 2** of the PABVAX Center overall objectives.

The PABVAX second overall objective is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined in vivo (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed as the complete genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If these objectives are successful, a a large battery of new reagents and tools will be available to share with the ReVAMPP network, as well as serving as key components for initiation and execution of Phase II of the PABVAX Center program.

The translation and testing the MNP vaccine plug-and-play approach will be initiated in the Phase II prototype viruses (**Table 1**) the milestones here will be similar to those outlined in **Figure 4**. The new virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the new divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new in vivo bioluminescence-based immune deficient mouse model (newly developed for Lyssavirus infection by the PIs of **PR2** and **RP3**) that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease in vivo safely and expediently at BSL-2 containment. If the model can be optimized (**Figure 5**) it will be deployed to test a critically important therapeutic need, the use of antivirals against CNS resident HNV infection, and RP3 will collaborate with RP5 in the testing of engineered nabs specific for the prototype HNVs NiV and HeV.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

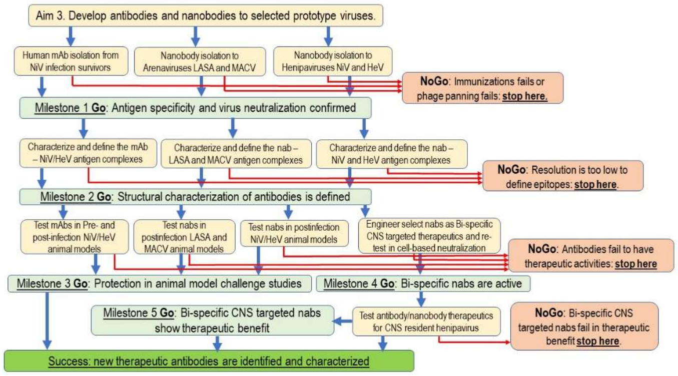

Figure 6. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

Commented [LZ13]: Do we need to add Jim's use of Alloy mice for the bunyas?

New human mAbs and nanobodies (nbs) as tools and potential therapeutics will be developed by RP4 and RP5 in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); and transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on the mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs and in collaboration with **RP2** neutralization potencies will be rapidly assessed as well as evaluating synergistic cell-based mAb neutralization that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

Nanobodies, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nanobodies can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nanobodies targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), and also for therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus) and select animal models of LASV and MACV by **Core E**. Success will be measured by the identification of virus-neutralizing nbs, potential discovery of more broadly reactive nbs, particularly to the multiple LASA clades, the evidence of therapeutic benefit in animal models, and the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

INDUSTRY PARTNERSHIPS

Industry Partnership

Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine

expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX.

Commented [LZ14]: I can expand on this if needed.

Formatted: Font: Not Italic

SPECIAL FEATURES OF THE PABVAX CENTER ENVIRONMENT AND OTHER RESOURCES ??

Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Galveston National Laboratory (GNL)

The GNL, is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics and therapeutics against them. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370~~187~~ separate NHP studies employing a total of 2,772~~1,318~~ animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses ~~Ebola and Marburg viruses and also Nipah and Hendra~~ have been successfully performed at the GNL. These NHP studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP~~nonhuman primate~~ facility and a staff of full-time veterinarians. In addition, **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above another special feature is the location of WRCEVA virus collection within the GNL.

Formatted: Not Highlight

Core E (Animal model development and preclinical evaluation)

Core E operations will be conducted at the GNL, and in conjunction with **Core A** also includes the UTMB Institutional Office of Regulated Nonclinical Studies (ONcRS). The ONcRS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, ~~to meet regulatory requirements by assuring regulatory compliance,~~ quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. ~~Quality system and regulatory science processes for NHP studies performed at UTMB will be implemented and executed in conjunction with the ORNcS.~~ Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses and the henipaviruses and he has published over 250~~XXX~~ peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI) was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Formatted: Font: Bold

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs)

Mapp Biopharmaceutical has deep experience with antigens and monoclonal antibodies (mAbs) against these antigens. ~~'s product development team has grown significantly in the last two years in response to the development efforts on its anti-Ebola therapeutic, ZMapp™ which is being advanced to licensure as part of Project Bioshield. OTHER MAbs~~ Their early development and research group has expertise in immunology, infectious diseases, and production of antigens, antibodies and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [52] [53]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1 [54]. ~~developed multiple products, including a licensed biodefense biologic. As with Profectus, Mapp Bio's expertise and experience will be a very important and valuable asset to the Center.~~

Core A (Administrative Core)

Research Project teams?? Maybe not depending on space

The investigators at USU, led by Dr. Broder have an extensive history in henipavirus research which he established in 1999, and he has published more than 75 articles, reviews and chapters in this area. His group has also made significant translational research accomplishments in the area of henipavirus countermeasure developments including Equivac® HeV (Zoetis, Inc.) for use in horses in Australia, and the human mAb (m102.4) having a Phase I clinical trial completed (2016) in Australia, in partnership with the Queensland Government and NIAID. Dr. Broder was the recipient of the Federal Laboratory Consortium for Technology Transfer, Excellence Award in 2013. His administrative experience and skills and his experience in translational research activities qualify him to serve as the director of the PABVAX Center and Administrative Core.

Dr. Crowe's (**RP4**) research focuses on the molecular basis for the development of effective B cell responses to viruses in humans and he has published over 200 peer-reviewed research articles in this area. The Crowe laboratory is one of the leading groups in the development of innovative technologies for isolation and study of human mAbs. Dr. Crowe's group has isolated human mAbs that neutralize HIV, influenza, dengue, chikungunya, respiratory syncytial virus, human metapneumovirus, rotavirus, norovirus, and recently henipaviruses NiV and HeV owing to the collaboration between the Crowe, Broder and Geisbert laboratories. Perhaps of greatest import, the SARS-CoV-2 mAbs generated by Dr. Crowe's laboratory were used in xxx,000 of people during the COVID-19 pandemic. RP4 will work closely with Cores D and E in advancing mAb prototypes. ~~The Core B of the Center will work together with RP2 and RP3 along with the Core C to develop the first cocktail human mAb immunotherapeutics, and facilitate the transition products suitable for IND filing and human testing including design, construction, assessment, and optimization of these antibody-based therapies.~~

As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

Formatted: Font: 11 pt

Commented [LZ15]: Chris…not sure where this fits best, but its something the RFA mentions we should address…

CENTER OVERVIEW: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction

Commented [CB1]: I think as you review this doc, perhaps specifically name the PIs and PLs in certain areas?

Emerging and periodically reemerging pathogenic enveloped RNA viruses are ~~a~~ continuous ~~infectious disease and potentially~~ pandemic threats to global public health. Among the many groups of these types of pathogens are viral zoonoses within the family **Paramyxoviridae** and order ***Bunyavirales*** where humans can acquire infections directly from animal reservoir hosts such as rodents or bats~~,~~ through an intermediate amplifying host such as livestock, or from arthropod vectors such as mosquitos and ticks (Fields virology). More often than not, humans represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur, and should RNA viral pathogens mutate and adapt to more efficient replication and shedding in the human host, the epidemic potential of these viruses could manifest (PMID: 23911335 -Nipah / others?). The viral order *Bunyavirales* is composed of several viral families known to contain multiple high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic fever diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) and are also identified as NIAID Category A pathogens due to their ease of dissemination and/or abilities to transmit person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special actions for public health preparedness. Also, within the WHO Priority Pathogens list is Nipah virus (NiV) and henipaviral disease which includes Hendra virus (HeV) which are zoonotic henipaviruses (HNVs) in the family **Paramyxoviridae**. NiV and HeV have long been considered the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease (PMID: 16357858). The genus now includes nine additional reported HNVs but only HeV and NiV are known to be associated with severe and often fatal henipaviral disease in humans and a number of animal species (PMID: 32991264). Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illnesses in humans [PMID: 35921459].

Taken together, these viral threats to global public health are heightened due to the absence of approved vaccines or therapeutics. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for vaccine and monoclonal antibody (mAb) countermeasures in developing prototype candidates (**Table 1**) against a selection of these viruses. In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Table 1. PABVAX selected prototype and test case viral agents.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old world), Machupo (New world)	Lujo (Old world), Chapare (New world)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Bunyavirales:

Arenaviridae: The family Arenaviridae is composed of three genera: Mammarenaviridae, Reptarenavirus, and Hartmanivirus. The Mammarenaviridae are composed of a large number rodent borne viruses, some of which are demonstrated human pathogens responsible for causing severe hemorrhagic fever, neurological damage, and if not fatal can result permanent neurological sequelae including hearing loss, vision impairment, and balance [1]derangement. While these genera exhibit a global distribution, two geographically distinct sub-genera have formed due to the separation across continents by the Atlantic and Pacific Ocean. Old World Mammarenaviruses (Lassa Virus (LASV), Lymphocytic Choriomeningitis Virus (LCMV), and the newly discovered Lujo Virus (LUJV)) and the New World Arenaviruses (Junin Virus (JUNV), Machupo Virus (MACV), Sabia Virus (SABV), and the newly emerging Chapare Virus (CHAPV)). Many of these viruses are identified as NIAID Category A pathogens requiring biosafety level 4 (BSL4) containment [2]. This classification is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness. While several

promising medical countermeasures are in development, there are currently no US FDA approved vaccines or therapeutics for any mammarenaviruses, though the attenuated JUNV “Candid-1” vaccine is approved for use in Argentina.

Infection in humans is often the result of exposure to rodent excreta from infected animals where disease severity and case fatality rates (CFR) can vary across the genera and even within genetic lineages as can be the case for infections with LASV where genetic diversity can be high, even within clades. While this genetic variability creates significant challenges for LASV molecular diagnostics, antigen-based diagnostics have seen high levels of cross reactivity across the seven known lineages of LASV suggesting cross protective antigens may be possible[3]. Lassa virus, the causative agent of Lassa fever (LF), likely causes the largest number of annual cases per year of LF, where its understood up to 500,000 cases per year can occur where the CFR can approach 70% in hospitalized cases [4]. Ribivirin has been used to treat infections with uncertain success [5]. Before the introduction of the JUNV Candid-1 vaccine, its believed that upwards of 60,000 cases of JUNV infection, also known as Argentine Hemorrhagic Fever (AHF) per year occurred where CFRs ranged from 15-30 %. Convalescent plasma from JUNV survivors is still the primary means to treat acute JUNV infections in Argentina [6]. The initial outbreak of Machupo virus had over 1000 cases and CFRs have ranged from 5-30%;~~ with a CFR~~, ~~where ~~outbreak frequency is thought to have been reduced through enhanced rodent abatement practices and potentially cross-protective immunity in populations who have taken the JUNV Candid-1 vaccine [7].

All mammarenaviruses share a common genomic organization consisting of two ambi-sense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP) [1]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge [8]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe) [9]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. To test these notions, investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccine approaches to test this idea and have demonstrated protection against lethal LASV-Josiah challenge using a stabilized prefusion, trimeric GPe, a highly conserved NP NTD epitope, or a combination of the two antigens using a lethal outbred guinea pig model.

Despite the considerable molecular diversity in LASV strains, there is understood that there is some conservation in key antigenic sites within both the GPe and the NP, suggesting that a PAN-LASV vaccine may be possible[3, 10, 11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

In **Phase I of RP1**, the ability for an optimized intramuscular (IM) LASV GPe/NP subunit vaccine to protect against disease after challenge multiple LASV lineages will be assessed in guinea pig and NHP models. This formulation will also be assessed using a microneedle skin patch (MNP) formulation optimized in Core C to determine if a needle-free vaccination route affords more potent vaccine mediated responses and protection. Similarly, we have already generated MACV GPe and will design a MACV NP-NTD subunit antigen to test following the same approach followed with LASV against both homologous lineage challenge and heterologous challenge of MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing

emerging OWAV (LUJV) and NWAV (CHAPV) for which there are no vaccines available. A unique feature of this proposal is its access to BSL4 facilities described in **Core E** capable of evaluating countermeasures in NHP. It is widely considered that the cynomolgus macaque is the current "gold standard" animal model for LASV, JUNV, and MACV research as there are a multitude of immunological reagents available and the disease pathogenesis appears to mirror that of human infection[15-17]. The evaluation of successful countermeasures for the prototype OWAV AND NWAV in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

Unique from most other bunyaviruses, orthonairoviruses are transmitted primarily by ticks in nature (REF). While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[18], Issyk-Kul virus[19], Songling virus[20]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[21] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[22]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[23]. CCHFV is listed on the WHO priority pathogen list[24] and is also a NIH-NIAID category A pathogen[2]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[25] (REF). Ribivirin has been used to treat infections with limited success[26].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [23]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[23]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[23]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[27].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP subunits with the highest level of homology across clades and assess their capacity to protect against disease after challenge with multiple CCHFV clades in established mouse[27, 28] and NHP[29] models with Core E. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best performing formulation of CCHFV GP/NP MNP vaccine approach against emerging test case mammarenaviruses representing emerging bat virus, Kasokero virus for which there are no vaccines available.

~~The *Bunyavirales*.~~

~~Fill out~~

The henipavirus paramyxoviruses. The recognized, highly pathogenic HNVs, NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality (Murray, PMID: 7701348). NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs which served as amplifying hosts (Chua, PMID: 10827955). NiV and HeV

can infect at least 18 animal species across 6 orders of mammals, and among these they will cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans (PMID: 32991264; PMID: 22476556). The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission (PMID: 23911335). Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and South East Asia and Australia. Their broad host tropism and ability of these viruses to infect livestock offers an amplification opportunity and increased risk of subsequent human infections. The henipaviruses are single-stranded, negative sense, enveloped RNA viruses and their biology also lends themselves to be synthetically produced and agents of potential and deliberate misuse. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS) and Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents [Possession, Use, and Transfer of Select Agents and Toxins; Biennial Review; Department of Health and Human Services (Ed.) United States Government, Federal Register: Washington, DC, USA, 2020; Volume 85, FR 15087]. because they could be engineered for mass dissemination and possess the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the WHO R&D Blueprint list of priority pathogens with epidemic potential (Sweileh, W. M. PMC5299748).

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb, postexposure treatments have been demonstrated to be effective therapies against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP) (PMID: 22013123, PMID: 24964990, PMID: 27484128, PMID: 31686101). The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia (PMID: 32027842). In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs and several vaccine platforms have clear potential for use in people (PMC8782152). The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies (PMC8782152). Such preventive vaccines would have utility for lab workers, first responders or individuals at high risk exposure and in mitigating the spread of an outbreak; whereas in the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent (Middleton, 2014 PMID: 24572697). It is widely considered that the African green monkey (AGM) is the current "gold standard" animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection (Geisbert, 2012;Geisbert, 2010). The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished) (PMID: 33809833). The PABVAX Center has chosen to initiate studies on the divergent LayV as the Phase II test case scenario. The choice is justifiable for several important reasons; 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Also, another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including the rescue of recombinant LayV (rLayV), explore animal model development, construct additional LayV and AngV reporter virus tools, and then translate and test the MNP

Commented [CRW2]: Reviewer may be looking for description of Phase I. Not mentioned in this section.

vaccine 'plug-and-play' approach, and also evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME

A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center's RPs and Core leaders currently have active and productive collaborative research programs in related areas, some spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

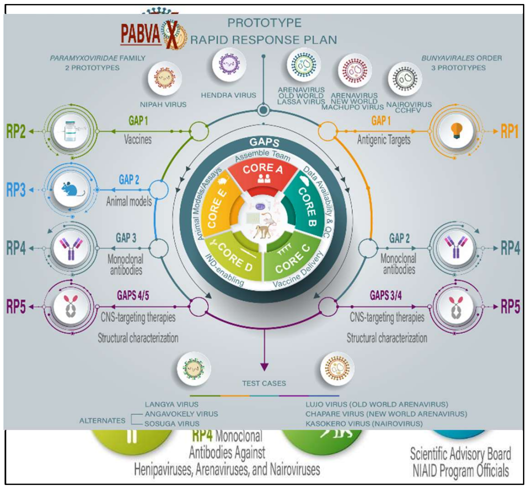

Figure 1: Organizational chart of the Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center-(PABVAX). **(connecting arrows are needed between elements and the SAB)**

The organizational structure of the PABVAX is diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **Arenaviridae** and **Nairoviridae** viruses, and **RP2** will target the prototype **henipaviruses** (HNVs). Both RP1 and RP2 will also be developing new prototype virus tools (recombinantly generated prototype viruses) along with existing tools, to be used in the analysis of vaccine responses as well as in the evaluation of new mAbs and nabs from the other RPs. A third RP will be engaged in the development of a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant Cedar henipavirus (rCedV) in vivo and a bioluminescence methodology that can longitudinally trace the dynamics and anatomical progression of luciferase encoding virus infection in individual animals (**RP3**). There will also be two RPs that will target the development of human mAbs and nanobodies to the PABVAX select viral prototypes. **RP4** will isolate human mAbs derived from NiV infected survivors with a specific focus on the F glycoprotein targeted mAbs, and additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses along with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will be engaged in manufacture and quality control & testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based prophylactics and therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform.
The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from

Commented [CRW3]: Tom asked me to insert this to see how it would look so we can see what changes are needed to ensure legibility since the figure needed to get shrunk to fit. Some of the graphics dead center might be a little too small, not sure anything can be done there…

Maybe be good to have the whole title per RP listed instead of abbreviated form?

May need to identify what is meant by Gaps as its not identified in this document, I think maybe it is spelled out in Core E document?. Assuming maybe these are Gaps identified in the main RFA?

Just an idea…. having RP4 and RP5 bubbles duplicated to demonstrate different GAPs addressed is a little confusing to me, maybe if we do end up enumerating the gaps somewhere in the text, it might simplify things by identify what gaps are addressed by each RP so that each RP only has one bubble? EG:

- RP1=gap 1
- RP2=gap 1
- RP3=gap 2
- RP4=gap 2,3
- RP5= gap 3,4,5

Commented [LZ4R3]: It would be nice if the emergent/moderna logos can be squeezed in somewhere…

the UPitt and IBBR/UMD (**Core C**) that has tested a dissolvable MNP-based vaccine technology that is ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine approach (PMID: 32924651). This vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable MNPs that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants (PMID: 19864632) to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as facilitate the improved vaccine storage and distribution due to their thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, a Scientific **Core C**: (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ) adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (Paramyxoviridae). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity in vitro and polyfunctional T-cell responses by in vitro stimulation of isolated cells with antigenic peptides, intracellular cytokine staining (ICS) and flow cytometry) responses.

Discover effective antibody-based prophylactics and therapies.
~~PREP can be critical in the absence of available vaccines or cases in which vaccination is not possible.~~
HELP

Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah [30], Hendra [31], Ebola [32, 33], Marburg [34] and Lassa [35]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc*.), a feature to be exploited in **Core D**. In addition to therapeutic applications, mAbs with Fc mutations to dramatically extend serum half-life [36-38] offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g.* rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures.
Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the A~~A~~nimal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation S~~s~~cientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective ~~therapeutic~~ efficacy of antivirals and vaccines as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation; including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera

or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they can be adapted to greater high-throughput platforms, are often less laborious, and they can make use of other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput florescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic Nipah and Hendra virus vaccine induced immune sera, mAbs (**RP4**) and nbs (**RP5**) and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either the HeV or NiV-B envelope glycoproteins) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals, ideally suited to explore nab based therapeutics to CNS resident henipavirus (PMID: 35821488).

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. ~~Data generated to support of possible future regulatory submissions to the Food and Drug Administration (FDA) must be collected in accordance with quality systems, like good laboratory practice (GLP) regulations, to be useful and reliable, and to facilitate FDA review to ensure safety and efficacy.~~ The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the henipaviruses (Paramyxoviridae) and the Bunyavirales (Arenaviridae and Nairoviridae) that will bolster vaccine endurance to storage and transportation; and also improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology and mAb and vaccine translational drug development and includes Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Henipaviruses: Nipah virus (NiV) and Hendra virus (HeV) are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals and are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of Cedar virus (CedV), Gamak virus, Daeryong virus, and Langya virus (LayV) [xxx] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV) [xxx]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV,

are old world pteropid fruit bats. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province). The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**.

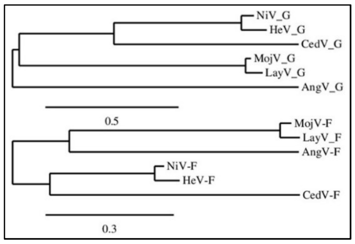

Figure 2. Phylogenetic analysis of select HNV G and F glycoproteins. Phylogenetic trees were constructed for the HNV F and G glycoproteins using the PhyML program's maximum likelihood method. The trees were generated by aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal henipaviral disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters (Geisbert 2012), and African green monkeys (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P), and the P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists (xx). The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2 (XXX) and CedV is now recognized as a BSL-2 restricted agent [CDC manual]. Because the HNV, LayV, is known to be a human pathogenic and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D, and E**).

Old Word Mammarenaviruses (OWAV): For **phase 1**, **RP1** will utilize **LASV as the prototype OWAV** due to the significant public health burden it creates throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[39]. LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to several countries outside of Africa over 35 documented times [40]. Case fatality rates (CFR) approaching 70% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) [41]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize the only the LASV GP as the target immunogen despite

Investigators in RP1, Core D, and Core E have already demonstrated protective efficacy of against disease after challenge with LASV in outbred guinea pigs in animals vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These antigens have been engineered to harness the homologous antigenic regions of both antigens to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach, suggest a similar strategy of using a subunit vaccine might also be effective against other arenaviruses. While LASV is the most common pathogenic arenavirus in Africa in terms of human infections, Lujo virus was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [42]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Formatted: Indent: First line: 0.5"

New World Mamarenaviruses (NWAV): A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina [43], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine [44, 45]. Further, there are safety concerns related to potential for reversion to pathogenic versions. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted. Building on the success of the LASV GPe/NP-NTD. Investigators in **RP1 and Cores D and E** will engineer MACV GPe and NP-NTD antigens and test for efficacy in established guinea pig and NHP models using MACV from multiple lineages to asses how broadly protective the approach is across MACV lineages. We will then extend this plug-and-play approach to other NWAV. First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [46, 47]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [47]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Orthonairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family responsible for often large outbreaks of human disease annually across Europe, Africa, and Asia. There are no FDA approved vaccines for CCHFV; however, a suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974 but has numerous safety concerns and limited demonstrated efficacy. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[48]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[49]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test for protective efficacy from disease after challenge with 6 different lineages of CCHFV clades using in established mouse and NHP models. Next we will deploy the same approach to a known human pathogen "test case" orthonairovirus for which no vaccine exists.

In 1977, **Kasokero virus (KASV),** a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [50]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV [51]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Formatted: Indent: First line: 0.5"

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as

for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs; such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**), (aarenavirus and nairovirus~~renaviridae and nairoviridae~~ projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine the active and passive immunization approaches to further improved the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

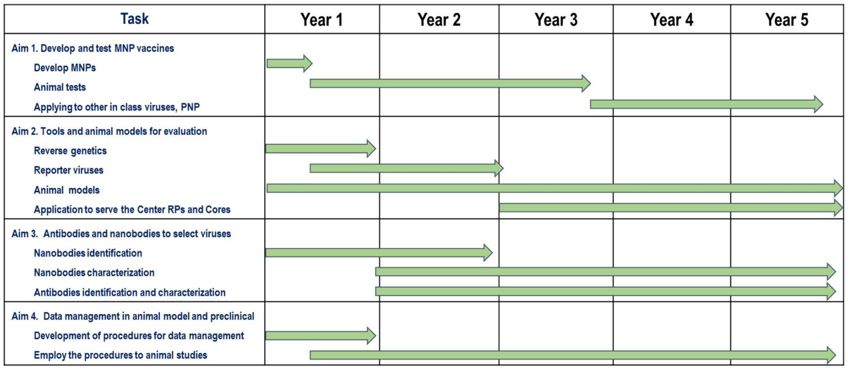
An additional and outstanding advantage of the PABVAX Center is the **Animal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL. (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for all the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.**
2. **Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.**
3. **Develop antibodies and nanobodies to selected prototype viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**.



Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. This is in addition to each PR's individual Milestone plan. The oversight and evaluation of progress will be in concert with quarterly reports to the

PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (Details are within the Administration **Core A**). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommend new directions as appropriate and provide Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

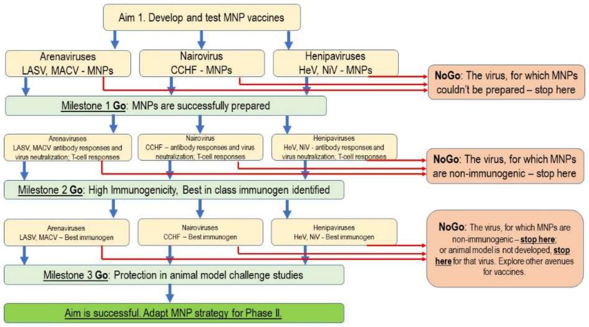


Figure 4. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will be whether proper formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be made based on immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen specific antibody induction and virus-neutralization and polyfunctional T-cell responses by in vitro stimulation of isolated cells). Go/no go decisions will be made based on the outcomes of these first tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as success. Comparisons will also be made, such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of best-in-class immunogens, or best combination immunogens which will also be explored, will be performed in order to down-select vaccine choice. The third milestone will be the determination of whether MNP vaccination affords protection in animal model challenge experiments. In the case of the NiV and HeV prototypes the animal models chosen (ferret and the African green monkey (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales* there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASA and there are guinea pig models for some but not all of those lineages. For MACV there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is that rhesus macaques are nearly unavailable and cynomolgus monkeys are now each greater than 35K. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be further developing and evaluating animal model systems, including new models, within the PABVAX program, including further development of the AGM for the arenaviruses and possibly also for CCHF as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Commented [LZ12]: Rather than a STOP if there is an issue with MNPs, should we shunt that into a subunit vaccine approach and/or other formulation determined in conjunction with Industrial Partners?

Aim 2. Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.

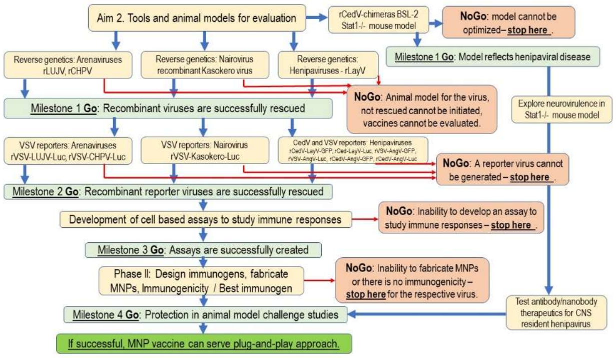

Figure 5. Milestones and criteria for progress for **Aim 2** of the PABVAX Center overall objectives.

The PABVAX second overall objective is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined in vivo (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed as the complete genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If these objectives are successful, a a large battery of new reagents and tools will be available to share with the ReVAMPP network, as well as serving as key components for initiation and execution of Phase II of the PABVAX Center program.

The translation and testing the MNP vaccine plug-and-play approach will be initiated in the Phase II prototype viruses (**Table 1**) the milestones here will be similar to those outlined in **Figure 4**. The new virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the new divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new in vivo bioluminescence-based immune deficient mouse model (newly developed for Lyssavirus infection by the PIs of **PR2** and **RP3**) that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease in vivo safely and expediently at BSL-2 containment. If the model can be optimized (**Figure 5**) it will be deployed to test a critically important therapeutic need, the use of antivirals against CNS resident HNV infection, and RP3 will collaborate with RP5 in the testing of engineered nabs specific for the prototype HNVs NiV and HeV.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

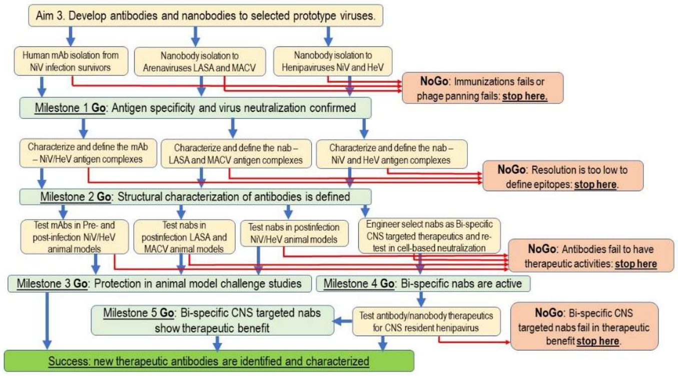

Figure 6. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

Commented [LZ13]: Do we need to add Jim's use of Alloy mice for the bunyas?

New human mAbs and nanobodies (nbs) as tools and potential therapeutics will be developed by RP4 and RP5 in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); and transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on the mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs and in collaboration with **RP2** neutralization potencies will be rapidly assessed as well as evaluating synergistic cell-based mAb neutralization that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

Nanobodies, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nanobodies can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nanobodies targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), and also for therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus) and select animal models of LASV and MACV by **Core E**. Success will be measured by the identification of virus-neutralizing nbs, potential discovery of more broadly reactive nbs, particularly to the multiple LASA clades, the evidence of therapeutic benefit in animal models, and the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

INDUSTRY PARTNERSHIPS

Industry Partnership

Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine

expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX.

Commented [LZ14]: I can expand on this if needed.

Formatted: Font: Not Italic

SPECIAL FEATURES OF THE PABVAX CENTER ENVIRONMENT AND OTHER RESOURCES ??

Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Galveston National Laboratory (GNL)

The GNL, is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics and therapeutics against them. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370~~187~~ separate NHP studies employing a total of 2,772~~1,318~~ animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses ~~Ebola and Marburg viruses and also Nipah and Hendra~~ have been successfully performed at the GNL. These NHP studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP~~nonhuman primate~~ facility and a staff of full-time veterinarians. In addition, **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above another special feature is the location of WRCEVA virus collection within the GNL.

Formatted: Not Highlight

Core E (Animal model development and preclinical evaluation)

Core E operations will be conducted at the GNL, and in conjunction with **Core A** also includes the UTMB Institutional Office of Regulated Nonclinical Studies (ONcRS). The ONcRS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, ~~to meet regulatory requirements by assuring regulatory compliance,~~ quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. ~~Quality system and regulatory science processes for NHP studies performed at UTMB will be implemented and executed in conjunction with the ORNcS.~~ Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses and the henipaviruses and he has published over 250~~XXX~~ peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI) was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Formatted: Font: Bold

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs)

Mapp Biopharmaceutical has deep experience with antigens and monoclonal antibodies (mAbs) against these antigens. ~~'s product development team has grown significantly in the last two years in response to the development efforts on its anti-Ebola therapeutic, ZMapp^{TM} which is being advanced to licensure as part of Project Bioshield. OTHER MAbs~~ Their early development and research group has expertise in immunology, infectious diseases, and production of antigens, antibodies and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies [52] [53]; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1 [54]. ~~developed multiple products, including a licensed biodefense biologic. As with Profectus, Mapp Bio's expertise and experience will be a very important and valuable asset to the Center.~~

Bonnie Genovac

Core A (Administrative Core)

Research Project teams?? Maybe not depending on space

The investigators at USU, led by Dr. Broder have an extensive history in henipavirus research which he established in 1999, and he has published more than 75 articles, reviews and chapters in this area. His group has also made significant translational research accomplishments in the area of henipavirus countermeasure developments including Equivac® HeV (Zoetis, Inc.) for use in horses in Australia, and the human mAb (m102.4) having a Phase I clinical trial completed (2016) in Australia, in partnership with the Queensland Government and NIAID. Dr. Broder was the recipient of the Federal Laboratory Consortium for Technology Transfer, Excellence Award in 2013. His administrative experience and skills and his experience in translational research activities qualify him to serve as the director of the PABVAX Center and Administrative Core.

Dr. Crowe's (**RP4**) research focuses on the molecular basis for the development of effective B cell responses to viruses in humans and he has published over 200 peer-reviewed research articles in this area. The Crowe laboratory is one of the leading groups in the development of innovative technologies for isolation and study of human mAbs. Dr. Crowe's group has isolated human mAbs that neutralize HIV, influenza, dengue, chikungunya, respiratory syncytial virus, human metapneumovirus, rotavirus, norovirus, and recently henipaviruses NiV and HeV owing to the collaboration between the Crowe, Broder and Geisbert laboratories. Perhaps of greatest import, the SARS-CoV-2 mAbs generated by Dr. Crowe's laboratory were used in xxx,000 of people during the COVID-19 pandemic. RP4 will work closely with Cores D and E in advancing mAb prototypes. ~~The Core B of the Center will work together with RP2 and RP3 along with the Core C to develop the first cocktail human mAb immunotherapeutics, and facilitate the transition products suitable for IND filing and human testing including design, construction, assessment, and optimization of these antibody-based therapies.~~

As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

Formatted: Font: 11 pt

Commented [LZ15]: Chris…not sure where this fits best, but its something the RFA mentions we should address…

CENTER OVERVIEW: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center – (PABVAX)

RESEARCH STRATEGY

Introduction

Emerging and periodically reemerging pathogenic enveloped RNA viruses are ~~a~~ continuous ~~infectious disease and potentially~~ pandemic threats to global public health. Among the many groups of these types of pathogens are viral zoonoses within the family **Paramyxoviridae** and order ***Bunyavirales*** where humans can acquire infections directly from animal reservoir hosts such as rodents or bats~~,~~ through an intermediate amplifying host such as livestock, or from arthropod vectors such as mosquitos and ticks (Fields virology). More often than not, humans represent a dead-end host infection, but for some viral agents several rounds of human-to-human transmission can occur, and should RNA viral pathogens mutate and adapt to more efficient replication and shedding in the human host, the epidemic potential of these viruses could manifest (PMID: 23911335 -Nipah / others?). The viral order *Bunyavirales* is composed of several viral families known to contain multiple high priority human pathogens. Notably, **Arenaviridae** and **Nairoviridae** families contain viruses which cause severe hemorrhagic fever diseases in humans across the world with mortality rates up to XX and significant, long-term sequelae in survivors. These viruses are on the World Health Organization's (WHO) List of Priority Pathogens where six arenaviruses – Lassa, Lujo, Chapare, Guanarito, Junin and Machupo (LASV, LUJV, CHPV, GTOV, JUNV, MACV) and one Nairovirus-Crimean-Congo Hemorrhagic Fever Virus (CCHFV) and are also identified as NIAID Category A pathogens due to their ease of dissemination and/or abilities to transmit person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special actions for public health preparedness. Also, within the WHO Priority Pathogens list is Nipah virus (NiV) and henipaviral disease which includes Hendra virus (HeV) which are zoonotic henipaviruses (HNVs) in the family **Paramyxoviridae**. NiV and HeV have long been considered the prototype members of the genus *Henipavirus* and have a uniquely broad host tropism, causing an often fatal respiratory and/or neurological disease (PMID: 16357858). The genus now includes nine additional reported HNVs but only HeV and NiV are known to be associated with severe and often fatal henipaviral disease in humans and a number of animal species (PMID: 32991264). Langya virus (LayV) is the most recently identified HNV and was associated with nonfatal febrile illnesses in humans [PMID: 35921459].

Commented [CB1]: I think as you review this doc, perhaps specifically name the PIs and PLs in certain areas?

Taken together, these viral threats to global public health are heightened due to the absence of approved vaccines or therapeutics. *There is a clear unmet need for countermeasures such as vaccines and antibody-based therapeutics to address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these viral agents*. The PABVAX Center will focus on elucidating key principles for vaccine and monoclonal antibody (mAb) countermeasures in developing prototype candidates (**Table 1**) against a selection of these viruses. In the out years of the Center effort, PABVAX will exploit these learned key principles in a "plug and play" demonstration against related viruses.

Table 1. PABVAX selected prototype and test case viral agents.

Family	Prototype	Plug and Play Test Case
Arenaviruses	Lassa (Old world), Machupo (New world)	Lujo (Old world), Chapare (New world)
Nairoviruses	CCHF	Kasokero
Paramyxoviruses	Nipah, Hendra	Langya

Bunyavirales:

Arenaviridae: The family Arenaviridae is composed of three genera: Mammarenaviridae, Reptarenavirus, and Hartmanivirus. The Mammarenaviridae are composed of a large number rodent borne viruses, some of which are demonstrated human pathogens responsible for causing severe hemorrhagic fever, neurological damage, and if not fatal can result permanent neurological sequelae including hearing loss, vision impairment, and balance [1]derangement. While these genera exhibit a global distribution, two geographically distinct sub-genera have formed due to the separation across continents by the Atlantic and Pacific Ocean. Old World Mammarenaviruses (Lassa Virus (LASV), Lymphocytic Choriomeningitis Virus (LCMV), and the newly discovered Lujo Virus (LUJV)) and the New World Arenaviruses (Junin Virus (JUNV), Machupo Virus (MACV), Sabia Virus (SABV), and the newly emerging Chapare Virus (CHAPV)). Many of these viruses are identified as NIAID Category A pathogens requiring biosafety level 4 (BSL4) containment [2]. This classification is owed to ease of dissemination or transmission person-to-person, produce significant morbidity and mortality, have potential for major public health impact, and require special action for public health preparedness. While several

promising medical countermeasures are in development, there are currently no US FDA approved vaccines or therapeutics for any mammarenaviruses, though the attenuated JUNV “Candid-1” vaccine is approved for use in Argentina.

Infection in humans is often the result of exposure to rodent excreta from infected animals where disease severity and case fatality rates (CFR) can vary across the genera and even within genetic lineages as can be the case for infections with LASV where genetic diversity can be high, even within clades. While this genetic variability creates significant challenges for LASV molecular diagnostics, antigen-based diagnostics have seen high levels of cross reactivity across the seven known lineages of LASV suggesting cross protective antigens may be possible[3]. Lassa virus, the causative agent of Lassa fever (LF), likely causes the largest number of annual cases per year of LF, where its understood up to 500,000 cases per year can occur where the CFR can approach 70% in hospitalized cases [4]. Ribivirin has been used to treat infections with uncertain success [5]. Before the introduction of the JUNV Candid-1 vaccine, its believed that upwards of 60,000 cases of JUNV infection, also known as Argentine Hemorrhagic Fever (AHF) per year occurred where CFRs ranged from 15-30 %. Convalescent plasma from JUNV survivors is still the primary means to treat acute JUNV infections in Argentina [6]. The initial outbreak of Machupo virus had over 1000 cases with a CFR, where outbreak frequency is thought to have been reduced through enhanced rodent abatement practices and potentially cross-protective immunity in populations who have taken the JUNV Candid-1 vaccine [7].

All mammarenaviruses share a common genomic organization consisting of two ambi-sense (bi-directional reading frame) RNA segments. Each segment contains two open reading frames encoding two proteins per strand, these include the Z protein (matrix), the L protein (polymerase), glycoprotein precursor (GPC), and the nucleoprotein (NP) [1]. Despite general similarity of their genomic architecture, these groups exhibit marked differences in their replication life cycles. This includes differences in attachment, entry, and immune evasion; nonetheless, the dominant antigenic proteins driving immune responses for both OWAV and NWAV are the glycoprotein (GP) and NP.

Monoclonal antibodies derived from human LASV survivors have been demonstrated to protect non-human primates (NHP), against lethal challenge [8]. Recent crystal structure studies have identified binding interactions with these antibodies using stabilized, pre-fusion trimeric LASV glycoproteins (GPe) [9]. These findings suggest a stabilized form soluble LASV glycoprotein could serve as a viable vaccine antigen. Humoral responses to LASV NP in survivors from Sierra Leone (LASV Lineage IV endemic region) and Nigeria (LASV Lineages II, III, and VI endemic region) are directed toward the highly conserved N-terminal domain (NTD) of NP, suggesting using this domain as a vaccine antigen may also be possible. To test these notions, investigators in the Center **RP1**, **Core E**, and **Core D** have developed adjuvanted vaccine approaches to test this idea and have demonstrated protection against lethal LASV-Josiah challenge using a stabilized prefusion, trimeric GPe, a highly conserved NP NTD epitope, or a combination of the two antigens using a lethal outbred guinea pig model.

Despite the considerable molecular diversity in LASV strains, there is understood that there is some conservation in key antigenic sites within both the GPe and the NP, suggesting that a PAN-LASV vaccine may be possible[3, 10, 11]. Indeed, **RP1** and **Core E** investigators have demonstrated that using a Vesicular Stomatitis Virus expressing the LASV-Josiah GPC is not only protective against homologous challenge with LASV Josiah (Lineage IV-Sierra Leone) in a lethal NHP model[12], but also that live attenuated vaccines expressing this same GPC can protect NHP against challenge with viruses from: Lineage II[13] , Lineage III (Cross, Geisbert unpublished), Lineage V[14] and Lineage VI (Cross and Geisbert Unpublished).

In **Phase I of RP1**, the ability for an optimized intramuscular (IM) LASV GPe/NP subunit vaccine to protect against disease after challenge multiple LASV lineages will be assessed in guinea pig and NHP models. This formulation will also be assessed using a microneedle skin patch (MNP) formulation optimized in Core C to determine if a needle-free vaccination route affords more potent vaccine mediated responses and protection. Similarly, we have already generated MACV GPe and will design a MACV NP-NTD subunit antigen to test following the same approach followed with LASV against both homologous lineage challenge and heterologous challenge of MACV genetic lineages. In **Phase II of RP1**, we will assess the **plug-and-play** potential of our stabilized GPe/NP-NTD MNP vaccine approach against emerging test case mammarenaviruses representing

emerging OWAV (LUJV) and NWAV (CHAPV) for which there are no vaccines available. A unique feature of this proposal is its access to BSL4 facilities described in **Core E** capable of evaluating countermeasures in NHP. It is widely considered that the cynomolgus macaque is the current “gold standard” animal model for LASV, JUNV, and MACV research as there are a multitude of immunological reagents available and the disease pathogenesis appears to mirror that of human infection[15-17]. The evaluation of successful countermeasures for the prototype OWAV AND NWAV in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

Unique from most other bunyaviruses, orthonairoviruses are transmitted primarily by ticks in nature (REF). While there are a number of human pathogenic orthonairoviruses (e.g. Dugbe virus[18], Issyk-Kul virus[19], Songling virus[20]), Crimean-Congo Hemorrhagic fever virus (CCHFV) is by far the most recognized public health threat to humans as it responsible for annual outbreaks across Europe, Africa, the Middle East, and Asia. There are growing concerns for endemic range expansion due to ongoing range expansion of tick hosts tied to bird migration changes, livestock trade, and even global warming are contributing to increasing numbers of infections in humans in areas otherwise not known to be endemic including central Spain[21] and most recently the reservoir Hyalomma ticks have been found as north as Sweden[22]. Infection in humans begins as a nonspecific febrile illness but can rapidly progress to cause a severe hemorrhagic fever which may progress to death in 30% of cases in some regions[23]. CCHFV is listed on the WHO priority pathogen list[24] and is also a NIH-NIAID category A pathogen[2]. There are no FDA approved vaccines or therapeutics for CCHF; however, a mouse-brain derived inactivated whole virus vaccine has been in use in Bulgaria with limited efficacy[25] (REF). Ribivirin has been used to treat infections with limited success[26].

CCHFV has a trisegmented genome encoding 4 proteins, NP, small non-structural protein (NSs), L polymerase protein, and a GPC [23]. Similar to mammarenaviruses, the NP and GP are the primary antigenic targets of the host immune response. The NP of CCFHV is highly conserved across the 6 genomic clades with up to 95% amino acid homology[23]. Conversely, he CCHFV GPC is considerably less conserved, where less than 75% amino acid conservation is present[23]. The genetic diversity of CCHFV correlates strongly with geography, and clades of CCHFV segregate based on geographical location which creates a challenge in terms of creating a pan-CCHFV vaccine or therapeutic based solely on one clade. Nonetheless, we have demonstrated that heterologous vaccine mediated protection can be afforded using a VSV vectored vaccine expressing the full GPC of CCHF[27].

In phase 1, **RP1 and Core D** will generate CCHFV GP and NP subunits with the highest level of homology across clades and assess their capacity to protect against disease after challenge with multiple CCHFV clades in established mouse[27, 28] and NHP[29] models with Core E. CCHFV GP and NP subunit vaccines will also be coupled to MNP (**Core C**) for comparison with IM vaccination. In **Phase II of RP1**, we will assess the **plug-and-play** potential of the best performing formulation of CCHFV GP/NP MNP vaccine approach against emerging test case mammarenaviruses representing emerging bat virus, Kasokero virus for which there are no vaccines available.

~~The *Bunyavirales*.~~

~~Fill out~~

The henipavirus paramyxoviruses. The recognized, highly pathogenic HNVs, NiV and HeV are zoonotic agents distinguished from the many paramyxoviruses that cause human and animal diseases by virtue of their uniquely broad host tropism and impressive lethality (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV was recognized first, and emerged in Queensland, Australia in 1994 causing a severe and fatal respiratory disease among horses along with a human case fatality (Murray, PMID: 7701348). NiV emerged just a few years later in Malaysia and Singapore in 1998-99 causing a large outbreak of encephalitis with high mortality in people and also respiratory disease in pigs which served as amplifying hosts (Chua, PMID: 10827955). NiV and HeV

can infect at least 18 animal species across 6 orders of mammals, and among these they will cause a systemic and often fatal respiratory and/or neurological disease in 11 mammalian species including humans (PMID: 32991264; PMID: 22476556). The NiV strain in Bangladesh (NiV-B) is of particular concern where outbreaks occur nearly on an annual occurrence and often with case fatality rates exceeding 90% with little evidence of subclinical infections, and well-documented person-to-person transmission (PMID: 23911335). Currently, there are no vaccines or therapeutics approved for human use. NiV and HeV emergence and reemergence remain continuous infectious disease transboundary threats to public health and economically important livestock throughout South and South East Asia and Australia. Their broad host tropism and ability of these viruses to infect livestock offers an amplification opportunity and increased risk of subsequent human infections. The henipaviruses are single-stranded, negative sense, enveloped RNA viruses and their biology also lends themselves to be synthetically produced and agents of potential and deliberate misuse. NiV and HeV are BSL-4 pathogens and also classified as priority agents by US Department of Health and Human Services (HHS) and Centers for Disease Control and Prevention (CDC) has recently proposed that NiV be added to the list of Tier 1 Select Agents [Possession, Use, and Transfer of Select Agents and Toxins; Biennial Review; Department of Health and Human Services (Ed.) United States Government, Federal Register: Washington, DC, USA, 2020; Volume 85, FR 15087]. because they could be engineered for mass dissemination and possess the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the WHO as an epidemic threat needing urgent research and development (R&D) action and has been included in the WHO R&D Blueprint list of priority pathogens with epidemic potential (Sweileh, W. M. PMC5299748).

While there are no licensed countermeasures for the treatment of NiV and HeV infections, there has been notable progress over the 15 years in the development of vaccines and postexposure human or humanized monoclonal antibody (mAb) therapies. Among antiviral countermeasures likely suitable for use in people, to date, one human monoclonal antibody (mAb) and one humanized mAb, postexposure treatments have been demonstrated to be effective therapies against NiV and HeV infection in animal challenge studies including nonhuman primates (NHP) (PMID: 22013123, PMID: 24964990, PMID: 27484128, PMID: 31686101). The success of one particular human mAb (m102.4) in the NHP model was instrumental in both its application in several emergency use protocols in Australia and the United States as a result of high-risk virus exposure (18 individuals to date), and also in the conduct of the very first Phase I clinical trial of an anti-HeV/NiV therapy in collaboration with USU and Queensland Health in Australia (PMID: 32027842). In contrast, several preventative vaccines against NiV and HeV have been shown to be 100% effective in preventing infection and disease in animal models including NHPs and several vaccine platforms have clear potential for use in people (PMC8782152). The HNV G and F membrane glycoproteins are the major targets of neutralizing antibodies and the cornerstone of all vaccine strategies (PMC8782152). Such preventive vaccines would have utility for lab workers, first responders or individuals at high risk exposure and in mitigating the spread of an outbreak; whereas in the case of a biological attack or natural outbreak, a postexposure treatment would augment a pandemic preparedness posture. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including NHPs. The HeV-sG immunogen is also the basis of the horse vaccine against HeV (Equivac® HeV) marketed by Zoetis, Inc., which is the first commercialized vaccine to a BSL-4 agent (Middleton, 2014 PMID: 24572697). It is widely considered that the African green monkey (AGM) is the current "gold standard" animal model for NiV and HeV research as the disease pathogenesis appears to mirror that of human NiV/HeV infection (Geisbert, 2012;Geisbert, 2010). The evaluation of successful countermeasures for the prototype NiV and HeV and other related HNVs in the NHP model will likely be pivotal for IND applications and future licensure of select countermeasures for human use.

More recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not appear to employ ephrin ligands as entry receptors (C. Broder and K. Xu unpublished) (PMID: 33809833). The PABVAX Center has chosen to initiate studies on the divergent LayV as the Phase II test case scenario. The choice is justifiable for several important reasons; 1) LayV is a known pathogenic zoonotic HNV; 2) there is a known virus genome sequence derived from a human sourced virus isolate; 3) we have already successfully engineered and expressed LayV sF (stabilized) and sG (tetramer) glycoproteins antigens. Also, another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. The Center will initiate studies on LayV in preparation for Phase II, including the rescue of recombinant LayV (rLayV), explore animal model development, construct additional LayV and AngV reporter virus tools, and then translate and test the MNP

Commented [CRW2]: Reviewer may be looking for description of Phase I. Not mentioned in this section.

vaccine ‘plug-and-play’ approach, and also evaluate new mAbs and nanobodies (nbs) to these new divergent and/or potential zoonotic HNVs.

PABVAX THEME

A strength of the PABVAX is that a majority of the Center Research Project (RP) and Core leaders have extensive experience in antiviral translational research and/or product development: Uniformed Services University (USU), University of Texas Medical Branch (UTMB), Vanderbilt Vaccine Center (VVC), University of Pittsburg (UPitt), Institute for Bioscience and Biotechnology Research (IBBR) at the University of Maryland (UMD), and Mapp Biopharmaceutical. In addition, nearly all of the Center’s RPs and Core leaders currently have active and productive collaborative research programs in related areas, some spanning more than a decade. Further, the PABVAX Industrial Partners, Emergent Biosolutions and Moderna, bring unique and valuable vaccine development expertise to the team.

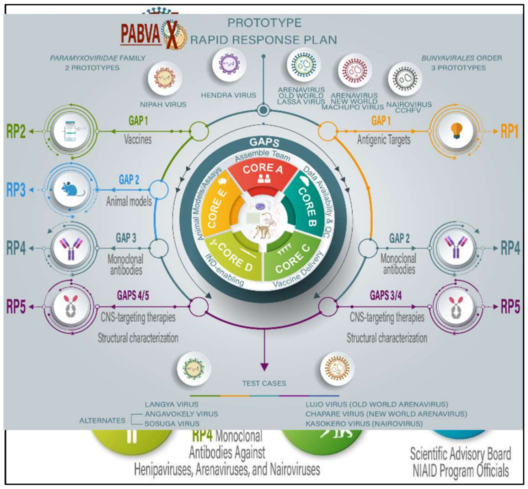

Figure 1: Organizational chart of the Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center-(PABVAX). **(connecting arrows are needed between elements and the SAB)**

Commented [CRW3]: Tom asked me to insert this to see how it would look so we can see what changes are needed to ensure legibility since the figure needed to get shrunk to fit. Some of the graphics dead center might be a little too small, not sure anything can be done there…

Maybe be good to have the whole title per RP listed instead of abbreviated form?

May need to identify what is meant by Gaps as its not identified in this document, I think maybe it is spelled out in Core E document?. Assuming maybe these are Gaps identified in the main RFA?

Just an idea…. having RP4 and RP5 bubbles duplicated to demonstrate different GAPs addressed is a little confusing to me, maybe if we do end up enumerating the gaps somewhere in the text, it might simplify things by identify what gaps are addressed by each RP so that each RP only has one bubble? EG:

- RP1=gap 1
- RP2=gap 1
- RP3=gap 2
- RP4=gap 2,3
- RP5= gap 3,4,5

The organizational structure of the PABVAX is diagramed in **Figure 1**. Two Research Projects (RPs) in the PABVAX Center will focus on developing and evaluating a new, thermostable, needle-free, adaptable, and widely deployable, dissolvable microneedle patch (MNP)-based skin immunization vaccine technology that will use recombinant viral protein subunit immunogens; **RP1** will target select prototype **Arenaviridae** and **Nairoviridae** viruses, and **RP2** will target the prototype **henipaviruses** (HNVs). Both RP1 and RP2 will also be developing new prototype virus tools (recombinantly generated prototype viruses) along with existing tools, to be used in the analysis of vaccine responses as well as in the evaluation of new mAbs and nabs from the other RPs. A third RP will be engaged in the development of a unique low-containment (BSL-2) mouse model of HNV infection that uses recombinant Cedar henipavirus (rCedV) in vivo and a bioluminescence methodology that can longitudinally trace the dynamics and anatomical progression of luciferase encoding virus infection in individual animals (**RP3**). There will also be two RPs that will target the development of human mAbs and nanobodies to the PABVAX select viral prototypes. **RP4** will isolate human mAbs derived from NiV infected survivors with a specific focus on the F glycoprotein targeted mAbs, and additional human mAbs will be generated from humanized mice by viral prototype antigen immunization. Finally, **RP5** will develop nanobody-based therapeutics targeting henipaviruses and arenaviruses along with a focus on targeting the CNS environment in animal modeling experiments using the select virus prototype vaccine antigens and immunization of nanomice as well as human nanobody phage library approaches. Critical research support to all the RPs will come from three Scientific Cores that will be engaged in manufacture and quality control & testing of MNP vaccines (**Core C**); production of recombinant viral proteins and antibody refinements (**Core D**); and animal modeling of prototype virus infections along with preclinical testing and evaluation of vaccines and antibody-based therapeutics (**Core E**).

With a focus on the Paramyxoviridae and Bunyavirales; the overall Objectives of the PABVAX are 3-fold:

1) Establish an effective and rapidly adaptable vaccination technology.

2) Discover effective antibody-based therapies.

3) Develop new tools and animal models to facilitate the translation of effective countermeasures.

An adaptable plug-and-play vaccine platform.
The PABVAX Center will take advantage of a successful piloted research project using recombinant soluble Hendra virus G glycoprotein (HeV-sG) that several lead investigators recently co-developed with scientists from

the UPitt and IBBR/UMD (**Core C**) that has tested a dissolvable MNP-based vaccine technology that is ideally suited for the development of a rapid and inherently safe, recombinant protein-based subunit vaccine approach (PMID: 32924651). This vaccine technology effectively harnesses the highly immunoresponsive cutaneous microenvironments using dissolvable MNPs that incorporates recombinant viral glycoprotein antigens and polyphosphazene (PPZ) adjuvants (PMID: 19864632) to elicit robust, strong, and long-lasting protective immunity against the target pathogen. PPZ macromolecules are emerging synthetic water-soluble biodegradable immunoadjuvants that have well-defined molecular properties and are fully compatible with dissolvable MNPs. PPZ macromolecules have excellent antigen-binding features, spontaneously self-assemble with antigens in aqueous solutions, forming nanoassemblies with virus particle dimensions (60-100 nm). The PPZ macromolecules serve as an immunoadjuvant that provides immune-potentiating features to complement subunit antigens, such as improved antigen uptake, multivalent antigen presentation, and innate immune stimulation, to rationally augment vaccine-induced immunity. Dissolvable MNPs will enable targeting vaccine components to the highly immunoresponsive cutaneous layers in a safe, reproducible, and self-applied manner for efficacious immunization, as well as facilitate the improved vaccine storage and distribution due to their thermostability. This broadly adaptable and widely deployable vaccination approach is enabled by a synergistic combination of a plug-and-play approach with a clinically feasible immunoadjuvant and skin-targeted vaccine delivery platform. Here, a Scientific **Core C**: (Microneedle Patch Vaccines Core) will produce polyphosphazene (PPZ) adjuvanted MNP vaccines with select recombinant vaccine antigens (prototype viral targets) in support of **RP1** (*Bunyavirales*) and **RP2** (Paramyxoviridae). **Core C** will batch release PPZ MNP vaccines on well-defined quantitative criteria of their validated physicochemical and immunological properties. The RPs focused on vaccine development will explore a variety of viral immunogens and combinations. Down selection of vaccine formulations and components will be made based on first tier immune response data derived from mouse immunization studies with a focus on assaying antigen-specific binding antibody levels by ELISA and virus-specific neutralization activity in vitro and polyfunctional T-cell responses by in vitro stimulation of isolated cells with antigenic peptides, intracellular cytokine staining (ICS) and flow cytometry) responses.

Discover effective antibody-based prophylactics and therapies.
~~PREP can be critical in the absence of available vaccines or cases in which vaccination is not possible.~~
HELP

Monoclonal antibodies (mAbs) are one of the most successful classes of drugs with the proven ability to address a variety of human health needs including oncology, inflammatory diseases, and infectious diseases. Recent studies have demonstrated therapeutic efficacy of mAbs against some of the most lethal viruses including Nipah [30], Hendra [31], Ebola [32, 33], Marburg [34] and Lassa [35]. MAbs also offer a stunning degree of customization based on the importance of mechanisms of action (such as viral neutralization, ADCC, ADCP, *etc.*), a feature to be exploited in **Core D**. In addition to therapeutic applications, mAbs with Fc mutations to dramatically extend serum half-life [36-38] offer an important tool for prophylactic use for indications in which vaccination is not possible: 1) for diseases where no vaccine is available; 2) in immunocompromised patients; and 3) in populations where the time required by a vaccine for protective immunity to be established by the host is not practical (*e.g.* rapid response personnel). Members of PABVAX have extensive experience with the discovery, characterization and translational activities necessary to advance mAbs to the clinic. The manufacturing platforms, formulation methods, and safety profiles of mAbs are well-established. Thus, mAbs offer a low-risk technology platform for prophylactics and therapeutics targeting the viral threats to be addressed by PABVAX.

Develop new tools and animal models to facilitate the translation of effective countermeasures.
Virological tools and animal models are essential in assessing the effectiveness and protective correlates of antiviral vaccines and therapeutic countermeasures. The investigators within the A~~A~~nimal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation S~~s~~cientific **Core E**, at the GNL, UTMB, have the expertise in a wide variety of high-containment and select agent research areas including ~~……..~~ animal model development and the use of animal models for the study of viral pathogenesis and assessing the protective ~~therapeutic~~ efficacy of antivirals and vaccines as well as studies to define mechanisms and/or correlates of protection. In addition, **Core E** has the facilities for cell-based assays for authentic pathogenic virus use and manipulation; including the establishment and use of reverse genetics for rescue of pathogenic viruses including novel reporter-gene encoding versions which will be performed within **RP1**. Such virus tools are essential for the characterization of vaccine responses such as neutralizing antibody induction in animal subjects, as well as validation of antisera

Commented [CB4]: Larry/Dafna you are needed for this.

or antiviral antibody neutralization using authentic viruses. Other reporter virus tools and alternative animal models that can be utilized at low-containment (BSL-2) are also useful in antiviral development strategies because they can be adapted to greater high-throughput platforms, are often less laborious, and they can make use of other innovative technologies. **RP2** will make use of recently generated rCedV chimeric viruses that allow for rapid high-throughput florescence-based virus neutralization assays at BSL-2 ideally suited to analyze otherwise BSL-4 restricted authentic Nipah and Hendra virus vaccine induced immune sera, mAbs (**RP4**) and nbs (**RP5**) and antibody neutralization synergy. **RP3** will make use of other versions of rCedV and chimeras (those bearing either the HeV or NiV-B envelope glycoproteins) in the development of a BSL-2 animal model that uses in vivo bioluminescence to visualize the anatomical location and progression of virus in live animals, ideally suited to explore nab based therapeutics to CNS resident henipavirus (PMID: 35821488).

The overall objectives of the PABVAX Center will be integrated into quality system data management processes (**Core B**) that will be employed in both the preparation of vaccines and downstream antibody-based therapeutics by the Center's highly experienced commercial partners, and in the conduct of animal studies by the Animal model development and preclinical evaluation **Core E** at the GNL, UTMB. ~~Data generated to support of possible future regulatory submissions to the Food and Drug Administration (FDA) must be collected in accordance with quality systems, like good laboratory practice (GLP) regulations, to be useful and reliable, and to facilitate FDA review to ensure safety and efficacy.~~ The UTMB and GNL is a national resource and benchmark provider for the conduct of high containment animal studies and quality system data management; often partnering with the FDA in academic development and training programs for GLP in high containment environments. We envision several deliverables emanating from the proposed studies of the Center, including significantly improved subunit vaccine formulations against several prototype viruses within the henipaviruses (Paramyxoviridae) and the Bunyavirales (Arenaviridae and Nairoviridae) that will bolster vaccine endurance to storage and transportation; and also improved human mAbs and/or nabs for the treatment of disease caused by the select prototype viruses.

The PABVAX team consists of highly credentialed experts in virology, structural biology, immunology and mAb and vaccine translational drug development and includes Moderna and Emergent Biosolutions as Industry Partners. The synergistic activities and research goals of this Center proposal through its RPs and Scientific Cores, will develop, test, and translate, prototype vaccines using a novel vaccination platform (an adjuvanted dissolvable microneedle patch (MNP) vaccine), develop new virus and animal model tools, and develop and test mAb and nanobody prototypes to foster pandemic preparedness.

THE PABVAX CENTER PROTOTYPE VIRUSES

The prototype viruses chosen by the PABVAX have been made based on several criteria discussed below, and because they represent known threats to global public health that is exacerbated due to a lack of approved vaccines or therapeutics. There is a clear need for effective countermeasures in order to improve a global pandemic preparedness posture that can address the threat of natural outbreaks, epidemics, or bio-weaponization and deliberate release of these prototype virus species and/or related viruses within those groups.

Henipaviruses: Nipah virus (NiV) and Hendra virus (HeV) are bat-borne viral zoonoses that were discovered in the mid to late 1990s in outbreaks of severe disease in livestock and people in Australia (HeV) and Malaysia (NiV-M). NiV and HeV are both considered the **prototype species** of the genus *Henipavirus*, family *Paramyxoviridae*. The natural reservoir of the two pathogenic and prototype HNVs, NiV and HeV, are old world fruit bats (flying foxes) of the genus *Pteropus* (Order *Chiroptera*, suborder, *Megachiroptera*, Family *Pteropodidae*). NiV and HeV are zoonotic agents, and human infection with either virus causes a widespread vasculitis, that will often progress to a fatal encephalitis or pneumonia. People who recover from acute infection with either of these HNVs are also at risk of recrudescent infection and encephalitis (Luby SP, Broder CC. 2014. Paramyxoviruses: Henipaviruses, p 519-536. In Kaslow RA, Stanberry LR, Le Duc JW (ed), Viral Infections of Humans, Epidemiology and Control. Springer Science+Business Media, New York.; Wang L-F, Mackenzie JS, Broder CC. 2013. Henipaviruses, p 1070-1085. In Knipe DM, Howley PM (ed), Fields Virology, vol 1. Lippincott Williams & Wilkins, Philadelphia). HeV and NiV are BSL-4 restricted pathogens because of their high lethality and lack of approved vaccines or antivirals and are transboundary agents of significant disease threats to livestock and people in Australia, and South and Southeast Asia, respectively. The genus *Henipavirus* now includes nine other reported HNVs; these include the four viral isolates of Cedar virus (CedV), Gamak virus, Daeryong virus, and Langya virus (LayV) [xxx] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiāng virus, Melian virus, Denwin virus, and Angavokely virus (AngV) [xxx]. Similar to NiV and HeV, the natural reservoirs of CedV, along with the genomic data of GhV and AngV,

are old world pteropid fruit bats. Whereas the six other HNVs are, or are likely, of rodent origins, including the human isolate LayV from East China (Shandong and Henan provinces), which is most closely related to Mòjiāng virus that is also of apparent rodent origin from Southeast China (Yunnan province). The phylogenetic relationship of selected HNVs by F and G glycoprotein comparisons is shown in **Figure 2**.

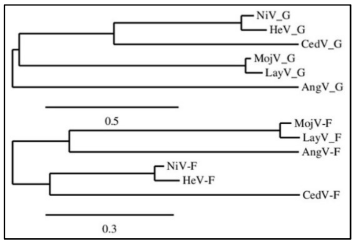

Figure 2. Phylogenetic analysis of select HNV G and F glycoproteins. Phylogenetic trees were constructed for the HNV F and G glycoproteins using the PhyML program's maximum likelihood method. The trees were generated by aligning the protein sequences with the MUSCLE algorithm. The genetic distance between the sequences is represented by the bar located under each tree, providing information about the level of divergence among them.

Investigators in the Center **PR2** and **RP5** have already initiated new studies on LayV, having engineered stabilized sG and sF glycoprotein antigens in collaboration with Genovac, Inc. (part of **Core D**) and identified cross-reactive mAbs to both F and G previously generated to Mòjiāng virus. Whereas HeV and NiV cause severe and often fatal henipaviral disease, LayV was associated with nonfatal febrile illnesses in humans. In contrast, CedV is the only HNV isolate demonstrated to be nonpathogenic in well-established animal models of NiV and HeV infection and disease including guinea pigs, ferrets, hamsters (Geisbert 2012), and African green monkeys (Geisbert and Broder, unpublished). An important distinction between CedV and other HNVs lies within the P gene which encodes the phosphoprotein (P), and the P gene transcripts of NiV and HeV undergo RNA editing to produce the V and W nonstructural proteins that are key interferon (IFN) antagonists (xx). The CedV P gene lacks both RNA editing and does not encode V or W. Several studies with recombinant NiV variants have demonstrated the differential importance of the V and W proteins in the pathogenesis brought about by NiV infection in both the hamster and ferret models, and a lack of the V protein resulted in nonlethal infections. All other recognized or proposed HNVs have the potential to express V and W proteins based on current genetic data. The absence of these proteins in CedV is the key factor underlying its nonpathogenic nature. These data permitted the rescue and characterization of rCedV by reverse genetics at BSL-2 (XXX) and CedV is now recognized as a BSL-2 restricted agent [CDC manual]. Because the HNV, LayV, is known to be a human pathogen and zoonotic HNV, is genetically divergent from NiV and HeV, and also of apparent alternate origin (rodent), together with some preliminary data on the sF and sG LayV glycoproteins, the PABVAX Center will explore LayV as part of the Center's Phase II research plan (**RP2** and **PR5** with **Cores C, D, and E**).

Old Word Mammarenaviruses (OWAV): For **phase 1**, **RP1** will utilize **LASV as the prototype OWAV** due to the significant public health burden it creates throughout West Africa with hundreds of thousands of estimated cases and approximately 5000 deaths annually[39]. LASV has is the most imported viral hemorrhagic fever (VHF) next to dengue virus and has been imported to several countries outside of Africa over 35 documented times [40]. Case fatality rates (CFR) approaching 70% in hospitalized cases and marked long term sequelae are the result of no approved vaccines or therapeutics, though several live attenuated virus candidates are approaching clinical evaluation with the assistance of Coalition for Epidemic Preparedness Initiative (CEPI) [41]. Of the vaccines supported by CEPI, 4/5 of these vaccines utilize the only the LASV GP as the target immunogen despite

Investigators in RP1, Core D, and Core E have already demonstrated protective efficacy of against disease after challenge with LASV in outbred guinea pigs in animals vaccinated IM with engineered stabilized, prefusion LASV GPe, NP-NTD, or a combination of both antigens. These antigens have been engineered to harness the homologous antigenic regions of both antigens to increase potential for pan-LASV lineage protection from disease after vaccination. Success with this approach, suggest a similar strategy of using a subunit vaccine might also be effective against other arenaviruses. While LASV is the most common pathogenic arenavirus in Africa in terms of human infections, Lujo virus was isolated over 10 years ago from a case of severe hemorrhagic fever originating in Zambia but quickly causing nosocomial infections in care givers after the index case's medical evacuation to South Africa [42]. The case fatality rate for this incredibly infectious virus was 80% in the small outbreak of 5 people. There are currently no approved or therapeutics available for this virus and its genetic divergence from LASV suggest countermeasures with antigenic targets may be of limited use, implying LUJV will be an ideal "test case" OWAV to assess the plug-and-play approach of stabilized, prefusion LUJV GPe/ NP-NTD vaccination. The PABVAX Center will explore LUJV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Formatted: Indent: First line: 0.5"

New World Mamarenaviruses (NWAV): A live attenuated vaccine for JUNV (Candid-1) is currently in use in Argentina [43], but there is conflicting evidence of whether cross protection with other NWAV is possible with this vaccine [44, 45]. Further, there are safety concerns related to potential for reversion to pathogenic versions. For **Phase 1, RP1** will use **MACV and JUNV** as the **prototype NWAVs** as there are no approved vaccines or therapeutics available for MACV and the safety concerns associated with Candid-1 vaccine suggest other approaches are warranted. Building on the success of the LASV GPe/NP-NTD. Investigators in **RP1 and Cores D and E** will engineer MACV GPe and NP-NTD antigens and test for efficacy in established guinea pig and NHP models using MACV from multiple lineages to asses how broadly protective the approach is across MACV lineages. We will then extend this plug-and-play approach to other NWAV. First reported in 2003 in Bolivia, Chapare virus (CHAPV) is a rodent borne mammarenavirus associated with development of severe hemorrhagic fever with case fatality rates up to 60% [46, 47]. Recent studies have demonstrated clear human-to-human transmission risk during the acute phase evidenced by several nosocomial infections but also detection of viable virus from semen at 86 days after symptom onset demonstrating a clear need to specialized management and treatment [47]. It is unknown if the JUNV Candid-1 vaccine employed for control of JUNV in Argentina would be protective against CHAPV. Otherwise, there are no known vaccines demonstrated effective for this virus. The PABVAX Center will explore CHAPV as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Orthonairoviruses: Here, **CCHFV will serve as the prototype virus** for vaccine development as is responsible for the largest global public health burden within the orthonairovirus family responsible for often large outbreaks of human disease annually across Europe, Africa, and Asia. There are no FDA approved vaccines for CCHFV; however, a suckling mouse brain derived, CHCl2/heat-inactivated aluminum hydroxide adsorbed whole virus vaccine for CCHFV has been approved for use only in Bulgaria since 1974 but has numerous safety concerns and limited demonstrated efficacy. Since then, several vaccine approaches have been examined ranging from viral vectored approaches to DNA based vaccines with varying efficacy, advantages, and disadvantages[48]; however only an MVA-CCHFV vaccine has begun to advance towards clinical trials[49]. Investigators in **RP1 and Cores D and E** will engineer CCHFV GP and NP subunit antigens and test for protective efficacy from disease after challenge with 6 different lineages of CCHFV clades using in established mouse and NHP models. Next we will deploy the same approach to a known human pathogen "test case" orthonairovirus for which no vaccine exists.

In 1977, **Kasokero virus (KASV),** a bat borne Orthonairovirus, was first isolated from Ugandan bats and responsible for causing several cases of acute febrile illness of laboratory workers from the same lab that processed infected bats [50]. Serosurveys of 109 laboratory workers from the same facility the virus was isolated and worked with demonstrated a 13% seropositivity where medical surveys revealed clinical symptoms in 4 to 15 months after the virus was isolated, suggesting either continued laboratory associated infections or chains of ongoing person-to-person transmission. Recently, tick surveys have demonstrated the potential for the reservoir, *Ornithodoros faini,* ticks to participate in enzootic maintenance of KASV [51]. While most chiropteran ticks exhibit host specificity, humans entering caves where these bats are have reported bites from *O.faini* ticks as well. The highly infectious potential for this virus in humans coupled to a complete lack of vaccines or therapeutics make suggest investment in countermeasure development is well advised. The PABVAX Center will explore **KASV** as part of the Center's **Phase II** research plan (**RP1** with **Cores C, D, and E**).

Formatted: Indent: First line: 0.5"

EXPECTED SYNERGIES PROVIDED BY THE CENTER

The 5 RPs and 3 scientific Cores, together with the Administration and Data Cores, that comprise the **Paramyxoviridae and Bunyavirales Vaccines and Antibodies – PABVAX** Center have been specifically tailored to be synergistic (**Figure 1**). All five RPs will work collaboratively and synergistically with the scientific Cores in support of developing and testing pre- and postexposure treatments for the selected virus prototypes. This includes the production of vaccine immunogens for both the manufacture of the vaccine patches as well as

for the conduct of assays to assess vaccine immune responses, isolation of mAbs and nbs, and in select cases the structural characterization of the important viral vaccine immunogens and interaction with antibodies. Additionally, individual RPs will conduct a variety of experimental lines of investigation in synergistic collaboration with other PRs; such as the conduct of virus neutralization analyses of vaccine-elicited antibody responses and virus specific mAbs and nbs (henipavirus projects: **RP2, RP3, RP4, RP5**), (aarenavirus and nairovirus~~renaviridae and nairoviridae~~ projects: **RP1, RP4, RP5**). Of unique importance to the goals of the PABVAX is that the countermeasures anticipated to be developed from the RPs may provide a future opportunity to combine the active and passive immunization approaches to further improved the therapeutic value in an inherently synergistic manner. The RPs will work closely together in a harmonious and cooperative manner with each group providing their own countermeasure and expertise so as not to duplicate effort. This opportunity would be difficult if not impossible if each project were pursued independently. This collaborative effort among all RPs and Cores will provide strong synergy among the groups and PABVAX participants, many of which have established collaborative and synergistic research activities. For example, the early development and testing of particular antiviral mAbs to some of the prototype viruses under investigation is already an established collaboration between PABVAX partners at Vanderbilt's VVC and USU and UTMB together with Mapp Biopharmaceutical. Also, the pilot MNP vaccine platform project was a collaboration between USU, UPitt, UMD-IBBR, and UTMB.

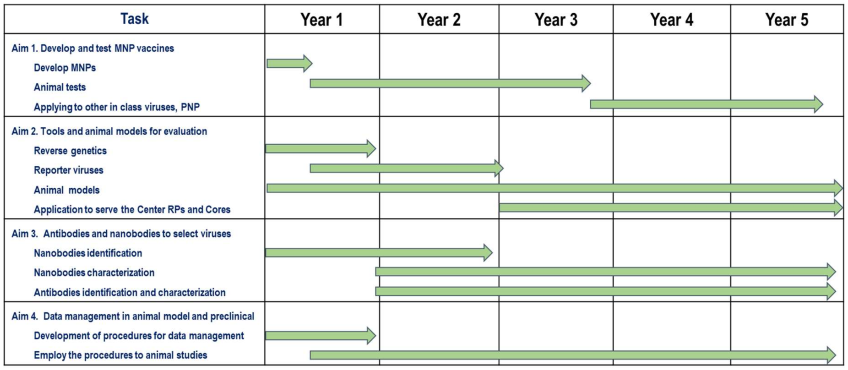
An additional and outstanding advantage of the PABVAX Center is the **Animal M~~m~~odel D~~d~~evelopment and P~~p~~reclinical E~~e~~valuation Core E** at the GNL, UTMB. Here, BSL-4 containment experiments on the select prototype viruses can be carried out. The strength of this Center partner is synergistically enhanced by the relationship of **Core E** with the World Reference Center for Emerging Viruses and Arboviruses (WRCEVA) also located within the GNL. (https://www.niaid.nih.gov/research/wrceva). Through the WRCEVA collection there is ease of access to many of the virus isolates that will be used in the conduct of the Center's proposed studies. All BSL-4 animal work done by **Core E** in support of the RPs and other Cores will utilize the exact same virus stocks in challenge doses, and challenge routes. In addition, all BSL-4 assays for all the Center RPs will be performed by the same BSL-4 staff under the same experimental conditions. This approach will allow for better comparison among countermeasures within the Center and will ensure consistency among results.

PABVAX MILESTONES AND TIMELINES

There are four overarching aims of the PABVAX Center:

1. **Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.**
2. **Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.**
3. **Develop antibodies and nanobodies to selected prototype viruses.**
4. **Employ quality system data management in animal model development and preclinical evaluation of candidate countermeasures.**

The projected timeline for the PABVAX to accomplish the Center objectives is diagramed in **Figure 3**.



Embedded within the overall PABVAX Aims are a cohort of specific Milestones that are laid out to gauge Center accomplishments and progress towards achieving the Center objectives. This is in addition to each PR's individual Milestone plan. The oversight and evaluation of progress will be in concert with quarterly reports to the

PABVAX Scientific Advisory Board (SAB) as well as an annual meeting with key Center researchers and leaders with SAB members (Details are within the Administration **Core A**). The SAB will meet yearly typically in coordination with the Center annual meeting, to review progress, the adherence to milestones and timelines, the continued relevance of each RP and Core to the Center's overall objectives, discuss each project and progress, and advise on directions for the coming year, both for the overall PABVAX Center and for individual RPs. The SAB will also be a key factor and advisory panel in facilitating go/no-go decision making on specific RP activities, recommend new directions as appropriate and provide Center Leadership and NIAID staff a comprehensive written evaluation of the group's activities and the panel's recommendations following the annual meeting.

Overall Objectives

Aim 1. Develop and test MNP vaccines for the Bunyavirales and Paramyxoviridae.

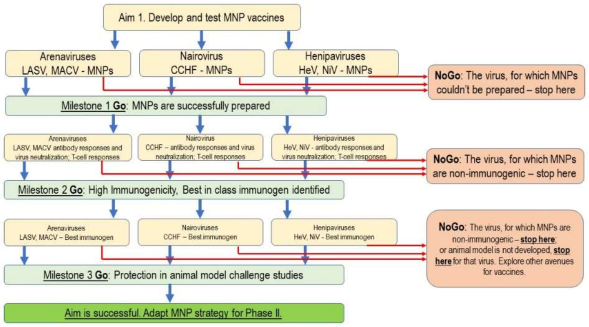


Figure 4. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

The first milestone will be whether proper formulation of recombinant antigens with adjuvant in the context of MNP fabrication can be made. The determination of MNP vaccine potential success will first be made based on immune response data derived from mouse immunization studies conducted in **Core C**. Multi-parameter humoral and cellular immune responses will be assessed (antigen specific antibody induction and virus-neutralization and polyfunctional T-cell responses by in vitro stimulation of isolated cells). Go/no go decisions will be made based on the outcomes of these first tier experiments as indicated. If robust humoral and cellular responses are evident this will be graded as success. Comparisons will also be made, such as the levels of virus-neutralizing antibody generated. Viral antigens producing poor immune responses will be terminated and an attempt in selection of best-in-class immunogens, or best combination immunogens which will also be explored, will be performed in order to down-select vaccine choice. The third milestone will be the determination of whether MNP vaccination affords protection in animal model challenge experiments. In the case of the NiV and HeV prototypes the animal models chosen (ferret and the African green monkey (AGM)) are extremely well-developed, and outcomes at this stage should be readily assessable. However, for the Center's chosen viral prototypes within the *Bunyavirales* there will be additional animal model refinements conducted. For example, there are seven genetically distinct lineages of LASA and there are guinea pig models for some but not all of those lineages. For MACV there are 8 clades with similar challenges, and for CCHF there are 6 clades. An additional confounding issue for both of these very important groups of viruses is that rhesus macaques are nearly unavailable and cynomolgus monkeys are now each greater than 35K. Thus, as proposed by **RP1**, together with **Core E**, a critical research avenue will be further developing and evaluating animal model systems, including new models, within the PABVAX program, including further development of the AGM for the arenaviruses and possibly also for CCHF as a risk mitigation strategy. Thus, individual go/no-go decisions will inevitably be more challenging during the first Phase I of the PABVAX.

Aim 2. Develop new tools and animal models for the conduct of cell-based and in vivo therapeutics evaluation.

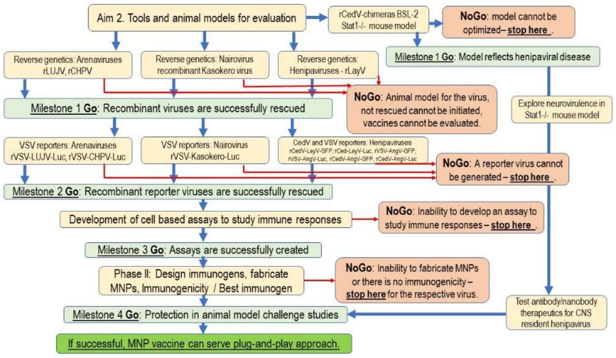

Figure 5. Milestones and criteria for progress for **Aim 2** of the PABVAX Center overall objectives.

The PABVAX second overall objective is primarily focused on the development of new viruses and tools for downstream initiation and testing of the Center's vaccine program and antiviral antibody testing and evaluation. These materials and viruses will be key in the execution of Phase II of the program. **RP1** will generate recombinant infectious clones (r = recombinant viruses) and reporter-gene versions, as well as alternate reporter virus tools (VSV-based) of LASV, MACV, and CCHFV isolates for which isolates are not available using reverse genetics. Rescued viruses will be characterized in cell-based assays. Recombinant viruses will be examined in vivo (animal model development) within **Core E**. In **RP2**, the most recently discovered pathogenic henipavirus, LayV, will be rescued by reverse genetics (rLayV) in collaboration with **Core E**, and additional LayV and AngV reporter virus tools also generated with alternate reporter virus platforms (VSV and/or rCedV based). New virus tools will be characterized in cell-based assays. Only AngV alternate reporter virus tools are proposed as the complete genomic data is incomplete. rLayV pathogenesis and animal model development will conducted by **Core E**. If these objectives are successful, a a large battery of new reagents and tools will be available to share with the ReVAMPP network, as well as serving as key components for initiation and execution of Phase II of the PABVAX Center program.

The translation and testing the MNP vaccine plug-and-play approach will be initiated in the Phase II prototype viruses (**Table 1**) the milestones here will be similar to those outlined in **Figure 4**. The new virus tools will also be used to evaluate new mAbs and nanobodies generated by **Core D** and **RP5** to the new divergent and/or potential zoonotic HNVs (LayV and AngV). Also embedded in this overall aim is a new in vivo bioluminescence-based immune deficient mouse model (newly developed for Lyssavirus infection by the PIs of **PR2** and **RP3**) that can longitudinally trace the dynamics and anatomical progression of rCedV-luciferase virus (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, the model can sustain replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. This new unique model can be used to study henipaviral disease in vivo safely and expediently at BSL-2 containment. If the model can be optimized (**Figure 5**) it will be deployed to test a critically important therapeutic need, the use of antivirals against CNS resident HNV infection, and RP3 will collaborate with RP5 in the testing of engineered nabs specific for the prototype HNVs NiV and HeV.

Aim 3. Develop antibodies and nanobodies to selected prototype viruses.

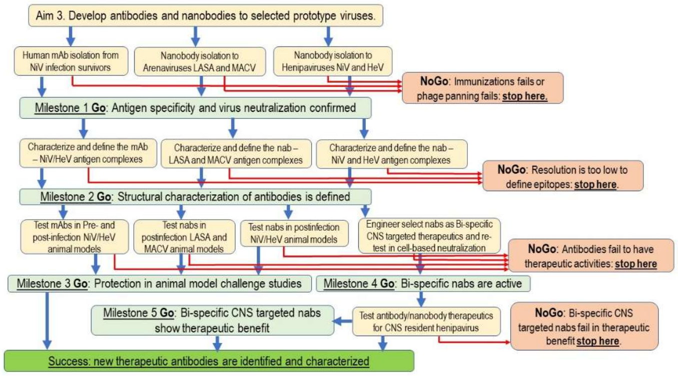

Figure 6. Milestones and criteria for progress for **Aim 1** of the PABVAX Center's overall objectives.

New human mAbs and nanobodies (nbs) as tools and potential therapeutics will be developed by RP4 and RP5 in collaboration with **RP2** and **Core D**. NiV infection survivor volunteers and MNP vaccination of transgenic mice will be used to generate human mAbs (**RP2** and **RP4**); and transgenic nanomice and human nb phage-display approaches will generate nbs (**RP5**) to the selected prototype and test case viruses. Human mAbs are expected to be valuable therapeutics as countermeasures to a variety of viral infections and disease in humans. Here, **RP4** will isolate panels of naturally occurring human mAbs that bind cross-reactively to both the NiV and HeV prototype HNVs and neutralize both viruses. This effort will focus especially on the mAbs to the HNV fusion (F) proteins derived from natural survivors of NiV infection, which to date has been an elusive goal. Previously, the **RP4** PI (Crowe) isolated multiple human mAbs to the G protein with several that exhibit very high potency in neutralization assays, suggesting they have high potential as prophylactic (PREP) and therapeutic molecules for humans. **RP4** will isolate new F mAbs and in collaboration with **RP2** neutralization potencies will be rapidly assessed as well as evaluating synergistic cell-based mAb neutralization that will then be translated and evaluated in animal models as both PREP and post-infection treatments by **Core E**. These new human mAbs will build on the findings to date generated by several of the collaborating Center investigators, and contribute significantly to the development and characterization of human mAbs reactive to the F and G glycoproteins of prototype HNVs in preparation for clinical studies.

Nanobodies, derived from the heavy chain-only antibodies of camelid animals, offer a promising new direction in antibody-based antiviral countermeasures. These small (15 kDa) antigen-binding entities exhibit full antigen specificity and possess the unique ability to recognize otherwise inaccessible epitopes, which could translate into a more cross-reactive feature between virus strains or clades. Importantly, nanobodies can efficiently penetrate tissues and cross the blood-brain barrier (BBB), making them particularly effective in treating CNS-resident viral infections. Here, the prototype viruses from the Center's viral groups to which there are no approved therapeutics and are also recognized to cause CNS pathogenesis will be targeted by **RP5**. To facilitate the development of nanobody-based therapies, three distinct nanobody development platforms will be employed. These include camelid animals, nanomice, and low-immunogenic human nanobody phage-displayed libraries that closely mimic the natural human antibody heavy chain variable domain. Leveraging these platforms will enable rapid identification of nanobody leads with minimal optimization required for clinical use. **RP5** will also engineer a combination of nanobodies targeting multiple epitopes using rational design. Additionally, we will enhance CNS bioavailability by engineering bi-specific nanobody therapy that utilizes transferrin receptor 1 (TfR1) for improved BBB penetration. Specific nanobodies and engineered nanobodies will be evaluated in cell-based virus neutralization tests by **RP1** (LASV and MACV) and **RP2** (NiV and HeV), and also for therapeutic activity in the rCedV-NiV-B chimera mouse model in **RP3** (Henipavirus) and select animal models of LASV and MACV by **Core E**. Success will be measured by the identification of virus-neutralizing nbs, potential discovery of more broadly reactive nbs, particularly to the multiple LASA clades, the evidence of therapeutic benefit in animal models, and the successful antiviral activity of nabs or engineered bi-specific nabs in treating CNS resident virus infections.

INDUSTRY PARTNERSHIPS

Industry Partnership

Each ReVAMPP Center is expected to have an established, or have plans to establish when appropriate, collaboration with an industry partner which will provide access to vaccine

expertise in manufacturing, clinical development, and regulatory pathways. For Centers proposing IND-enabling translational research, an industry partnership is required.

PABVAX has partnered with Emergent Biosolutions (Rockville, MD) and Moderna (Cambridge, MA). Emergent and Moderna have extensive experience developing medical countermeasures that protect against public health threats, including development and approval of multiple vaccine and antibody products for infectious diseases. They can contribute regulatory, manufacturing, and commercial experience for the prototypes and make an ideal partner for PABVAX.

Commented [LZ11]: I can expand on this if needed.

Formatted: Font: Not Italic

SPECIAL FEATURES OF THE PABVAX CENTER ENVIRONMENT AND OTHER RESOURCES ??

Our proposal combines the expertise of several established groups including investigators in academia and in private industry. The Center is supported by outstanding physical resources and an experienced and skilled group of researchers and support staff.

Galveston National Laboratory (GNL)

The GNL, is a NIH-funded, maximum-containment facility that serves as a national resource in support of NIH's biodefense and emerging infectious diseases research agenda. The GNL is a state-of-the-art facility uniquely designed to allow the safe conduct of research into emerging infectious diseases and agents of bioterrorism for the purpose of developing vaccines, diagnostics and therapeutics against them. The 7-story GNL offers over 12,000 square feet of BSL-4/ABSL-4 space. Additionally, there are BSL-4 aerobiology facilities. The GNL BSL 4/ABSL-4 laboratories were inspected by the CDC and were approved for operations and handling of Select Agents and became operational in September of 2010. The first NHP studies were performed in the new GNL BSL-4 laboratories in April of 2011. To date, 370~~187~~ separate NHP studies employing a total of 2,772~~1,318~~ animals and 10 different BSL-4 viruses including arenaviruses, nairoviruses, and henipaviruses ~~Ebola and Marburg viruses and also Nipah and Hendra~~ have been successfully performed at the GNL. These NHP studies include a number of collaborative efforts between Drs. Geisbert, Cross, Crowe, Broder and Zeitlin. The GNL has a fully Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC)-accredited NHP~~nonhuman primate~~ facility and a staff of full-time veterinarians. In addition, **Core E** is staffed with an experienced team of GNL researchers and technicians several of which have more than 25 years of BSL-4/ABSL-4 experience. This team also includes a BSL-4/ABSL-4 trained ACVP board-certified veterinary pathologist. As noted above another special feature is the location of WRCEVA virus collection within the GNL.

Formatted: Not Highlight

Core E (Animal model development and preclinical evaluation)

Core E operations will be conducted at the GNL, and in conjunction with **Core A** also includes the UTMB Institutional Office of Regulated Nonclinical Studies (ONcRS). The ONcRS's primary responsibility is to work with academic researchers who are doing product-oriented research and to help them design and conduct their studies with good documentation, ~~to meet regulatory requirements by assuring regulatory compliance,~~ quality assurance, and data management. NIH has requested that all NHP studies conducted in the GNL BSL-4 laboratory at UTMB that are on a product development path be conducted under a "well documented" quality system program. ~~Quality system and regulatory science processes for NHP studies performed at UTMB will be implemented and executed in conjunction with the ORNcS.~~ Dr. Geisbert (Overall Center PI and Core E Director) has over 34 years of BSL-4/ABSL-4 experience at the US Army Medical Research Institute of Infectious Diseases (USAMRIID), the GNL and other BSL-4 facilities. His research interests have focused on hemorrhagic fever viruses and the henipaviruses and he has published over 250~~XXX~~ peer-reviewed articles in these areas. Dr. Geisbert's research group, in collaboration with Dr. Broder (Center Co-PI and PR2 PI) was the first to develop a NHP model of NiV/HeV infection and disease and also to demonstrate complete protection of NHPs against both NiV and HeV using henipavirus vaccines and also human mAb therapy.

Formatted: Font: Bold

Core D (Early and IND-Enabling Translational Research for Vaccines and mAbs)

Mapp Biopharmaceutical has deep experience with antigens and monoclonal antibodies (mAbs) against these antigens. ~~'s product development team has grown significantly in the last two years in response to the development efforts on its anti-Ebola therapeutic, ZMapp^{TM} which is being advanced to licensure as part of Project Bioshield. OTHER MAbs~~ Their early development and research group has expertise in immunology, infectious diseases, and production of antigens, antibodies and antibody fusion proteins in CHO systems. The advanced development group has experience in medium-size and large pharmaceutical companies and expertise in various aspects of mAb development and commercialization including chemistry, manufacturing & controls, analytical development, clinical and nonclinical development, regulatory affairs, quality assurance, and project management. The team has advanced multiple mAb discoveries to the clinic, including: ZMapp, a 3 mAb cocktail for Ebola Zaire virus, tested in two Phase 3 studies {Mulangu, 2019 #818} {Group, 2016 #649}; MBP091, a pan-*Marburgvirus* therapeutic that has completed Phase 1 safety testing; MBP134, a pan-*Ebolavirus* therapeutic that has completed Phase 1; and MB66, a vaginal microbicide film containing anti-HIV and anti-HSV mAbs that has completed Phase 1 {Politch, 2021 #897}. ~~developed multiple products, including a licensed biodefense biologic. As with Profectus, Mapp Bio's expertise and experience will be a very important and valuable asset to the Center.~~

Bonnie Genovac

Core A (Administrative Core)

Research Project teams?? Maybe not depending on space

The investigators at USU, led by Dr. Broder have an extensive history in henipavirus research which he established in 1999, and he has published more than 75 articles, reviews and chapters in this area. His group has also made significant translational research accomplishments in the area of henipavirus countermeasure developments including Equivac® HeV (Zoetis, Inc.) for use in horses in Australia, and the human mAb (m102.4) having a Phase I clinical trial completed (2016) in Australia, in partnership with the Queensland Government and NIAID. Dr. Broder was the recipient of the Federal Laboratory Consortium for Technology Transfer, Excellence Award in 2013. His administrative experience and skills and his experience in translational research activities qualify him to serve as the director of the PABVAX Center and Administrative Core.

Dr. Crowe's (**RP4**) research focuses on the molecular basis for the development of effective B cell responses to viruses in humans and he has published over 200 peer-reviewed research articles in this area. The Crowe laboratory is one of the leading groups in the development of innovative technologies for isolation and study of human mAbs. Dr. Crowe's group has isolated human mAbs that neutralize HIV, influenza, dengue, chikungunya, respiratory syncytial virus, human metapneumovirus, rotavirus, norovirus, and recently henipaviruses NiV and HeV owing to the collaboration between the Crowe, Broder and Geisbert laboratories. Perhaps of greatest import, the SARS-CoV-2 mAbs generated by Dr. Crowe's laboratory were used in xxx,000 of people during the COVID-19 pandemic. RP4 will work closely with Cores D and E in advancing mAb prototypes. ~~The Core B of the Center will work together with RP2 and RP3 along with the Core C to develop the first cocktail human mAb immunotherapeutics, and facilitate the transition products suitable for IND filing and human testing including design, construction, assessment, and optimization of these antibody-based therapies.~~

As per NIAID's expectations described in the RFA, PABVAX intends to provide lead candidates for comparative studies using NIAID's preclinical services or other mechanisms. The Center PIs, the Scientific Advisory Committee and NIAID staff will select prototype candidates at the appropriate development stage for these studies. Members of PABVAX have over 10 years of experience working with NIAID's preclinical services for *in vitro* anti-viral testing, *in vivo* animal model testing (RSV, filoviruses), and IND-enabling GLP studies. Additionally, the team has experience collaborating with DoD and BARDA to advance candidate countermeasures to the clinic.

here is 12 pages
there is ~10% left space on page 12

i did not mess with formatting, so if you want an UNformatted
version , then use this to unformat

i edited throughout to tighten up, did not remove any reffs

Only larry's comment (2) remain to finalize

Subject: Re: overall 12 page res plan

problem is jims aims draft did even mention
alloy mice and LagV or bunya

you can definitely say you wll test nanobodies in SNTs to arenas
and then retest nanobody bi-specifics and then end with testing candidates
in vivo
we could use both big figures one in Admin core the other in the overalll

> I am crashing on RP1 today in order to get the final to the group for another round of review by tomorrow morning.
>
> Might be good if someone else has some time today to go through and accept the edits and fill in the refs. I can send the associated endnote library from my stuff if needed. Also, I'm good if we need to condense any of my section to be more concise, I figured I'd put more than needed and we could reduce and refine to make it all fit.
>
> I'm in the dark on a lot of the other projects beyond the specific aims as I've not even seen working drafts for really anything other than cores C, D, and E. So I'm trying my best to ensure cohesion with at least these cores, but might be good to ensure I'm on the right track in terms of ensuring formatting is consistent and I'm not missing any sections. I can't say how my RP will interact much with the other RPs as I don't fully know what they are doing and/or if it even makes sense to interact. BTW, did we ever get a specific aims page from Jim? I'm not sure I fully understand the direction he is going in and if I need to demonstrate interaction with his RP.

someone has to take this version, and go through an accept edits and get the remaining refs in remove comments unless there is a need for one more round to discuss

then we can see where it stands?

<Overall_Research-Strategy_PABVAX-12pages-060523.docx>

PROJECT SUMMARY/ABSTRACT - RP3 (Cedar Henipavirus Animal Model)

Pathogenic RNA viruses represent continuous infectious disease and pandemic threats to public health. Among these are the two emerged zoonotic paramyxoviruses: the ‘prototype’ henipaviruses (HNVs); Nipah virus (NiV) and Hendra virus (HeV), discovered in the mid to late 1990s. The prototype HNVs have a uniquely broad tropism capable of infecting 18 species across 6 orders of mammals using the conserved ephrin-B2 and -B3 ligands as entry receptors. NiV and HeV infection often results in a systemic and fatal respiratory and/or neurological disease in multiple mammalian species including humans. NiV and henipaviral disease are also included in the WHO List of Priority Pathogens, and they are significant biothreats to humans and livestock in South and Southeast Asia and Australia. HNVs have two membrane glycoproteins: the attachment glycoprotein (G) and the fusion glycoprotein (F) that are the major targets of neutralizing antibodies and the focus of all vaccine and antiviral monoclonal antibody (mAb) strategies. The most extensively studied HNV vaccine is a soluble recombinant form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including nonhuman primates (NHPs). With no licensed vaccines or treatments available for human use, this project will use the prototype HNVs as a model to develop, test, and translate a novel vaccination platform (a thermostable, needle-free, adaptable, and widely deployable polyphosphazene (PPZ) adjuvanted dissolvable microneedle patch (MNP)). Preliminary data demonstrates potent immunogenicity of a PPZ-MNP-HeV-sGvaccine in mice, inducing robust antigen-specific HNV cross-neutralizing antibody and cellular immune responses. The MNP vaccines will be used to evaluate HeV-sG and compare stabilized soluble forms of HNV G and F (sGtet and sFstb) and combinations in challenge studies. A reverse genetics system has been developed to generate recombinant, nonpathogenic Cedar virus (rCedV) and rCedV chimeric virus tools by swapping the G and F glycoproteins with those of NiV/HeV as a rapid, surrogate, BSL-2 high-throughput neutralization platform to be used to rapidly evaluate HNV vaccine responses. Also, divergent and pathogenic zoonotic HNVs have been discovered including the related rodent borne Mòjiāng virus and Langya virus (LayV)), and the divergent bat-borne Angavokely virus (AngV). This project will develop and test the rapid, adaptable and readily deployable MNP vaccine platform together with new virological tools to facilitate the translational nature of this pandemic preparedness approach. Specifically, we will: 1) Develop PPZ-MNP-based sGtet and sFstb prototype HNV vaccines; 2) Construct new reporter virus tools; 3) Evaluate vaccine-induced immune responses and HNV-specific mAbs and nbs; and 4) Validate the PPZ-MNP platform with another paramyxovirus antigen.

FACILITIES AND OTHER RESOURCES - RP3 (Cedar Henipavirus Animal Model)

USUHS

Project Lead: Brian Schaefer, Ph.D.

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Schaefer is a tenured Professor in the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators, including the Department of Microbiology and Immunology chair, Dr. Christopher Broder, who is an internationally-known virologist (and centrally involved in this proposal).

USU is directly across the street from the main NIH campus and close to Johns Hopkins, the University of Maryland and several other outstanding institutions, facilitating opportunities to establish productive collaborations with world-class investigators. For example, Dr. Schaefer has had a multi-PI U01 grant with Dr. Wolfgang Losert (Dept of Physics, University of Maryland) as the co-PI and Dr. Hari Shroff (NIH/NIBIB) as a collaborator. Dr. Schaefer is also primary PI on a multi-PI R01 from NIAID with Dr. YouWen He at Duke University Medical Center, and Dr. Thomas Conrads (Women's Health Integrated Research Center). Dr. Schaefer and his staff have also collaborated with the Advanced Imaging Center (AIC) at the Howard Hughes Medical Institute (HHMI) for some of their imaging-based research. Overall, the broader scientific environment at USU and the greater Bethesda/Washington D.C. metropolitan region is highly conducive to productive collaborations. Dr. Schaefer has been using these resources to his advantage, and has been very active in establishing collaborative relationships to facilitate his research objectives. Notably, Dr. Schaefer and Dr. Broder have been collaborating for several years on lyssavirus- and henipavirus-related project, and they have a very strong working relationship.

Members of the Schaefer lab participate in a weekly multi-lab Immunology journal club, Immunology data club, virology journal club, and virology data club. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club. Also, members of the Schaefer lab participate in a bi-weekly data presentation/discussion group which meets monthly.

Dr. Schaefer has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., The IVIS® Spectrum CT preclinical in vivo imaging system; Cytek Aurora spectral flow cytometer), and 10x Genomics Visium Spatial Transcriptomics instruments are not overbooked and therefore readily available to laboratory personnel. Dr. Schaefer is also Chair of the USU Biomedical Instrumentation Center (BIC), and thus plays a central role in directing equipment purchases, ensuring that needed technologies are available for the research of the PI and his USU colleagues. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase core facility equipment. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by recent USU purchases of cutting-edge equipment including a Perkin-Elmer IVIS® Spectrum CT preclinical in vivo imaging system, a Zeiss Elyra PS.1 super-resolution microscope, an Agilant Seahorse XPe96 Analyzer, a BD FACSAria Fusion flow sorter, and many other pieces of advanced research equipment. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional.

USU has several Ph.D. programs, including an Emerging Infectious Diseases (EID) program, a Molecular and Cellular Biology (MCB) program and a Neuroscience (NES) program. Dr. Schaefer holds secondary appointments in all three programs and is currently Interim Director of the Emerging Infectious Diseases Graduate Program. Ds. Schaefer has been very active in training graduate students, having trained >10 Ph.D. students. USU recruits strong graduate students, and Dr. Schaefer's students have been very productive, during and beyond their dissertation studies. The availability of talented graduate students is a further resource, promoting productivity and enhancing the overall vibrancy of the scientific environment at USU. **Laboratory**: Dr. Schaefer's laboratory area consists of three rooms of 450 sq. ft, 300 sq. ft and 225 sq.ft., and a dedicated microscopy suite of 110 sq. ft. The Schaefer lab contains routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, waterbaths, free-standing biosafety cabinets, and CO_2-tissue culture incubators. Additionally, Dr. Schaefer's lab is equipped

with an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope), a BioRad CFX Connect real-time PCR system, a Coulter Z1-Dual cell counter, a DeNovix CellDrop-FL cell counter and a Lonza Nucleofector 4D Shuttle. Postdocs, students, and technicians have desks and computers in the laboratory.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. The USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. The facility also includes two preclinical behavior cores (one for mice, one for rats). The facility and the University's animal care and use program is managed by the Department of Laboratory Animal Medicine (DLAR), which is directed by a veterinarian who is an ACLAM Diplomate and staffed with three other veterinarians, a graduate animal husbandryman, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates and lower vertebrates to higher vertebrates including non-human primates and domestic livestock, as well as more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers (Intel i5/i7 or similar processors and ≥8GB of RAM) are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories of both investigators. Dr. Schaefer's laboratory also has a dedicated workstation for use for analysis of microscopy and in vivo imaging data. Image analysis software in the Dr. Schaefer's lab includes Zeiss Zen, with a digital deconvolution module and numerous tools for quantitative image analysis. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro. Dr. Schaefer also maintains a license for FlowJo software, which can be used on any networked computer in the laboratory. The computers are connected by a central server to each other and to the Internet. A variety of USU-supported software programs are available, including EndNote, Microsoft Office, Adobe Creative Cloud, Geneious Prime and Graph Pad Prism 9.

Office: Drs. Schaefer's office is separate from but proximal to each of his laboratories. Trainees and technicians have desks in the laboratory. Four full-time administrative officers and one part-time administrator are available to provide support within the department.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely meet with BCC consultants regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data.

The USU Biomedical Research Imaging Core (BRIC) houses state-of-the art equipment for pre-clinical studies, including a IVIS® Spectrum CT, a Siemens Inveon SPECT/PET/CT Scanner and a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system. A Scientist and several staff provide technical support and manage the facility.

The USU American Genome Center (TAGC) is one of only four academic genome centers in the United States. It is the Department of Defense operations subsidiary of the Collaborative Health Initiative Research Program (CHIRP) established between the National Heart, Lung, and Blood Institute (NHLBI) and USU. Since inception, TAGC has generated more than 40,000 whole Genome Sequences across 107 research studies sourced from NHLBI, other NIH Institutes, DoD and USU investigators. TAGC is also the sequencing center and genome data analysis center for the APOLLO Cancer Moonshot project, and collaborates for this purpose with the Murtha Cancer Center (MCC) at Walter Reed, the National Cancer Institute, and the Veterans Administration. Through a collaborative relationship with 10x Genomics, USU has early access to newly released platforms such as Visium Spatial Transcriptomics (including improvements to that platform).

The USU TAGC includes a large array of next-generation sequencing instruments including Illumina NovaSeq 6000 systems, Illumina HiSeq X systems, and an Illumina NextSeq 500 system. A 10x Genomics Chromium Connect automated single-cell NGS library workstation is available for automated single cell partitioning, barcoding and NGS library preparation. A 10x Genomics Chromium Controller massively parallel sample partitioning platform is available for barcoding single cell RNA for library preparation and for single cell transcriptome profiling, including CITE-seq workflows. 10x Genomics Visium CyAssist transcriptomic probe transfer system is available to facilitate spatial transcriptomics workflows. Electrophoresis systems include Agilent Fragment Analyzers and a Bio-Rad Experion LabChip Platform. Sequencing platforms are connected to a high-speed network switch for data storage on a petabyte-scale Isilon SAN.

The USU Biomedical Instrumentation Center (BIC) consists of five core equipment facilities for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). Each core is run by a full-time Director with an advanced science background (most hold a PhD) and a high degree of technical expertise. The majority of cores have at least one additional employee to help manage the core and provide guidance and assistance to users.

The BIC Flow Cytometry Core includes three analyzers (Cytek Aurora 5-laser, 64-channel Spectral Analyzer; Becton-Dickinson 5-laser, 30-parameter FACSymphony A5; Becton-Dickinson 4-laser, 15-parameter LSRII) and two sorters (BD FACSAria Fusion 4-laser, 18-parameter flow sorter; BD FACSAria IIIu 4-laser, 17-parameter flow sorter) and an Amnis Image Stream X Mark II imaging flow cytometer. Other equipment includes a Bio-Rad Bio-Plex 200 multi-analyte detection system and an Agilant Seahorse XPe96 Analyzer. The core has several off-line analysis workstations with FlowJo and other data analysis platforms.

The BIC Imaging Core houses a wide array of microscopes, including a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. Other microscopes include aZeiss 980 Confocal with Airyscan2, a Zeiss 700 confocal system, a Zeiss 7 MP Multi-photon Confocal Electrophysiology System, a Zeiss Lightsheet Z.1 and a Zeiss Axioscan Z1 Slide Scanner. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize. For electron microscopy needs, the core is equipped with a JEOL JEM-1011 transmission electron microscope, an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment), and a grid stainer (Leica EM AC20).

The BIC Genomics core includes a 3500 XL Applied Biosystems Genetic Analyzer, a Gene Forge 3900 and an ABI 3900 and DNA Synthesizer, a U-3000 Thermo-Scientific HPLC system, an Agilent 1200 HPLC, a QX200 Droplet Digital PCR System, a Roche LightCycler 480 Real-Time PCR System and an Agilent Capillary Electrophoresis Fragment Analyzer.

The BIC Structural Biology and Proteomics Core includes a GE Healthcare Biacore 3000 Surface Plasmon Resonance instrument, an AB Sciex 4000 QTRAP LC/MS/MS System, an Agilent 1200 HPLC, a Wyatt DynaPro NanoStar Dynamic Light Scattering analyzer, an Art Robbins Instruments Phoenix Crystallization Robot, and a JANSi UVEX Fluorescence Microscope (for crystal inspection).

The BIC Histopathology Core includes a Leica Autostainer XL, a Leica CV 5030 Robotic Coverslipper, a Sakura Tissue-Tek VIP tissue Processor, a Leica CM 3050 S Cryostat, and a Microm HM 325 Microtome.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology.

Washington State University

Paul G. Allen School of Global Health at Washington State University in Pullman, WA (Bronwyn Gunn)

The Paul G. Allen Center for Global Health at Washington State University, completed in 2012, is a 62,000-square-foot state-of-the-art infectious disease research facility equipped to meet today's standards for investigating pathogens and emerging diseases. The facility includes first floor administrative offices and 5,000 sq. ft. of CDC- and USDA-certified Biosafety Level 3 (BSL3) laboratory space, and two floors with meeting rooms, faculty BSL2 laboratories and office space. Meeting rooms are well-equipped for presentations and connecting with colleagues across the globe, while open spaces on each floor also encourage informal interactions among the students, faculty, and staff. Shared facilities including common equipment rooms and licensed work sites for bioinformatics are also available throughout the building.

Laboratory: The Gunn laboratory is located on the 2nd floor of the Paul G. Allen School of Global Health at Washington State University in Pulllman, WA. The BSL2 laboratory space includes 8 six-ft benches, equipped with standard laboratory equipment (pipettes, serological pipet-aids, vortex, heat blocks, PCR machine, 4C refrigerator, -20C freezer, -80C freezer etc), with a dedicated space for molecular DNA and protein analysis. There are two class II biosafetly cabinets located in a separate room attached to the main lab space that contains a double stack New Brunswick 37C 5% CO_2 incubator and a shaking CO_2 incubator (New Brunswick S41i) for culture of suspension cell lines. A Luminex MagPix and a magneic plate washer (AquaMax4000, Molecular Devices) and an OctetRed 96 biolayer interferometry instrument (ForteBio/Sartorius) are housed within the Gunn lab space for multiplexed analysis of antibody levels and affinity measurements, respectively. The Gunn lab also houses a Cytek Aurora Spectral Flow Cytometer, equipped with 5 lasers (UV, violet, blue, yellow-green, red) and automated 96 well high throughput sampler that is used to analyze all cell-based effector assays. Dr. Gunn also has access to a Biotek Synergy HTX multimode microplate reader equipped with luminescence and fluorescence detectors for highthroughput analysis of pseudotyped virus entry.

Dr. Gunn also has access to additional facilities and resources within the rest of the Paul G. Allen School of Global Health. All investigators' laboratories and the core facilities are fully equipped for research in molecular biology and infectious diseases. The BSL2 laboratories have been approved for pathogen use, recombinant DNA experiments, and radioisotope use. The BSL-3 and ABSL-3 labs are USDA and CDC certified for select agent use. A full range of centrifuges, a scintillation counter, microscopes, spinning disc fluorescence microscope, spectrophotometers, electrophoresis instrumentation, thermal cyclers for PCR, real-time PCR and digital PCR, multi-plate fluorimeters and proteomic instrumentation (isoelectric focuser) as well as other general equipment are available on-site, and gamma counters, HPLC and FPLC are available nearby. Major equipment in the Allen Center also includes instrumentation for microarray fabrication and an Illumina MiSeq system that is used routinely for DNA sequencing and RNAseq experiments. Shared instrumentation includes photographic equipment, an automatic radiograph processor, an upright flourescent microscope, image analysis equipment, large-scale incubators, ultra - and high-speed centrifuges.

BSL-3 laboratory: Dr. Gunn has dedicated BSL-3 space in the Paul G. Allen School of Global Health BSL-3 suite and currently approved to work with SARS-CoV-2. Equipment in the BSL-3 laboratory space include a Class II biosafety cabinet, centrifuge equipped with biocontainment rotors, and 37C 5% CO_2 tissue culture incubator.

Computer: All members of the Gunn laboratory are supplied a laptop 13" MacBook Pro for their research needs, with licenses to Office Software (Word, Excel, PowerPoint, Outlook), Adobe Creative Cloud (Illustrator, Photoshop, Acrobat), GraphPad Prism, and EndNote20. In addition, two lab desktop computers are available that have licenses to Cytek SpectroFlo analysis software and Geneious. Computers are networked and wireless connectivity is available throughout the building. High-performance computing needs on campus are met by an SGI Power Challenge L computer, an NSF-funded 16-processor IBM SP2 parallel computer, and the Amazon Cloud (AWS). Critical data bases including various DNA and protein sequence data bases (GenBank, EMBL, SwissPro and others), the Brookhaven Protein Data Bank, and the Cambridge Crystallographic Structure Data Bank for small molecules are available locally and through network access. Software for sequence analysis, clustering orthologous proteins, detecting SNPs, and exploration of phylogenetic relationships is available, as are numerous programs available via network access.

Office: Office space for graduate students and post-docs in the Gunn lab are located directly outside of the laboratory space, allowing for easy access and transition between spaces. Dr. Gunn's office is located adjacent to the general office space, allowing for easy communication and interactions.

Animal: All animals on the WSU campus are maintained in accordance with USDA and NIH regulations that include twice-yearly inspections of all facilities by the Institutional Animal Care and Use Committee (IACUC). The facilities and procedures for maintenance and care of animals are accredited by the American Association for Accreditation of Laboratory Animal Care. Personnel trained in the care of laboratory animals staff all animal facilities.

Scientific Environment: The research environment is strengthened by an interactive faculty. These include interactions with many faculty members within the College of Veterinary Medicine Departments of Veterinary Microbiology and Pathology (VMP), Integrated Physiology and Neurosciences (IPN) and the School of Molecular Biosciences (SMB) which provide opportunities for scientific exchange and collaborations as well as extended expertise in infectious diseases, cell biology and biochemistry.

Palouse Virology group: There is a bi-weekly Virology Group meeting of laboratories from WSU, USDA, and the University of Idaho that contributes to the interactive intellectual environment. Participating virologists are from the Nicola, Bose, Cunha, Fortunato, Goodman, Gunn, Koehler, Letko, Miura, Ramsay, Rowley, Schwartz and Seifert laboratories, covering a range of viral pathogens including those impacting human and animal species.

Research in Progress (RIP): Weekly meetings where students, staff, and faculty from VMP, Allen School, and USDA present their research in 20- or 45-minute seminars. RIP is well attended both in person and on Zoom.

EQUIPMENT - RP3 (Cedar Henipavirus Animal Model)

USUHS

Project Lead: Brian Schaefer, Ph.D.

Schaefer Laboratory

Epifluorescence microscopy system (Fully-automated Zeiss AxioObserver epifluorescence microscope)
BioRad CFX Connect real-time PCR system
Lonza Nucleofector 4D Shuttle – core unit and X-unit
Coulter Z1-Dual cell counter
DeNovix CellDrop-FL cell counter with fluorescence
centrifuges: Eppendorf 5425 microfuges (3); Beckman Allegra 25R; Thermo-Fisher Jouan GR4i; various rotors NestAdvance Bullet Blender bead mills (2)
Miltenyi QuadroMACS separator (2)
inverted microscopes for tissue culture (2)
gel electrophoresis equipment for protein (3) and DNA (5) gels
semi-dry protein transfer apparatus (2)
Bio-Rad thermal cyclers (2)
balances (4)
pH meter
refrigerators
freezers (-20 C, -80 C)
platform orbital shakers (5)
sonicator with cup horn and microtip
bacterial shaker
heating blocks (6)
waterbaths (8)
biosafety cabinets (2)
CO_2-tissue culture incubators (3)
Thermo-Fisher Locator 4 liquid nitrogen storage tank with electronic monitoring

Departmental

GE Healthcare Life Sciences Amersham Imager 680 (for imaging of protein and DNA gels and blots)
Alpha-Innotech gel documentation system (EtBr-stained gels)
2D gel electrophoresis system (protein)
MilliQ ultra-pure water system
Nanodrop spectrophotometer
Luminometer
Fluorescence plate readers (2)

USU CORE FACILITIES (fee for service or free)

Biomedical Research Imaging Core (BRIC)

IVIS® Spectrum CT preclinical *in vivo* imaging system (2D and 3D bioluminescence and CT imaging)
Siemens Inveon SPECT/PET/CT Scanner
Bruker Biospec 70/20 USR MRI
Image Guided Therapy 7T MR guided Focused Ultrasound System for neurological applications

The American Genome Center (TAGC)

Illumina NovaSeq 6000 systems (7)
Illumina HiSeq X systems (6)
Illumina NextSeq 500 system
10x Genomics Visium CyAssist transcriptomic probe transfer system
10x Genomics Chromium Connect automated single-cell NGS library workstation
10x Genomics Chromium Controller massively parallel sample partitioning platform
Bio-Rad Experion LabChip Platform automated electrophoresis system
PRIMER Data Science Core - direct connection to a high-speed network switch for data

Biomedical Instrumentation Center (BIC)

Flow Cytometry
Cytek Aurora 5-laser, 64-channel Spectral Analyzer
Becton-Dickinson 5-laser, 30-parameter FACSymphony A5
Becton-Dickinson 4-laser, 15-parameter LSRII FACS analyzer
BD FACSAria Fusion 4-laser, 18-parameter flow sorter
BD FACSAria IIIu 4-laser, 17-parameter flow sorter
Amnis Image Stream X Mark II imaging flow cytometer with IDEAS statistical image analysis software
Bio-Rad Bio-Plex 200 multi-analyte bioassay detection system
Agilant Seahorse XPe96 Analyzer
Offline data analysis stations (3) with software packages including: FlowJo, WinList, and ModFit

Microscopy
Zeiss 980 Confocal with Airyscan2
Zeiss 700 confocal system with 405/458/488/514/561/633 laser lines
Zeiss 7 MP Multi-photon Confocal Electrophysiology System
Zeiss Elyra PS.1 Superresolution microscope for superresolution structured illumination microscopy (SR-SIM), photoactivated localization microscopy (PALM), and direct stochastic optical reconstruction microscopy (dSTORM). System is fully equipped, including the 3D-PALM/dSTORM option.
Zeiss Lightsheet Z.1
Zeiss Axioscan Z1 Slide Scanner
Zeiss AxioImager M2 upright microscope and MicroBrightField Stereo Investigator software (stereology analysis).
Leica AF6000 system, including an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control
Transmission electron microscope (JEOL JEM-1011)
Ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment)
Grid stainer (Leica EM AC20)
Wide-field fluorescence microscopes (3)
Offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph.

Genomics
3500 XL Applied Biosystems Genetic Analyzer
Gene Forge 3900 and ABI 3900 and DNA Synthesizer
U-3000 Thermo-Scientific HPLC system
Agilent 1200 HPLC
QX200 Droplet Digital PCR System (ddPCR)
Roche LightCycler 480 Real-Time PCR System
Agilent Capillary Electrophoresis Fragment Analyzer

Structural Biology/Proteomics
AB Sciex 4000 QTRAP LC/MS/MS System
Agilent 1200 HPLC
Wyatt DynaPro NanoStar Dynamic Light Scattering
GE Healthcare Biacore 3000 Surface Plasmon Resonance
Art Robbins Instruments Phoenix Crystallization Robot
JANSi UVEX Fluorescence Microscope

Histopathology
Leica Autostainer XL
Leica CV 5030 Robotic Coverslipper
Sakura Tissue-Tek VIP tissue Processor
Leica CM 3050 S Cryostat
Microm HM 325 Microtome

Washington State University

Paul G. Allen School of Global Health, Washington State University in Pullman, WA

- Laminar Flow Hoods
- Fume Hoods
- Inverted Microscopes
- Microcentrifuges
- Nucleocounters
- LN2 Storage Freezers
- Biorad Thermal Cycler (PCR)
- ThermoCycler (real-time PCR)
- Digital PCR
- Spinning disc fluorescent microscope
- Spectrophotometers
- Tissue Culture Incubators
- Sequencing Power Pack and Gel Apparatus
- Beckman Centrifuges
- Thermo floor ultracentrifuges
- Microplate shakers
- New Brunswick shaking cell culture incubator (S41i)
- Cytek Biosciences Aurora Spectral Flow Cytometer equipped with 5 lasers (UV, Violet, Blue, YellowGreen, and Red), 60 fluorescent detector channels, and a high throughput sampler.
- Molecular Devices AquaMax 4000 Magnetic Plate Washer equipped with a 96 well head.
- Luminex MagPix
- Octet Red Biolayer Interferometer
- Tecan multifluorescent plate reader
- BioTek Synergy HTX Reader
- Analytical scales
- AKTA Avlant HPLC
- -80ºC Freezers

- Autoclaves
- Illumina MiSeq

School of Molecular Biosciences, Washington State University in Pullman, WA

- NanoString nCounter System
- NanoString GeoMx Digital Spatial Profiler (DSP)
- Becton-Dickenson FACSCalibur flow cytometer
- Sony Biotechnology SH800 and SY3200 High Speed Sorter
- Illumina NextSeq 2000 sequencer (December 2022)
- PacBio Sequel II
- Agilent Tape Station and Bioanalyzer
- 10X Genomics ChromiumTM Controller
- Nexcelom cell counter
- Computational: 64-core node (Intel Xeon Scalable 6338) with 512GB, 3200 MT/s DDR4 of memory); 40 TB storage equipped with a GPFS file system
- The storage system is backed up by WSU’s KAMIAK Supercomputer center and backed up in time snap shots on a server powered by different power sources and physically located in a different part of the building. For security reasons all servers are only accessible via SSH within the WSU network or the VPN.

OMB No. 0925-0001 and 0925-0002 (Rev. 10/2021 Approved Through 09/30/2024)

BIOGRAPHICAL SKETCH

NAME: Schaefer, Brian Charles

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Professor of Microbiology and Immunology, and Director (Interim), Emerging Infectious Diseases Graduate Program

EDUCATION/TRAINING *(Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)*

INSTITUTION AND LOCATION	DEGREE *(if applicable)*	Completion Date MM/YYYY	FIELD OF STUDY
Massachusetts Institute of Technology	B.S.	1989	Biology
Harvard University	PhD	1995	Immunology
Harvard Univ/Dana Farber Cancer Institute	(Postdoc)	1995-1996	Tumor Virology
National Jewish Medical and Research Center	(Postdoc)	1996-2002	Immunology

A. Personal Statement

My group has historically focused on two major research programs. Our longest-standing program involves elucidation of mechanisms of signal transduction in immune cells and regulation of immune cell effector function, with a particular emphasis on the pathway that connects the T cell receptor (TCR) signaling to the transcription factor, NF-κB. This work has also stimulated our studies of the function of an understudied CARD protein, CARD19, which was originally (incorrectly) identified as a negative regulator of TCR signaling to NF-κB. These studies have resulted in numerous publications that define novel signaling mechanisms in the CARD11-BCL10-MALT1 signaling cascade and additional pathways. Our second major area of research is centered on immune responses in the central nervous system. Our initial work in this area involved elucidation of the role of the immune response initiated by traumatic brain injury, particularly NF-κB-mediated inflammatory responses. However, we have now shifted our emphasis to translational research on immune responses to neurotropic viruses, with an overall goal of developing immunotherapy strategies that are broadly effective against this dangerous class of human pathogens. This work is focused on lyssaviruses and henipaviruses, due to their neurotropic nature and propensity to cause severe human disease with a very high fatality rate. Our use of bioluminescence imaging to track viral replication has been a particularly important innovation for this work, as it allows us to collect highly granular data regarding viral spread and amplification from individual animals in a longitudinal manner. Specific current projects include a DoD-funded translational study in which we are defining the utility of a novel, mAb-based anti-lyssavirus immunotherapy against rabies strains circulating in Europe and Africa, and a study to develop novel henipavirus therapies (both are collaborations with Dr. Christopher Broder's group).

I am ideally suited to be PI of RP3: *Cedar henipavirus animal model*, as my group has established the only mouse model of Cedar virus infection (to our knowledge), and we now have several years of experience in the development of this very important BSL-2 animal model to investigate mechanisms of henipavirus pathogenesis, and to test efficacy of novel therapies. The following are notable ongoing projects:

HU00011920118 (**PI: Schaefer**), USU Center for Global Health Engagement
09/30/2019 – 09/29/2022 (NCE to 9/30/23)
"Efficacy testing of a novel human monoclonal antibody therapy for late-stage rabies/lyssavirus infection"

U19 AI142764-01 (PI:Broder; **Schaefer Co-I**), NIH/NIAID
03/01/2019 – 02/29/2024
"Advancement of Vaccines and Therapies for Henipaviruses"

R01 AI125552 (**PI: Schaefer**). NIH/NIAID
06/01/2017 – 05/31/2022 (NCE to 5/31/2024)
“T cell receptor-activated autophagy as a regulator of T cell effector responses”

HU00011921048 (**PI: Schaefer**), USU Multi-domain Operations Research (MDO)
02/28/2023 - 09/30/2025
“Defining the mechanism of enhancement of the pathogen-directed host adaptive immune response following anti-lyssavirus monoclonal antibody therapy”

B. Positions, Scientific Appointments, and Honors

Positions

2017 - current	Professor (with tenure) in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
2009 - 2017	Associate Professor (with tenure) in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
2002 - 2009	Assistant Professor in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
1996 - 2002	Post-doctoral Research Associate, Howard Hughes Medical Research Institute, National Jewish Medical and Research Center, Denver, CO.
1995 - 1996	Research Fellow in Pathology, Harvard University, Dana-Farber Cancer Institute

Professional Memberships and Service

2011 - 2016	NIH CMIB (Cell and Molecular Immunology-B) study section for review of R01/R21 grants (Ad hoc member Feb & May 2011, Feb & May 2013, Feb 2014, Feb 2015, May 2016)
2008, 2021	ZRG1 CB-D 30 Confocal Microscopy Shared Instrumentation NIH Study Section (Ad hoc member)
2006 - current	American Society for Cell Biology (ASCB)
2006 - current	American Association of Immunologists (AAI)
2006 - 2007	ZRG1 IMM-L 29 L, DBBD Minority and Disability Predoctoral Fellowship NIH Study Section (Ad hoc member)
2005-2006	ZRG1 F07 Immunology Fellowship and AREA NIH Study Section (Ad hoc member)

Honors

2016	Uniformed Services University Henry Wu Award for excellence in basic science research
2005 - 2008	Dana Foundation Program in Brain and Immuno-Imaging
2004 - 2006	Kimmel Scholar - Sidney Kimmel Foundation for Cancer Research
2000 - 2002	Leukemia and Lymphoma Society Special Fellowship
1989 - 1992	Office of Naval Research Graduate Research Fellowship
1989	Phi Beta Kappa
(1989)	National Science Foundation Graduate Research Fellowship (Declined)

Patents

2007	US Patent 7,169,570: *Method to Identify Regulators of Cellular Activation Using Bcl10* – BC Schaefer, JW Kappler and P Marrack

Mouse strains developed

2001	C57BL/6-Tg(UBC-GFP)30Scha/J: Ubiquitously expressed EGFP transgene on a pure C57BL/6 background. Repository strain at Jackson Laboratory (stock# 004353). This strain has been used and cited in hundreds of publications.

C. Contributions to Science

1. My Ph.D. thesis studies involved identification of the molecular mechanisms controlling distinct latency-associated Epstein Barr virus (EBV) transcriptional programs. Prior to my dissertation work, it was known that there were three forms of EBV latency which displayed two distinct phenotypes with regard to expression of EBV nuclear antigens (EBNAs): Type III latency is characterized by expression of all six EBV nuclear antigens (EBNA1-EBNA6) whereas Type I and Type II latency is characterized by expression of EBNA1 only. The molecular basis restricted EBNA expression in Types I and II latency was not known. My work demonstrated the existence of a novel EBV promoter "Qp," responsible for driving exclusive expression of EBNA1 in Types I and II latency. My studies also showed that the choice between latency programs was contingent on whether the Type III latency promoter, Cp, is methylated in the host cell. Collectively, this work contributed significantly to the current understanding of regulation of EBV latency, which is relevant to elucidating how EBV persists for life in immunocompetent individuals, how EBV emerges as a life-threatening pathogen in specific immunodeficiencies, and how specific programs of EBV latency may be related to EBV-associated tumors, such as Burkitt lymphoma.

2. My early work as an independent investigator involved determining whether NF-κB signaling proteins undergo molecular redistribution in response to TCR signaling. Previous work had shown that several different signaling molecules are recruited to "supramolecular activation clusters (SMACs)," membrane-proximal enrichments of signaling proteins that form on the cytoplasmic face of the antigen-engaged TCR. An assumption in the field, prior to our work, was that SMAC recruitment would be a shared feature of all cytoplasmic proteins important in TCR signaling. Surprisingly, our investigations demonstrated that NF-κB signaling proteins, including Bcl10 and Malt, redistribute to punctate cytoplasmic structures, which we named POLKADOTS. Our ongoing signal transduction work has involved mechanistic studies connecting the POLKADOTS signalosome to TCR activation of NF-κB. Key findings include demonstration that (i) TCR activation of NF-κB is *digital*. In other words, in contrast to pharmacological stimulation of NF-κB (PMA + ionomycin), which results in graded activation of NF-κB as the stimulus is increased, increasing TCR ligand changes only the *number* of T cells that respond, but not the *intensity* of the response; (ii) polyubiquitination of Bcl10 leads to recruitment to pre-existing p62 "speckles," forming the POLKADOTS signalosome; (iii) the POLKADOTS signalosome is required for activation of the IKK complex; (iv) the POLKADOTS signalosome contemporaneously directs a signal dampening activity that involves a highly novel regulatory mechanism: *selective* autophagy of Bcl10, which results in degradation of Bcl10, but not its direct binding parther, Malt1; (v) effector T cells form POLKADOTS signalosomes and use autophagy to degrade Bcl10, whereas naïve T cells use a distinct mechanism of NF-κB activation that appears to be independent of p62, involving recruitment of signaling proteins to SMACs. Collectively, these contributions provide key mechanistic details regarding how signals are transmitted from the TCR to the NF-κB transcription factor. Most recently, we have collaborated with Drs. Wolfgang Losert and Arpita Upadhyaya, biophysicists at the

University of Maryland, to define biophysical features of TCR-mediated activation and degradation of Bcl10. Our study with Dr. Losert in PLOS Computational biology has shown that the regulated polymerization and degradation of Bcl10 has characteristics of an excitable system, providing new insights regarding the digital behavior of this signaling module.

3. During our studies on TCR signaling to NF-κB, we became interested in the understudied CARD protein, CARD19. Although CARD19 was initially described as a cytoplasmic negative regulator of TCR signaling to NF-κB, we found that this work was based on analysis of a partially spliced cDNA clone, and that the conclusions of this initial study were therefore spurious. Our work with a properly spliced CARD19 cDNA showed that CARD19 is a mitochondrial protein that plays no role in TCR activation of NF-κB. Our latest work has shown that CARD19 interacts with the mitochondrial cristae organizing system (MICOS), and that it plays a role in determining cristae morphology. Notably, 3 of the 7 current publications focused on CARD19 were generated by my laboratory or as a collaboration with my group. We are currently performing further studies to determine whether CARD19 regulates other aspects of mitochondrial function via its interaction with MICOS components.

4. A second major research focus in my lab is the study of immune responses in the central nervous system. Our initial studies focused on inflammatory responses in traumatic brain injury (TBI), using mice as a model system: The first study demonstrated that the gene expression program induced by mild vs. severe TBI is remarkably similar, with the main distinction being that the expression of certain inflammatory genes remains persistently elevated in severe TBI. The second study presented evidence that the anti-inflammatory drug salsalate is a candidate therapy for TBI, reducing inflammation and improving functional recovery, as assessed by behavior assays. Our more recent work has focused on developing novel animal models and immunotherapies for neurotropic viral infections. Our published work on this project includes a description of our methodology for longitudinal tracing of lyssavirus infections and a description of isolation and in vitro characterization of two anti-lyssavirus neutralizing mAbs.

5. A distinct area of emphasis in my career has been the development of new tools for research and the optimization of existing tools. Among many publications in this area, I have edited a protocols book and written a review on methodology for identification of cDNA ends by RACE (which included an optimized protocol). I produced a C57BL/6 transgenic mouse strain ubiquitously expressing GFP, which has been a highly utilized tool for cell transfer studies. I also generated a set of retroviral vectors for rapid and reliable creation of stable cell lines. My lab has published optimized protocols for visualizing NF-κB signaling intermediates via confocal microscopy, and for quantifying NF-κB activation using imaging flow cytometry. We have most recently described our methodology for using bioluminescence imaging to semi-quantitatively trace lyssavirus infection in laboratory mice. A central goal of this work is to facilitate progress across the biomedical research community, through the development and distribution of better tools and clear explanation of how to reliably execute challenging techniques.

VERTEBRATE ANIMALS - RP3 (Cedar Henipavirus Animal Model)

1. **Description of Procedures**

   The following mouse strains will be used in this proposal:

   i) **B6-albino-Ifnar1-/- mice**. We maintain a breeding colony of B6-albino Ifnar1-/- mice at Charles River Labs (CRL). We generated these mice by crossing the B6-albino strain (Jackson Laboratory B6(Cg)-Tyrc-2J/J, Strain #:000058) with the Ifnar1-/- strain (Jackson Laboratory B6(Cg)-Ifnar1<tm1.2Ees>/J, Strain # 028288), followed by crossing F1 mice back to B6-albino and then intercrossing white progeny that carried the Infar1- allele. This colony is now producing only albino mice that are homozygous Ifnar1-/-.

   ii) **B6-albino-STAT1-/- mice.** We are currently establishing a breeding colony of B6-albino STAT1-/- mice at CRL. We are currently crossing the B6-albino strain (Jackson Laboratory B6(Cg)-Tyrc-2J/J, Strain #:000058) with the STAT1-/- strain (Jackson Laboratory B6.129S(Cg)-Stat1tm1Dlv/J, Strain # 012606), followed by crossing F1 mice back to B6-albino and then intercrossing white progeny that carry the STAT1- allele. We anticipate establishing a colony of the desired genotype by early 2024..

   We will use mice for in vivo infection with rCedVs, with many experiments including bioluminescent imaging. Animals are housed in an approved ABSL-2 room and all laboratory and animal care staff follow BSL-2 safety precautions. The total number of required mice (including all mice produced during breeding) is 5440. Experiments will be performed with male and female mice. The PI has an IACUC-approved experimental protocol and an IBC-approved biosafety protocol that details the use of the above strains of mice for the described experiments.

2. **Justifications for Use**

   The goal of this project is to validate the mouse as a BSL-2 model for henipavirus pathogenesis, and as a platform for development and testing of countermeasures. For this work, we must use an experimental animal model to allow the course of in vivo infection and the host immune response to be studied. There is no in vitro model which can model the complex in vivo dynamics of viral infection, moving between distinct cell types and anatomical locations, or the host immune response to infection. We have chosen to utilize mice due to their ease of care, the existence of well-characterized inbred strains and knockout models, and our preliminary data with rCedVs showing robust and reproducible infection of mice which is highly amenable to statistical analysis. The number of animals to be used is based on power analyses, as detailed in our approved IACUC protocols.

3. **Minimization of Pain and Distress**

   Experiments will involve the euthanasia of infected animals experiencing pain or distress. Our IACUC protocols also define a weight loss threshold or a combined disease score criterion as end points for virus-infected animals requiring euthanasia. Animals not euthanized for the above reasons will be euthanized for tissue collection, at time points described in our IACUC protocol. Euthanasia will be performed as described in part 4, below. Mice reaching criteria/endpoints described in 3, above, will be euthanized by ketamine or ketamine-xylazine overdose. This method is consistent with AMVA guidelines.

DEPARTMENT OF DEFENSE · UNITED STATES OF AMERICA

UNIFORMED SERVICES UNIVERSITY OF THE HEALTH SCIENCES
4301 JONES BRIDGE ROAD
BETHESDA, MARYLAND 20814-4799

June 1st, 2023

Dr. Schaefer,

It is with great enthusiasm that I can confirm support for your proposed research study: *Research Project 3 (RP3), Cedar henipavirus animal model*, that is part of the multi-site center application, Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center (PABVAX). This project is a sound representation of your research expertise in cellular, histological and molecular methodologies to understanding the modulation of infectious viral consequences in the mammalian brain and central nervous system, using mice as a model system. This proposal is centered on exciting preliminary data suggesting that infection of STAT1-/- mice with chimeric recombinant Cedar viruses (rCedVs) causes neurovirulence and mortality (whereas immunocompetent animals rapidly control infection). Through your proposed transcriptomics studies, we can facilitate your experimental plan to define gene expression changes across cell types in the brains of infected animals. Moreover, through your use of distinct recombinant viruses and different immunocompromised mouse strains, we can identify those gene expression changes that correlate with neurovirulence and mortality. The proposed unbiased approach to defining pathogenic mechanisms will represent a truly important step in establishing, validating and gaining biological insights from this novel BSL-2 model of henipavirus disease.

We are well poised to collaboratively support the high complexity molecular workflows from the well curated tissue specimens your team will provide. At the laboratories of The American Genome Center (TAGC), we have model system experience in transcriptomic and proteomic profiling for experimental models using whole rodent brain (see PubMed Id (PMID): 21190398, 22291617 and 23118733). Specifically, we will assist your laboratory in bulk transcriptomics, single cell RNA-sequencing and Visium spatial transcriptomics using 10x Genomics workflows. We have current standard operating procedures for your experiments using the 10x Genomics CytAssist platform and tissue compatibility for fixed tissues. We will also provide data analysis through validated pipelines and data storage from our compute infrastructure and storage area network. Importantly, we will build cross-compatible protocols with your laboratory team, including a key liason in your laboratory, who has previously trained in our genome center. Our laboratory and Data Science division computational biology associates will be available for analysis and interpretation of the data, with your leadership.

I look forward to working with you on this exciting project!

Sincerely,

(b) (6)

Clifton Lee Dalgard, PhD

RESOURCE SHARING PLAN - RP3 (Cedar Henipavirus Animal Model)

Sharing Model Organisms: No model organisms will be generated from this research. Strains of mice to be used in this proposal are directly available from Jackson labs, or will be derived via breeding of these commercial strains. As these strains are readily available to the scientific community, no further action on our part is required.

All genomic data resulting from this project will be deposited in NCBI GEO (Gene Expression Omnibus) prior to or concurrent with publication.

Sharing Research Tools: In general, we will adhere to NIH policies regarding sharing of resources and data. Our lab has demonstrated its commitment to sharing by providing published reagents upon request for the last 20+ years. Regarding any novel materials and resources that may be generated in this proposal, the general Resource Sharing Plan developed by the Henry M. Jackson Foundation and USUHS is as follows: Unique research resources, research tools, novel materials, including model organisms or modified strains, and related protocols, genetic and phenotypic data (including data from Genome-Wide Association Studies) that may arise out of the funded studies will be made available to others in the private and public sector as soon as appropriate agreements covering such transfer can be executed. In the case of project data, findings shall be published as soon as possible or otherwise shared with other researchers pursuant to NIH policies regarding data sharing. The USUHS-HJF Joint Office of Technology Transfer (JOTT) will manage all technology transfer activities for data and resources generated by researcher of either USUHS or HJF. The JOTT will adhere to all applicable policies, principles, guidelines and procurement rules in making unique research resources readily available for research purposes to qualified individuals and entities, and in ensuring that there is no more than a short–term restriction on publication or public dissemination of data in order for the JOTT to evaluate and file for patent protection on any subject invention that may arise from the funded study. Dissemination of unpublished data that is considered to be proprietary or confidential shall occur pursuant to a suitable confidential disclosure agreement prepared by the JOTT. Patient data shall be de-identified and shared in accordance with USU and HJF policies and applicable laws and regulations. Data associated with Genome-Wide Association Studies (GWAS) will be submitted to the NIH-designated GWAS data repository. Material transfer agreements, license agreements, and Cooperative Research and Development Agreements (CRADAs), as appropriate, will be used to transfer material property. Material transfer agreements will be established to share resources among the research community for noncommercial research use.

AUTHENTICATION OF KEY BIOLOGICAL AND CHEMICAL RESOURCES - RP3 (Cedar Henipavirus Animal Model)

USUHS

Project Lead: Brian Schaefer, Ph.D.

The reagents that are used in the Schaefer lab are routinely authenticated as follows:

Expression constructs: All new expression constructs are verified by (1) restriction digest and electrophoretic separation of fragments to ensure fragments of the predicted size are generated and (2) sequencing to ensure the correct sequence is present with no spurious mutations.

Antibodies: Antibodies are tested for specificity as follows: (1) For antibodies used repeatedly, the staining/blotting performance of new antibody lots are compared against previous lots; (2) For new antibodies, banding/staining patterns are compared against published data; (3) Whenever possible, new antibodies are also validated using objective controls, such as cells known to lack the protein of interest (e.g., knockout cells) or cells engineered to over-express an epitope-tagged form of the molecule (i.e., staining by the new antibody is compared side-by-side with staining by the epitope-tag antibody).

Cell lines: Cell lines are routinely validated using flow cytometry for key cell surface markers and/or functional tests. Cell lines transfected for virus production are validated via measuring titers of virus in the resultant supernatants.

Viruses: Viruses are validated through a combination of genome sequencing, infectivity and functional testing. Rescued recombinant viruses are validated through genome sequencing, with comparison to the original cloned full length viral genomes.

Mice: Every new litter of knockout animals is PCR screened for both the wild-type and inactivated allele, with validated wild-type and knockout control DNAs included in every screen. For transgenic animals, presence of the transgene is PCR verified in every litter, with validated controls included in the screen. Additional screens include periodic western blotting and/or FACS analysis of tissues/cells from knockout animals, to validate that PCR-identified knockouts indeed fail to express the protein product of the inactivated gene.

Commercial chemical reagents: Such reagents are validated by one or both of the following: (1) performance comparison to previous lots of the same reagent; (2) use in an established assay that incorporates one or more validated performance controls.

BUDGET JUSTIFICATION - RP3 (The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. in partnership with the Uniformed Services University of the Health Sciences)

KEY PERSONNEL

Brian. C. Schaefer, Ph.D., Project Lead (1.2 calendar months, 10% effort) is a Professor of Microbiology and Immunology at USUHS. His expertise is in cellular immunology, animal models of immune responses in the central nervous system and applying advanced imaging methods to biological questions. He and Dr. Broder have been collaborating for nearly a decade on creating animal models and investigating therapeutic interventions for neurotropic viral infections. The preliminary data in this application resulted from this collaboration, through an NIH-funded U19 grant (with aims that do not overlap the aims of this proposal). Dr. Schaefer will direct all animal studies in this project, managing and advising staff and overseeing data collection and data analysis. Dr. Schaefer will manage the overall experimental direction, the writing and editing of manuscripts for publication and the preparation of progress reports and other administrative functions related to this project, with assistance from the Senior Staff Scientist. (Dr. Schaefer is a full-time Federal employee. Hence, no salary is requested for this project).

OTHER PERSONNEL

†**To be named** (Scientist II, 9 calendar months, 75% effort). A Scientist with experience in animal models and transcriptomics analysis will be recruited for this project. This Scientist will supervise animal research studies, coordinate, conduct and supervise data analyses for transcriptomics studies. The scientist will also coordinate overall data analysis and will participate with Dr. Schaefer in preparation of manuscripts for funding and in preparing progress reports and performing other administrative tasks related to the conduct of this project. The Scientist II will be employed by the Henry M. Jackson Foundation, and salary support is requested on this project.

†**To be named** (Postdoctoral fellow, 12 calendar months, 100% effort). A Postdoctoral fellow with experience in animal research and virology will be recruited for this project. The Postdoctoral fellow will perform approximately half of the animal experiments proposed for this study. The Postdoctoral fellow will be employed by the Henry M. Jackson Foundation, and salary support is requested on this project.

†**Celeste Huaman** (Graduate Student, 12 calendar months,100% effort) will perform approximately half of the proposed in vivo experiments described in this proposal. Ms. Huaman is a senior graduate student in Dr. Schaefer's lab, who has been working collaboratively with members of the Broder lab on this project. Notably, Ms. Huaman generated the majority of preliminary data in this proposal and has extensive experience in all procedures and analysis techniques required for the execution of the proposed experiments. Ms. Huaman worked in Dr. Schaefer's lab as a Research Assitant II for 5 years before joining the USU Emerging Infectious Diseases graduate program, and she acquired a very deep technical skill set during that time. Ms. Huaman completed the CEEZAD BSL-3 training course at the Biosecurity Research Institute of Kansas State University in 2021, and she has trained most current laboratory staff in proper BSL-2 technique. Ms. Huaman is currently employed by the Henry M. Jackson Foundation, and salary support is requested for her on this project.

†**Caitlyn Clouse** (Research Assistant II, 9 calendar months, 75% effort) will provide general technical support, performing routine tissue culture, ordering reagents, and maintaining databases, as required for the project. Ms. Clouse will also perform genotyping of animals breeding at Charles River Lab and she will maintain detailed records of animal genotypes. She will also assist the postdoctoral fellow and Ms. Huaman with all animal experiments. Ms. Clouse completed the CEEZAD BSL-3 training course at the Biosecurity Research Institute of Kansas llent technical support, including assistance to Ms. Huaman in gathering the preliminary data for this project. Ms. Clouse is an employee of the Henry M. Jackson Foundation and we are requesting salary support for her on this project.

†**Camille Alba** (Research Associate, The American Genome Center (TAGC), 1.85 calendar months, 15.4% effort) will be responsible for leading the collaborative performance task for this study. She will oversee performance of library preparation, library quality assessment, library clustering and whole genome sequencing of the samples across the entire project. She will report Illumina NovaSeq platform performance metrics to the collaborating staff scientist and oversee data transfer batches. Ms. Alba is employed as a Henry Jackson Foundation employee therefore salary support is requested.

†A merit increase has been added to years 2-5 of the personnel budget to account for salary increases for Henry M. Jackson Foundation personnel.

EQUIPMENT
An ultralow (-80 C) freezer, ThermoFisher Scientific Model TSX60086A ($12,123), is needed for storage of the many RNA samples, viral stocks and frozen tissues (for sectioning) and slides with frozen sections. Dr. Schaefer's current -80 freezers are filled to capacity.

TRAVEL
Funds are requested to attend two domestic scientific conferences or one international conference in Year 1. This travel is for data presentation, exchange of ideas with colleagues, and for keeping up-to-date regarding the latest research findings relevant to the proposed project. Meeting attendance and data presentation is a key component of postdoctoral and graduate student training.

MATERIALS AND SUPPLIES
For the laboratory to successfully complete the experiments, the project will need to procure the following reagents and supplies:

General Laboratory Supplies
Serological pipettes, microscope slides and coverslips, pipet tips, microcentrifuge tubes, sterile conical tubes, ultracentrifuge tubes, syringes, needles, gloves, respirators, gowns, buffers, flasks, plates, etc.

Materials
Trizol reagents, RNAse-free DNAse, RNAse-free water and buffers, Reverse Transcriptase, Taq Polymerase, qPCR master mix, RNAse-free consumables for tissue homogenization, magnetic beads for cell sorting, tissue culture media, fetal bovine serum, antibiotics, etc

Real-time PCR probes DNA oligonucleotide
Labeled antibodies for histology and flow cytometry

Animal Costs (procurement and husbandry):

Animal Breeding at Charles River Labs
The breeding of experimental mice at USU is contracted to Charles River Labs (CRL). All aspects of animal care and breeding are managed by CRL, while genotyping of progeny is performed by Dr. Schaefer's group, using biosamples collected and shipped by CRL. We maintain a colony of B6-albino Ifnar1-/- mice and B6-albion STAT1-/- mice in our breeding colony at CRL. For this project, we expect to maintain 12 breeding cages and 12 progeny cages to supply the animals needed for the proposed experiments. ($1.80/cage/day x 24 cages x 365 days = $15,768 + Transportation charges $1,500 = $20,768).

Animal Husbandry at USU
Animal facility (DLAR) mouse per diems:
USU DLAR FY24 per diem for biohazardous mice is $4.78/cage/day. We expect to have an average of 8 experimental cages housed in the facility (8 cages x 365 days x $4.78/cage/day = $13,957.60/yr)

Translational Imaging Core (BRIC):
BRIC – IVIS Spectrum CT bioluminescence imaging (9 hr/week x 52 weeks/yr x $50/hr = $23,400/yr)

Biomedical Instrumentation Core (BIC):
BIC – flow cytometry (4 hr/week x 52 weeks/yr x $36/hr = $7,488/year).
BIC – confocal microscopy (2 hr/week x 52 weeks/yr x $30/hr =$3,120/year)

The American Genome Center (TAGC):
Transcriptomics studies performed at the USU American Genome Center

Total RNAseq on brain slices from 32 animals/year x $300 per animal = $9,600/year

Supplies for Visium Spatial Gene Expression:

Visium CytAssist Spatial Gene Expression for FFPE, Mouse Transcriptome 6.5mm slides (quantity of 16 per year) $24,500/year
Visium CytAssist Tissue Slide Cassettes = $1,800/year Dual INdex Kit TS set A = $620/year
S1 Novaseq Flow cells (for spatial transcriptomics sequencing), 2 flow cells/year = $8,600/year

Supplies for Single-cell RNAseq:
Chromium Next GEM Automated Single Cell 3' Library and Gel Bead Kit v3.1 = $27,130/year Chromium Next GEM Automated Chip G Single Cell Kit = $630/year
S1 Novaseq Flow cells (for single-cell RNAseq), 1 flow cell/year = $4,300/year

Publication Costs: (Year 2)

We estimate 2 manuscripts per year for an average cost of $2,500 per publication. This cost estimate is based on our average fee paid per open access journal publication for the last 3 years.

INDIRECT COSTS

HJF indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The fringe rate used is 29.42 % for Tier 1 employees and 7.29% for Tier 2 employees (all employees in this proposal are Tier 1).

The HJF indirect cost is calculated based on the value-added cost base overhead rates. The IDC rate is 36.74% USU Onsite Overhead. Additionally, 16.70% Companywide G&A and applied on the total direct cost less subaward plus the USU Onsite Overhead. For proposals including subawards, an additional 1.93% is applied on total external subaward costs.

The above fringe benefits and indirect cost rates for FY2023 were approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

Hello,
We have made a pass through the files that have been sent over from both of you for RP5 on the UTMB/USUHS U19 (PABVAX). Please let me know if you have any last changes or comments for the files attached before we upload them into the application. Also, please send over to us as soon as possible the items listed below by the end of the day **Monday, June 5.**

- Final Specific Aims – 1 pg
- Final Research Strategy – 12 pgs plus bibliography

Thank you,

Sherry L. Haller, PhD
Associate Director

	Research Fellow	06/2022	Antiviral Nanobody Development
Vaccine Research Center, NIAID/NIH	Research Fellow	05/2023	Antiviral Antibody/Nanobody

A. Personal Statement

I am an assistant professor with expertise in advanced nanobody and antibody technologies in the Department of Biology at Georgia State University. The SARS-CoV-2 pandemic has highlighted the urgent need for new antiviral drugs and for rapidly deployable novel drug development technologies that are prepositioned to respond rapidly when emergent pathogens arise. My expertise can contribute to this important goal. Nanobodies are antigen-binding entities derived from the heavy chain-only antibodies of camelid animals, and they retain full antigen specificity at a very small size (15 kDa). They can penetrate tissues and recognize epitopes that are often inaccessible to conventional antibodies. Such "hidden" epitopes also have the potential to be conserved across viral strains, making nanobodies ideal antiviral drugs with great cross-reactivity to multiple viral pathogens. More interestingly, some nanobodies can naturally cross blood-brain barrier (BBB), and more can passively cross BBB through receptor and adsorptive-mediated transcytosis, enabling them to fulfill therapeutic, diagnostic, and theragnostic promises for the benefit of patients suffering from central nervous system (CNS) pathologies.

I have recently engineered a novel nanobody-producing mouse model (nanomouse, NIH invention), and demonstrated the power of both nanomouse and nanobody by developing potent cross neutralizing nanobody molecules against SARS, SARS-CoV-2 and Bat WIV 16, utilizing structure-based engineering approach (Xu et al., *Nature*, 2021). For this work, I was awarded the 23rd Annual Norman P. Salzman Memorial Award in Basic and Clinical Virology. *Nature News and Views* commented that "*Just as the development of mice with antibodies containing human variable domains (such as Regeneron's VelocImmune mouse) has helped to deliver the 100th FDA-approved monoclonal antibody, perhaps the nanomouse will give nanobody-based therapeutics a push in the same direction.*". In addition to the nanomouse nanobody-development platform, I have recently cloned the CDR regions of human antibodies (IgM, IgD, IgG1-4, IgE, IgA1-2) heavy chain from 60 healthy donors of various demographic backgrounds, assembled them on Ighv3 family framework, and generated a human nanobody library that is close to natural human antibody heavy chain variable domain. The potentially low immunogenicity of such a library will enable us to quickly identify nanobody leads that need minimum optimization for clinical use. My ongoing work on HIV-1 has further highlighted the power of nanobody engineering in developing broad and potent antiviral drugs, with the best nanobody molecule neutralizing 96% of 208 HIV-1 strains at half maximal inhibitory concentration (geometric mean IC50) of 0.016 ug/ml. Structure guided engineering results in ultra-potent HIV-1 bispecific antibodies that target CD4 binding site and V2-Apex of HIV envelope protein simultaneously.

My postdoctoral training with Professor Tasuku Honjo at Kyoto University focused on the mechanism of antibody maturation and diversification. I then extended this work in Dr. Rafael Casellas's lab at NIAMS, where I studied transcription factor dynamics in primary B cells, engineered nanomouse for nanobody development. The one-year training at Dr. Peter Kwong's lab at Vaccine Research Center/NIAID afforded me great opportunity to learn and practice structure-based immunogen design and antibody improvement.

My long-term research goal is to establish efficient nanobody development platforms that will result in novel biological molecules across multiple therapeutic areas, including infectious diseases and immuno-oncology. My research builds upon three nanobody platforms: 1) conventional camelid animals; 2) the nanomouse model that I have established and newer versions that I am going to engineer; 3) human nanobody libraries with low immunogenicity that I am currently constructing and optimizing. The focus of my research will be on developing broad and potent neutralizing nanobodies against SARS-CoV-2, HIV-1, human metapneumovirus (HMPV), respiratory syncytial virus (RSV) and henipavirus (HNV), but the underlying principle can be adapted for other viruses, as well as cancer targets. These studies have the potential to result in life-saving therapeutics, and also will broaden our understanding of the mechanisms of viral infection, guide vaccine development, thereby advancing our societal goal of better public health crisis preparedness.

B. Positions, Scientific Appointments and Honors

Positions and Scientific Appointments

2023 -	Assistant Professor, Georgia State University, Atlanta, GA
2022 - 2023	Research Fellow, Vaccine Research Center, NIAID/NIH, Bethesda, MD
2018 - 2022	Research Fellow, NIAMS/NIH, Bethesda, MD
2014 - 2018	Postdoctoral Fellow, NIAMS/NIH, Bethesda, MD
2010 - 2014	Postdoctoral Fellow, Kyoto University, Kyoto, KY, Japan

Honors

2023	NIH Earl Stadtman Investigator (Semi-finalists)
2021	23rd Annual Norman P. Salzman Memorial Awards in Basic and Clinical Virology, Foundation for the National Institutes of Health
2016	Fellows Award for Research Excellence (FARE), NIH
2014	JMF Young Scholar Award, Frontiers in Immunology
2004	Excellent Undergraduate Student, Nanjing Agriculture University
2003	Award of National Scholarship, Nanjing Agriculture University

C. Contribution to Science

1. Identification of potent neutralizing nanobody against SARS-CoV-2

   Equipped with systematic knowledge in nanobody development and the ready to use platform, I identified potent SARS-CoV-2 neutralizing nanobodies from nanomouse and llama. These nanobodies could potently neutralizing all variants of concern tested, including Alpha, Beta, Gamma and Delta variants. More importantly, with the help of structural analysis I demonstrated two distinct mechanisms of the enhanced neutralization breadth of nanobody trimers: by increasing avidity and by targeting conserved region on RBD. These nanobodies have very good potential of becoming a treatment for COVID19. I also participated in a project led by Dr. Michel Nussenzweig and demonstrated that mRNA-vaccines (Moderna and Pfizer) can elicit neutralizing antibodies against SARS-CoV-2 circulating variants.

Nature. 2021 Apr;592(7855):616-622. PubMed Central PMCID: PMC8503938.

2. Establishment of a mouse model for nanobody development

   With deep understanding of the mechanism of antibody development and maturation, I wondered whether one could produce heavy chain-only antibodies in mouse instead of their original host, camelid animals. With bioinformatic analysis of camelid immunoglobulin variable genes, sophisticated design and extensive genome editing of ES cells by CRISPR/Cas9, I successfully established a Igh camelized mouse strain (Nanomouse, NIH invention) in which B cells express heavy chain-only IgM and IgG1 of camelid origin instead of the conventional heavy and light chain-paired IgM and IgG1. Dr. James E. Voss in the Department of Immunology and Microbiology at The Scripps Research Institute commented in Nature News and Views that “Just as the development of mice with antibodies containing human variable domains (such as Regeneron’s VelocImmune mouse) has helped to deliver the 100th FDA-approved monoclonal antibody, perhaps the nanomouse will give nanobody-based therapeutics a push in the same direction.”.

Nanobodies from camelid mice and llamas neutralize SARS-CoV-2 variants. Nature. 2021 Jul;595(7866):278-282. PubMed Central PMCID: PMC8260353.

3. Regulation of chromatin dynamics and nuclear architecture during B cell activation

   I generated two knock-in mouse strains (CTCF-Halo, Jund-Halo) and used the novel single molecule imaging microscope technique to study transcription factor dynamic in primary B cells. I demonstrated that activated B cells decondense chromatin and the chromatin architectural change facilitates promoter-enhancer contacts and requires Myc and continual ATP production. These novel findings defined the nature and transcriptional impact of chromatin decondensation and revealed an unexpected role for Myc in the establishment of nuclear topology in mammalian cells.

H, Aiden EL, Casellas R. Myc Regulates Chromatin Decompaction and Nuclear Architecture during B Cell Activation. Mol Cell. 2017 Aug 17;67(4):566-578.e10. PubMed Central PMCID: PMC5854204.

4. Role of critical molecules in antibody diversification

   I demonstrated that, although APE1 is important for CSR, it is dispensable for SHM as well as IgH/c-myc translocation. I further proved that during CSR process, APE1 repairs rather than induces DNA breaks and function as a DNA end-processing enzyme to facilitate the joining of broken ends. I also demonstrated that the C-terminal region of activation induced deaminase (AID) is required for efficient generation of DNA breaks in CSR and gene conversion (GC) and for the pairing/synapse formation of cleaved DNA ends. To identify chromatin components that bind to the antibody gene locus after AID-induced DNA breaks, I genetically modified antibody gene to enable locus-specific proteomic study. Mass spectrometry analysis led to the identification of 39 chromatin-binding proteins, many with known functions in DNA break repair. Among them I found that a protein called sterile alpha motif and histidine-aspartic acid domain-containing protein 1 (SAMHD1), serves as a novel DNA repair regulator of antibody class switch recombination as well as aberrant genomic rearrangements via regulating the cellular dNTP level. My findings have deepened our understanding of the fundamental mechanisms of AID-induced antibody diversification.

5. Transcriptional regulation of oncogene PRL-3

   My doctoral training centered on the transcriptional regulation of oncogene PRL-3. I demonstrated MEF2C as a VEGF-dependent transcription factor that controls PRL-3 gene expression in epithelia cells. The work was recommended by Faulty 1000 as “must read”.

   a. Xu J, Cao S, Wang L, Xu R, Chen G, Xu Q. VEGF promotes the transcription of the human PRL-3 gene in HUVEC through transcription factor MEF2C. PLoS One. 2011;6(11): e27165. PubMed Central PMCID: PMC3206935.

A. Personal Statement

My research primarily focuses on investigating the intricate mechanisms of viral-host interaction during viral entry. I study the humoral immune response triggered by natural infections and vaccinations, and apply this knowledge to inform the design of vaccines and antiviral therapeutics. Throughout my interdisciplinary research endeavors, I have honed my expertise in conducting both structural and functional analyses of viral envelope proteins. Notably, I have utilized advanced techniques such as X-ray protein crystallography and Electron Microscopy single particle analysis to gain a comprehensive understanding of their properties. By employing a structure-based approach, I have made significant contributions to vaccine design and the development of protective antibodies.

Furthermore, I possess extensive experience in conducting animal immunization studies involving various species, including mice, guinea pigs, and NHPs. This has provided valuable insights into the immune response generated by these animals. Additionally, I have conducted rigorous studies to identify antibodies using mice and NHPs, resulting in crucial findings. In line with recent advancements, I have successfully isolated nanobodies from "Nanomice," thereby expanding my repertoire of techniques and contributing to the field of antibody research.

In the current U19 proposal, I have been appointed as the co-PI for project 5, which focuses on the development of nanobody therapeutics against Henipaviruses and Bunyaviruses. In this role, I will utilize my expertise to structurally and functionally characterize nanobody epitopes and understand the viral neutralization mechanism. Additionally, I will employ a structure-based rational design approach to improve the efficacy of protection and the delivery of nanobody therapies to the brain.

I have established long-term collaborations with several members of the team, namely Dr. Christopher Broder, Dr. Jianliang Xu, Dr. Brian Schaefer, Dr. Moushimi Amaya, and Dr. Eric Laing. Notably, I have closely collaborated with Dr. Broder on glycoprotein structures, antigenicity, and entry mechanisms, resulting in the co-publication of many high-impact papers over the years. Additionally, I have collaborated closely with Dr. Jianliang Xu in the past on the identification of potent and broad nanobodies against SARS-CoV2 variants, leading to a co-published Nature paper in 2021.

Ongoing projects that I would like to highlight:

B. Positions, Scientific Appointments, and Honors

Positions and Employment

2021-pres	Assistant Professor, Department of Veterinary Biosciences, The Ohio State University, Columbus, OH
2014-2021	IRTA fellow, Senior Scientist, Project Team Lead and Senior Scientific Project Manager, Vaccine Research Center, National Institute of Health, Bethesda, MD
2014-2014	Senior Research Scientist, Structural Biology Program, Sloan-Kettering Institute, New York, NY

Scientific Appointments

2021-pres	Member, Infectious Diseases Institute, The Ohio State University
2021-pres	Member, Cancer Biology Group, The Comprehensive Cancer Center, The Ohio State University

Honors

2021	NIH Director's Award (Outstanding efforts in the pursuit of efficacious vaccines to prevent COVID-19)
2019	NIH Earl Stadtman Investigator (Semi-finalists)
2019	NIAID Merit Awards (Advancing HIV Vaccine Research)
2019	MSC Award for Excellence in HIV-1 Vaccine Research
2010	Sloan-Kettering Institute Annual Award for the Outstanding Postdoctoral Research
2009	Gordon Conference Travel Award (Chemical and Biological Terrorism Defense)
2009	MSKCC Award for Excellent Graduate Students
2009	Cornell University Medical College Award for the Excellent Graduate Students

C. Contributions to Science

1. **Henipavirus glycoproteins’ structure, function and protective immune recognition mechanism.** I have a long track record in the study of HNV glycoproteins through collaboration with Dr. Christopher Broder (USU). Our structural and functional studies uncovered the functional role of G and F proteins in viral entry process, and how they can be recognized by protective antibodies, which paves the way for further vaccine and therapeutic design.

4. **Ligand-receptor interaction and receptor activation in neuronal development and degenerative diseases.** Axons travel long range to reach their final destination during neuronal development and neuron circuit formation. This process depends on the precise control assisted by a few classes of molecules named guidance cues. We used structural and functional analyses to reveal ligand-receptor interaction and signa activation mechanism underlying axon guidance.

BUDGET JUSTIFICATION – RP5 (The Ohio State University)

KEY PERSONNEL

Kai Xu, Ph.D., Project Lead. Dr. Xu will dedicate 3.6 calendar months for this grant, which includes 2.7 months of academic year and 0.9 months of summer. Dr. Xu will be responsible for the design and implementation of all experiments, interpretation of study results, and preparation of progress reports and publications. He will oversee the entire project and supervise other personnel (two postdoctoral researchers and a graduate student) to carry out the experiments proposed in this grant.

OTHER PERSONNEL

We are seeking to hire two postdoctoral researchers for this grant project. Both postdoctoral researchers will work collaboratively and contribute to the overall success of the project.

Postdoctoral Researcher to be hired (100% effort, 12 calendar months). He or She will have extensive training in molecular biology, cell biology, and combinatorial biology. The postdoc will also have experience in mouse work and phage-display technology. His or her primary responsibilities will include immunizing nanomice and identifying nanobodies against the listed viruses in this project. He or She will conduct experiments, collect and analyze data, prepare research reports and manuscripts, and provide assistance to the graduate student researcher.

Postdoctoral Researcher to be hired (100% effort, 12 calendar months). He or She will have strong training in molecular biology, cell biology, and structural biology, with specific experience in protein purification, crystallographic techniques, and electron microscopic structural analysis. His or her main role will involve the structural and functional characterization of the nanobodies identified in the proposed project. He or She will conduct experiments, collect and analyze data, and contribute to the preparation of research reports and manuscripts.

MATERIALS AND SUPPLIES

$98,375 per year is requested to help defray costs for general research supplies, including reagents and supplies for cell culture, and materials for biological assays, antibodies, supplies for cloning. The funds requested is based on current operating costs in the laboratory.

Cell Culture Supplies:	$12,000
Nanobody Phage Library Construction and Screening:	$15,000
Supplies and Reagent for Protein Purification:	$10,000
Supplies and Reagents for structural determination (EM and crystal):	$25,000
Reagents and Chips for affinity measurement:	$9,000
Plasticware:	$5,000
Nanobody Production:	$8,000
Molecular Biology Reagents and Enzyme:	$5,000
General Lab Supplies:	$3,875
DNA and RNA Purification Kits:	$3,000
Chemicals:	$2,500
Subtotal	$98,375

EQUIPMENT COST

Mosquito® Xtal3 - liquid handler for high-throughput crystal screening	$113,109

This expense occurs in Year-1 only. Nanobodies, being small in size, are often amenable to high-resolution structure determination using X-ray crystallography. The proposed equipment, the Mosquito® Xtal3, will be utilized to efficiently screen protein crystals in a high-throughput manner, thereby reducing the expenses associated with protein production and crystallization reagents. This liquid handler will enhance our capabilities for crystal screening, allowing us to optimize the conditions for obtaining high-quality crystals suitable for structural analysis. The acquisition of this equipment is crucial for facilitating our research on nanobodies and their structural characterization.

TRAVEL

$8,000 per year is requested to support travel and meeting registration related expenses to attend and present research findings at relevant national/international scientific conferences such as, Keystone Symposia, Gordon Research Conferences. The PI and postdoctoral researchers will attend these meetings. These meetings provide an opportunity to gain feedback from other experts in the field, which will help guide the direction of future research.

PUBLICATION COSTS

$6,000 is requested to support costs associated with publishing results in peer-reviewed scientific journals.

SERVICES and SHARED RESOUCES COSTS

Funds in the amount of $50,500 per year is requested to support user fees for the following Shared Resources and Services:

Mouse Facility:	$15,000
Electron Microscopy:	$20,000
Gene Synthesis (Glycoproteins and Nanobodies)	$8,000
Sanger Sequencing: (Nanobody and Regular)	$7,500
Subtotal	$50,500

FACILITIES AND ADMINISTRATIVE COSTS

In accordance with the Ohio State University’s Federally-negotiated F&A rate agreement, indirect costs are calculated at 57.5% MTDC.

EQUIPMENT – RP5 (Nanobody Discovery and Structural Biology)

Ohio State University, Columbia OH (OSU)

Laboratory and major equipment: Dr. Xu's laboratory is fully equipped for structural, cellular, molecular and virological studies in the newly renovated Center for Retrovirus Research at The Ohio State University (OSU). It includes a fully equipped cell-culture room of about 120 sq. ft. and a lab space of ~1,100 sq. ft. with multiple benches. The following shared rooms and equipment are available for Xu laboratory use, a virus containment BLS-2 room (370 sq. ft. shared by four PIs) that is equipped with four laminar flow hoods and four CO2 incubators, a shared storage room, a cold room, a freezer room, a PCR-prep room, a service room, and a conference room (shared by 4 laboratories). Major equipment includes: a Octet Red instrument for affinity measurement of protein-protein interaction with Bio-Layer Interferometry, a Thermo Fisher Sorvall LYNX 6000 Superspeed Centrifuge for media clearance in glycoprotein production, two INFORS HT CO2 incubator shakers for high yield suspension mammalian cell culture, a Sorvall X4R Pro-MD benchtop centrifuge for cell culture and protein concentration, multiple -80 and -20 freezers, two CO2 incubators, a bacterial culture shaker, a Leica cell-culture microscope, a stereo microscopy, Bio-Rad cell counter, a GE DeltaVision Elite imaging system, a Nanodrop spectrometer, a PerkinElmer multifunctional Victor X3 plate reader, a Bio-Rad CFX96 Real-Time PCR Detection System, a mini PCR machine, a liquid nitrogen tank, a Cytiva Go FPLC system for protein purification, an automatic plate washer, various gel apparatus and power supplies for electrophoresis, as well as other standard small equipment for molecular biology research.

Computer and office: Dr. Xu's lab has six computers, two printers and a scanner in his laboratory and offices. All computers are installed with software for protein structural processing and analysis and sequence analysis and database searching. Dr. Xu has a workstation with 4GPUs, as well as access to a remote cryo-EM data processing server with 10 GPUs and 200TB data storage. The department and college have strong support of computer and information systems. Dr. Xu has over 160 sq. ft. of office space near his laboratory. Dr. Xu's lab also has an office for postdoctoral fellows and students (~145 sq. ft.). Built-in desks, bookshelves, file cabinets and telephones are installed in all offices.

Access to shared equipment: Dr. Xu's laboratory has access to various campus-wide Shared Resource Facilities available at OSU' Columbus campus and Nationwide Children's Hospital, which is accessible by 10-minute drive from the main campus. In addition, as a member Dr. Xu has full access to the OSU Comprehensive Cancer Center (OSUCCC) Shared Resources and Cores. The OSUCCC has 20 Shared Resources and Cores that provide specialized services to researchers. Collectively, at the institutional level, there are core services for genomics, proteomics, flow cytometry, microscopy, and biostatistics among others.

Georgia State University, Atlanta GA (GSU)

Major Equipment: The Biology and Chemistry Departments share the state-of-the-art Advanced Biotechnology Core (ABC Core) Facilities under the auspices of the Center of Biotechnology and Drug Design http://biology200.gsu.edu/core directed by the Chairs of Biology and Chemistry. The ABC Core is supervised by Dr. Houghton, an Associate Professor in the Biology Department. There are 10 full time staff members with different expertise, including 4 Research Scientists with Ph.D. degrees in Chemistry or Biology, who provide the consultation, services and maintenance of the facilities.

DNA/Protein Core Facility: This facility is staffed by five full-time technicians. The core facilities and instruments are located mainly on the 5th floor of the 4-year old Petit Science Center, close to the laboratory space on the 5th floor. Equipment housed in this facility includes three DNA sequencers (two ABI 3100 and one Beckman CEQ 8000), a Genomic Gene-Chip analysis system with Fluidics/Hybridization unit (Affymetrix), an Ettan DALTII Proteomics 2-D gel electrophoresis system - including Typhoon 9400 Variable Mode Imager, MD Personal Densitometer SI, automated spot picker and automated digestion platform (Amersham), three additional automated workstations (two Beckman Biomek 2000 and one ABI Symbiot work station), N2 generator (Parkin-Balston), Ciphergen SELDI-mass spectrometry system (Ciphergen), Prism 7500 RT-PCR Systems (ABI), two densitometers (BioRad), four capillary electrophoresis units (MDQ/P/ACE 5010 + LIF detector,P/ACE 5510, 2 P/ACE 5500 Beckman), fluoroimager (Molecular Dynamics), FACSCanto Cell sorter (Becton Dickinson), XLA-analytical ultracentrifuge (Beckman-Coulter), four AKTA Automated FPLC Systems (Pharmacia), and 2100

Bioanalyzer (Agilent), Affimetrix GeneChip Analyger. The core has recently added a DNA 454 Junior genome sequencer.

The core facility also includes: Analytical Centrifuge, a Biacore 3000 for analysis of protein interactions by plasmon resonance spectroscopy, and a MicroCal Isothermal Titration Calorimeter (VP-ITC) and Differential Scanning Calorimeter (VP-DSC).

Jianliang Xu Lab: The lab is newly established in June 2023. By the end of 2023, the lab will be equipped with Electroporator, incubator shakers (for bacteria and mammalian cells separately), CO2 incubators, cell counter, nanodrop, photometer, thermocyclers, protein/DNA electrophoresis system, Orbital shaker, AKTA Automated FPLC System, Octet® R8 Protein Analysis System, fridges, freezers, balance, fluorimeter/spectrophotometer microplate reader, biosafety cabinets, superspeed centrifuges, water purifiers, Gel documentation system, and microscopes. As part of University System of Georgia (USG connect), all lab members have also access to all molecular imaging and sequencing core facilities at Emory University and Georgia Institute of Technology.

FACILITIES AND OTHER RESOURCES - RP5 (Nanobody Discovery and Structural Biology)

Ohio State University

Scientific environment:

Dr. Xu is a member of the **Center for Retrovirus Research (CRR)** at OSU. The Center is directed by Dr. Patrick Green. The membership of the CRR includes more than 20 principal investigators at OSU, Nationwide Children's Hospital Research Institute, Cincinnati Children's Hospital Research Institute, and Wright State University. The research interests of Center members are diverse and form a highly interdisciplinary network of collaboration for research initiatives. This multi-disciplinary team is available to collaborate and to help design and carryout comprehensive research studies on retrovirus diseases and related topics that would not be possible by individual laboratories.

Dr. Xu is a member of the newly established **Infectious Diseases Institute (IDI)** of Ohio State. The mission of the IDI is to embrace the broad biological studies applicable to the complex analysis of microbe-host interactions, including the interface between viruses and their hosts. There are currently 170 faculty members in the IDI from throughout OSU. The collective IDI faculty is involved in and represents the fields of immunology, cell biology, pathology, biochemistry and pharmacology, microbiology, genetics, structural biology, and bioinformatics.

Dr. Xu actively participates in **interdisciplinary graduate programs** at OSU, including Molecular, Cellular, and Developmental Biology (MCDB) graduate program, and Microbiology and Biomedical Science Graduate Program (MBS). These training programs prepare students for careers as research scientists and educators in an academic or industrial environment. These programs are interdisciplinary in nature and include the combined talents of more than 130 Ph.D. students and 170 faculty members from more than 25 departments in six colleges.

Taken together, these unique features of the collaborative scientific environment and intellectual rapport will strongly enhance the proposed studies and contribute to the probability of success of the project.

Departmental and college shared research facilities:

The Department of Veterinary Biosciences and College of Veterinary Medicine Biochemistry and Molecular Biology Core provide and maintain selected instrumentation and provide sufficient training to facilitate end- user operation. Major pieces of supported equipment include: GloMax® – Multi Detection System, Real-time PCR (Roche LightCycler 480), Typhoon Imager (GE), Phosphorimager (Molecular Dynamics), PTC-225 PCR Tetrad (MJ Research/BioRad), two AlphaImagers (Alpha Innotech), Wallac MicroBeta TriLux. Other shared-use equipment includes: UV/Vis spectrometer (Lambda 45, Perkin Elmer), Luminescence spectrometer (LS55, Perkin Elmer), High pressure liquid chromatograph (Waters), Medium pressure liquid chromatograph (Pharmacia Biosciences), Lyopholyzer (Virtis), French pressure cell (Aminco), hydraulic press (Carver), and Attune NxT Flow Cytometer (Thermo Fisher).

The Imaging Core is a college-wide service, supported by the Department of Veterinary Biosciences, which offers state-of-the-art instrumentation for flow cytometry analysis, high-resolution confocal microscopy (Leica TCS SP2 AOBS Confocal Laser Scanning Microscope), and magnetic cell sorting. The autoMACS from Miltenyi Biotec is an automated bench-top magnetic cell sorter. It is capable of sorting up to 10 million cells per second from samples of up to $4x10^9$ total cells. Instruments are staffed with full time technicians who are responsible for processing samples for examination by flow cytometry and confocal microscopy. The Department has a 3-laser Coulter EPICS Elite flow cytometer operated by experienced staff. The Flow Cytometry Service can simultaneously analyze up to five fluorescent parameters plus forward scatter and time for cell samples provided by the investigator. Analysis possibilities include cell surface phenotype markers, gene expression reporters, cell cycle analysis, cytokine production, apoptosis, cell viability, rare cell detection, and calcium metabolism. Assistance with experimental design and data analysis is available. The core also has a BD Biosciences FACSCalibur, which is a 2-laser flow cytometer that can be used to simultaneously analyze up to 4 fluorescent parameters. Moreover, a high-speed, state-of-the-art flow cytometry sorter (i-Cyt Reflection) is available in a biosafety cabinet in a BSL-II facility of the Flow Cytometry Core, which can be used to sort virus-infected cells. In addition, the Immunospot ELISPOT reader (Cellular Technology) permits fully automated, high-throughput ELISPOT plate scanning and analysis.

Campus-wide Shared Resources:

Dr. Xu has access to various campus-wide shared resources available at OSU' Columbus campus and Nationwide Children's Hospital, which is accessible by 10 minute drive from the main campus. In addition, Dr.

Xu has full access to the **OSU Comprehensive Cancer Center (OSUCCC) Shared Resources and Cores**. The OSUCCC has 20 Shared Resources and Cores that provide specialized services to researchers. They offer cost-effective, state-of-the-art technology and instrumentation; expert guidance and training; and clinical, administrative and technical support. Collectively, at the institutional level, there are core services for genomics, proteomics, flow cytometry, microscopy, and biostatistics among others. Relevant to this proposal:

Core facility of Chemistry and Biochemistry includes Biophysical Interaction and Characterization Facility that provide equipment for protein-protein interaction measurement, Chemical and Biophysical Dynamics provides various biophysical analysis platforms, and X-ray Crystallography Laboratory provides instruments and tools for X-ray crystallographic study.

The **Analytical Cytometry Shared Resource** provides state-of-the-art flow cytometry analysis and sorting of cell populations. They assist investigators with experimental design and assay development and provide individual training and 24-hour access to flow cytometry instrumentation. The facility provides researchers access to five cell analyzers and two cell sorters. Detection capabilities on these instruments range to five excitation lasers and eighteen color emission.

The **Genomics Shared Resource** provides both Nucleic Acid services and Microarray services. It offers instrumentation and expertise for DNA and RNA analysis using sequencing, genotyping, real-time PCR, Affymetrix GeneChips, nCounter Analysis, next-generation sequencing, DNA synthesis support and genome-wide analysis using the Illumina NGS platform and Affymetrix and customizable gene chips.

The **Center for Electron Microscopy and Analysis (CEMAS)** is located in a custom-designed facility at The Ohio State University's main campus. All cryo-EM instruments at CEMAS meet or exceed manufacturer performance specifications. CEMAS has a Thermo Scientific Glacios Cryo-TEM with a Falcon III direct electron detector and a Ceta-D camera for MicroED analysis. In addition, CEMAS has a Thermo Scientific Krios G3i Cryo-TEM equipped with a Bioquantum imaging filter and a K3 direct electron detector, imaging phase plates, STEM/TEM tomography, and an image spherical aberration corrector. CEMAS is able to assist users in all aspects of the cryo-EM workflow, which may include initial negative stain analysis, cryo sample preparation, grid screening, high resolution data collection, and preliminary data analysis.

The **Center for Biostatistics and Bioinformatics** provide collaborative support in all areas of biostatistical expertise, including study design, grant proposal development, data management, manuscript preparation, and statistical analysis of clinical, epidemiological, and laboratory research data. The Center's team consists of over 20 biostatisticians, each of whom has developed expertise in specific areas through hands on collaboration with investigators.

The Ohio State University's large consolidated **animal care program** supports an extensive and comprehensive research program including the Colleges of Medicine, Public Health, Veterinary Medicine, Dentistry, Pharmacy, Biological Sciences, and Social and Behavioral Sciences. The university's centralized animal vivaria consist of over 14 buildings located primarily within the Health Sciences complex. Approximately 70,000 sq ft of animal housing space consists primarily of rodent barrier housing utilizing individually ventilated caging systems. In addition, facilities for accommodating large animals, rabbits, and nonhuman primates are available. Support facilities include an experimental surgery suite, small animal imaging core, and biohazard housing at the ABSL2 and ABSL3 levels.

Summary:

All of the equipment, scientific environment, facility and research resources required for Dr. Xu's research are in place at the OSU, which will ensure the continued success of the Xu lab, including the project described in this application.

GEORGIA STATE UNIVERSITY, ATLANTA GA (GSU)

Scientific Environment at GSU: With total annual research awards of $128.1 million received in the fiscal year 2019 (the fifth year in a row that the University has earned more than $100 million in external investments), GSU is one of the nation's premier urban public research universities. The University ranks among the top 115 public and private universities in the Carnegie Foundation's elite category of R1: Highest Research Activity. The scientific environment in which the research will be carried out at GSU is highly conducive to the success of the proposed project. The University and its Departments are expanding via faculty recruited into new University Research Centers. We collaborate with a number of faculty in the Departments of Biology, Chemistry, and Computer Science and participate in several University Centers and Interdisciplinary Programs. The presence of these colleagues, both new and old, offers opportunities to discuss projects and results in both informal and formal collaboration. In addition, the scientific community at GSU has the privilege of working in the Atlanta area, where other important institutions, such as Emory University, Georgia State University (GSU), University of Georgia, Georgia Institute of Technology, and the Centers for Disease Control and Prevention (CDC) are located. These institutions work collaboratively for advancements in scientific research with special emphasis on infectious diseases.

Jianliang Xu Laboratory: The Xu lab has an 800-sq.ft. BSL-2 laboratory with bench space for eight investigators in the Petit Science Center (the building was completed in June 2010). The lab is newly established in June 2023. By the end of 2023, the lab will be equipped with Electroporator, incubator shakers (for bacteria and mammalian cells separately), CO2 incubators, cell counter, nanodrop, photometer, thermocyclers, protein/DNA electrophoresis system, Orbital shaker, AKTA Automated FPLC System, Octet® R8 Protein Analysis System, fridges, -20°C and -80°C freezers, balance, fluorimeter/spectrophotometer microplate reader, biosafety cabinets, superspeed centrifuges, water purifiers, Gel documentation system, and microscopes. The laboratory is fully prepared for microbial, molecular genetics, biochemistry, protein production, purification and characterization work. As part of University System of Georgia (USG connect), all lab members have also access to all molecular imaging and sequencing core facilities at Emory University and Georgia Institute of Technology. The department provides excellent office facilities for staff and students and provides numerous seminars and journal clubs which staff are encouraged to attend.

Animals: GSU has in place two full-time university veterinarians, veterinarian technicians, animal facilities manager, and six full-time animal caretaker staff, many of whom are certified by the American Association of Laboratory Animal Science. An AAALAC-approved, state-of-the-art 25,000 sq. ft. facility is housed in the PSC building. It is composed of 28 housing rooms, eight procedural rooms, a full surgical suite, full BSL-2 and BSL-3 suites. The facility is equipped with high-capacity autoclave and cage-washers, an imaging room with bioluminescent and fluorescent imaging machine. The facility has automated temperature, humidity, illumination, and air flowing monitoring that remotely alerts personnel of any system failures. A security officer is located inside the building 24/7 to monitor and secure the building. All animal rooms are under the supervision of animal facility personnel.

Computer: In addition to computers that are running the Octet protein analysis system, the protein purification system, and the gel imagine system, the Xu lab also has computer workstations that are available for his personnel. Each lab member has an individual workstation providing access to extensive computational resources, including access to ARCTIC (Advanced Research Computing Technology & Innovation Core) at GSU.

Office: Dr. Xu has a ~100 sq. ft. office with iMac and printer. His students use two shared office rooms. The laboratory and all office spaces are nearby on the same floor.

RESOURCE SHARING PLAN

All nanobody sequence data, nanobody constructs, and reagents generated in this application will be made available to the scientific community upon request following publication. All data sets will be submitted to public databases, such as Sequence Read Archive (SRA), allowing access to researchers in the field.

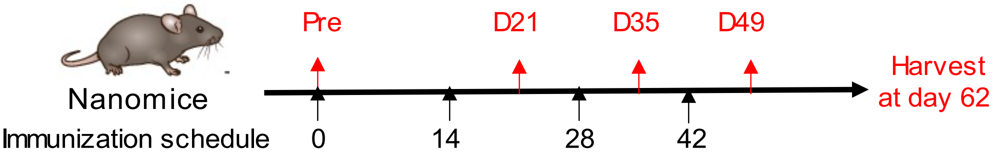
Sharing Research Tools: We routinely present data derived from our studies at scientific meetings such as the Gordon Conferences, Keystone Symposia among others. When components are completed, invention disclosures filed, and following consultation with the OSU technology transfer offices, we publish and disclose our findings. Material transfer agreements will be established to share resources among the research community for noncommercial research use. If research findings we deem sensitive are requested by outside parties, prior to publication mutual non-disclosure agreements will be put in place. In addition, we will have a free exchange of findings and data with all our collaborators. We will adhere to all institutional, state and federal resource sharing guidelines and agree to share knowledge, research materials, and any other resources necessary and relevant to the particular focus of the grant, recognizing that final authorization will be cleared with all appropriate organizational parties.

Sharing Model Organisms: All generated expression vectors, cell lines and experimental protocols will be made available to the public. Results will be presented at scientific meetings in the form of posters and oral presentations. All sequencing data and structural data will be deposited to public databases, such as GenBank or Protein Structural Data Bank and these data will be available for all to use.

VERTEBRATE ANIMALS SECTION - RP5 (Nanobody Discovery and Structural Biology)
Ohio State University

The following sections of the proposal will use mice and/or camelid animals: **Aim 1** (To identify cross-reactive nanobodies to HNVs); **Aim 2** (Identification of nanobodies to ARVs.); and **Aim 5** (Expanding to other members of the viral groups in Center Phase 2.). The Jianliang Xu lab at Georgia State University, Atlanta, and Kai Xu lab at the Ohio State University will perform the experiments using nanomice to develop neutralizing nanobodies (Aim 1, 2 and 5). When needed, contracting company (Capralogics, etc.) will immunize camelid animals housed in their farm and provide PBMC to Xu labs (Aim 1, 2 and 5).

1. Description of Procedures:



1.1 Nanomice immunization: Male and female nanomice (B6.129P2-Ighem1Rcas/J) at 8-12 weeks old will be used. Each virus protein nanobody development will involve 8 gender balanced mice, and considering potential different designs of some immunogens, in total about 300 mice will be used in the study. Mice will be injected with recombinant proteins purified through mammalian cell culture system. Protein antigens include HNV G and F proteins, and ARV GPC proteins. All proteins are obtained by transfecting 293 cells with plasmids that express these recombinant proteins, and then purified from cell culture supernatant and dissolved in PBS. Mice immunization will be performed over a 62-day immunization protocol. Specifically, mice will be immunized intraperitoneally (*i.p.*) with 50 ug of recombinant protein in the presence of Complete Freund's Adjuvant (CFA) on day 0, and boost immunized intraperitoneally with 25 ug of protein in the presence of Incomplete Freund's Adjuvant (IFA) on days 14, 28 and 42. Two more immunizations with 25 ug of protein in PBS will be performed on day 56 and 59, intraperitoneally and intravenously (to stimulate memory B cell expansion), respectively. Bone marrow, spleen and blood samples will be collected on day 62. On day 0, 21, 35 and 49, per ARAC guidelines, about 200ul of blood samples will be drawn and analyzed by ELISA for antibody titer. Typically, experiment ends at day 62, but for certain immunogens, more boost injections may be performed to induce stronger antigen-specific antibody response. In that case, after the fourth immunization on day 42, mice will be boost immunized once every 2 weeks and blood samples collected one week after each immunization. Immunization will end when antigen-specific antibodies in serum is detected or maximum of 8 injections reached. For the extended experiments, about 200ul of blood samples will be drawn every 4 weeks or longer. In total, starting from the first blood draw on day 0, no more than 6 times of blood draw will be performed. Mice immunization will be performed under pathogen-free conditions at an AAALAC accredited animal facility in the PSC building and housed in accordance with the procedures outlined in the Guide for the Care and Use of Laboratory Animals under an animal study proposal approved by the GSU or OSU Animal Care and Use Committee. Animals used in this study are either generated and maintained by Xu labs or purchased directly from Jackson Laboratory. The animal protocol is approved by the Institutional Laboratory Animal Care and Use Committee (ILACUC) at GSU or OSU.

1.2 Camelid animal immunization: For immunogens that fail to elicit strong immune response in nanomice, company (Capralogics, etc.) housing camelid animals will be contracted to perform llama or alpaca immunization and provide PBMC to Xu labs. Animal will be immunized subcutaneously (*s.c.*) with 1 mg of recombinant protein in the presence of CFA on day 0 and boost immunized (*s.c.*) with 0.5 mg of protein in the presence of IFA on days 14, 28, 42, 56 and 70. Test blood/serum will be collected 10 days after each injection for monitoring antibody response by ELISA. On day 80, about 500 ml of whole blood will be collected for library preparation. All procedures will be done with the approval from company’s Animal Care and Use Committee.

2. Animal use justifications:

Nanobody was traditionally obtained by vaccinating camelids. Nanomouse is a camelid antibody knock-in mouse model in which B cells express single domain nanobody instead of conventional antibody. It has been demonstrated robust in our recent work of generating potent and broadly protective nanobodies against variants of SARS-CoV2. The introduction of nanomice has replaced the sacrifice of large animals. To obtain affinity-matured and antigen-specific nanobodies against various virus envelope proteins, nanomice model is necessary for the immunization and nanobody identification procedure described in our study. The number of animals used in each group is a calculation based on past experience of the variable immune responses rate. For most immunogens, it can range from 25 to 75% of nanomice in a group who showed strong antigen-specific immune response. To promote nanobody epitope diversity, we assign eight animals in each group to ensure at least two high responders from which nanobodies will be identified. In the case of ideal antibody response not achieved from nanomice immunization, camelid animal immunization will be tried. When possible, multiple immunogens will be pooled for injection in one llama or alpaca.

3. Minimization of Pain and Distress:

Our procedures include *i.p.* injections of protein immunogens adjuvanted with or without CFA/IFA. Injection (*i.p.*) of small volume of non-viscous solution is generally not considered a painful procedure by the USDA and are therefore done without anesthesia. Animals may experience minor distress related to the immunization protocol. Complications are not expected. No adverse reactions to the immunizations are anticipated. The animal appearance and behavior post infection will be observed twice daily, and their weight will be recorded daily. Procedure time and laboratory personnel schedules will be arranged to allow for this frequent mouse monitoring. Mice showing severe stress signs such as being hunched, lethargy, head tilt, paralysis, labored breathing, or show ~20% weight deviation from age matched control mice will be euthanized. The project trained personnel, the veterinarian staff, and or the veterinarian may determine the animal comfort level and make the decision regarding humane endpoints and euthanasia. In general, inflammation at immunization sites subsides 6 - 7 days post- injection. At this point, the immune response concentrates in spleen for intraperitoneal injections. This "acquired" response peaks approximately 16 days in intraperitoneal immunizations. In case excessive inflammation (swollen severely that mice cannot move freely) occurs in some mice from lateral tarsal immunizations, those mice will be treated with the analgesic Buprenorphine HCl at a dose of 2.0 mg/kg BW, SQ, every 12 hrs. while inflammation is visible (or until the inflammation resolves). Anesthesia may be induced by inhalation of isoflurane. Topical anesthetic (proparacaine or tetracaine) or general anesthesia will be used for retro-orbital sinus blood collection depending upon technician preference. No surgical procedures will be done. No restraint devices will be required for the proposed studies. Animals will be euthanized with CO2 followed by cervical dislocation in accordance with American Veterinary Medical Association.

Georgia State University

The following sections of the proposal will use mice and/or camelid animals: **Aim 1** (To identify cross-reactive nanobodies to HNVs); **Aim 2** (Identification of nanobodies to ARVs.); and **Aim 5** (Expanding to other members of the viral groups in Center Phase 2.). The Xu lab at Georgia State University, Atlanta, will perform the experiments using nanomice to develop neutralizing nanobodies (Aim 1, 2 and 5). When needed, contracting company (Capralogics, etc.) will immunize camelid animals housed in their farm and provide PBMC to Xu lab (Aim 1, 2 and 5).

Each virus protein nanobody development will involve 8 gender balanced mice, and considering potential different designs of some immunogens, in total about 300 mice will be used in the study. Mice will be injected with recombinant proteins purified through mammalian cell culture system. Protein antigens include HNV G and F proteins, and ARV GPC proteins. All proteins are obtained by transfecting 293 cells with plasmids that express these recombinant proteins, and then protein purified from cell culture supernatant and dissolved in PBS. Mice immunization will be performed over a 62-day immunization protocol. Specifically, mice will be immunized intraperitoneally (*i.p.*) with 50 ug of recombinant protein in the presence of Complete Freund's Adjuvant (CFA) on day 0, and boost immunized intraperitoneally with 25 ug of protein in the presence of Incomplete Freund's Adjuvant (IFA) on days 14, 28 and 42. Two more immunizations with 25 ug of protein in PBS will be performed on day 56 and 59, intraperitoneally and intravenously (to stimulate memory B cell expansion), respectively. Bone marrow, spleen and blood samples will be collected on day 62. On day 0, 21, 35 and 49, per ARAC guidelines, about 200ul of blood samples will be drawn and analyzed by ELISA for antibody titer. Typically, experiment ends at day 62, but for certain immunogens, more boost injections may be performed to induce stronger antigen-specific antibody response. In that case, after the fourth immunization on day 42, mice will be boost immunized once every 2 weeks and blood samples collected one week after each immunization. Immunization will end when antigen-specific antibodies in serum is detected or maximum of 8 injections reached. For the extended experiments, about 200ul of blood samples will be drawn every 4 weeks or longer. In total, starting from the first blood draw on day 0, no more than 6 times of blood draw will be performed. Mice immunization will be performed under pathogen-free conditions at an AAALAC accredited animal facility in the PSC building and housed in accordance with the procedures outlined in the Guide for the Care and Use of Laboratory Animals under an animal study proposal approved by the GSU Animal Care and Use Committee. Animals used in this study are either generated and maintained by Xu lab or purchased directly from Jackson Laboratory. The animal protocol is approved by the Institutional Laboratory Animal Care and Use Committee (ILACUC) at GSU.

1.2 Camelid animal immunization: For immunogens that fail to elicit strong immune response in nanomice, company (Capralogics, etc.) housing camelid animals will be contracted to perform llama or alpaca immunization and provide PBMC to Xu lab. Animal will be immunized subcutaneously (*s.c.*) with 1 mg of recombinant protein in the presence of CFA on day 0 and boost immunized (*s.c.*) with 0.5 mg of protein in the presence of IFA on days 14, 28, 42, 56 and 70. Test blood/serum will be collected 10 days after each injection for monitoring antibody response by ELISA. On day 80, about 500 ml of whole blood will be collected for library preparation. All procedures will be done with the approval from company’s Animal Care and Use Committee.

2. Animal use justifications:

Nanobody was traditionally obtained by vaccinating camelids. Nanomouse is a camelid antibody knock-in mouse model in which B cells express single domain nanobody instead of conventional antibody. It has been demonstrated robust in our recent work of generating potent and broadly protective nanobodies against variants of SARS-CoV2. The introduction of nanomice has replaced the sacrifice of large animals. To obtain affinity-matured and antigen-specific nanobodies against various virus envelope proteins, nanomice model is necessary for the immunization and nanobody identification procedure described in our study. The number of animals used in each group is a calculation based on past experience of the variable immune responses rate. For most immunogens, it can range from 25 to 75% of nanomice in a group who showed strong antigen-specific immune response. To promote nanobody epitope diversity, we assign eight animals in each group to ensure at least two high responders from which nanobodies will be identified. In the case of ideal antibody response not achieved from nanomice immunization, camelid animal immunization will be tried. When possible, multiple immunogens will be pooled for injection in one llama or alpaca.

3. Minimization of Pain and Distress:

Our procedures include *i.p.* injections of protein immunogens adjuvanted with or without CFA/IFA. Injection (*i.p.*) of small volume of non-viscous solution is generally not considered a painful procedure by the USDA and are therefore done without anesthesia. Animals may experience minor distress related to the immunization protocol. Complications are not expected. No adverse reactions to the immunizations are anticipated. The animal appearance and behavior post infection will be observed twice daily, and their weight will be recorded daily. Procedure time and laboratory personnel schedules will be arranged to allow for this frequent mouse monitoring. Mice showing severe stress signs such as being hunched, lethargy, head tilt, paralysis, labored breathing, or show ~20% weight deviation from age matched control mice will be euthanized. The project trained personnel, the veterinarian staff, and or the veterinarian may determine the animal comfort level and make the decision regarding humane endpoints and euthanasia. In general, inflammation at immunization sites subsides 6 - 7 days post- injection. At this point, the immune response concentrates in spleen for intraperitoneal injections. This "acquired" response peaks approximately 16 days in intraperitoneal immunizations. In case excessive inflammation (swollen severely that mice cannot move freely) occurs in some mice from lateral tarsal immunizations, those mice will be treated with the analgesic Buprenorphine HCl at a dose of 2.0 mg/kg BW, SQ, every 12 hrs. while inflammation is visible (or until the inflammation resolves). Anesthesia may be induced by inhalation of isoflurane. Topical anesthetic (proparacaine or tetracaine) or general anesthesia will be used for retro-orbital sinus blood collection depending upon technician preference. No surgical procedures will be done. No restraint devices will be required for the proposed studies. Animals will be euthanized with CO2 followed by cervical dislocation in accordance with American Veterinary Medical Association.

BUDGET JUSTIFICATION – RP5 (Georgia State University)

KEY PERSONNEL

Jianliang Xu, Ph.D., Co-Project Lead (*5% effort or 0.45 person months during the academic year – years 1 & 2 12.5% effort or 1.13 person months during the academic year – years 3-5 100% effort or 3 person months during summer – years 1 & 2; 75% effort or 2.25 person months during summer – years 3-5).* Dr. Xu will serve as the co-Lead for research project 5 (RP5). He is an expert in antibody and nanobody research, especially in the areas of nanobody engineering and antiviral nanobody discovery. He has engineered a novel nanobody-producing mouse model, nanomouse, and demonstrated the power of both nanomouse and nanobody by developing potent cross neutralizing nanobody molecules against SARS- CoV-2, SARS and Bat WIV 16. He has recently generated a human nanobody library that is close to natural human antibody heavy chain variable domain. The potentially low immunogenicity of such a library will enable quick identification of nanobody leads that need minimum optimization for clinical use. Dr. Xu will be responsible for overall project direction, program administration and reporting. In addition, he will oversee the experiments conducted at GSU; these include the animal immunization, nanobody phage library construction and screening, nanobody production and characterization (Aim 1 and 2), support for structure analysis (Aim 3), nanobody optimization, engineering, production and functional assay (Aim 4), and work for additional viral targets (Aim 5). Dr. Xu will super vise the experimental design, data analysis and manuscript preparation. He will hire and train graduate students and postdocs, and participate in collaborative meetings to discuss the project.

OTHER PERSONNEL

Postdoctoral Fellow, TBN (*100% effort or 12 person months during the calendar year – years 1-5).* The postdoctoral fellow will be responsible for the project aspects including immunizing animals, constructing nanobody phage libraries, identifying and characterizing nanobody candidates that bind to henipavirus F and G proteins, arenaviruses GPC proteins (Aim 1 and 2), nanobody engineering, small- scale production and characterization (Aim 3 and 4), and work on additional viral targets (Aim 5). She/he will manage the laboratory, perform experiments, record and collect data, write manuscripts and supervise the students.

Graduate Students, TBN, Total of 2 Grad students (*100% effort or 12 person months, each, during the calendar year – years 1-5)* Two students will be recruited for the project. They will be responsible for the project aspects including screening nanobody phage libraries, preparing nanobody deep sequencing libraries, producing and charactering nanobodies (Aim 1-5). They will perform experiments, collect and record data and write manuscripts, and work closely with the postdoctoral fellow to help achieving all aim goals.

FRINGE BENEFITS

The negotiated fringe benefits rate for both the academic year and for summer is 36.0% for faculty and full-time staff. The fringe benefits rate for part-time faculty and temporary staff is 4.0% and for graduate students is 3.40%. A 2% salary increase is included on all personnel salaries for years 2-5.

TRAVEL

Domestic travel support is requested for the following: The domestic travel budget includes expenses for Dr. Xu, Post-Doctoral associates, and/or graduate students to travel to relevant national conferences that are significant to the project and scope of work and to visit the Co-PI Dr. Kai Xu at Ohio State University, and PD/PI Dr. Christopher Broder at Uniformed Service University.

Foreign Conference travel support is requested for the following: The foreign travel budget includes expenses for Dr. Xu and/or Post-Doctoral associates to travel to relevant international national conferences that are significant to the project and scope of work.

OTHER DIRECT COSTS

Materials & Supplies – Year 1: $168,949, Year 2: $165,148, Year 3: $162,591, Year 4: $158,707, Year 5: $154,769

The supplies will include:

1) Media, chemicals, antibiotics, growth supplements, and disposables - $23,949 (Year 1), $25,148 (Year 2), $22,591 (Year 3), $ 23,707 (Year 4) and 24,769 (Year 5)

2) Molecular and biochemical reagents and supplies, including molecular cloning enzymes, kits and reagents, antibodies for ELISA and FACS staining, TG1 competent cells for nanobody library construction and screening, protein purification resin and column, protein buffer exchange and desalt columns, FPLC affinity and ion exchange columns, and kits for site specific mutagenesis, DNA and RNA preparation - $50,000 (Year 1-3), $45,000 (Year 4-5).

3) Nanobody sanger sequencing and deep sequencing - $20,000 per year.

4) Nanobody DNA synthesis - $20,000 per year.

5) Octet biosensors for nanobody affinity and epitope mapping test - $20,000 (Year 1-4), $15,000 (Year 5).

6) Mice purchasing and housing - $5,000 per year.

7) Camelid animal immunization and maintenance - $20,000 (Year 1), $15,000 (Year 2-5).

8) Funds for equipment maintenance, and small equipment items. $5,000 per year.

9) Computer costs including software licenses, replacement of aging computers, backup equipment - $5,000 per year.

Publication Costs – Years 1-5: $3,000 per year.

Other Costs - Conference Registration Fees - Years 1-5: $3,000 per year for Dr. Xu, Post-Doctoral associates, and/or graduate student.

INDIRECT COSTS: The Georgia State University negotiated F&A/Indirect Cost rates are calculated at the federally approved rate of 56%. Indirect Costs are calculated on a modified total direct costs basis. Equipment and Participant Support are excluded from the calculation. Only the first $25,000 of each subaward is included in the calculation.

Importance: High

Hello,

We have made a pass through the files that have been sent over from both of you for RP5 on the UTMB/USUHS U19 (PABVAX). Please let me know if you have any last changes or comments for the files attached before we upload them into the application. Also, please send over to us as soon as possible the items listed below by the end of the day **Monday, June 5.**

- Abstract/Summary – 30 lines (Word doc)
- Multi-PI Plan – (Word doc) - *if either Kai or Jianliang prefer to be Project Lead and the other Co-I, we will not need this. If Co-Leading, we will need a plan to describe how the responsibilities will be shared and the justification for the shared leadership.
- Authentication of Key Biologicals and Chemical Resources
- Resource Sharing Plan – (Word doc attached; please be sure to add information about sharing research tools and model organisms)
- Final Specific Aims (Word doc) – 1 pg
- Final Research Strategy (Word doc) – 12 pgs plus bibliography

Thank you,

Sherry L. Haller, PhD

OMB No. 0925-0001 and 0925-0002 (Rev. 10/2021 Approved Through 09/30/2024)

BIOGRAPHICAL SKETCH

NAME: Schaefer, Brian Charles

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6)

POSITION TITLE: Professor of Microbiology and Immunology, and Director (Interim), Emerging Infectious Diseases Graduate Program

EDUCATION/TRAINING *(Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)*

INSTITUTION AND LOCATION	DEGREE *(if applicable)*	Completion Date MM/YYYY	FIELD OF STUDY
Massachusetts Institute of Technology	B.S.	1989	Biology
Harvard University	PhD	1995	Immunology
Harvard Univ/Dana Farber Cancer Institute	(Postdoc)	1995-1996	Tumor Virology
National Jewish Medical and Research Center	(Postdoc)	1996-2002	Immunology

A. Personal Statement

My group has historically focused on two major research programs. Our longest-standing program involves elucidation of mechanisms of signal transduction in immune cells and regulation of immune cell effector function, with a particular emphasis on the pathway that connects the T cell receptor (TCR) signaling to the transcription factor, NF-κB. This work has also stimulated our studies of the function of an understudied CARD protein, CARD19, which was originally (incorrectly) identified as a negative regulator of TCR signaling to NF-κB. These studies have resulted in numerous publications that define novel signaling mechanisms in the CARD11-BCL10-MALT1 signaling cascade and additional pathways. Our second major area of research is centered on immune responses in the central nervous system. Our initial work in this area involved elucidation of the role of the immune response initiated by traumatic brain injury, particularly NF-κB-mediated inflammatory responses. However, we have now shifted our emphasis to translational research on immune responses to neurotropic viruses, with an overall goal of developing immunotherapy strategies that are broadly effective against this dangerous class of human pathogens. This work is focused on lyssaviruses and henipaviruses, due to their neurotropic nature and propensity to cause severe human disease with a very high fatality rate. Our use of bioluminescence imaging to track viral replication has been a particularly important innovation for this work, as it allows us to collect highly granular data regarding viral spread and amplification from individual animals in a longitudinal manner. Specific current projects include a DoD-funded translational study in which we are defining the utility of a novel, mAb-based anti-lyssavirus immunotherapy against rabies strains circulating in Europe and Africa, and a study to develop novel henipavirus therapies (both are collaborations with Dr. Christopher Broder's group).

I am ideally suited to be PI of RP3: *Cedar henipavirus animal model*, as my group has established the only mouse model of Cedar virus infection (to our knowledge), and we now have several years of experience in the development of this very important BSL-2 animal model to investigate mechanisms of henipavirus pathogenesis, and to test efficacy of novel therapies. The following are notable ongoing projects:

HU00011920118 (**PI: Schaefer**), USU Center for Global Health Engagement
09/30/2019 – 09/29/2022 (NCE to 9/30/23)
"Efficacy testing of a novel human monoclonal antibody therapy for late-stage rabies/lyssavirus infection"

U19 AI142764-01 (PI:Broder; **Schaefer Co-I**), NIH/NIAID
03/01/2019 – 02/29/2024
"Advancement of Vaccines and Therapies for Henipaviruses"

R01 AI125552 (**PI: Schaefer**). NIH/NIAID
06/01/2017 – 05/31/2022 (NCE to 5/31/2024)
“T cell receptor-activated autophagy as a regulator of T cell effector responses”

HU00011921048 (**PI: Schaefer**), USU Multi-domain Operations Research (MDO)
02/28/2023 - 09/30/2025
“Defining the mechanism of enhancement of the pathogen-directed host adaptive immune response following anti-lyssavirus monoclonal antibody therapy”

B. Positions, Scientific Appointments, and Honors

Positions

2017 - current	Professor (with tenure) in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
2009 - 2017	Associate Professor (with tenure) in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
2002 - 2009	Assistant Professor in Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD.
1996 - 2002	Post-doctoral Research Associate, Howard Hughes Medical Research Institute, National Jewish Medical and Research Center, Denver, CO.
1995 - 1996	Research Fellow in Pathology, Harvard University, Dana-Farber Cancer Institute

Professional Memberships and Service

2011 - 2016	NIH CMIB (Cell and Molecular Immunology-B) study section for review of R01/R21 grants (Ad hoc member Feb & May 2011, Feb & May 2013, Feb 2014, Feb 2015, May 2016)
2008, 2021	ZRG1 CB-D 30 Confocal Microscopy Shared Instrumentation NIH Study Section (Ad hoc member)
2006 - current	American Society for Cell Biology (ASCB)
2006 - current	American Association of Immunologists (AAI)
2006 - 2007	ZRG1 IMM-L 29 L, DBBD Minority and Disability Predoctoral Fellowship NIH Study Section (Ad hoc member)
2005-2006	ZRG1 F07 Immunology Fellowship and AREA NIH Study Section (Ad hoc member)

Honors

2016	Uniformed Services University Henry Wu Award for excellence in basic science research
2005 - 2008	Dana Foundation Program in Brain and Immuno-Imaging
2004 - 2006	Kimmel Scholar - Sidney Kimmel Foundation for Cancer Research
2000 - 2002	Leukemia and Lymphoma Society Special Fellowship
1989 - 1992	Office of Naval Research Graduate Research Fellowship
1989	Phi Beta Kappa
(1989)	National Science Foundation Graduate Research Fellowship (Declined)

Patents

2007	US Patent 7,169,570: *Method to Identify Regulators of Cellular Activation Using Bcl10* – BC Schaefer, JW Kappler and P Marrack

Mouse strains developed

2001	C57BL/6-Tg(UBC-GFP)30Scha/J: Ubiquitously expressed EGFP transgene on a pure C57BL/6 background. Repository strain at Jackson Laboratory (stock# 004353). This strain has been used and cited in hundreds of publications.

C. Contributions to Science

1. My Ph.D. thesis studies involved identification of the molecular mechanisms controlling distinct latency-associated Epstein Barr virus (EBV) transcriptional programs. Prior to my dissertation work, it was known that there were three forms of EBV latency which displayed two distinct phenotypes with regard to expression of EBV nuclear antigens (EBNAs): Type III latency is characterized by expression of all six EBV nuclear antigens (EBNA1-EBNA6) whereas Type I and Type II latency is characterized by expression of EBNA1 only. The molecular basis restricted EBNA expression in Types I and II latency was not known. My work demonstrated the existence of a novel EBV promoter "Qp," responsible for driving exclusive expression of EBNA1 in Types I and II latency. My studies also showed that the choice between latency programs was contingent on whether the Type III latency promoter, Cp, is methylated in the host cell. Collectively, this work contributed significantly to the current understanding of regulation of EBV latency, which is relevant to elucidating how EBV persists for life in immunocompetent individuals, how EBV emerges as a life-threatening pathogen in specific immunodeficiencies, and how specific programs of EBV latency may be related to EBV-associated tumors, such as Burkitt lymphoma.

   ‡Cited >85 times.

2. My early work as an independent investigator involved determining whether NF-κB signaling proteins undergo molecular redistribution in response to TCR signaling. Previous work had shown that several different signaling molecules are recruited to "supramolecular activation clusters (SMACs)," membrane-proximal enrichments of signaling proteins that form on the cytoplasmic face of the antigen-engaged TCR. An assumption in the field, prior to our work, was that SMAC recruitment would be a shared feature of all cytoplasmic proteins important in TCR signaling. Surprisingly, our investigations demonstrated that NF-κB signaling proteins, including Bcl10 and Malt, redistribute to punctate cytoplasmic structures, which we named POLKADOTS. Our ongoing signal transduction work has involved mechanistic studies connecting the POLKADOTS signalosome to TCR activation of NF-κB. Key findings include demonstration that (i) TCR activation of NF-κB is *digital*. In other words, in contrast to pharmacological stimulation of NF-κB (PMA + ionomycin), which results in graded activation of NF-κB as the stimulus is increased, increasing TCR ligand changes only the *number* of T cells that respond, but not the *intensity* of the response; (ii) polyubiquitination of Bcl10 leads to recruitment to pre-existing p62 "speckles," forming the POLKADOTS signalosome; (iii) the POLKADOTS signalosome is required for activation of the IKK complex; (iv) the POLKADOTS signalosome contemporaneously directs a signal dampening activity that involves a highly novel regulatory mechanism: *selective* autophagy of Bcl10, which results in degradation of Bcl10, but not its direct binding parther, Malt1; (v) effector T cells form POLKADOTS signalosomes and use autophagy to degrade Bcl10, whereas naïve T cells use a distinct mechanism of NF-κB activation that appears to be independent of p62, involving recruitment of signaling proteins to SMACs. Collectively, these contributions provide key mechanistic details regarding how signals are transmitted from the TCR to the NF-κB transcription factor. Most recently, we have collaborated with Drs. Wolfgang Losert and Arpita Upadhyaya, biophysicists at the

University of Maryland, to define biophysical features of TCR-mediated activation and degradation of Bcl10. Our study with Dr. Losert in PLOS Computational biology has shown that the regulated polymerization and degradation of Bcl10 has characteristics of an excitable system, providing new insights regarding the digital behavior of this signaling module.

3. During our studies on TCR signaling to NF-κB, we became interested in the understudied CARD protein, CARD19. Although CARD19 was initially described as a cytoplasmic negative regulator of TCR signaling to NF-κB, we found that this work was based on analysis of a partially spliced cDNA clone, and that the conclusions of this initial study were therefore spurious. Our work with a properly spliced CARD19 cDNA showed that CARD19 is a mitochondrial protein that plays no role in TCR activation of NF-κB. Our latest work has shown that CARD19 interacts with the mitochondrial cristae organizing system (MICOS), and that it plays a role in determining cristae morphology. Notably, 3 of the 7 current publications focused on CARD19 were generated by my laboratory or as a collaboration with my group. We are currently performing further studies to determine whether CARD19 regulates other aspects of mitochondrial function via its interaction with MICOS components.

4. A second major research focus in my lab is the study of immune responses in the central nervous system. Our initial studies focused on inflammatory responses in traumatic brain injury (TBI), using mice as a model system: The first study demonstrated that the gene expression program induced by mild vs. severe TBI is remarkably similar, with the main distinction being that the expression of certain inflammatory genes remains persistently elevated in severe TBI. The second study presented evidence that the anti-inflammatory drug salsalate is a candidate therapy for TBI, reducing inflammation and improving functional recovery, as assessed by behavior assays. Our more recent work has focused on developing novel animal models and immunotherapies for neurotropic viral infections. Our published work on this project includes a description of our methodology for longitudinal tracing of lyssavirus infections and a description of isolation and in vitro characterization of two anti-lyssavirus neutralizing mAbs.

5. A distinct area of emphasis in my career has been the development of new tools for research and the optimization of existing tools. Among many publications in this area, I have edited a protocols book and written a review on methodology for identification of cDNA ends by RACE (which included an optimized protocol). I produced a C57BL/6 transgenic mouse strain ubiquitously expressing GFP, which has been a highly utilized tool for cell transfer studies. I also generated a set of retroviral vectors for rapid and reliable creation of stable cell lines. My lab has published optimized protocols for visualizing NF-κB signaling intermediates via confocal microscopy, and for quantifying NF-κB activation using imaging flow cytometry. We have most recently described our methodology for using bioluminescence imaging to semi-quantitatively trace lyssavirus infection in laboratory mice. A central goal of this work is to facilitate progress across the biomedical research community, through the development and distribution of better tools and clear explanation of how to reliably execute challenging techniques.

A. Personal Statement

As an active researcher in the development of novel therapeutics and vaccine candidates against emerging and re-emerging henipaviruses in relation to pandemic preparedness, I am uniquely qualified to participate as a Co-Investigator in **Research Project 2: Vaccines and antibodies to henipaviruses** of the present U19 application (ReVAMPP). The extensive experience in henipavirus reverse genetics platforms necessary to conduct the proposed studies began in my postdoctoral training, under the guidance and mentorship of **Dr. Christopher Broder**, a leading expert in henipavirus biology. During my fellowship, I rescued and fully characterized a replication competent recombinant Cedar virus (rCedV) as non-reporter and luciferase expressing reporter versions that can safely be utilized at BSL-2. This work resulted in a first co-author publication (see below). In addition, I generated replication competent chimeric viruses as non-reporter and reporter versions that express the envelope glycoproteins of either Nipah virus Bangladesh (NiV-B) (rCedV-NiV-B) or Hendra virus (HeV) (rCedV-HeV) instead of those of CedV. All 6 chimeric viruses were fully characterized in in vitro studies. Together with **Dr. Thomas Geisbert**, at the University of Texas Medical Branch (UTMB), with whom I have a 5-year collaboration, we demonstrated that the chimeras can serve as suitable surrogate viruses for authentic NiV-B or HeV as determined by plaque reduction neutralization tests. Moreover, the fluorescent reporter chimeric viruses were further characterized in a high throughput fluorescence reduction neutralization test (FRNT) to analyze neutralization potencies of sera from henipavirus immunized animals and monoclonal antibodies. This work resulted in a first author manuscript that was very recently published (see below). The FRNT has also been implemented in several neutralization and synergistic neutralization tests that resulted in 2 co-author publications (see below). The highly productive collaborations between Drs. Broder, Geisbert and I underscore the feasibility of the proposed project. The research proposed in this application will not only build on my work developed thus far but also strengthen my scientific portfolio to achieve my long-term goal of vaccine development for priority pathogens.

C. Contributions to Science

1. **Graduate career:** My Ph.D. thesis research involved characterizing the host viral interactions in human cells with a focus on the least characterized non-structural protein, nsP3, from VEEV. I initially constructed a tagged version of nsP3 both as an overexpression construct and in the context of the viral genome. Mass spectrometry analyses revealed that VEEV-nsP3 interacted with multiple host factors. Those of particular interest were chosen for additional studies, namely the kinase IKKβ and the RNA helicases DDX1 and DDX3. I validated that VEEV-nsP3 interacted and complexed with IKKβ, DDX1 and DDX3 and furthermore, siRNA knockdown studies indicated a reliance of these host factors for productive and continuous viral replication. These findings formed the basis of the functional model where VEEV-nsP3 interacts with the host translational machinery via DDX3 to potentially aid in translation of viral proteins that could be part of the replication complex, and that this interaction could be essential in the viral life cycle. This contribution will aid in elucidating the functionality of nsP3 in the viral life cycle as well as to promote the development of host based therapeutic options to treat RNA viral infections or disease. Results from my research were highly relevant as they provided new details and insight in understanding the role of the uncharacterized VEEV protein, nsP3, in

the new world alphavirus life cycle. As such, this work resulted in two first author research publications and one review article (see below). My Ph.D. research on host viral interactions was expanded to include host pathways that were altered during viral infection by utilizing small molecule inhibitors. Such pathways included the host phospho-signaling and the ubiquitin proteasome pathways. I validated, as a collaboration, that the MAPK/ERK signaling pathway was activated and necessary for the infectious process in VEEV infected human cells through utilization of the small molecule inhibitor, Ag-126. This joint effort resulted in a second author publication. In a different study, I had revealed with the use of an FDA approved proteasome inhibitor, Bortezomib that VEEV requires the ubiquitin proteasome pathway in the viral life cycle. My results indicated the likely mechanism was that K48 ubiquitination of VEEV capsid protein may be necessary for the early stages of infection. This study was the first to demonstrate that the capsid protein was post translationally modified with ubiquitin and this resulted in a first author publication (see below). In addition, I had also collaborated to investigate the requirement of the ubiquitin proteasome pathway in the negative stranded RNA virus, RVFV infection. We showed that with Bortezomib treatment, the formation of the characteristic nuclear filaments formed by the virulence factor NSs was abolished, thereby preventing NSs interaction with host repressor proteins SAP30 and mSin3A. This study resulted in a second author publication. Cumulatively, these studies would pave the way for developing host-based therapies and/or repurposing FDA approved drugs to treat these re-emerging diseases.

(2014). The role of IKKbeta in Venezuelan equine encephalitis virus infection. *PLoS One*, *9*(2), e86745. https://doi.org/10.1371/journal.pone.0086745

2. **Postdoctoral career:** My postdoctoral training involved the development and characterization of a recombinant henipavirus platform that can safely be used at BSL-2 to investigate and understand henipavirus infection with respect to pathogenesis, neutralization, drug discovery, therapeutics and vaccine potential. The reverse genetics system for the rCedV platform resulted in a first co-author publication (see below). A collaborative research project entailed the optimization of a replication competent rCedV-Luc for high throughput screening assays to identify small drug like molecules that can target multiple stages in the henipavirus life cycle, which resulted in a first co-author publication (see below). Building on the rCedV platform, I designed and characterized a robust recombinant chimeric henipavirus reverse genetics system to be used as a surrogate system for pathogenic henipaviruses. The envelope glycoproteins of rCedV were replaced with those of either NiV-B (rCedV-NiV-B) or HeV (rCedV-HeV) and non-reporter and reporter versions were generated. I optimized and implemented a rapid high throughput cell-based fluorescence reduction microneutralization assay using rCedV chimeras to determine monoclonal antibody neutralization potencies and detect the presence of neutralizing antibodies and measure neutralizing titers in henipavirus immunized animal sera. This work resulted in a first author manuscript (see below). In a collaborative effort, I generated recombinant henipavirus chimeric virus escape mutants to understand the structure of henipavirus envelope glycoproteins. This collaboration resulted in a co-author manuscript (see below). In addition, my work has been recently presented at multiple meetings such as the Keystone Symposia, Bat Infectious Diseases Symposium, and the World One Health Congress.

University of Florida, Gainesville, FL	Ph.D.	1989	Immunology and Med-Micro

A. Personal Statement

The objectives of this ReVAMPP Center proposal are to support Pandemic Preparedness through the study and advancement of a broadly applicable viral subunit immunogen vaccine delivery platform and antibody-based countermeasures for bunyavirales and paramyxovirus agents. I will serve as Co-PI with Thomas Geisbert (Center PI) of the **Administrative Core A**; and as Project Leader of **Research Project 2 (RP2): Vaccines and antibodies against henipaviruses.** I have researched enveloped virus-host cell interactions for 34 years, funded primarily by multiple NIAID and DoD grants on HIV and zoonotic viral agents. 1999, I established a collaborative international group of research experts in Hendra and Nipah virus biology, and later over a 14-year period I was the PI of two multi-component, international, NIAID, U01 awards, and also the Co-PI of a third U01 with the Center PI (Geisbert) all focused on henipavirus research, and have collaborated with Dr. Geisbert for the past 16 years. I also currently serve as PI on a NIAID CETR U19 focused on henipavirus countermeasures. Some of my collaborative henipavirus research contributions include: structural biochemistry on the viral G and F glycoproteins; animal model development and *in vivo* pathogenesis studies in the feline and ferret (with the AAHL-CSIRO, Australia), and the African green monkey (with Geisbert); development and testing of vaccines and therapeutics; discovery of the entry receptors ephrin-B2/B3; development of antiviral mouse and human monoclonal antibodies (mAb) including m102.4 that successfully completed a Phase 1 trial in Australia (2020) and since used by emergency protocol in 18 people in Australia and the US as a post-exposure treatment; developed and patented the Hendra/Nipah soluble G (sG) and soluble F (sF) subunit vaccine candidates, including HeV-sG for horses called Equivac® HeV (Zoetis, Inc.), the first commercialized vaccine to a BSL-4 agent; and now in Phase I trial in the US (Auro Vaccines/PATH/CEPI). More recently my lab developed a reverse genetics platform for generating recombinant Cedar henipavirus (rCedV) that can be utilized at BSL-2 for both high-throughput antiviral drug discovery and rCedV chimeras for performing rapid neutralization tests for Nipah and Hendra. I have the expertise in many aspects of the henipavirus-related project goals proposed here, and I have led both basic and translational research projects in a broad area of study on Nipah and Hendra. Here **RP2** will be focused on the implementation of a new, rapid and dissolvable, microneedle patch (MNP) vaccine technology with the 'prototype' viruses Nipah and Hendra; develop reporter virus platforms for the divergent Langya and Angavokely henipaviruses; assess vaccine responses and test neutralizing antibodies and nanobodies to be developed by the Center's **Core D** and **RP4** and **RP5**. We will also pivot and adapt the MNP approach and new tools in Phase 2 of the Center to another virus.

Ongoing projects that I would like to highlight:

U19 AI142764. NIAID, Center of Excellence for Translational Research (CETR): Role: PI
03/20/19-02/29/24. "Advancement of Vaccines and Therapies for Henipaviruses"

U19 AI171413. NIAID AViDD: "UTMB-Novartis Alliance for Pandemic Preparedness": PIs: Diagana and Shi.
05/01/2022-04/30/2027; Sub-project 3: Henipaviruses. Role: Co-PI with Geisbert

CRADA; Auro Vaccines; CEPI (Coalition for Epidemic Preparedness Innovations): Role: Co-PI with Hamm
07/01/18-06/30/2023; "A Subunit Vaccine (HeV-sG) to Protect against Nipah and Hendra Diseases"

C. Contributions to Science

My Ph.D. thesis studies centered on the discovery and characterization of a specific receptor for human plasmin on Group A Streptococci during my rotation project as a first year student. My studies revealed that certain group A streptococci elaborated surface receptors that could bind selectively a key fibrinolytic enzyme, plasmin. The bacterium-bound plasmin remained enzymatically active including its ability to hydrolyze a fibrin clot and could not be inhibited by its physiological regulator, alpha 2-plasmin inhibitor. Since these organisms produced streptokinase producing an active enzyme that can convert plasminogen to plasmin, they could accelerate the destruction of the extracellular matrix environment: a model for the "flesh-eating streptococci".

d. Lottenberg, R., **C.C. Broder**, M.D.P. Boyle, S.J. Kain, B.L. Schroeder, and R. Curtiss III. Cloning, Sequence Analysis, and Expression in *Escherichia coli* of a Streptococcal Plasmin Receptor. J. Bacteriology. 174:5204-5210, 1992.

My independent work as a postdoctoral fellow focused on the early stages of HIV-1 envelope glycoprotein mediated membrane fusion as a surrogate model of HIV-1 entry. I established a vaccinia virus-based reporter gene assay for measuring viral (HIV-1) glycoprotein-mediated membrane fusion and generated the first panel of T-cell tropic and Macrophage-tropic HIV-1 envelope glycoprotein (Env) encoding recombinant vaccinia virus vectors and I used these tools to be the first to hypothesize that the cellular tropism of HIV-1 could be explained by specific membrane fusion factors required for the different classes of HIV-1 Envs. I also developed the first soluble and secreted full-length oligomeric HIV-1 gp140 glycoprotein and explored the importance of its native oligomeric structure in terms of its presentation of conformational and virus-neutralizing epitopes through the development and characterization of more than 100 murine monoclonal antibodies.

My early studies on the cellular and viral membrane fusion tropism of HIV-1 and the development of a sensitive and specific reporter gene assay of cell-cell membrane fusion facilitated the discovery of the first membrane fusion accessory factor (“fusin”; CXCR4) that I earlier hypothesized existed, and this rapidly led to the discovery by us and others of the second factor for macrophage-tropic Envs (CCR5); the HIV-1 coreceptors. These findings were a significant breakthrough in HIV research leading to numerous new directions in understanding HIV-1 pathogenesis as well as new therapeutic strategies.

My initial work on HIV-1 entry led to further independent studies which focused on follow-up investigations characterizing the roles of the HIV-1 coreceptors in the virus entry process. These studies revealed the interplay between the HIV-1 entry receptors, mapped important domains of the coreceptors involved in HIV-1 Env interaction, and also revealed possible avenues of how an HIV-1 Env might engage and differently utilize the CXCR4 and CCR5 coreceptors for infection. In addition, I also engaged in collaborative follow-up studies exploring the utility of soluble oligomeric HIV-1 envelope glycoproteins as subunit vaccine immunogens (gp140) which I initiated at NIH while a postdoctoral fellow.

My recent efforts have focused on emerging viruses that impact human and domestic livestock populations; including lyssaviruses, filoviruses, and henipaviruses for the past 23 years. I obtained the first NIAID funded biodefense project providing fiscal support on select agent research to an overseas laboratory (2003; U01 AI056423). I developed the first henipavirus peptide-based fusion inhibitors, subunit vaccines, and neutralizing human and humanized monoclonal antibodies (mAb), and my NIAID grants supported the development of the feline, ferret and African green monkey models of Hendra and Nipah pathogenesis. Henipavirus countermeasures development is a major a focus of my lab and supported by a NIAID U19 CETR. Here, we are developing next-generation mAb therapies and next-generation vaccines and delivery methods against Nipah and Hendra for both human and livestock use. I am also heavily engaged in collaborative virus surveillance activities focusing on henipaviruses, filoviruses, coronaviruses, and others, in wildlife and human populations in more than 10 countries in South Asia, Southeast Asia, West Africa and Southern Africa; using the Luminex xMAP-based platform which has proven to be more sensitive than ELISAs for the detection of antibodies to viral infections. The key feature of our multiplex microsphere immunoassays (MMIA) are the use of my lab’s production of recombinant, soluble, native-like, oligomeric viral glycoproteins, designed similar to our HeV-sG subunit vaccine. Our MMIA array presently contains more than 20 different soluble glycoprotein ectodomains. These programs are funded by the NIAID and the Defense Threat Reduction Agency (DTRA), an agency within the US Department of Defense.

BIOGRAPHICAL SKETCH

Provide the following information for the Senior/key personnel and other significant contributors.
Follow this format for each person. **DO NOT EXCEED FIVE PAGES.**

NAME: Antony S. Dimitrov

eRA COMMONS USER NAME (credential, e.g., agency login): (b) (6) [redacted]

POSITION TITLE: Senior Staff Scientist

EDUCATION/TRAINING *(Begin with baccalaureate or other initial professional education, such as nursing, include postdoctoral training and residency training if applicable. Add/delete rows as necessary.)*

INSTITUTION AND LOCATION	DEGREE *(if applicable)*	Completion Date MM/YYYY	FIELD OF STUDY
Sofia State University, Bulgaria	M.Sci.	06/1987	Chemistry
The University of Tokyo, Japan	Ph.D.	04/1995	Physical Chemistry
NCI-Frederick, NIH, Frederick, MD	Postdoctoral Training	04/2004	Biochemistry, Viral entry

A. Personal Statement

I have been familiar with HeV-sG since its discovery. I am a co-author of the HeV-sG characterization article in JVI 2005. It shows that HeV and NiV as well G-glycoproteins, membrane attached and soluble as well, exist as dimers and dimers of dimers. Under the supervision of Dr. Broder I played a major role in the discovery of ephrin B2 as a functional receptor for Nipah and Hendra viruses, sharing an equal contribution with Dr. Bonaparte in the related PNAS article (2005). I had been also characterizing the binding site of ephrin B2 to HeV and NiV G glycoprotein and found aminoacid residues on ephrin B2 that are critical for the virus receptor binding.

I was a PI (MPI, with Dr. Fouts) of two pre-clinical development programs – one for the HeV-sG as subunit vaccine against henipavirus infections and the other for the human antibody, m102.4, as postexposure treatment against such infections. I am currently involved in the clinical investigation of the HeV-sG subunit vaccine led by Auro Vaccines LLC. I am also actively involved in coordination the work of the research projects and cores within the CETR U19- AI142764 "Advancement of Vaccines and Therapies for Henipaviruses" (Christopher Broder, PI), where I wrote the proposal for RP1 related to the next generation HeV-sG human vaccine. Although the subunit vaccine in its current formulation has an excellent efficacy, its stability at ambient condition and efficacy are expected to be significantly enhanced within RP1 of the above CETR U19, there is still room to explore the immunization efficiency by decreasing the cost of storage and application procedure. Within one of the latest awards we are developing patches of soluble microneedle arrays for intradermal delivery of HeV-sG. The vaccine is expected to be stable at ambient conditions and ready for easy self-administration by pressing the patch to a bare skin place, like on the shoulder. During the past 2 decades I accumulated relevant experience related to GLP, GMP, and partly GCP and believe that I can significantly contribute to the proposed project.

B. Positions, Scientific Appointments, and Honors

2019 – Senior Scientist, USUHS, Bethesda, MD 20814 / HJF, Bethesda, MD 20817

2006 – 2019 Senior Staff Scientist, Profectus BioSciences, Inc., 6411 Beckley Str., Baltimore, MD 21224

2004 – 2006 Research Associate, Dept. of Microbiology at USUHS, Bethesda, MD 20814

1999 – 2004 Post-Doctoral Fellow, Laboratory of Experimental and Computational Biology, CCR, NCI, NIH, Bldg. 469, Rm. 211, P.O. Box B, Frederick, MD 21702-1201

1995 – 1999 Scientist, L'ORÉAL Tsukuba Center, Tokodai 5-5, Tsukuba, Japan

1992 – 1995 Senior Research Associate, Nagayama Protein Array Project, ERATO, JRDC, Tokodai 5-5, Tsukuba, Japan

1987 – 1993 Research Specialist (Chemist), Faculty of Chemistry, Sofia State University, Sofia, Bulgaria

C. Contributions to Science

1. *Development of HeV-sG as a human subunit vaccine against henipavirus infection.*
Relates to my current activities described above in the Personal Statement.

A. Geisbert TW, Bobb K, Borisevich V, Geisbert JB, Agans KN, Cross RW, Prasad AN, Fenton KA, Yu H, Fouts TR, Broder CC, **Dimitrov AS**. A single dose investigational subunit vaccine for human use against Nipah virus and Hendra virus. **NPJ Vaccines**, 2021 Feb 8;6(1):23. doi: 10.1038/s41541-021-00284-w

2. *Discovery that ephrin B2 is a functional receptor for both HeV and NiV. Characterization of HeV-sG.*
Dr. Broder (USUHS, Bethesda) pioneered the research on HeV and NiV starting the beginning of the century. I joint his group in 2004. Dr. Bossart had already created soluble versions of HeV and NiV G glycoproteins and was spending time on a search for the viral receptors. It was anticipated that both viruses share common receptor indicated by immune response crossreactivity and anti-G antibody crossreactivity, including m102. Dr. Broder suggested me to join in the efforts of receptor discovery. We mainly attempted to co-immunoprecipitate the receptor with soluble G from lysates of permissive and non-permissive cells using coomassie stain, radiolabeling, and different modification. It later became clear that the S-agarose we used for co-IP with the S-tagged soluble G produces a non-specific band overlapping ephrin B2 and, thus, the band was considered false positive. When Matthew Bonaparte joint the team proposed to use gene chip technology developed at his university, SUNY. He sent lysates from permissive and non-permissive cells for analyses. Using the gene chip data he successfully narrowed the possibilities for the receptor down to low 20s. Farther on, narrowing couldn't be justified by the available data. Then, I proposed to purchase plasmids with the identified genes from Origene, transfect non-permissive cells, and find out which gene will render them permissive to HeV or NiV. Thus, ephrin B2 was discovered as receptor for HeV and NiV. Looking back into those data ephrin B3 shows a signal higher than background, but we have ignored it at that time, being excited of ephrin B2 identification.

3. *Having a contribution in the discovery of m102.4 by identifying its parent m102 as a crossreactive neutralizer.*
Being in the laboratory of Dr. Broder I was using HeV and NiV mediated cell-cell fusion assays to study mutant G glycoproteins created by inactivating glycosylation sites. At that time, Dr. Zhu had found Fab binders to HeV-sG and asked me to test those for inhibitory activities in the cell-cell fusion assay. His Fabs showed different inhibitory potency to HeV and NiV with Fab m102, although not the best against either virus, showing a balanced inhibition to both viruses. Then, Dr. Zhu optimized m102 by in vitro maturation to m102.4.

C. Prado I, Fouts TR, **Dimitrov AS**. (2009) Methods Mol Biol. v. 525 pp. 517-31. "*Neutralization of HIV by antibodies.*"

5. *Studying the mechanism of HIV entry. Applying mAbs to inhibit HIV entry*

While postdoc under the supervision of Dr. Blumenthal, we proposed that HIV-1 Env gp41 destabilizes target cell or its own membrane upon activation of gp120 by CD4 and respective coreceptor, CCR5 or CXCR4, complexes, resulting in fusion or viral inactivation, respectively. In relation to HIV-1 entry to cells we detected intermediates of the fusion process by using conformation specific mAb. Later, at Profectus I worked with anti-HIV antibodies as entry inhibitors. Results from the completed grant awards identify sweet epitopes that are simultaneously targeted by inhibitory antibodies show synergistic effect and an exceptional efficacy in vitro.

RESEARCH & RELATED Senior/Key Person Profile (Expanded)

Additional Senior/Key Person Form Attachments

When submitting senior/key persons in excess of 8 individuals, please attach additional senior/key person forms here. Each additional form attached here, will provide you with the ability to identify another 8 individuals, up to a maximum of 4 attachments (32 people).

The means to obtain a supplementary form is provided here on this form, by the button below. In order to extract, fill, and attach each additional form, simply follow these steps:

- Select the "Select to Extract the R&R Additional Senior/Key Person Form" button, which appears below.
- Save the file using a descriptive name, that will help you remember the content of the supplemental form that you are creating. When assigning a name to the file, please remember to give it the extension ".xfd" (for example, "My_Senior_Key.xfd"). If you do not name your file with the ".xfd" extension you will be unable to open it later, using your PureEdge viewer software.
- Using the "Open Form" tool on your PureEdge viewer, open the new form that you have just saved.
- Enter your additional Senior/Key Person information in this supplemental form. It is essentially the same as the Senior/Key person form that you see in the main body of your application.
- When you have completed entering information in the supplemental form, save it and close it.
- Return to this "Additional Senior/Key Person Form Attachments" page.
- Attach the saved supplemental form, that you just filled in, to one of the blocks provided on this "attachments" form.

Important: Please attach additional Senior/Key Person forms, using the blocks below. Please remember that the files you attach must be Senior/Key Person Pure Edge forms, which were previously extracted using the process outlined above. Attaching any other type of file may result in the inability to submit your application to Grants.gov.

1) Please attach Attachment 1 ☐

2) Please attach Attachment 2 ☐

3) Please attach Attachment 3 ☐

4) Please attach Attachment 4 ☐

Research Strategy

A. Significance

The constant threat posed to global public health by emerging and reemerging pathogenic zoonotic viruses emphasizes the importance for pandemic preparedness by developing much needed countermeasures. The highly pathogenic HeV and NiV are the prototype members in the genus Henipavirus in the family Paramyxoviridae[1]. HeV was first discovered almost 30 years ago (1994), in Queensland, Australia where it was the causative agent of a severe and fatal respiratory disease among horses along with a human case fatality[1,2]. Whereas, in 1998-1999 in Malaysia and Singapore an outbreak of encephalitis in people and respiratory disease in pigs was due to NiV[3,4]. These viruses are capable of causing a systemic and often fatal respiratory and/or neurological disease in at least 11 mammalian species including humans, with fatality rates ranging from 40-100%[5,6]. As a result of this high lethality and lack of approved vaccines or antivirals, HeV and NiV are classified as Biosafety Level-4 (BSL-4) pathogens. NiV and henipaviral diseases are also included in the WHO's Blueprint List of Priority Pathogens[7], and NiV is among the Coalition for Epidemic Preparedness Innovations (CEPI) list of Priority Diseases needing urgent research and countermeasure development[8,9].

To date, HeV has spilled over in Australia on 63 occasions, the most recent in 2022[10]. In total HeV has caused the death or euthanasia of >100 horses, 2 HeV antibody positive and euthanized dogs, and 4 fatalities of 9 human cases[10,11]. The yearly outbreaks of NiV in Bangladesh and India have significant human case fatality rates that can reach up to 100%. Transmission in these outbreaks occur by humans consuming contaminated fruits or date palm sap and person-to-person transmission[12-15]. There have been >620 human cases of NiV infection with over 330 fatalities, 7 of them in 2023[16]. The henipavirus genus now includes nine other reported henipaviruses; the four viral isolates of CedV, Gamak virus, Daeryong virus, and Langya virus (LayV)[17-19] and five additional species known only from nucleic acid sequence information; Ghana bat virus (GhV), Mòjiang virus, Melian virus, Denwin virus, and Angavokely virus (AngV)[20-23]. Pteropid fruit bats, known as flying foxes, are recognized natural reservoir hosts for NiV, HeV[24,25], CedV[18], GhV and AngV. One of these, CedV, has been shown to be nonpathogenic in several animals susceptible to HeV and NiV disease including mice, guinea pigs and ferrets[18,26] and African green monkeys (AGMs) (Geisbert, T.W. and Broder, C.C., unpublished). The remaining six reported henipaviruses are likely of rodent origins. One of these six, the isolate LayV, is associated with nonfatal febrile illness in humans[19].

Henipaviruses are membrane enveloped, single-stranded, negative sense RNA viruses that share a similar genomic makeup. There are two major membrane anchored glycoproteins involved in the virus entry: the attachment (G) glycoprotein that engages the host cell receptor and the fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F glycoproteins are the major antigenic targets for neutralizing antibodies and the main focus for vaccine and therapeutic antiviral strategies[27,28]. CedV is distinct from the other henipaviruses, in that the phosphoprotein (*P*) gene does not have an mRNA editing site to produce the interferon antagonist proteins V and W[18,29-31]. The nonpathogenic phenotype of CedV is most likely attributed to the lack of these nonstructural proteins. Based on genetic data, all identified henipaviruses, except CedV, can potentially express the V and W proteins. Furthermore, CedV is recognized as a BSL-2 restricted agent[32].

B. Innovation

There are multiple layers of innovation within RP2. **First**, the proposed development of henipavirus subunit vaccine candidates using an innovative microneedle array patch (MNP) technology that may be suitable for the incorporation of other undiscovered pathogenic henipaviruses in the future. **Second**, the construction of a rLayV reverse genetics system will be highly valuable in the henipavirus toolbox to study putative differences in pathogenesis and vaccine design between henipaviruses of bat and rodent origin. **Third**, generation of BSL-2 surrogate platforms that are based on rCedV and VSV will allow for a wide-variety of *in vitro* studies to investigate infection and host responses and to screen in a high throughput manner the neutralization potentials of immune sera and monoclonal antibodies all without the requirement for high containment. **Fourth**, considering that the LayV and AngV F and G proteins are functionally fusion active, the generation of viable rCedV chimeras bearing either LayV or AngV F and G glycoproteins is feasible.

C. Approach

Scientific Premise

The most extensively studied NiV/HeV vaccine is the soluble recombinant G glycoprotein of HeV (HeV-sG)[11,27,33] demonstrating complete protection against lethal challenge with NiV or HeV in multiple animal models[34-40]. It has shown complete protection of AGMs against NiV challenge performed a week post-immunization[41]. HeV-sG subunit is marketed by Zoetis as a horse vaccine since November 2012 and is the first commercialized vaccine against any BSL-4 pathogen. HeV-sG /alum intramuscular formulation is in clinical trials funded by CEPI as an anti-NiV vaccine.

We have been developing Cedar virus (CedV) as a new experimental tool set to study henipavirus host cell interactions, including ephrin receptor use, host cell tropism, and in the development of henipavirus countermeasures. Experiments with CedV can be conducted in a BSL-2 containment setting. The rCedV reverse genetics system[42,43] allowed us to develop a rCedV chimeric platform, where the CedV F and G glycoproteins are replaced with that of either NiV-Bangladesh (NiV-B) or with HeV, thus generating replication competent chimeric viruses (rCedV-NiV-B and rCedV-HeV). We have successfully rescued, grown and characterized the chimeric viruses with and without reporter genes[44]. The neutralizing potencies of several well-characterized cross-reactive NiV/HeV F and G specific mAbs against these rCedV chimeras highly correlate with the potencies obtained for the same antibodies to neutralize authentic NiV-B and HeV in the plaque reduction neutralization tests (PRNTs). The GFP reporter chimeras were employed to developed a rapid, high-throughput, and quantitative fluorescence reduction neutralization test (FRNT). The antibody potencies to neutralize the reporter chimeras in the FRNT corelates with the respective potencies obtained in the PRNT[44].

rCedV chimeras have their most important application in an authentic henipavirus-based surrogate neutralization assay that is rapid, cost-effective, and can be utilized in BSL-2 containment. We believe that the rCedV reverse genetics system can serve as a plug and play platform for other emerging henipaviruses that may have pandemic potential. To accomplish this, we propose here to develop a variety of rCedV variants with reporter genes that will serve as important BSL-2 containment tools for the other RPs and Cores within this U19 ReVAMPP.

Scientific Rigor: The premise of our proposed studies is based on basic science discoveries and clinical observations. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistics and any required testing for multiple comparisons have been properly performed. rCedV laboratory manipulation guidelines and standard operating procedures under BSL-2 conditions were developed for the laboratory and staff, and all procedures were reviewed and approved by the Uniformed Services University Institutional Biosafety Committee in accordance with NIH guidelines.

Aim 1: Develop PPZ-MNP-based sG_{tet} and sF_{stb} prototype HNV subunit vaccines.

Rationale and Preliminary Data. We intend to compare NiV vaccine immunogens (sG_{tet} and sF_{stb}), HeV (HeV-sF_{stb}) and a combination of NiV-sF_{stb}+HeV-sG to the clinical subunit HeV-sG. All immunogens will be delivered by microneedle array patches (MNPs). Immunogenicity will be initially tested in mice. The immune mouse sera will be evaluated *in vitro* for neutralizing potencies to either NiV or HeV. Selected top 2 neutralizing immunogens will be evaluated in ferrets and non-human primates (NHPs), AGMs, challenge studies with either NiV-B[45] or HeV-Redlands isolate from the 2008 outbreak. MNPs are promising resources to achieve systemic effects by transdermal delivery. They are a minimally invasive, painless system, which can bypass the stratum corneum and overcome the potential drawbacks of subcutaneous injections[46]. (See **Core C** application for details).

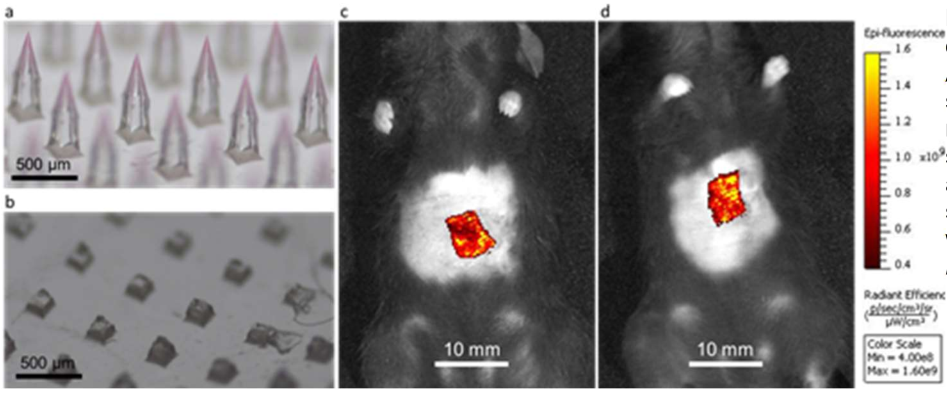

Figure 1: In vivo intracutaneous delivery efficacy of HeV-sG ± PCEP MNPs in mice. An optical stereomicroscopy image of HeV-sG AF555+PCEP CMC/Trehalose microneedles prior to (**a**) and after (**b**) *in vivo* skin application to mice. Effective administration of HeV-sG AF555 **(c)** and HeV-sG AF555+PCEP **(d)** to mouse skin *in vivo* with MNPs, captured by using a fluorescence *in vivo* imaging system (IVIS).

Manufacturing and characterization of HeV-sG ± PCEP MNPs. The technology to manufacture dissolvable MNPs incorporating HeV-sG antigen with or without polydi(sodium carboxylatoethylphenoxy) phosphazene (PCEP) as an adjuvant has been developed by **Core C**. During the development phase HeV-sG was labeled with fluorescent Alexa Fluor 555 dye, HeV-sG AF555, to visualize its penetration into skin. Spin-casting of carboxymethyl cellulose and trehalose was used to create MNPs incorporating HeV-sG AF555±PCEP into obelisk-shaped microneedles (**Figure 1a**). These HeV-sG AF555±PCEP MNPs were applied to the abdomen skin of C57BL/6 mice for 15 min and then removed. HeV-sG AF555±PCEP MNPs were imaged before and after *in vivo* skin applications by using an *in vivo* live animal fluorescent imaging system (IVIS Lumina XR). The acquired images were then post-processed using Living Image software (PerkinElmer). **Figure 1** shows a summary of the intracutaneous delivery capacity of HeV-sG±PCEP MNPs. Images of the HeV-sG AF555±PCEP MNPs before (**Figure 1a**) and after (**Figure 1b**) the patch application, confirm a nearly complete dissolution of the microneedles into the skin demonstrating that the vaccine was effectively deposited into the skin (**Figure 1c**: HeV-sG AF555 and **Figure 1d**: HeV-sG AF555+PCEP).

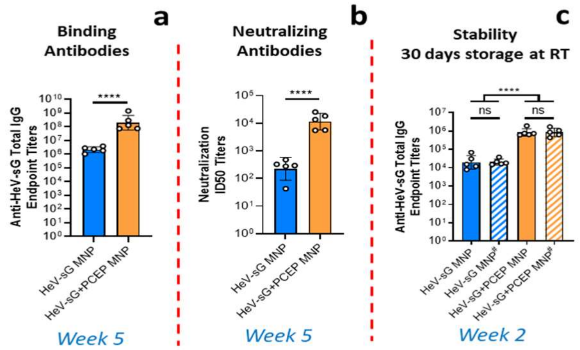

Figure 2: Efficacy of MNPs to induce humoral responses and initial MNP stability data. Mice were immunized using the prime/boost schedule. MNPs were applied to the abdominal skin of anesthetized C57BL/6 mice for 15 min, and then removed on D0 (prime) and D21 (boost). Endpoint binding titers **(a)** were determined by ELISA. Neutralizing ID_{50} titers **(b)** were obtained using the FRNT assay. Stability of the MNPs **(c)** measured as a decrease in the d14 endpoint binding titers when a 30-day-old MNP is used for immunization compared to the titers obtained with a fresh MNP.

Next, HeV-sG vaccine MNPs were tested to induce immune responses in mice. Groups of 5 mice were immunized on D0 (prime) and D21 (boost) with either non-adjuvanted or adjuvanted HeV-sG MNP. Pooled sera from D35 were tested by ELISA for total binding antibodies (endpoint binding titers), **Figure 2a**, and to neutralize henipavirus by using the recently developed FRNT reporter assay[44]. These preliminary data show that MNPs induce significantly higher immune responses. Other tests indicate the efficacy of the MNP is comparable or higher than that of the clinical HeV-sG with Alhydrogel vaccine formulation (see **Core C: Figure 4a**).

To test the stability, mice were immunized with fresh (group 1) and 30-day-old MNP (group 2) by using a single dose immunization. Mice were bled on D14 post immunization and the total IgGs were measured by endpoint antibody binding titers ELISA. **Figure 2c** shows no statistically significant differences in the antibody binding titers induced by the fresh and the 30-day-old MNPs.

Experimental Design.

Aim 1.1: Manufacturing of the MNPs. GLP-like HeV-sG is available in stock, and manufactured by Catalent Pharma Solutions, LLC. Catalent has developed the HeV-sG GLP manufacturing process for Profectus BioSciences, Inc. who led the HeV-sG subunit vaccine preclinical studies. A GLP-like lot manufactured by using the developed process was utilized in the rabbit GLP toxicology study with HeV-sG/Alum formulation, which is currently in clinical studies funded by CEPI. The remaining 3 immunogens will be prepared and delivered to us by **Genovac GmbH**, Freiburg, Germany. **Core C** will prepare fresh MNPs with each of NiV-sG_{tet}, NiV-sF_{stb}, HeV-sF_{stb}, HeV-sG+NiV-sF_{stb} and HeV-sG, all adjuvanted with PCEP. The technology for fabricating MNPs pioneered by Bediz et al.,[47] was developed and is described in detail in the **Core C** application. Based on the experience with fabricating HeV-sG MNP, we expect the technology to be plug and play applicable to the remaining 3 immunogens, also to the combo immunogen with minimal or no adjustments.

Aim 1.2: Mouse immunogenicity study. Six groups of 5 female C57BL/6 mice will be used in the mouse immunogenicity study, which will be executed by **Core C**. Group 1 will be immunized with NiV-sG_{tet}+PCEP formulation MNPs, group 2 – with NiV-sF_{stb}+PCEP, group 3 – with HeV-sF_{stb}+PCEP, group 4 – with HeV-sG+PCEP, group 5 – with combo HeV-sG+NiV-sFstb+PCEP, and group 6 will be naïve mice to read the background naïve mice immunity. Schematics of the immunization and bleeding schedule is given in **Figure 3**. The sera will be tested for binding to the respective immunogens and for cross-binding with the other 3 immunogens by ELISA. IgG1 and IgG2c titers will be recorded. The sera will also be tested at **USUHS** for neutralization of each of HeV and NiV-B by using the respective reporter rCedV chimeras – rCedV-HeV-GFP and rCedV-NiV-B-GFP in the FRNT assay[44]. Cellular immune responses will also be evaluated at the **University of Pittsburg** as described in the **Core C** application (within Core C Aim 2).

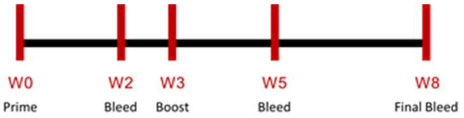

Figure 3. Immunization and bleeding schedule for the mouse immunogenicity study.

Aim 1.3: Efficacy in ferrets. The 2 immunogens with the best immune responses on W2 and W5 combined, *Imun1* and *Imun2*, from the mouse study, will be tested in ferret challenge protection studies executed at **UTMB**. Four vaccine groups and one control group of 6 ferrets each will be challenged with lethal doses of either NiV-B or HeV Redlands, 5000 $TCID_{50}$, in year 2 of the project. Groups 1 and 3 will be immunized with *Imun1*+PCEP MNPs, groups 2 and 4 – with *Imun2*+PCEP and group 5 will be naïve nonvaccinated ferrets. Groups 1 and 2 will be immunized on D0 and D21 (prime/boost schedule), while groups 3 and 4 will be immunized once, on D0. Immunization, challenge and blood and swab sampling schedules are diagramed in **Figure 4**. All protected animals and survived controls will be euthanized on day 21 post-infection (end of study) and tested for cultivatable virus and viral genome in the lung and brain tissue in addition to the blood samples and swabs.

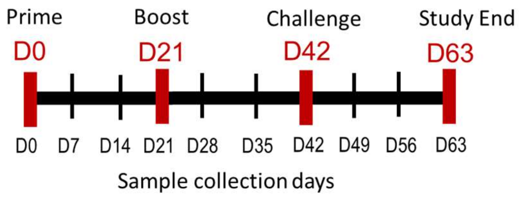

Figure 4. Expected schedule to immunize ferrets and AGMs in the planned efficacy studies. Blood and swabs, oral and rectal, samples will be taken weekly, on days 0, 7, 14, 21, 28, 35, 42, 49, 56 and 63. Single dose groups do not receive boost immunization on D21.

Aim 1.4: Efficacy in AGM. This challenge study will be performed in year 3 of the project at **UTMB**. The immunogen that provides the best cross-protection in the ferret studies will be tested to protect AGMs against either NiV or HeV. Fresh MNPs will be fabricated for this study. Two groups of 3 monkeys per challenge virus, total 4 groups of 3 AGMs each, will be vaccinated by applying the MNP (groups 1 and 2 will be immunized on D0 and D21 while groups 3 and 4 will be immunized only on D0, boost will be skipped). One control per virus will be naïve nonvaccinated. Time schedule will mimick the ferret study schedule in **Figure 4**. Groups 1 and 3 will be challenged with NiV-B, groups 2 and 4 will be challenged with HeV Redlands.

Aim 1.5: Stability Studies will be initiated starting with the mouse immunogenicity studies and finishing at the AGM challenge studies end. Each quarter, a group of 5 mice will be single dose immunized and the SNT titers will be evaluated 2 weeks post immunization by using the FRNT assay[44]. We assume that the MNA patches are stable if the average SNT titers have fallen less than 33%, i.e., from relative 100 the SNT titer stays above 67. Additional stability testing will be initiated with the freshly manufactured MNP for the AGM challenge study.

Bio-sample collection and RNA test. Swabs (oral and rectal), blood and tissue samples (lung, brain) will be tested for viral RNA by TaqMan PCR performed by using the primer sets and probes[35].

Virus isolation will only be attempted from specimens positive for NiV or HeV genome by PCR. Virus titration will be performed by plaque assay on Vero cells. The limit for detection will be 25 pfu/ml.

Expected results, potential pitfalls and alternatives. We expect to obtain sterile protection in AGMs. There is a minimal risk of not finding any protecting immunogen given the complete protection provided by a single dose HeV-sG subunit vaccine[41]. The foreseen problems are already reflected in the experimental design. The team is sufficiently experienced to handle and resolve any possible unforeseen issues and pitfalls.

<u>Aim 2:</u> Rescue Langya virus and construct LayV and AngV glycoprotein bearing reporter virus tools.

Rationale and Preliminary Data: Negative stain electron microscopy (EM) was performed on LayV F and G glycoproteins. The 2D (**Figure 5a**) and 3D classifications (**Figure 5b**) of LayV F and G revealed distinct trimer and tetramer assembly, respectively. In addition, using LayV sF and LayV sG mAbs that we generated at USUHS, we performed ELISAs and demonstrated that there was a dose dependent increase in LayV sF (**Figure 5c**) and LayV sG (**Figure 5d**) binding. This data forms the premise for rescuing a rCedV bearing LayV F and G glycoproteins. We will design and construct a full-length recombinant LayV that encodes a green fluorescent protein (GFP). The LayV F and G coding sequences will be based on the LayV isolate SDQD_H1801 (GenBank: OM101125.1). The GenBank accession numbers for LayV F and LayV G are UUV47205.1 and UUV47206.1, respectively. The authentic, replication competent henipavirus platform, rCedV is an innovative approach that can be utilized at BSL-2. We will design, construct and rescue a new rCedV chimera that encodes the envelope glycoproteins (fusion (F) and attachment (G) glycoproteins) of LayV, i.e., a rCedV-LayV reporter virus encoding GFP. We will characterize it using cell-based infection tropism and growth kinetic assays.

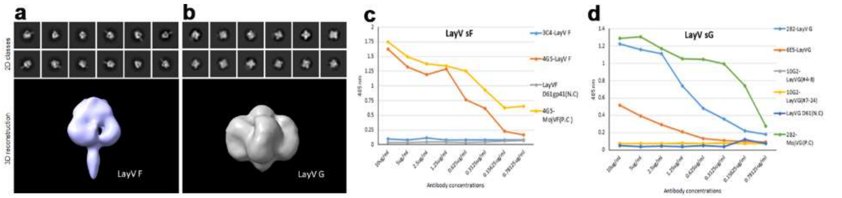

Figure 5. Negative stain EM analysis of LayV envelope glycoproteins. 2D and 3D classifications of LayV F trimers (**a**) and LayV G tetramers (**b**). ELISA indicating cross-reactivity between Mojiang virus (MojV) F mAb (**c**, yellow) with LayV sF and MojV G mAb (**d**, green) with LayV sG.

We utilized an established quantitative fusion assay based on a dual-split-luciferase reporter assay[42,43,48,49] to determine functionality of Angavokely virus (AngV) envelope glycoproteins (F and G glycoproteins). In this assay, content mixing between a virus-infected effector cell or a cell that expresses the F and G glycoproteins and a target cell expressing or not the known henipavirus receptors allows the two halves of Renilla luciferase to functionally interact and produce a luciferase signal that can be measured[43] (**Figure 6a**).

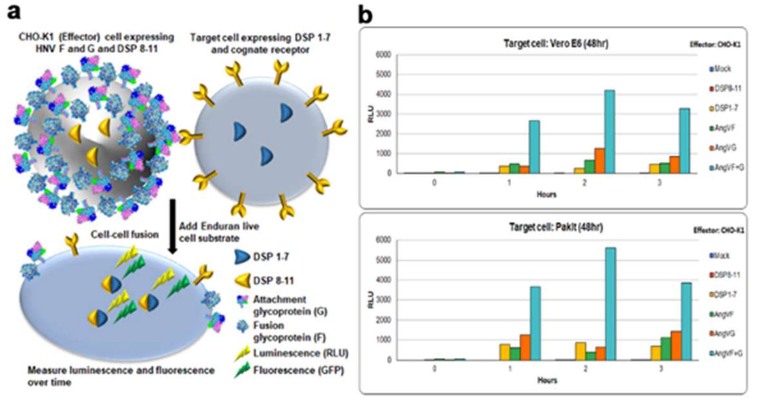

Figure 6. AngV F and G cell-cell fusion using a dual split luciferase. A schematic representation of the dual split luciferase cell-cell fusion assay (**a**). A quantitative dual split luciferase cell-cell fusion assay with AngV F and G plasmid constructs (**b**).

High levels of fusion were observed in Vero E6 cells and the bat kidney cell line, PaKiT, indicating that the AngV glycoproteins are functional and can mediate fusion in susceptible cells (**Figure 6b**). Based on this data, the rescue of a rCedV-AngV reporter virus encoding a GFP and a luciferase protein (Luc) is feasible. We will characterize these viruses using cell-based infection tropism and growth kinetics assays. In other projects in our lab, we have previously used reverse genetics to generate several types of replication competent VSV-GFP reporter viruses including those encoding Australian bat lyssavirus (ABLV) G glycoproteins (VSV-ABLV G-GFP)[50,51], as well as employed reverse genetics to rescue authentic ABLV and various reporter gene-encoding viruses[52,53]. Using a similar strategy, we will also construct a recombinant replication competent VSV encoding the AngV F and G glycoproteins. We will generate reporter versions encoding either GFP or Luc.

Experimental Design.

Aim 2.1: Design and construct a recombinant Langya virus reporter virus. Figure 7 diagrams each of the proposed virus constructs that will be generated. The genome design, length and position of the green fluorescent protein gene are shown, and the experimental plans are described below. LayV helper plasmids for the N, P, and L genes will be synthesized. To construct the rLayV-GFP antigenome plasmid, large gene fragments of LayV will be synthesized and sequentially cloned into pOLTV5$_{opt}$ (**Figure 7a**). Unique restriction sites will be chosen to facilitate ligation of the LayV DNA fragments and to ensure adherence to the genomic “rule of six”. All cloning will be performed with *E.coli* Stbl2 cells. The fully sequenced plasmids will be transferred to **Dr. Thomas Geisbert at UTMB**. Virus rescue will be conducted in collaboration with **Core E** at UTMB. In addition, rLayV will be examined in vivo by **Core E**.

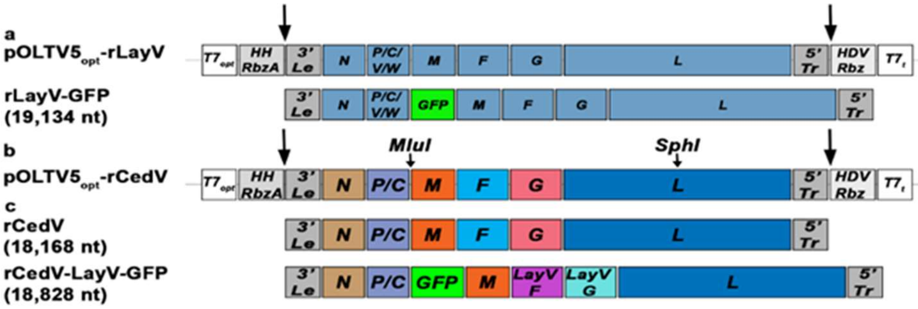

Figure 7. Schematic representation of recombinant reporter viruses. The pOLTV5$_{opt}$-rLayV plasmid (**a** top). The arrows indicate regions of self-cleavage. The rLayV-GFP genome (**b** bottom). The pOLTV5$_{opt}$-rCedV plasmid (**c**). The long arrows indicate regions of self-cleavage. Shown are the unique restriction sites MluI and SphI that will be used to construct rCedV-LayV-GFP. (**c**) The rCedV-LayV-GFP genome.

Aim 2.2: Construct, rescue and characterize a recombinant Cedar reporter virus encoding Langya virus envelope glycoproteins.

Generation of rCedV encoding LayV envelope glycoproteins. rCedV-LayV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the LayV F and G coding sequences. The CedV non-coding intergenic regions are retained to adhere to the genomic “rule of six”. Unique restriction sites, will facilitate the insertion of the LayV F and G gene cassette into the genome clone (pOLTV5$_{opt}$-rCedV) (**Figure 7b**) generating rCedV-LayV-GFP (**Figure 7c**). All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-LayV-GFP antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (henipavirus CPE). BSR-T7/5 cells and supernatants from successful rescue wells are collected and passaged onto naïve Vero 76 cells (T-75 flasks) to prepare a virus stock. When maximal syncytia and GFP is observed (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C[42,43,54].

In vitro characterization of rCedV-LayV-GFP. The growth kinetics of rCedV-LayV-GFP compared to rCedV or rCedV-NiV/HeV chimeras will be assessed by infecting Vero cells with MOIs of 0.01, 0.1 and 1 and progeny virus recovered in 24hr intervals over a 72hr period and titered. In parallel experiments, infected cells will also be imaged for fluorescence and syncytia (henipavirus CPE). **Figure 8** illustrates the syncytia (indicated by the yellow arrows) formed in Vero E6 cells infected with either rCedV-NiV-B-GFP or rCedV-HeV-GFP chimeras. The rCedV-LayV-GFP neutralization assays will be conducted by FRNT. We have also already generated several murine mAbs to LayV F and G (3C4-LY and 4G5-LY to LayV F; and 2B2-LY and 6E5-LY to LayV F) and these will be used in neutralization assays. In addition, we will develop rabbit sera to LayV N, P and L proteins.

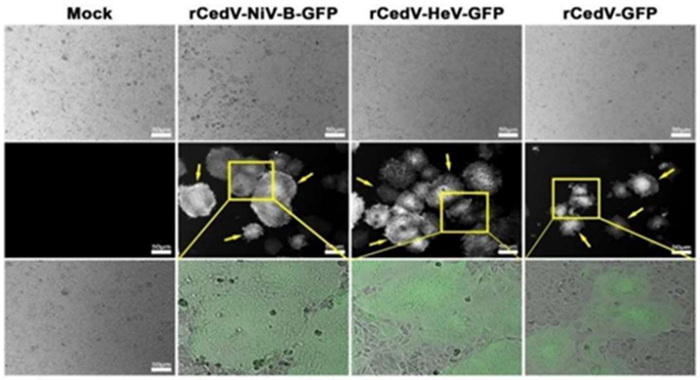

Figure 8. Syncytia induced by rCedV expressing NiV-B or HeV envelope glycoproteins. Vero E6 cells were uninfected (Mock) or infected with either rCedV-NiV-B-GFP, rCedV-HeV-GFP, or rCedV-GFP. All images were taken 24hrs post infection. The respective zoomed-in fluorescence images (3rd row) are regions from the yellow boxes. Arrows indicate giant multinucleated cells (syncytia). Representative images from three independent experiments are shown. Scale bar, 50 µm.

Aim 2.3: Construct, rescue and characterize recombinant reporter viruses encoding Angavokely virus envelope glycoproteins.

Generation of rCedV encoding AngV envelope glycoproteins. Figure 9 diagrams each of the proposed virus constructs that will be prepared. The genome designs, lengths and position of the *GFP* and *Luc* reporter genes are also shown, and the methodology and experimental plans are described below. rCedV-AngV-GFP will be produced by synthesizing large gene cassettes comprising CedV F and G untranslated intergenic regions flanking the AngV F and G coding sequences. The AngV F and G coding sequences will be based on the GenBank: ON613535.1 sequence. The GenBank accession numbers for AngV F and AngV G are UVG43988.1 and UVG43989.1, respectively. The CedV non-coding intergenic regions are retained to adhere to the genomic "rule of six". Unique restriction sites, will facilitate the insertion of the AngV F and G gene cassette into the rCedV antigenome plasmid (**Figure 9a**) generating rCedV-AngV-GFP (**Figure 9b**). The rCedV-AngV-Luc clone will be produced by swapping the reporter gene coding sequences. All cloning is performed in *E. coli* Stbl2 cells and plasmids verified by sequencing. Rescue is by transfection of BSR-T7/5 cells (12-well plates) with CedV helper plasmids, pCMV-CedV-N, pCMV-CedV-P, pCMV-CedV-L and pOLTV5$_{opt}$-rCedV-AngV-GFP or pOLTV5$_{opt}$-rCedV-AngV-Luc antigenome plasmid. Typically, after 4 days, cells will be observed for GFP expression and syncytia (henipavirus CPE). BSR-T7/5 cells and supernatants from successful rescue wells are collected and passaged onto naïve Vero 76 cells (T-75 flasks) to prepare a virus stock. When maximal syncytia and GFP is observed (~2–3 days), supernatants are collected and clarified and stored as single-use aliquots at -80°C. Virus stocks will be characterized and deep sequenced. Working virus stocks are prepared by culture amplification and titered by plaque assay and stored as single use aliquots at -80°C[42,43,54].

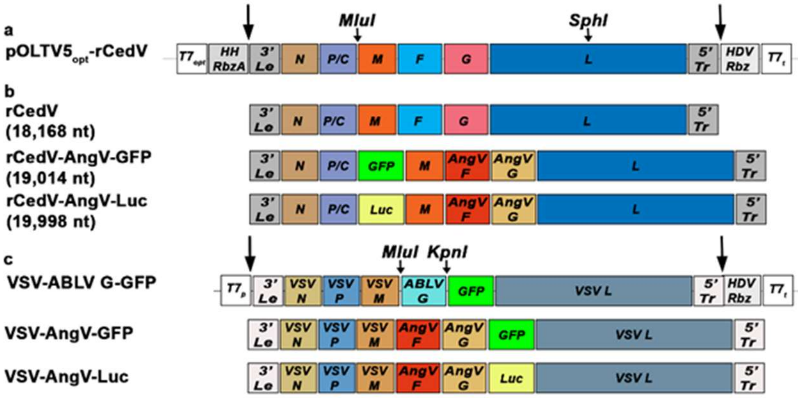

Figure 9. Schematic representation of the AngV chimeric reporter viruses. The pOLTV5$_{opt}$-rCedV plasmid (**a**). Shown are the unique restriction sites MluI and SphI that will be used to construct rCedV-AngV-GFP and rCedV-AngV-Luc. The rCedV-AngV-GFP and rCedV-AngV-Luc genome (**b**). Shown are the unique restriction sites MluI and KpnI that will be used to construct VSV-AngV-GFP and VSV-AngV-Luc (**c**). The long arrows indicate regions of self-cleavage.

Generation of a VSV encoding AngV envelope glycoproteins. We will also construct reporter gene encoding versions of a replication competent VSV encoding the AngV F and G glycoproteins (GFP and Luc) (**Figure 9c**).

A large gene cassette comprising VSV untranslated intergenic regions flanking the AngV F and G coding sequences will be synthesized. Unique restriction enzyme sites, will facilitate the insertion of the AngV F and G gene cassette into the VSV backbone plasmid to generate VSV-AngV-GFP (**Figure 9c**). The VSV-AngV-Luc clone will be produced by swapping the reporter gene coding sequences. Cloning procedures are performed in *E. coli* Stbl2 cells and all plasmid clones verified by sequencing. Rescue of VSV-AngV-GFP and VSV-AngV-Luc, will be performed in BSR-T7/5 cells, in 12-well plates, transfected with helper plasmids, VSV-N, VSV-P, and VSV-L and the VSV-AngV-GFP or VSV-AngV-Luc antigenome plasmids. After 48hrs the cells and supernatants are collected and subjected to freeze-thawing and clarified by centrifugation. Amplification of rescued virus is performed using HEK293T cells (6-well plates) by inoculation with the supernatant from step 1. Typically, when GFP fluorescence and/or cytopathic effects (CPE) is observed, the cells and supernatants are harvested as above and the virus stocks stored at -80°C. Larger viral stocks are prepared in T-150 flasks in HEK293T cells, and harvested virus supernatants are purified by buffered sucrose cushion centrifugation and virus pellets resuspended in 10% sucrose/TNE buffer, and small volume single use aliquots stored at -80°C. All virus stocks are deep sequenced. Virus stocks (GFP) are titered (infectious units/ml (IU/ml)) by serial dilution on HEK293T cells in 96-well black walled plates. At 24hrs post-infection plates are fixed with 4% formaldehyde, washed 3x with diH$_2$0 and imaged (fluorescence) with a CTL S6 analyzer. Luciferase encoding VSV stocks are titered by plaque assay[55].

Characterization of the recombinant reporter viruses in cell-based infection assays: The replication kinetics of the rCedV-based and VSV-based AngV F/G encoding viruses will be assayed by Vero cell culture infection using MOIs of 0.01, 0.1 and 1, and progeny virus recovered in several 24hr intervals and titered. rCedV-AngV-GFP virus replication can be compared to rCedV or rCedV NiV/HeV chimeras. Similarly, VSV-AngV F/G virus replication can be compared to expected virus production of wildtype VSV or VSV-ABLV G[51]. The rCedV-AngV-GFP and VSV-AngV-GFP assays will be conducted by FRNTs and rCedV-AngV-Luc and VSV-AngV-Luc in luciferase assays.

Expected results, potential pitfalls and alternatives. We expect that rCedV-LayV-GFP and rCedV-AngV reporter viruses will be readily rescued and viable. In addition, we expect that these chimeric viruses will induce syncytia and replicate to high titers. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9. In the event that the rescue of rCedV chimeric viruses are not viable, multiple strategies may be examined. 1) test different ratios of helper plasmids and antigenome plasmid; 2) perform rescue in different cell lines; 3) construct alternate versions of the LayV and/or AngV F and G genes within the antigenome plasmids, such as, fuse the LayV and/or AngV F and G ectodomains with the transmembrane and/or cytoplasmic tail domains of the corresponding CedV F and G elements which may facilitate virus particle formation and membrane fusion activity.

Aim 3: Evaluate HNV-specific antibodies and nanobodies developed by the Center's RPs and Core D.

Rationale and Preliminary Data. We established a surrogate neutralization assay for the pathogenic henipaviruses, NiV and HeV using the rCedV platform[44]. This rCedV chimeric system can serve as surrogate viruses for authentic NiV and HeV in neutralization assays without the requirement for BSL-4 containment. Neutralization values of well-characterized NiV/HeV cross-reactive neutralizing mAbs highly correlated between rCedV-NiV-B-GFP and rCedV-HeV-GFP and authentic NiV-B and HeV at BSL-4 when tested by conventional PRNT[44]. The Pearson correlation analysis between the rCedV chimeras BSL-2 PRNT and the NiV-B or HeV BSL-4 PRNT is shown in **Figure 10a**. We further developed the rCedV-NiV-B-GFP and rCedV-HeV-GFP neutralization assay into a high-throughput and quantitative assay that is based on the reduction of GFP foci, a FRNT[44]. The Pearson correlation analysis between the chimeras PRNT and FRNT is shown in **Figure 10b**. Taken together, these data demonstrate that rCedV-NiV-B-GFP and rCedV-HeV-GFP chimeric viruses are an ideal set of suitable surrogate viruses for authentic NiV-B and HeV for conducting a rapid FRNT-based assay for assessing NiV and HeV antibody neutralization.

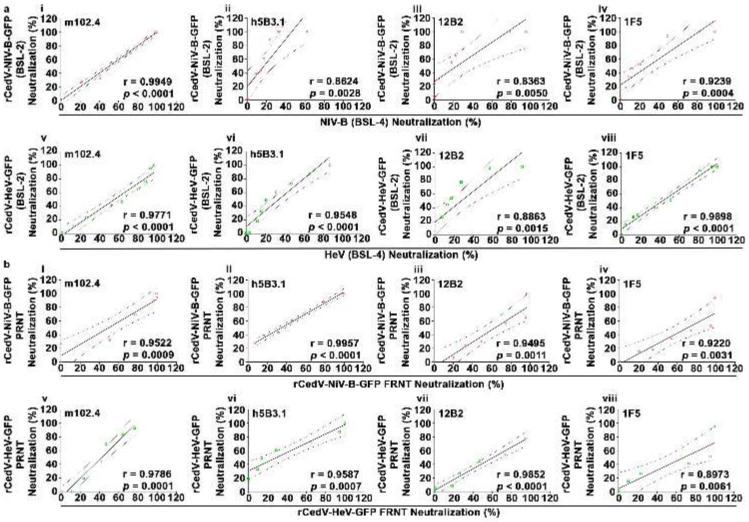

Figure 10. Pearson correlation analysis of rCedV chimeras. Pearson correlation analysis of PRNT neutralization (%) values of rCedV-NiV-B-GFP versus NiV-B (**a**, **i-iv**) and rCedV-HeV-GFP versus HeV (**a**, **v-viii**). Pearson correlation analysis from PRNTs (y-axes) and FRNTs (x-axes) of rCedV-NiV-B-GFP (**b, i-iv**) and rCedV-HeV-GFP (**b, v-viii**). Neutralization values with mAbs m102.4, h5B3.1, 12B2 or 1F5 are shown. The Pearson correlation coefficient 'r,' p-value (two-tailed), linear regression line (solid lines), and 95% confidence intervals (dashed lines).

Experimental Design.
Here, using the newly developed tools (rCedV-LayV-GFP, rCedV-AngV-GFP, VSV-AngV-GFP and VSV-AngV-Luc) we will assess for neutralizing activity, a variety of henipavirus specific mAbs and/or sera from henipavirus immunized mice that will be generated by **Core D**. The FRNT is high throughput and performed in 96-well plates to establish a 7-point dose response. Serially diluted immune sera or mAbs are mixed with either rCedV-NiV-B-GFP or rCedV-HeV-GFP for 2hrs. The virus-mAb or virus-sera mixtures are then added in triplicate to confluent pre-seeded Vero 76 cells in black-walled clear bottom 96-well plates and incubated for an additional 24hrs. Plates are then fixed and imaged and fluorescent foci counted using the CTL Basic Count software. The 50% inhibitory concentration (IC_{50}) will be determined as the mAb concentration or serum dilution at which there was a 50% reduction in fluorescent foci versus untreated control wells. Neutralization assays will typically be conducted as 3 independent repeats and the data generated from these assays will be analyzed and graphed using GraphPad Prism 9.
Expected results, potential pitfalls and alternatives. We do not anticipate any unexpected limitations in assessing the neutralization potential of antibodies and sera generated from other research projects and/or cores as we have successfully demonstrated that the rCedV-GFP chimeric FRNT platform can serve as a surrogate BSL-2 neutralization assay that is high throughput with a fast turnaround time.

Aim 4: Validate PPZ-MNP platform with another paramyxovirus-specific antigen in Phase 2.

At completion of Phase I we will have i) a procedure to fabricate PPZ adjuvanted MNP using sG, sF or a combination of both viral glycoproteins; ii) generated rLayV with an associated animal model in collaboration with **Core E** with reporter virus construct (rCedV-LayV-GFP); and iii) generated reporter viruses AngV (rCedV-AngV-GFP, VSV-AngV-GFP and VSV-AngV-Luc). Here, in Phase II we propose to test the hypothesis that the PPZ-MNP vaccine platform technology can be adapted and transferred as a 'plug and play' strategy for other paramyxoviruses, namely the divergent henipaviruses LayV and AngV. The major goal rests on the rescue of LayV and establishing an infection/disease model of this most recently discovered pathogenic, zoonotic, HNV. Nevertheless, if rescue of rLayV with an associated animal model is not achieved, we will still be able to test the the MNP approach as proof-of-concept to the extent of generating robust immune responses in animals and testing neutralizing antibody responses using both LayV and AngV reporter virus systems.

PPZ-MNP manufacture. The fabrication of the MNPs by **Core C** will be prepared for both the F and G viral glycoproteins: LayV-sG, LayV-sF, AngV-sG and AngV-sF depending on the data and outcomes, and vaccine down-selection in Phase I we may also include a combination of sG and sF. Vaccine antigens will have been prepared by within **Core D**. It will remain important to evaluate both the attachment and fusion glycoprotein immunogens for LayV and AngV in Phase II. Although the preponderance of data to date for the pathogenic prototype HNVs (NiV/HeV) indicates that the attachment glycoprotein (G) alone can serve as an effective vaccine immunogen, this is presently unknown for these two divergent henipaviruses, so it remains prudent to test both sF and sG in this regard.

Immunogenicity. Groups of 5 mice will be utilized for each of the chosen immunogens and one control nonimmunized group will serve to measure the naïve mice background immunity. Sera will be drawn as scheduled in **Figure 3**. ELISA titers of sera to vaccine immunogens will be evaluated by **Core C** and sera will be evaluated for virus neutralization with newly developed reporter viruses. Cellular immune responses will be assessed as described in **Aim 1**.

Animal challenge studies. The experimental design for these studies will be adjusted once the animal model has been developed. The basic design will follow those for ferrets and AGMs described in **Aim 1**. The immunogen will be chosen based on the results from the neutralization tests described above.

Expected results, potential pitfalls and alternatives.

We fully anticipate that LayV and AngV recombinant glycoprotein based MNPs will be possible because we have already produced native-like sG and sF ectodomains of each of these viruses. The immunizing mice with the MNPs using the recombinant LayV and AngV recombinant glycoprotein immunogens are likely to be uncomplicated, we will be able to rapidly assess immune mouse sera using newly generated reporter viruses. The new data will also determine whether the sG or sF is the immunogen of choice for eliciting the higher virus neutralization titer. In the absence of rescue of authentic recombinant LayV (rLayV) and establishing an animal model capable of measuring virus infection, immune responses, and/or pathogenesis, we expect at a minimum the establishment of an ability to measure virus infection in cell-based assays and its inhibition, using either the generated reporter viruses or a cell-cell fusion surrogate assay. The results obtained from the mouse immunogenicity studies, together with the virus neutralization assays will provide a strong foundation to support the advancement of a potential anti-LayV and/or anti-AngV vaccine MNPs.

TITLE: Vaccines and antibodies to henipavirus
Funding announcement: RFA-AI-23-020
Funding Title: Research and Development of Vaccines and Monoclonal Antibodies for Pandemic
Preparedness (ReVAMPP) Centers for Bunyavirales, Paramyxoviridae and Picronaviridae
PRINCIPAL INVESTIGATOR: Christopher Broder, Ph.D., Site Principal Investigator
Moushimi Amaya, Ph.D and Antony Dimitrov, Ph.D., Co-investigators
Prime PI: Thomas Geisbert, Ph.D., UTMB
Period of Performance: March 1, 2024 - February 28, 2029

Project Summary/Abstract

Pathogenic RNA viruses represent continuous infectious disease and pandemic threats to public health. Among these are the two emerged zoonotic paramyxoviruses: the ‘prototype’ henipaviruses (HNVs); Nipah virus (NiV) and Hendra virus (HeV), discovered in the mid to late 1990s. The prototype HNVs have a uniquely broad tropism capable of infecting 18 species across 6 orders of mammals using the conserved ephrin-B2 and -B3 ligands as entry receptors. NiV and HeV infection often results in a systemic and fatal respiratory and/or neurological disease in multiple mammalian species including humans. NiV and henipaviral disease are also included in the WHO List of Priority Pathogens, and they are significant biothreats to humans and livestock in South and South East Asia and Australia. HNVs have two membrane glycoproteins: the attachment glycoprotein (G) and the fusion glycoprotein (F) that are the major targets of neutralizing antibodies and the focus of all vaccine and antiviral monoclonal antibody (mAb) strategies. The most extensively studied HNV vaccine is a soluble recombinant form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including nonhuman primates (NHPs). With no licensed vaccines or treatments available for human use, this project will use the prototype HNVs as a model to develop, test, and translate a novel vaccination platform (a thermostable, needle-free, adaptable, and widely deployable polyphosphazene (PPZ) adjuvanted dissolvable microneedle patch (MNP)). Preliminary data demonstrates potent immunogenicity of a PPZ-MNP-HeV-sG vaccine in mice, inducing robust antigen-specific HNV cross-neutralizing antibody and cellular immune responses. The MNP vaccines will be used to evaluate HeV-sG and compare stabilized soluble forms of HNV G and F (sG_{tet} and sF_{stb}) and combinations in challenge studies. A reverse genetics system has been developed to generate recombinant, nonpathogenic Cedar virus (rCedV) and rCedV chimeric virus tools by swapping the G and F glycoproteins with those of NiV/HeV as a rapid, surrogate, BSL-2 high-throughput neutralization platform to be used to rapidly evaluate HNV vaccine responses. Also, divergent and pathogenic zoonotic HNVs have been discovered including the related rodent borne Mòjiāng virus and Langya virus (LayV)), and the divergent bat-borne Angavokely virus (AngV). This project will develop and test the rapid, adaptable and readily deployable MNP vaccine platform together with new virological tools to facilitate the translational nature of this pandemic preparedness approach. Specifically, we will: 1) Develop PPZ-MNP-based sG_{tet} and sF_{stb} prototype HNV vaccines; 2) Construct new reporter virus tools; 3) Evaluate vaccine-induced immune responses and HNV-specific mAbs and nbs; and 4) Validate the PPZ-MNP platform with another paramyxovirus antigen.

USUHS
Site Principal Investigator: Christopher Broder, Ph.D.
Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

AUTHENTICATION OF KEY BIOLOGICAL AND/OR CHEMICAL RESOURCES

Molecular biology tools. Oligonucleotides and gene fragments for PCR and cloning will be purchased and verified by internal quality control at Twist Biosciences, Integrated DNA Technologies or Genscript. All clonal products will be validated by whole plasmid sequencing. All new expression constructs are verified by (1) restriction digest and electrophoretic separation of fragments to ensure fragments of the predicted size are generated and (2) sequencing to ensure the correct sequence is present with no spurious mutations.

Cells. All cells were originally obtained from ATCC or collaborators and maintained by the PI. They are tested monthly for mycoplasma contamination by two complementary methods (qPCR analysis and Lonza MycoAlert biochemical luminescence-based assay). Cells used will be used from the listed initial passage number for a maximum of 50 passages, and then discarded for a fresh vial from the working freezer stock to prevent any long-term selection of altered cell populations. To avoid cross-contamination between different cell lines, only one cell line is used at a time in a biosafety cabinet. Cell lines are routinely validated using either flow cytometry and/or functional tests.

Recombinant Cedar viruses and recombinant vesicular stomatitis viruses (VSV). Viruses are validated through genome sequences or infectivity/functional tests. SOPs, as detailed documents, for work with either recombinant Cedar virus, recombinant Cedar virus chimeras (encoding either Hendra virus or Nipah virus F and G glycoproteins), and recombinant VSVs have been established in the Broder/Amaya laboratory and all laboratory staff are required to be familiar with this documentation. Rescued recombinant viruses are validated through genome sequencing and compared to the original cloned full length viral genomes. Use of recombinant Cedar virus recombinant Cedar virus chimeras has been approved at USU.

Antibodies. Antibodies are tested for specificity as follows: (1) For antibodies used repeatedly in the PI's lab, the staining/blotting performance of new antibody lots are compared against previous lots; (2) For new antibodies, banding/staining patterns are compared against published data; (3) Whenever possible, new antibodies are also validated using objective controls, such as cells known to lack the protein of interest (e.g., knockout cells) or cells engineered to over-express an epitope-tagged form of the molecule (i.e., staining by the new antibody is compared side-by-side with staining by the epitope-tag antibody).

Commercial chemical reagents. Such reagents are validated by one or both of the following: (1) performance comparison to previous lots of the same reagent; (2) use in an established assay that incorporates one or more validated performance controls.

Rigor and Reproducibility

The Broder laboratory employs quality systems to ensure rigor, reproducibility, and robust and unbiased results in all experiments. All findings in our work have been and will be validated by multiple independent lines of evidence to ensure scientific rigor. All experiments are carried out with several internal controls with multiple replications to guarantee reproducibility.

Budget Justification - RP 2 - Broder

The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (HJF) in partnership with the Uniformed Services University of the Health Sciences (USUHS) will manage this proposal, if awarded.

Key Personnel:

Christopher Broder, Ph.D., (Principal Investigator, 1.2 calendar months, 10% effort), is a Professor of Microbiology and Immunology at USUHS and will serve as PI on the proposed project. He is a leading expert in henipavirus biology and genetics, as well as development of glycoprotein-based vaccines and monoclonal antibody-based therapeutics against these viruses; many tested in collaboration with Dr. Thomas Geisbert (Project Lead on this application). Dr. Broder has more than 15 years of collaborative research projects with Dr. Geisbert focused on henipaviruses and together have published on a variety of henipavirus countermeasures including the use of recombinant CedVs. Dr. Broder's group recently developed the reverse genetics platform for designing and rescue of recombinant Cedar henipaviruses (rCedV) that can be utilized at BSL-2, some of which have been successfully used in drug library HTS assays and one report on the successful use of Cedar virus in antiviral drug discovery for henipaviruses including Nipah (NiV), Hendra (HeV) and CedV has been published in collaboration with Dr. Geisbert. Dr. Broder's group generated and characterized the recombinant Cedar chimeric viruses that were used to generate the preliminary data for this application. He will oversee all aspects of the recombinant Cedar chimeric virus construction and characterization. In addition, he and Dr. Amaya will collaborate on the design of all experiments and the preparation of progress reports and manuscripts. Dr. Broder is a federal employee and no salary support is requested.

Moushimi Amaya, Ph.D., (Co-investigator, 2.0 calendar months, 16.67% effort). Dr. Amaya is an experienced biochemist and molecular virologist with expertise in a variety of areas including gene cloning and expression and mutagenesis specifically with viruses and viral culture and propagation, and viral protein purification and analysis. She has considerable experience in henipavirus reverse genetics systems. Using the rCedV platform, Dr. Amaya designed, generated and characterized replication competent chimeric viruses as non-reporter and reporter versions that express the envelope glycoproteins of either NiV-Bangladesh (NiV-B) (rCedV-NiV-B) or HeV (rCedV-HeV) instead of those of CedV. In a collaborative effort, Drs. Amaya, Broder and Geisbert demonstrated that the chimeras can serve as suitable surrogate viruses for authentic NiV and HeV viruses. Dr. Amaya developed and characterized the fluorescent reporter chimeric viruses in a high throughput fluorescence reduction neutralization test (FRNT) to analyze neutralization potencies of sera from henipavirus immunized animals and monoclonal antibodies. She will design, oversee and conduct the research plans related to the generation and characterization of the rCedV chimeric viruses and VSV reporter viruses outlined in this proposal. She will develop, perform quality assurance and test the new chimeric viruses for use in henipavirus neutralization assays. Dr. Amaya is a federal employee and no salary support is requested.

Antony S. Dimitrov, Ph.D., (Co-investigator, 6.0 calendar months, 50% effort). In addition to Dr. Dimitrov's duty to the day-to-day operations of this ReVAMPP and the Admin Core, he will oversee and conduct the research plans related to the production and characterization of all rCedV chimeric viruses and VSV reporter viruses; including generation, quality control, and in vitro cell-based studies. Dr. Dimitrov is highly familiar with all scientific and translational development activities of the proposed ReVAMPP. He was a former member of Broder laboratory and played major roles in the development and biochemical characterization of the HeV-sG subunit glycoprotein (JVI 2005), the discovery of the NiV and HeV entry receptor ephrin B2 (PNAS 2005) and in the development, characterization and efficacy testing of the first neutralizing human monoclonal antibody to NiV and HeV, the latter studies conducted with Profectus Biosciences in collaboration with Dr. Geisbert. When at Profectus Bio, Dr. Dimitrov led their program in the pre-clinical development of HeV-sG as a subunit vaccine and the human antibody, m102.4, for treatment of henipavirus infections. Dr. Dimitrov is an employee of the Henry M. Jackson Foundation and salary support is requested.

Other Personnel

TBD (Research Assistant, 12.0 calendar months, 100% effort). This individual will provide technical laboratory support for this project. In addition, this individual will also be responsible for ordering supplies, organizing shipments, and other laboratory support as instructed by the senior staff. As an employee of the Henry M. Jackson Foundation salary support is requested for this individual.

Lianying Yan (Linda) (Manager/Lead Research Associate 3, 6 calendar months, 50% effort) has been in Dr. Broder's laboratory since 2003 and is well-versed in all aspects of the research in his laboratory. Ms. Yan is a highly trained molecular biologist skilled in expression construct design, screening techniques, and stable cell line development for protein expression using immunoprecipitation and Western blot techniques. Ms. Yan is highly experienced in designing soluble and secreted viral glycoprotein constructs and establishing stable cell-lines to express and produce, purify and characterize the proteins using protocols that include Bio-Plex bead coupling and assay development. She is also expert in confocal and fluorescent microscopy techniques and has been co-author of several manuscripts. Ms. Yan is an employee of the Henry M. Jackson Foundation and salary support is requested.

Madison Thammavong (Research Assistant I, 4 calendar months, 33% effort). Mr. Thammavong will assist Ms. Yan in the production of proteins. He will be trained as a back-up support with various laboratory responsibilities. Mr. Thammavong is an employee of the Henry M. Jackson Foundation and salary support is requested.

Kimberly Boxley, (4.0 calendar months, 33% effort), serves as the Center Financial and Post-Award Administrative Manager. Ms. Boxley, is currently a Program Manager III with the Henry M. Jackson Foundation and her office is located adjacent to Dr. Broder within the Department of Microbiology, USU. Ms. Boxley has been working in grants management for over 15 years and successfully completed the Grants Management Certificate Program (GMCP) from Management Concepts in both the federal and pass-thru tracks. She is enrolled in the Program Management Program (PMP) at the Program Management Institute. She currently manages a department portfolio of approximately $32M in direct funded research awarded during the last 3 years. Her day to day grants management includes budget analysis, employee supervision, training of project managers, forecasting burn rates and compliance issues. Ms. Boxley is an employee of the Henry M. Jackson Foundation and salary support is requested.

Supplies

The costs for materials and supplies are based on historical and current supply needs for these types of studies and on current costs for these supplies. The research teams will be engaged with numerous recombinant gene cloning strategies to produce new expression plasmids and recombinant viral stocks. Several large genomic segments will need to be synthesized and the final clones of all these viral genomes assembled and cloned into expression plasmids.

There will be five different chimeric virus stocks that will need to be prepared, qualified, stored and characterized: three rCedV chimeric viruses and two VSV reporter virus stocks. Piloting and rescuing these new viruses will require significant amounts of materials for all the plasmid preparations and transfection reagents and the multiple anticipated variations in plasmid ratios to achieve virus rescues. We estimate $2000 per construct for gene synthesis and sequencing and $4000 per construct for reagents. Once rescued and cloned each virus genome (the viral stock) will have to be deep sequenced. In addition, the proposed studies will require a significant amount of both cell line and virus culture as well consumables, disposables and reagents (enzyme substrate for the luciferase reporter assays) for the serum neutralization tests with rCedV chimeric reporter viruses. The reporter viruses will be designed and rescued within the first 2 years. The budget for supplies includes molecular biology reagents as well as bacterial culture media and supplements, although reagents and chemicals will be needed to run the assays with the newly created reporter chimeric viruses.

Categories of supplies:

Cell and virus culture media, sera and reagents
Molecular biology reagents; enzymes, primers, plasmid purification kits, ligation kits, gene synthesis, whole plasmid sequencing, virus genome sequencing
Chemicals,
Consumables; flasks, plates, pipettes, gloves, tips

Steady-Glo® Luciferase Assay System for in vitro luciferase assays
CTL S6 analyzer (Fluorescent neutralization tests) and Promega GloMax (luciferase based assays)
Other miscellaneous expenses

Indirect Costs:

HJF indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The fringe rate used is 29.42 % for Tier 1 employees and 7.29% for Tier 2 employees (all employees in this proposal are Tier 1).

The HJF indirect cost is calculated based on the value-added cost base overhead rates. The IDC rate is 36.74% USU Onsite Overhead. Additionally, 16.70% Companywide G&A and applied on the total direct cost less subaward plus the USU Onsite Overhead. For proposals including subawards, an additional 1.93% is applied on total external subaward costs.

The above fringe benefits and indirect cost rates for FY2023 were approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

Equipment

The laboratories are located in the Department of Microbiology and Immunology at USU.

The following equipment is supplied in the laboratory:

- Epifluorescence microscopy system (Fully-automated Zeiss AxioObserver epifluorescence microscope)
- BioRad BioPlex 200 HTF multiplexing system
- Luminex MagPIX multiplexing system
- BioRad iQ5 real-time PCR system
- Lonza Nucleofector 4D Shuttle – core unit and X-unit
- Coulter Z1-Dual cell counter
- centrifuges: Eppendorf 5425 microfuges (4); Beckman Allegra 25R; Thermo-Fisher Jouan GR4i; various rotors
- inverted microscopes for tissue culture (3)
- gel electrophoresis equipment for protein (7) and DNA (12) gels
- semi-dry protein transfer apparatus (4)
- Perkin-Elmer and Eppendorf thermal cyclers (5)
- ELISA plate readers (2)
- balances (6)
- pH meter (2)
- refrigerators
- freezers (-20 C, -80 C)
- platform orbital shakers (5)
- sonicator with cup horn and microtip
- bacterial shakers (6)
- heating blocks (16)
- waterbaths (14)
- biosafety cabinets (6)
- CO_2-tissue culture incubators (11)
- Thermo-Fisher Locator 4 liquid nitrogen storage tank with electronic monitoring (6)
- GE-ATKA low pressure chromatography systems, including UV detectors and fraction collectors (2)
- CTL S6 Universal Analyzer

The following equipment is supplied as common support equipment within the department:

- Fuji LAS-4010 chemiluminescence/fluorescence CCD camera imaging system
- IVIS in vivo imaging system (equipped to detect luminescence and fluorescence)
- 2D gel electrophoresis system (protein)
- Alpha-Innotech gel documentation system (EtBr-stained gels)
- MilliQ ultra-pure water system
- Nanodrop spectrophotometer
- Luminometer
- Fluorescence plate readers (2)

The University Biomedical Instrumentation Center, USUHS provides other resources and is also located on- site and provides a wide variety of services, including:

USUHS
Site Principal Investigator: Christopher Broder, Ph.D.
Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

Translational Imaging Facility

- Siemens Inveon SPECT/PET/CT Scanner
- Bruker In-Vivo Xtreme II: supports bioluminescence, X-ray, and direct radioisotopic imaging
- Bruker Biospec 70/20 USR MRI
- Image Guided Therapy 7T MR guided Focused Ultrasound System for neurological applications

Flow Cytometry

- Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers (2)
- 15-parameter FACSAria II FACS sorter, including a 541nm laser upgrade for sorting of RFP-expressing cells
- Amnis Image Stream X Mark II imaging flow cytometer with IDEAS statistical image analysis software
- Bio-Rad Bio-Plex 200 multi-analyte bioassay detection system
- Offline data analysis stations (3) with software packages including: FlowJo, WinList, and ModFit

Microscopy

- Zeiss 710NLO confocal system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm
- Zeiss 700 confocal system with 405/458/488/514/561/633 laser lines
- Zeiss Elyra PS.1 Superresolution microscope for superresolution structured illumination microscopy (SR-SIM), photoactivated localization microscopy (PALM), and direct stochastic optical reconstruction microscopy (dSTORM). System is fully equipped, including the 3D-PALM/dSTORM option.
- Becker-Hickl 2-detector FLIM system (for FRET – attached to Zeiss 710NLO)
- Zeiss AxioExaminer.Z1 upright confocal system with Coherent Chameleon multiphoton laser for in vivo imaging and electrophysiology
- Zeiss AxioImager.M2 upright microscope and MicroBrightField Stereo Investigator software (stereology analysis).
- Leica AF6000 system, including an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control
- Wide-field fluorescence microscopes (3)
- Transmission electron microscope (Philips CM100 transmission EM)
- Ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment)
- Offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph.

Genomics

- Fuji FLA-5000/LAS-3000 chemiluminescence/fluorescence CCD/laser scanning imaging systems
- ABI 9800 Fast Thermal Cycler
- ABI 7500 Real Time PCR System
- ABI 3500xl Genetic Analyzer
- ABI 394 DNA/RNA Synthesizer (2)
- ABI 3900 DNA Synthesizer
- Eppendorf epMotion 5075 VAC Liquid handling robot
- Thermo Scientific Evolution 300 UV/Vis Spectrophotometer
- Systec MediaPrep & Plate Pourer

Proteomics

- Agilent 1100 HPLC (2)
- AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer

USUHS
Site Principal Investigator: Christopher Broder, Ph.D.
Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

- AB SCIEX Q-TOF tandem mass spectrometer
- Genetix QArray2 Micro array printer

Histopathology

- Fee-for-service histology and immunohistochemistry
- Nanozoomer digital slide scanner

Structural Biology

- X-ray crystallography facility with a Rigaku HighFlux HomeLab X-ray diffraction system, including:
    - MicroMax-007 HF, a microfocus rotating anode generator
    - R-AXIS Imaging Plate detector
    - X-stream 2000 cryogenic system
    - AB Sciex 4000 QTRAP LC/MS/MS System

Facilities and Other Resources

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Broder (PI) is a tenured Professor and Chair of the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators. Dr. Broder, the PI, has had and is currently involved in active collaborations within the University, in areas of viral immunology and vaccine and antiviral therapeutics and animal model development. USU is also physically located directly across from the main NIH campus in Bethesda. The overall broad scientific environment at both USU and the NIH is highly conducive to productive collaborations. The PI often uses these resources to his advantage, both for his research objectives and interests and in assisting in adjunct faculty appointments within the Emerging Infectious Diseases graduate program for both on and off-campus scientists interested in participating in graduate education and graduate student training. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional. In addition, multi-lab Immunology journal club, Immunology data club, Virology journal club, and virology data club exist. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club.

Dr. Broder has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., Bruker In Vivo Xtreme II; Siemens Inveon SPECT/PET/CT Scanner) are not overbooked and therefore readily available to the laboratory personnel. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase advanced and very expensive equipment, including the Zeiss 710NLO system and the FACSAria 15-parameter cell sorter. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by the most recent USU purchase of cutting-edge equipment: the Zeiss Elyra PS.1 super-resolution microscope.

Laboratory: Dr. Broder’s laboratories are divided into 3 rooms totaling 1,440 sq. ft. Both investigators possess routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, water baths, free-standing biosafety cabinets, and CO_2-tissue culture incubators. Additionally, Dr. Broder’s lab is equipped with an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope, upgraded in 2015), a BioRad iQ5 real-time PCR system, and a Lonza Nucleofector 4D Shuttle. Dr. Broder’s lab also includes two complete GE-ATKA low pressure chromatography systems, with integrated UV detectors, fraction collectors, and pump systems, and gradient fractionator apparatus. Dr.
Broder’s lab performs virus based assays that incorporate primarily 2 techniques: plaque assays and neutralization assays. Both of these techniques determine viral concentration and/or viral quantity and require manual counting of plaques/clear areas (plaque assay) or manually counting GFP foci using a fluorescent microscope (neutralization assays). Since a large number of iterations with multiple viruses are performed routinely, Dr. Broder acquired a CTL S6 analyzer, which is an automated plate reader that can read up to 4 fluorescent colors, captures 25 megapixel images and is able to recognize over 11,000 spots per well in a 96-well plate format. The analyzer can efficiently handle a large number of 96-well plates required for assay characterization and development thus allowing for a high-throughput workflow with the use of minimal reagents. Operator bias is also diminished when counting plaques/GFP foci from processed images allowing for consistent, objective and statistically reliable results. Washed formalin fixed 96-well plates are first loaded into the analyzer and the software takes a high quality image of each well. Using the Basic count feature in the software package the user establishes parameters, which is used to enumerate GFP foci in each well of a single 96-well plate or from batch processing multiple plates. The counts can then be exported as an Excel file, which can be used to generate neutralization profiles for example. Conventional plaque assays and virus neutralization assays can take between 5- 7 days to complete, whereas the protocol established with the CTL

S6 analyzer has reduced the time to 3 days. Postdocs, students, and technicians have desks and computers in the laboratory.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. It, and the University's animal care and use program, is managed by the Center for Laboratory Animal Medicine, which is directed by a veterinarian who is an ACLAM Diplomat and staffed with three other veterinarians, a graduate animal husbandry man, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates to lower vertebrates, to higher vertebrates including non-human primates and domestic livestock, as well as the more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers as well as Apple Mac all within 4 years of life cycle. They are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro.

Office: Dr. Broder has an office separate from but proximal to the laboratories. Trainees and technicians have desks in the laboratory. The department employs one senior program manager, administrative officer, administrative specialist and a microbiologist. Other personnel can be provided as necessary to support the program.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely consult with Cara Olsen, Research Assistant Professor (the full-time Biostatistics Consultant of the BCC), regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data.

The USU Translational Imaging Facility (TIF) houses state-of-the art equipment for live animal imaging, including a Siemens Inveon SPECT/PET/CT Scanner, a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system, and a Bruker In-Vivo Xtreme II bioluminescence and X-ray imaging sytem.

The USU Biomedical Instrumentation Center (BIC) houses core equipment for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). The BIC Flow Cytometry Core includes two Becton-Dickinson (10- and 13-parameter) LSRII FACS analyzers, one 15-parameter FACSAria FACS sorter, and one Amnis Image Stream X Mark II imaging flow cytometer, as well as off-line analysis workstations.

The BIC Imaging Core houses three confocal microscopes, including a Zeiss 700 inverted system with 405/458/488/514/561/633 laser excitation; a Zess 710NLO inverted system with 405/458/488/514/561/633 conventional lasers and a Coherent Ultra2 Ti-Sapphire laser for multiphoton excitation, continuously tunable over the range of 690 to 1080 nm; and a Zeiss AxioExaminer-Z1 upright microscope equipped with a direct-coupled Coherent Chameleon tunable infrared laser for ex vivo and in vivo mutliphoton imaging projects. A Becker-Hickl two-detector FLIM system (for FRET analyses) is connected to the inverted Zeiss 710NLO system. Recently, the BIC has also acquired a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. The BIC also houses a Leica AF6000 system, consisting of an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control, allowing extended term (days) live cell analyses. Additionally, there is a stereology system consisting of a Zeiss AxioImager.M2 upright microscope connected to MicroBrightField's Stereo Investigator software package. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph Basic. The Imaging Core also includes a transmission electron microscope (Philips CM100 transmission EM) and an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment).

The BIC Genomics core includes an ABI 3900 DNA synthesizer, an ABI3500xl Genetic Analyzer (for sequencing), a RochLightCycler 480 for real-time PCR, and Systec Mediaprep and Plate Pourer instrument. There is also an integrated Fuji FLA-5000/LAS-3000 imaging system for many applications that involve fluorescence and chemiluminescence imaging of gels and blots. The BIC Proteomics Core includes two Agilent 1100 HPLCs, an AB SCIEX Voyager DSTR MALDI-TOF mass spectrometer, and an AB SCIEX Q-TOF tandem mass spectrometer.

The BIC Structural Biology Core includes a Rigaku HighFlux HomeLab X-ray diffraction system, with a MicroMax-007 HF microfocus rotating anode generator, an R-AXIS Imaging Plate detector, and an X-stream 2000 cryogenic system. Other available BIC instruments and services include histopathology and PET/CT instrumentation for small animal research.

A full-time statistician is available at the University for consultation on data analysis and to help with statistical analysis.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available in print and via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology and is maintained through extramural grant support.

Thomas W. Geisbert, PhD
Professor, Microbiology and Immunology
University of Texas Medical Branch
Galveston National Laboratory
301 University Blvd.
Galveston, TX 77550-0610

Dear Tom,

We are writing to indicate our full support for your Center grant submission: "**Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center – (PABVAX)**" in response to RFA-AI-23-020: Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP). The Research Projects and Scientific Cores you have assembled for this effort will have superior and synergistic plan for the Center's research objectives, and will significantly advance the rapid development of vaccines and antibody-based countermeasures against several very important viral pathogens within the *bunyavirales* and paramyxoviridae.

Our lab's have been working together on emerging viruses and host cell interactions, with particular focus on vaccines and antibody-based countermeasures for henipaviruses for more than 15 years, and together our groups have made a number of significant contributions to this field.

Together, we have developed and tested several new Nipah/Hendra virus vaccine platforms, discovered some new antiviral drug leads, and have made great progress in mAb based pre- and post-exposure treatments against Nipah and Hendra virus infection. More recently the new authentic henipavirus tools using the nonpathogenic Cedar henipavirus (CedV) for use at BSL-2 we developed in collaboration with you, will be very useful in rapidly accessing vaccine induced Nipah/Hendra neutralizing antibody responses and mAbs that the Center will be testing and developing. For Center programs like this, having collaborative and multidisciplinary teams is critical and the partners UTMB and USU have in place will augment this Center's success in achieving its objectives. This ReVAMMP proposal is critically important, and I, Drs. Amaya and Dimitrov, and our team at USU look forward to this opportunity to work towards the development of new and effective antivirals together with the world class team you and your colleagues have pulled together!

Sincerely,

(b) (6)

Christopher C. Broder, Ph.D.
Professor and Chair Staff
Microbiology and Immunology

Antony Dimitrov, Ph.D.

Resource Sharing Plan (to include sharing research data, model organisms and data)

We routinely present data derived from our studies at scientific meetings such as the American Society for Virology (ASV), American Society for Microbiology, Keystone Symposia among others, and when components are completed, invention disclosures filed, and following consultation with our appropriate technology transfer offices, we publish and disclose our findings. We have always made our reagents and data available to other investigators, and when appropriate, complete MTAs in a timely fashion. If research findings we deem sensitive are requested by outside parties, prior to publication mutual non-disclosure agreements will be put in place. In addition, we will have a free exchange of findings and data with all our consultants and collaborators. We will adhere to all institutional, state and federal resource sharing guidelines and agree to share knowledge, research materials, and any other resources necessary and relevant to the particular focus of the grant, recognizing that final authorization will be cleared with all appropriate organizational parties. We will make all data gathered available quickly and in an easy-to-interpret format, adhering to confidentiality regulations, provided that this does not conflict with our local requirements.

Research resources, research tools, research procedures and protocols, and novel materials such as recombinant viruses like VSV and rCedV based reporters for LayV and other emerging viruses that may arise out of the funded studies will be made available to others in the private and public sector as soon as appropriate agreements covering such transfer can be executed, or in the case of project data, shall be published as soon as possible or otherwise shared with other researchers pursuant to NIH policies regarding data sharing.

The USU and HJF Joint Office of Technology Transfer (JOTT) will coordinate all technology transfer activities for data and resources generated by USU and UTMB and Novartis. The JOTT will adhere to all applicable policies, principles, guidelines and procurement rules in making unique research resources readily available for research purposes to qualified individuals and entities, and in ensuring that there is no more than a short–term restriction on publication or public dissemination of data in order for the JOTT to evaluate and file for patent protection on any subject invention that may arise from the funded study. Dissemination of unpublished data that is considered to be proprietary or confidential shall occur pursuant to a suitable confidential disclosure agreement prepared by the JOTT as required. Material transfer agreements, license agreements, and Cooperative Research and Development Agreements (CRADAs), as appropriate, will be used to transfer material property. Material transfer agreements will be established to share resources among the research community for noncommercial research use.

USUHS
Site Principal Investigator: Christopher Broder, Ph.D.
Co-investigators: Moushimi Amaya, Ph.D.
Antony Dimitrov, Ph.D.

Select Agents

No select agents are used in this research.

We will generate and characterize recombinant forms of Cedar virus and Vesicular Stomatitis Virus. These viruses are categorized as BSL-2. Drs. Broder and Amaya have approved biosafety protocols for in vitro research with Cedar virus. All members of the Broder lab have received specific training in laboratory safety and the proper use and disposal of BSL-2 organisms. Dr. Broder has BSL-2 certified laboratories where work with these agents will be conducted.

SPECIFIC AIMS

Pathogenic RNA viruses represent continuous infectious disease and pandemic threats to public health. Among these are the two emerged zoonotic paramyxoviruses: the ‘prototype’ henipaviruses (HNVs); Nipah virus (NiV) and Hendra virus (HeV), discovered in the mid to late 1990s. The prototype HNVs have a uniquely broad tropism capable of infecting 18 species across 6 orders of mammals using the conserved ephrin-B2 and -B3 ligands as entry receptors, and infection often results in a systemic and fatal respiratory and/or neurological disease in multiple mammalian species including humans. NiV and henipaviral disease are also included in the WHO List of Priority Pathogens, and are significant threats to humans and livestock in South and South East Asia and Australia. HNVs have two membrane glycoproteins: the attachment (G) and the fusion (F) glycoproteins that are the major targets of neutralizing antibodies and focus of all vaccine and antiviral monoclonal antibody (mAb) strategies. The most extensively studied HNV vaccine is a soluble form of HeV G (HeV-sG), shown to provide complete protection against lethal challenge by either NiV (both Malaysia (NiV-M) and Bangladesh (NiV-B) or HeV in 4 species including nonhuman primates (NHPs). With no licensed vaccines or treatments available for human use, **Research Project 2 (RP2)** will address this critical need using the prototype HNVs as a model to develop, test, and translate a novel vaccination platform. We have recently tested a thermostable, needle-free, adaptable, and widely deployable polyphosphazene (PPZ) adjuvanted dissolvable microneedle patch (MNP)-based HeV-sG vaccine as a new tool for pandemic preparedness against HNVs. Our preliminary data demonstrate potent immunogenicity of the PPZ-MNP-HeV-sG vaccine in mice, inducing robust antigen-specific HNV cross-neutralizing antibody and cellular immune responses. This new approach may afford a new, rapid, adaptable and readily deployable vaccination strategy. We will use MNP vaccines and evaluate HeV-sG and new stabilized soluble forms of HNV G and F glycoproteins **(**sG_{tet} and sF_{stb}) in immunogenicity and challenge studies. We have also extensively studied the nonpathogenic HNV, Cedar virus (CedV); develop a reverse genetics system, generated recombinant CedV (rCedV) and rCedV chimeric virus tools by swapping the G and F glycoproteins with those of NiV/HeV as a rapid, surrogate, BSL-2 high-throughput neutralization platform. Recently, divergent and pathogenic zoonotic HNVs have been discovered, namely the related Mòjiāng virus and Langya virus (LayV), and in contrast to NiV/HeV, both appear to be rodent borne and do not use ephrins as entry receptors. Also, another divergent bat-borne HNV, Angavokely virus (AngV), has recently been described. Here, we also propose to adapt the MNP vaccine platform to LayV, rescue rLayV in collaboration with **Core E,** and develop additional LayV and AngV reporter virus tools, and we will translate and test the MNP vaccine **plug-and-play** approach, and evaluate new mAbs and nanobodies generated by **Core D** and **RP4** and **RP5** to the prototype HNVs and new divergent and/or potential zoonotic HNVs. Specifically, we will:

Aim 1: Develop PPZ-MNP-based sG_{tet} and sF_{stb} prototype HNV subunit vaccines.

We will test and compare NiV-sG_{tet}, NiV-sF_{stb}, HeV-sF_{stb} and HeV-sG as vaccine immunogens using PPZ-MNPs. Murine studies will evaluate their immunogenicity and antiviral humoral responses and homologous and heterologous neutralizing antibody inducing potentials. Best-in-class vaccines will then be evaluated in NiV-B and HeV challenge studies in ferrets, and then selected vaccines advanced to evaluation in NHPs.

Aim 2: Rescue Langya virus and construct LayV and AngV glycoprotein bearing reporter virus tools.

We will construct reverse genetics tools and rescue rLayV and reporter-gene encoding rLayV. Virus rescue will be conducted in collaboration with **Core E** at UTMB. Alternate reporter virus tools will also be generated using rCedV and vesicular stomatitis virus (VSV) platforms encoding HNV F/G glycoproteins. Rescued viruses will be characterized in cell-based assays. rLayV virus will be examined in vivo (new animal models) **by Core E**.

Aim 3: Evaluate HNV-specific antibodies and nanobodies developed by the Center’s RPs and Core D.

We will utilize our unique HNV tools and high-throughput virus neutralization platforms to evaluate PPZ-MNP vaccine-induced immune sera and the virus specific mAbs and nanobodies developed by Center. These experiments will help facilitate down-selection of vaccine antigens and prioritize best-in-class antiviral antibodies.

Aim 4: Validate PPZ-MNP platform with another paramyxovirus-specific antigen in Phase 2.

We will demonstrate the broad applicability of the PPZ-MNP subunit-based vaccine platform for the development of safe, skin-targeted, and effective vaccines using alternate recombinant paramyxovirus glycoprotein antigens.

These proposed studies to develop and apply the rapid, adaptable and readily deployable MNP vaccination platform is innovative and unique, and the development of the new virological tools to help facilitate the translational nature of this approach and evaluate new antiviral antibody-based countermeasures will foster pandemic preparedness tool-set to combat future emerging paramyxovirus threats.

TITLE: Cedar henipavirus animal model

Funding announcement: RFA-AI-23-020

Funding Title: Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP) Centers for Bunyavirales, Paramyxoviridae and Picronaviridae

PRINCIPAL INVESTIGATOR: Brian Schaefer, Ph.D., Site Principal Investigator

Prime PI: Thomas Geisbert, Ph.D., UTMB

Period of Performance: March 1, 2024 - February 28, 2029

Abstract

Henipaviruses are single-stranded, negative-sense enveloped RNA viruses of the paramyxovirus family. Two henipaviruses, Nipah virus (NiV) and Hendra virus (HeV), cause a systemic and often fatal respiratory and/or encephalitic disease in humans and ten other mammalian species. Importantly, NiV and HeV are significant biothreats to humans and economically important livestock in Australia and Southeast Asia. There are currently no vaccines or therapeutics approved for human use. Notably, development of countermeasures for NiV and HeV is hampered by the fact that these viruses require BSL-4 containment, meaning that very few research groups worldwide have access to the required biocontainment facilities to perform preclinical studies with these important human viral pathogens. To address this problem, we are developing a BSL-2 animal model that is based on Cedar virus (CedV), which is a non-pathogenic henipavirus. Specifically, we are employing recombinant Cedar viruses (rCedVs) in which the NiV and HeV fusion (F) and receptor-binding glycoprotein (G) are expressed in the rCedV genome, replacing CedV F and G. Additionally, we have also incorporated our recently developed *in vivo* bioluminescence methodology to longitudinally trace the dynamics and anatomical progression of rCedV-luciferase (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host innate immune response in mice, we have demonstrated sustained replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Importantly, whereas rCedV-luc does not establish stable expression in the brain, both of the chimeric viruses do. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in specific strains of mice. The rCedV-luc platform is thus an authentic henipavirus system that can be used to study henipavirus *in vivo* biology safely and expediently under BSL-2 containment. Our overall hypothesis is that rCedV-luc infection of mice lacking specific innate immune responses represents a BSL-2 platform for the study of henipavirus biology and pathogenesis, as well as for development and testing of anti-viral countermeasures. We will address this hypothesis through three Specific Aims: Aim 1: To optimize the use of immunodeficient mice and rCedV-NiV-luc/rCedV-HeV-luc chimeras as a robust BSL2 model of pathogenic henipavirus disease; Aim 2: To determine the mechanism of rCedV-NiV neurovirulence; Aim 3: To define the efficacy and mechanisms of mAb-based therapeutics for CNS-resident henipavirus infections. Aims involve synergistic collaborations with several other research projects and cores in this U19 program. Successful completion of these Aims will establish the rCedV-luc mouse model as a robust BSL-2 platform for the exploration of henipavirus pathogenesis and countermeasures.

USUHS

Site Principal Investigator: Brian Schaefer, Ph.D.

Authentication of Key Biological and Chemical Resources

The reagents that are used in the Schaefer lab are routinely authenticated as follows:

Expression constructs: All new expression constructs are verified by (1) restriction digest and electrophoretic separation of fragments to ensure fragments of the predicted size are generated and (2) sequencing to ensure the correct sequence is present with no spurious mutations.

Antibodies: Antibodies are tested for specificity as follows: (1) For antibodies used repeatedly, the staining/blotting performance of new antibody lots are compared against previous lots; (2) For new antibodies, banding/staining patterns are compared against published data; (3) Whenever possible, new antibodies are also validated using objective controls, such as cells known to lack the protein of interest (e.g., knockout cells) or cells engineered to over-express an epitope-tagged form of the molecule (i.e., staining by the new antibody is compared side-by-side with staining by the epitope-tag antibody).

Cell lines: Cell lines are routinely validated using flow cytometry for key cell surface markers and/or functional tests. Cell lines transfected for virus production are validated via measuring titers of virus in the resultant supernatants.

Viruses: Viruses are validated through a combination of genome sequencing, infectivity and functional testing. Rescued recombinant viruses are validated through genome sequencing, with comparison to the original cloned full length viral genomes.

Mice: Every new litter of knockout animals is PCR screened for both the wild-type and inactivated allele, with validated wild-type and knockout control DNAs included in every screen. For transgenic animals, presence of the transgene is PCR verified in every litter, with validated controls included in the screen. Additional screens include periodic western blotting and/or FACS analysis of tissues/cells from knockout animals, to validate that PCR-identified knockouts indeed fail to express the protein product of the inactivated gene.

Commercial chemical reagents: Such reagents are validated by one or both of the following: (1) performance comparison to previous lots of the same reagent; (2) use in an established assay that incorporates one or more validated performance controls.

Budget Justification – RP3 – Schaefer

The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc. (HJF) in partnership with the Uniformed Services University of the Health Sciences (USUHS) will manage this proposal, if awarded.

Key Personnel:

Brian. C. Schaefer, Ph.D. (Site Principal Investigator, 1.2 calendar months, 10% effort) is a Professor of Microbiology and Immunology at USUHS. His expertise is in cellular immunology, animal models of immune responses in the central nervous system and applying advanced imaging methods to biological questions. He and Dr. Broder have been collaborating for nearly a decade on creating animal models and investigating therapeutic interventions for neurotropic viral infections. The preliminary data in this application resulted from this collaboration, through an NIH-funded U19 grant (with aims that do not overlap the aims of this proposal). Dr. Schaefer will direct all animal studies in this project, managing and advising staff and overseeing data collection and data analysis. Dr. Schaefer will manage the overall experimental direction, the writing and editing of manuscripts for publication and the preparation of progress reports and other administrative functions related to this project, with assistance from the Senior Staff Scientist. (Dr. Schaefer is a full-time Federal employee. Hence, no salary is requested for this project).

Other Personnel

†**To be named** (Scientist II, 9 calendar months, 75% effort). A Scientist with experience in animal models and transcriptomics analysis will be recruited for this project. This Scientist will supervise animal research studies, coordinate, conduct and supervise data analyses for transcriptomics studies. The scientist will also coordinate overall data analysis and will participate with Dr. Schaefer in preparation of manuscripts for funding and in preparing progress reports and performing other administrative tasks related to the conduct of this project. The Scientist II will be employed by the Henry M. Jackson Foundation, and salary support is requested on this project.

†**To be named** (Postdoctoral fellow, 12 calendar months, 100% effort). A Postdoctoral fellow with experience in animal research and virology will be recruited for this project. The Postdoctoral fellow will perform approximately half of the animal experiments proposed for this study. The Postdoctoral fellow will be employed by the Henry M. Jackson Foundation, and salary support is requested on this project.

†**Celeste Huaman** (Graduate Student, 12 calendar months,100% effort) will perform approximately half of the proposed in vivo experiments described in this proposal. Ms. Huaman is a senior graduate student in Dr. Schaefer's lab, who has been working collaboratively with members of the Broder lab on this project. Notably, Ms. Huaman generated the majority of preliminary data in this proposal, and has extensive experience in all procedures and analysis techniques required for the execution of the proposed experiments. Ms. Huaman worked in Dr. Schaefer's lab as a Research Assitant II for 5 years before joining the USU Emerging Infectious Diseases graduate program, and she acquired a very deep technical skill set during that time. Ms. Huaman completed the CEEZAD BSL-3 training course at the Biosecurity Research Institute of Kansas State University in 2021, and she has trained most current laboratory staff in proper BSL-2 technique. Ms. Huaman is currently employed by the Henry M. Jackson Foundation, and salary support is requested for her on this project.

†**Caitlyn Clouse** (Research Assistant II, 9 calendar months, 75% effort) will provide general technical support, performing routine tissue culture, ordering reagents, and maintaining databases, as required for the project. Ms. Clouse will also perform genotyping of animals breeding at Charles River Lab and she will maintain detailed records of animal genotypes. She will also assist the postdoctoral fellow and Ms. Huaman with all animal experiments. Ms. Clouse completed the CEEZAD BSL-3 training course at the Biosecurity Research Institute of Kansas llent technical support, including assistance to Ms. Huaman in gathering the preliminary data for this project. Ms. Clouse is an employee of the Henry M. Jackson Foundation and we are requesting salary support for her on this project.

[†] **Camille Alba** (Research Associate, The American Genome Center (TAGC), 1.85 calendar months, 15.4% effort) will be responsible for leading the collaborative performance task for this study. She will oversee performance of library preparation, library quality assessment, library clustering and whole genome sequencing of the samples across the entire project. She will report Illumina NovaSeq platform performance metrics to the collaborating staff scientist and oversee data transfer batches. Ms. Alba is employed as a Henry Jackson Foundation employee therefore salary support is requested.

[†] A merit increase has been added to years 2-5 of the personnel budget to account for salary increases for Henry M. Jackson Foundation personnel.

Equipment:

An ultralow (-80 C) freezer, ThermoFisher Scientific Model TSX60086A ($12,123), is needed for storage of the many RNA samples, viral stocks and frozen tissues (for sectioning) and slides with frozen sections. Dr. Schaefer's current -80 freezers are filled to capacity.

Travel: (Year 1)

Funds are requested to attend two domestic scientific conferences or one international conference. This travel is for data presentation, exchange of ideas with colleagues, and for keeping up-to-date regarding the latest research findings relevant to the proposed project. Meeting attendance and data presentation is a key component of postdoctoral and graduate student training.

Materials and Supplies: $48,000 - year 1-2; $43,200 - year 3; $33,000 - year 4; $20,000 - year 5

For the laboratory to successfully complete the experiments, the project will need to procure the following reagents and supplies:

General Laboratory Supplies

Serological pipettes, microscope slides and coverslips, pipet tips, microcentrifuge tubes, sterile conical tubes, ultracentrifuge tubes, syringes, needles, gloves, respirators, gowns, buffers, flasks, plates, etc.

Materials

Trizol reagents, RNAse-free DNAse, RNAse-free water and buffers, Reverse Transcriptase, Taq Polymerase, qPCR master mix, RNAse-free consumables for tissue homogenization, magnetic beads for cell sorting, tissue culture media, fetal bovine serum, antibiotics, etc

Real-time PCR probes

DNA oligonucleotide

Labeled antibodies for histology and flow cytometry

Animal costs (procurement and husbandry): $34,728 - year 1; $ 48,046 - year 2-5

Animal Breeding at Charles River Labs

The breeding of experimental mice at USU is contracted to Charles River Labs (CRL). All aspects of animal care and breeding are managed by CRL, while genotyping of progeny is performed by Dr. Schaefer's group, using biosamples collected and shipped by CRL. We maintain a colony of B6-albino Ifnar1-/- mice and B6-albion STAT1-/- mice in our breeding colony at CRL. For this project, we expect to maintain 12 breeding cages and 12 progeny cages to supply the animals needed for the proposed experiments. ($1.80/cage/day x 24 cages x 365 days = $15,768 + Transportation charges $1,500 = $20,768).

Animal Husbandry at USU

Animal facility (DLAR) mouse per diems:
USU DLAR FY24 per diem for biohazardous mice is $4.78/cage/day. We expect to have an average of 8 experimental cages housed in the facility (8 cages x 365 days x $4.78/cage/day = $13,957.60/yr)

Translational Imaging Core (BRIC): $23,400 year 1; $39,000 year 2 - 5
BRIC – IVIS Spectrum CT bioluminescence imaging (9 hr/week x 52 weeks/yr x $50/hr = $23,400/yr)

Biomedical Instrumentation Core (BIC): $10,608 year 1 - 5
BIC – flow cytometry (4 hr/week x 52 weeks/yr x $36/hr = $7,488/year).
BIC – confocal microscopy (2 hr/week x 52 weeks/yr x $30/hr =$3,120/year)

The American Genome Center (TAGC): $52,680 year 1 - 5

Transcriptomics studies performed at the USU American Genome Center

Total RNAseq on brain slices from 32 animals/year x $300 per animal

Supplies for Visium Spatial Gene Expression:

Visium CytAssist Spatial Gene Expression for FFPE, Mouse Transcriptome 6.5mm slides (quantity of 16 per year)

Visium CytAssist Tissue Slide Cassettes

Dual INdex Kit TS set A

S1 Novaseq Flow cells (for spatial transcriptomics sequencing), 2 flow cells/year

Supplies for Single-cell RNAseq:

Chromium Next GEM Automated Single Cell 3' Library and Gel Bead Kit v3.1

Chromium Next GEM Automated Chip G Single Cell Kit

S1 Novaseq Flow cells (for single-cell RNAseq), 1 flow cell/year

Publication costs: $5,000 - year 2
We estimate 2 manuscripts per year for an average cost of $2,500 per publication. This cost estimate is based on our average fee paid per open access journal publication for the last 3 years.

Indirect Costs:

HJF indirect cost (IDC) is calculated based on the value-added cost base overhead rates. The fringe rate used is 29.42 % for Tier 1 employees and 7.29% for Tier 2 employees (all employees in this proposal are Tier 1).

The HJF indirect cost is calculated based on the value-added cost base overhead rates. The IDC rate is 36.74% USU Onsite Overhead. Additionally, 16.70% Companywide G&A and applied on the total direct cost less subaward plus the USU Onsite Overhead. For proposals including subawards, an additional 1.93% is applied on total external subaward costs.

The above fringe benefits and indirect cost rates for FY2023 were approved by the U.S. Army Medical Research Acquisition Activity on September 1, 2022.

USUHS

Site Principal Investigator: Brian Schaefer, Ph.D.

EQUIPMENT

Schaefer Laboratory

Epifluorescence microscopy system (Fully-automated Zeiss AxioObserver epifluorescence microscope)
BioRad CFX Connect real-time PCR system
Lonza Nucleofector 4D Shuttle – core unit and X-unit
Coulter Z1-Dual cell counter
DeNovix CellDrop-FL cell counter with fluorescence
centrifuges: Eppendorf 5425 microfuges (3); Beckman Allegra 25R; Thermo-Fisher Jouan GR4i; various rotors NestAdvance Bullet Blender bead mills (2)
Miltenyi QuadroMACS separator (2)
inverted microscopes for tissue culture (2)
gel electrophoresis equipment for protein (3) and DNA (5) gels
semi-dry protein transfer apparatus (2)
Bio-Rad thermal cyclers (2)
balances (4)
pH meter
refrigerators
freezers (-20 C, -80 C)
platform orbital shakers (5)
sonicator with cup horn and microtip
bacterial shaker
heating blocks (6)
waterbaths (8)
biosafety cabinets (2)
CO_2-tissue culture incubators (3)
Thermo-Fisher Locator 4 liquid nitrogen storage tank with electronic monitoring

Departmental

GE Healthcare Life Sciences Amersham Imager 680 (for imaging of protein and DNA gels and blots)
Alpha-Innotech gel documentation system (EtBr-stained gels)
2D gel electrophoresis system (protein)
MilliQ ultra-pure water system
Nanodrop spectrophotometer
Luminometer
Fluorescence plate readers (2)

USU CORE FACILITIES (fee for service or free)

Biomedical Research Imaging Core (BRIC)

IVIS® Spectrum CT preclinical *in vivo* imaging system (2D and 3D bioluminescence and CT imaging)
Siemens Inveon SPECT/PET/CT Scanner
Bruker Biospec 70/20 USR MRI
Image Guided Therapy 7T MR guided Focused Ultrasound System for neurological applications

The American Genome Center (TAGC)

Illumina NovaSeq 6000 systems (7)
Illumina HiSeq X systems (6)
Illumina NextSeq 500 system
10x Genomics Visium CyAssist transcriptomic probe transfer system
10x Genomics Chromium Connect automated single-cell NGS library workstation
10x Genomics Chromium Controller massively parallel sample partitioning platform
Agilent Fragment Analyzer automated parallel capillary electrophoresis systems (2)
Bio-Rad Experion LabChip Platform automated electrophoresis system
PRIMER Data Science Core - direct connection to a high-speed network switch for data storage on a petabyte-scale Isilon SAN

Biomedical Instrumentation Center (BIC)

Flow Cytometry
Cytek Aurora 5-laser, 64-channel Spectral Analyzer
Becton-Dickinson 5-laser, 30-parameter FACSymphony A5
Becton-Dickinson 4-laser, 15-parameter LSRII FACS analyzer
BD FACSAria Fusion 4-laser, 18-parameter flow sorter
BD FACSAria IIIu 4-laser, 17-parameter flow sorter
Amnis Image Stream X Mark II imaging flow cytometer with IDEAS statistical image analysis software
Bio-Rad Bio-Plex 200 multi-analyte bioassay detection system
Agilant Seahorse XPe96 Analyzer
Offline data analysis stations (3) with software packages including: FlowJo, WinList, and ModFit

Microscopy
Zeiss 980 Confocal with Airyscan2
Zeiss 700 confocal system with 405/458/488/514/561/633 laser lines
Zeiss 7 MP Multi-photon Confocal Electrophysiology System
Zeiss Elyra PS.1 Superresolution microscope for superresolution structured illumination microscopy (SR-SIM), photoactivated localization microscopy (PALM), and direct stochastic optical reconstruction microscopy (dSTORM). System is fully equipped, including the 3D-PALM/dSTORM option.
Zeiss Lightsheet Z.1
Zeiss Axioscan Z1 Slide Scanner
Zeiss AxioImager M2 upright microscope and MicroBrightField Stereo Investigator software (stereology analysis).
Leica AF6000 system, including an inverted microscope equipped with a fully motorized 3-axis stage plus atmosphere and temperature control
Transmission electron microscope (JEOL JEM-1011)
Ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment)
Grid stainer (Leica EM AC20)
Wide-field fluorescence microscopes (3)
Offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize; Metamorph.

Genomics
3500 XL Applied Biosystems Genetic Analyzer
Gene Forge 3900 and ABI 3900 and DNA Synthesizer
U-3000 Thermo-Scientific HPLC system
Agilent 1200 HPLC
QX200 Droplet Digital PCR System (ddPCR)
Roche LightCycler 480 Real-Time PCR System
Agilent Capillary Electrophoresis Fragment Analyzer

Structural Biology/Proteomics
AB Sciex 4000 QTRAP LC/MS/MS System

Leica Autostainer XL
Leica CV 5030 Robotic Coverslipper
Sakura Tissue-Tek VIP tissue Processor
Leica CM 3050 S Cryostat
Microm HM 325 Microtome

Facilities and Other Resources

Overall Scientific Environment: Uniformed Services University (USU) is the medical school at which approximately half of the physicians in the Armed Services receive their graduate training. Research at USU is supported primarily by extramural grants, as in other medical schools. Dr. Schaefer is a tenured Professor in the Department of Microbiology and Immunology, which includes 12 full-time Faculty members. The overall focus of the Department is mechanisms of infectious diseases and the host response/immunology. Faculty interests and active research programs at USU are diverse, with many nationally- and internationally-known investigators, including the Department of Microbiology and Immunology chair, Dr. Christopher Broder, who is an internationally-known virologist (and centrally involved in this proposal).

USU is directly across the street from the main NIH campus and close to Johns Hopkins, the University of Maryland and several other outstanding institutions, facilitating opportunities to establish productive collaborations with world-class investigators. For example, Dr. Schaefer has had a multi-PI U01 grant with Dr. Wolfgang Losert (Dept of Physics, University of Maryland) as the co-PI and Dr. Hari Shroff (NIH/NIBIB) as a collaborator. Dr. Schaefer is also primary PI on a multi-PI R01 from NIAID with Dr. YouWen He at Duke University Medical Center, and Dr. Thomas Conrads (Women's Health Integrated Research Center). Dr. Schaefer and his staff have also collaborated with the Advanced Imaging Center (AIC) at the Howard Hughes Medical Institute (HHMI) for some of their imaging-based research. Overall, the broader scientific environment at USU and the greater Bethesda/Washington D.C. metropolitan region is highly conducive to productive collaborations. Dr. Schaefer has been using these resources to his advantage, and has been very active in establishing collaborative relationships to facilitate his research objectives. Notably, Dr. Schaefer and Dr. Broder have been collaborating for several years on lyssavirus- and henipavirus-related project, and they have a very strong working relationship.

Members of the Schaefer lab participate in a weekly multi-lab Immunology journal club, Immunology data club, virology journal club, and virology data club. Approximately 10 groups regularly participate in the immunology journal/data club and 5 groups regularly participate in the virology journal/data club. Also, members of the Schaefer lab participate in a bi-weekly data presentation/discussion group which meets monthly.

Dr. Schaefer has been well-supported by the Department of Microbiology and Immunology and the USU Office of Research. Although USU is a modest-sized medical school, the technical resources are outstanding, rivaling many very large institutions (see below). The modest size of the school is an advantage, as key pieces of equipment (e.g., The IVIS® Spectrum CT preclinical in vivo imaging system; Cytek Aurora spectral flow cytometer), and 10x Genomics Visium Spatial Transcriptomics instruments are not overbooked and therefore readily available to laboratory personnel. Dr. Schaefer is also Chair of the USU Biomedical Instrumentation Center (BIC), and thus plays a central role in directing equipment purchases, ensuring that needed technologies are available for the research of the PI and his USU colleagues. In addition to University funds, we have successfully used the NIH S10 mechanism to purchase core facility equipment. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional, as is illustrated by recent USU purchases of cutting-edge equipment including a Perkin-Elmer IVIS® Spectrum CT preclinical in vivo imaging system, a Zeiss Elyra PS.1 super-resolution microscope, an Agilant Seahorse XPe96 Analyzer, a BD FACSAria Fusion flow sorter, and many other pieces of advanced research equipment. Overall, the available technical resources (and University support for continually improving technical resources) is exceptional.

USU has several Ph.D. programs, including an Emerging Infectious Diseases (EID) program, a Molecular and Cellular Biology (MCB) program and a Neuroscience (NES) program. Dr. Schaefer holds secondary appointments in all three programs and is currently Interim Director of the Emerging Infectious Diseases Graduate Program. Ds. Schaefer has been very active in training graduate students, having trained >10 Ph.D. students. USU recruits strong graduate students, and Dr. Schaefer's students have been very productive, during and beyond their dissertation studies. The availability of talented graduate students is a further resource, promoting productivity and enhancing the overall vibrancy of the scientific environment at USU.

Laboratory: Dr. Schaefer's laboratory area consists of three rooms of 450 sq. ft, 300 sq. ft and 225 sq.ft., and a dedicated microscopy suite of 110 sq. ft. The Schaefer lab contains routine equipment for microbiology, molecular biology, and biochemistry including incubators, centrifuges, inverted microscopes, gel electrophoresis equipment for protein and DNA gels, thermal cyclers, balances, pH meters, refrigerators, freezers, platform orbital shakers, sonicator, UV transilluminator, shakers, heating blocks, waterbaths, free-standing biosafety cabinets, and CO_2-tissue culture incubators. Additionally, Dr. Schaefer's lab is equipped

with an epifluorescence microscopy system (a Zeiss AxioObserver inverted fluorescence microscope), a BioRad CFX Connect real-time PCR system, a Coulter Z1-Dual cell counter, a DeNovix CellDrop-FL cell counter and a Lonza Nucleofector 4D Shuttle. Postdocs, students, and technicians have desks and computers in the laboratory.

Animal: Animals are maintained in University facilities under the supervision of a full-time veterinarian. The USUHS maintains a modern AAALC Accredited, Central Animal Facility of about 50,000 square feet. The facility also includes two preclinical behavior cores (one for mice, one for rats). The facility and the University's animal care and use program is managed by the Department of Laboratory Animal Medicine (DLAR), which is directed by a veterinarian who is an ACLAM Diplomate and staffed with three other veterinarians, a graduate animal husbandryman, and about 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates and lower vertebrates to higher vertebrates including non-human primates and domestic livestock, as well as more commonly used species such as rodents and rabbits. The facility also includes a number of properly equipped ABSL-2 rooms.

Computer: Windows-based computers (Intel i5/i7 or similar processors and ≥8GB of RAM) are available for routine use by postdoctoral fellows, graduate students, and technicians located in the laboratories of both investigators. Dr. Schaefer's laboratory also has a dedicated workstation for use for analysis of microscopy and in vivo imaging data. Image analysis software in the Dr. Schaefer's lab includes Zeiss Zen, with a digital deconvolution module and numerous tools for quantitative image analysis. The University maintains site licenses for other image and data analysis software, including Zeiss Axiovision, VisioPharm, and OriginPro. Dr. Schaefer also maintains a license for FlowJo software, which can be used on any networked computer in the laboratory. The computers are connected by a central server to each other and to the Internet. A variety of USU-supported software programs are available, including EndNote, Microsoft Office, Adobe Creative Cloud, Geneious Prime and Graph Pad Prism 9.

Office: Drs. Schaefer's office is separate from but proximal to each of his laboratories. Trainees and technicians have desks in the laboratory. Four full-time administrative officers and one part-time administrator are available to provide support within the department.

Clinical: N/A

Other: The Biostatistics Consulting Center (BCC), a service of the Department of Preventive Medicine and Biometrics, provides statistical consulting to USUHS scientific investigators. We routinely meet with BCC consultants regarding proper design of experiments for statistical testing and for statistical analysis of the resulting data.

The USU Biomedical Research Imaging Core (BRIC) houses state-of-the art equipment for pre-clinical studies, including a IVIS® Spectrum CT, a Siemens Inveon SPECT/PET/CT Scanner and a Bruker Biospec 70/20 USR Magnetic Resonance Imaging system. A Scientist and several staff provide technical support and manage the facility.

The USU American Genome Center (TAGC) is one of only four academic genome centers in the United States. It is the Department of Defense operations subsidiary of the Collaborative Health Initiative Research Program (CHIRP) established between the National Heart, Lung, and Blood Institute (NHLBI) and USU. Since inception, TAGC has generated more than 40,000 whole Genome Sequences across 107 research studies sourced from NHLBI, other NIH Institutes, DoD and USU investigators. TAGC is also the sequencing center and genome data analysis center for the APOLLO Cancer Moonshot project, and collaborates for this purpose with the Murtha Cancer Center (MCC) at Walter Reed, the National Cancer Institute, and the Veterans Administration. Through a collaborative relationship with 10x Genomics, USU has early access to newly released platforms such as Visium Spatial Transcriptomics (including improvements to that platform).

The USU TAGC includes a large array of next-generation sequencing instruments including Illumina NovaSeq 6000 systems, Illumina HiSeq X systems, and an Illumina NextSeq 500 system. A 10x Genomics Chromium Connect automated single-cell NGS library workstation is available for automated single cell partitioning, barcoding and NGS library preparation. A 10x Genomics Chromium Controller massively parallel sample partitioning platform is available for barcoding single cell RNA for library preparation and for single cell transcriptome profiling, including CITE-seq workflows. 10x Genomics Visium CyAssist transcriptomic probe transfer system is available to facilitate spatial transcriptomics workflows. Electrophoresis systems include Agilent Fragment Analyzers and a Bio-Rad Experion LabChip Platform. Sequencing platforms are connected to a high-speed network switch for data storage on a petabyte-scale Isilon SAN.

The USU Biomedical Instrumentation Center (BIC) consists of five core equipment facilities for use by investigators throughout the University. Instrumentation is available either free or on a fee-for-service basis, depending on which instruments have annual service contracts (which are paid largely through per-hour use fees). Each core is run by a full-time Director with an advanced science background (most hold a PhD) and a high degree of technical expertise. The majority of cores have at least one additional employee to help manage the core and provide guidance and assistance to users.

The BIC Flow Cytometry Core includes three analyzers (Cytek Aurora 5-laser, 64-channel Spectral Analyzer; Becton-Dickinson 5-laser, 30-parameter FACSymphony A5; Becton-Dickinson 4-laser, 15-parameter LSRII) and two sorters (BD FACSAria Fusion 4-laser, 18-parameter flow sorter; BD FACSAria IIIu 4-laser, 17-parameter flow sorter) and an Amnis Image Stream X Mark II imaging flow cytometer. Other equipment includes a Bio-Rad Bio-Plex 200 multi-analyte detection system and an Agilant Seahorse XPe96 Analyzer. The core has several off-line analysis workstations with FlowJo and other data analysis platforms.

The BIC Imaging Core houses a wide array of microscopes, including a Zeiss Elyra PS.1 super-resolution microscope, which is capable of 4-parameter SR-SIM (super-resolution structured illumination) imaging, 3-parameter PALM (Photoactivation localization microscopy) and dSTORM (direct stochastic optical reconstruction microscopy), as well as 3D-PALM/dSTORM. Other microscopes include aZeiss 980 Confocal with Airyscan2, a Zeiss 700 confocal system, a Zeiss 7 MP Multi-photon Confocal Electrophysiology System, a Zeiss Lightsheet Z.1 and a Zeiss Axioscan Z1 Slide Scanner. The facility also includes several additional wide-field fluorescence microscopes, and three offline data analysis stations with software packages including: Zeiss Zen software and full Physiology package; Media Cybernetics' 3D Constructor, Image Pro Analyzer, Autodeblur, and Autovisualize. For electron microscopy needs, the core is equipped with a JEOL JEM-1011 transmission electron microscope, an ultramicrotome (Leica EM UC6 with EM FC6 cryo attachment), and a grid stainer (Leica EM AC20).

The BIC Genomics core includes a 3500 XL Applied Biosystems Genetic Analyzer, a Gene Forge 3900 and an ABI 3900 and DNA Synthesizer, a U-3000 Thermo-Scientific HPLC system, an Agilent 1200 HPLC, a QX200 Droplet Digital PCR System, a Roche LightCycler 480 Real-Time PCR System and an Agilent Capillary Electrophoresis Fragment Analyzer.

The BIC Structural Biology and Proteomics Core includes a GE Healthcare Biacore 3000 Surface Plasmon Resonance instrument, an AB Sciex 4000 QTRAP LC/MS/MS System, an Agilent 1200 HPLC, a Wyatt DynaPro NanoStar Dynamic Light Scattering analyzer, an Art Robbins Instruments Phoenix Crystallization Robot, and a JANSi UVEX Fluorescence Microscope (for crystal inspection).

The BIC Histopathology Core includes a Leica Autostainer XL, a Leica CV 5030 Robotic Coverslipper, a Sakura Tissue-Tek VIP tissue Processor, a Leica CM 3050 S Cryostat, and a Microm HM 325 Microtome.

The University also has an equipment repair service, central duplicating service, audiovisual service, and microcomputer support service. The University Learning Resource Center is a high quality medical and scientific library with additional microcomputers and support. A wide variety of scientific journals are available via remote computer access. A central autoclave/glassware washroom serves the Department of Microbiology and Immunology.

June 1st, 2023

Dr. Schaefer,

It is with great enthusiasm that I can confirm support for your proposed research study: *Research Project 3 (RP3), Cedar henipavirus animal model*, that is part of the multi-site center application, Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center (PABVAX). This project is a sound representation of your research expertise in cellular, histological and molecular methodologies to understanding the modulation of infectious viral consequences in the mammalian brain and central nervous system, using mice as a model system. This proposal is centered on exciting preliminary data suggesting that infection of STAT1-/- mice with chimeric recombinant Cedar viruses (rCedVs) causes neurovirulence and mortality (whereas immunocompetent animals rapidly control infection). Through your proposed transcriptomics studies, we can facilitate your experimental plan to define gene expression changes across cell types in the brains of infected animals. Moreover, through your use of distinct recombinant viruses and different immunocompromised mouse strains, we can identify those gene expression changes that correlate with neurovirulence and mortality. The proposed unbiased approach to defining pathogenic mechanisms will represent a truly important step in establishing, validating and gaining biological insights from this novel BSL-2 model of henipavirus disease.

We are well poised to collaboratively support the high complexity molecular workflows from the well curated tissue specimens your team will provide. At the laboratories of The American Genome Center (TAGC), we have model system experience in transcriptomic and proteomic profiling for experimental models using whole rodent brain (see PubMed Id (PMID): 21190398, 22291617 and 23118733). Specifically, we will assist your laboratory in bulk transcriptomics, single cell RNA-sequencing and Visium spatial transcriptomics using 10x Genomics workflows. We have current standard operating procedures for your experiments using the 10x Genomics CytAssist platform and tissue compatibility for fixed tissues. We will also provide data analysis through validated pipelines and data storage from our compute infrastructure and storage area network. Importantly, we will build cross-compatible protocols with your laboratory team, including a key liason in your laboratory, who has previously trained in our genome center. Our laboratory and Data Science division computational biology associates will be available for analysis and interpretation of the data, with your leadership.

I look forward to working with you on this exciting project!

Sincerely,

(b) (6)

RESEARCH STRATEGY

Significance and Premise

The health threats and pandemic potential posed by Nipah virus and Hendra virus. The emergence and reemergence of pathogenic zoonotic viruses are continuous threats to global public health. Two particularly pathogenic examples with clear pandemic potential are the henipaviruses, Nipah virus (NiV) and Hendra virus (HeV). NiV and HeV are bat-borne paramyxoviruses that are distinguished from the many paramyxoviruses that cause human and animal diseases by their uniquely broad host tropism (18 animal species across 6 orders of mammals) and their high degree of lethality[13]. Henipaviruses, like all paramyxoviruses, are membrane enveloped, single-stranded negative-sense RNA viruses, and they possess two major membrane anchored glycoproteins involved in virus entry: One mediates host cell receptor attachment (G) glycoprotein and the other is a Class I fusion (F) glycoprotein, which facilitates virion and host cell membrane fusion. The viral G and F glycoproteins are both the major antigenic targets of neutralizing antibodies and the main focus of vaccine and therapeutic antiviral strategies[14]. NiV and HeV are Biosafety Level-4 (BSL-4; risk group 4) pathogens. Moreover, they are classified as priority agents by US Department of Health and Human Services (HHS) because they could be engineered for mass dissemination, and they possess the potential for high morbidity and mortality rates and major public health impacts. Recently, NiV was selected by the World Health Organization (WHO) as an epidemic threat needing urgent research and development (R&D) action, and NiV has been included in the WHO R&D Blueprint list of priority pathogens with epidemic potential[15]. To date, there have been >630 cases of human NiV infection with >370 fatalities[10]. Characteristics of NiV enhancing its global pandemic potential include: (i) humans are susceptible to infection; (ii) it is capable of person-to-person transmission; (iii) it is an RNA virus with potential to mutate; and (iv) if a human-adapted NiV strain were to infect communities in South Asia, high population densities and global interconnectedness would rapidly spread the infection[16].

Additional members of the henipavirus family, including a non-pathogenic species, Cedar virus. Nucleic acid-based detection studies have also identified additional henipavirus species for which complete genomic sequences are now available[17, 18], including Langya virus, which has also been reported to cause human morbidity during zoonotic spillovers[19], and Angavokely virus, which may be capable of mammalian pathogenesis, due to likely ability to produce V and W proteins[20]. Another member of the henipavirus family, Cedar virus (CedV), was identified in pteropid bats in 2012[7]. Importantly, although CedV is closely related to HeV and NiV and shares the same bat host species as HeV, CedV is not known to be zoonotic and has been shown to be **non**pathogenic in animals susceptible to HeV and NiV disease including mice, guinea pigs, and ferrets[7, 21, 22]. A notable distinction between CedV and HeV/NiV lies in the phosphoprotein gene (P), which contains the open reading frames for the C, V and W proteins in HeV/NiV. The CedV P gene does not encode the C, V and W proteins, which contribute to HeV/NiV pathogenicity[21, 23-25]. The absence of C, V and W is an important factor underlying the failure of CedV to cause disease in infections of mice, ferrets or guinea pigs[7, 22, 25]. Despite the pathogenic differences and lower level of sequence homologies of CedV G to HeV and NiV G (29% and 30%, respectively), CedV infection, like both HeV and NiV, is supported by the cell surface protein ephrin-B2[7, 26] (as well as additional ephrins[26]) as a functional entry receptor.

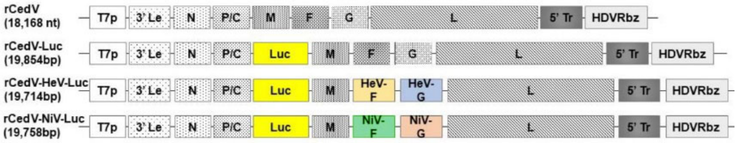

Figure 1. rCedPV variants used in this proposal. Maps are of plasmid-based rCedV antigenomes, all of which have been generated, sequence validated and utilized to produce infectious virus via an in vitro rescue system[27]. The top line shows the genome features of the parental rCedV with only CedV open reading frames (ORFs) and no reporter gene. The second line is rCedV with a firefly luciferase reporter inserted between P and M (rCedV-luc). The third and fourth lines are the rCedV-luc chimeras in which HeV F and G and NiV F and G (respectively) replace CedV F and G. T7p: promoter; HDVRbz: hepatitis D virus ribozyme; Le: leader; Tr: trailer.

CedV as a potential BSL-2 platform for the study of henipavirus biology and preclinical testing of candidate henipavirus therapies. The **Broder group (RP2)** has been developing CedV as a new experimental tool set to study henipavirus host cell interactions, including ephrin receptor use, and host cell tropism. Moreover, they have recently developed a CedV reverse genetics system to rescue recombinant CedV (rCedV)[27], adding a gene for firefly luciferase (rCedV-luc)[28] to enable bioluminescence imaging of viral replication. Additionally, they have created chimeric viruses that express the F and G glycoproteins of NiV or HeV in place of the endogenous CedV F and G (rCedV-NiV-luc and rCedV-HeV-luc; see **Fig. 1**). Importantly, there is **no** evidence that NiV and HeV F and G suppress the immune response or contribute to any viral activity beyond binding and fusion to target cells, nor is there evidence that NiV or HeV F and/or G increase the pathogenicity of rCedV in immunocompetent hosts. Thus, work with rCedVs can be carried out under BSL-2 containment settings[28].

The Schaefer group has optimized use of bioluminescence imaging to semi-quantitatively track lyssavirus replication in individual animals in a longitudinal manner[8, 9]. Working collaboratively, the Schaefer group and **Broder group (RP2)** groups are now developing the rCedV-luc platform as a new technology for the study of henipavirus *in vivo* biology, using mouse models deficient in interferon signaling. *From a translational perspective, rCedVs are an authentic henipavirus platform suitable for developing live-attenuated NiV/HeV vaccines and for preclinical testing of other types of NiV/HeV-directed countermeasures (e.g., mAb and nanobody therapy; novel small molecule antivirals).*

In this proposal, we will build on important preliminary data, showing that (i) rCedVs replicate and infect multiple organs in mouse strains deficient in interferon signaling; (ii) rCedV-NiV-luc and rCedV-HeV-luc rapidly enter and efficiently replicate in the brains of Ifnar1-/- mice; and (iii) rCedV-NiV-luc infection causes neurological disease signs and mortality in STAT1-/- mice. Our goal is to further develop and optimize this model for the study of henipavirus neuropathogenesis and the development and validation of novel countermeasures, under BSL-2 conditions. A robust rCedV chimera-based model would represent a considerable advance in throughput for preclinical validation of NiV- and HeV-directed therapeutics, in contrast to the current cumbersome and costly BSL-4 containment required for such work with NiV and HeV.

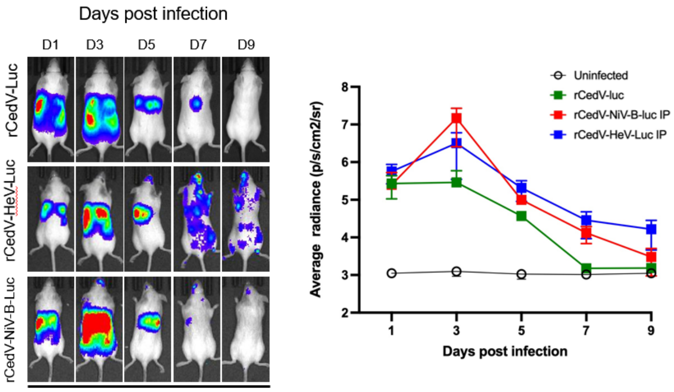

Figure 2. rCedV-luc and rCedV-luc chimeras replicates in Ifnar1-/- albino mice with similar kinetics. B6-albino-Ifnar1-/- mice were infected IP with 10^7 pfu of rCedV-luc, rCedV-HeV-luc or rCedV-NiV-luc. Bioluminescence intensity is reported as average radiance (log scale).

Innovation

Scientific Innovation: The generation of a BSL-2 mouse model of authentic henipavirus infection is novel. Due to the use of the mouse model, there is a potential to leverage powerful genetic tools and a wide array of antibody-based phenotyping reagents to characterize the mechanistic basis of the host-virus interaction, particularly with regard to the antiviral response. A further innovation is use of the STAT1-/- strain in combination with rCedV chimeras to achieve a model of CNS-tropic infection that leads to neurological disease and mortality. We have thus created a tractable *in vivo* system in which henipavirus-directed therapeutics can be evaluated for protection against lethality. Collectively, these innovations should dramatically reduce costs and enhance throughput of translational studies of henipavirus countermeasures, generally making such studies widely accessible to the scientific community.

Technical Innovation: Our use of luciferase-expressing henipaviruses in mice enables longitudinal tracking of infection kinetics and anatomical location[8, 9] of rCedV replication. This innovation was crucial for following and semi-quantitatively measuring the progression of infection with a virus that causes no apparent disease signs (in the Ifnar1-/- strain that we utilized for our initial pilot investigations). Application of robust transcriptomics approaches, including spatial transcriptomics, represents a further technical innovation that may yield a more granular understanding of mechanisms of henipavirus-dependent CNS pathogenesis, thereby potentially suggesting novel targets for countermeasures.

Approach

Scientific Rigor: We will utilize both male and female animals for experiments in this proposal. Animal studies are planned in consultation with the USU Biostatistics Consulting service. These planning phases include power analyses to determine group size and discussion of appropriate statistical methods for the given type of data. Additionally, prior to publication, collected data are analyzed via in-depth discussions with biostatistics consultants to ensure that statistical analyses and any required testing for multiple comparisons have been properly performed. rCedV laboratory manipulation guidelines and standard operating procedures under BSL-2 conditions were developed for the laboratory and staff, and all procedures were reviewed and approved by the Uniformed Services University Institutional Biosafety Committee in accordance with NIH guidelines (see *Select Agents* for further details regarding **biosafety measures** and approvals).

Aim 1: To optimize the use of Stat1-/- mice and rCedV-NiV-luc/rCedV-HeV-luc chimeras as a robust BSL2 model of pathogenic henipavirus disease. Hypothesis: *Infection of Stat1-/- mice with recombinant rCedVs will recapitulate major hallmarks of pathogenic NiV and HeV infections in humans*.

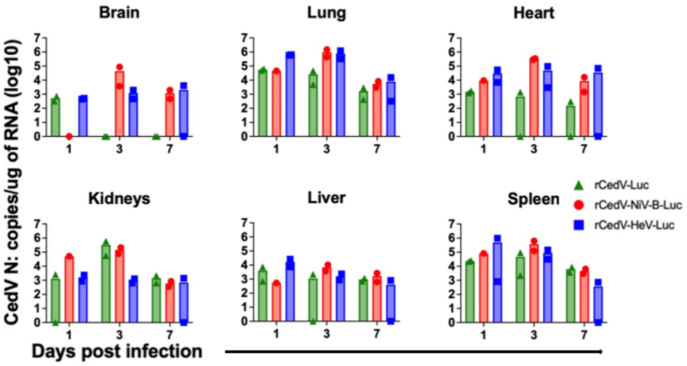

Figure 3. *N*-gene transcription in Ifnar1-/- albino mice infected with rCedV-luc and rCedV-luc chimeras. B6-albino-Ifnar1-/- mice were infected IP with 10^7 pfu of rCedV-luc, rCedV-HeV-luc or rCedV-NiV-luc. Animals were sacrificed and organs were harvested at the indicated time points. qPCR was performed to determine N-gene transcripts/µg total RNA.

Rationale:

The **Broder (RP2)** group at USU has constructed and rescued a series of rCedV chimeras that include the *Photinus pyralis* (firefly) luciferase gene to enable longitudinal *in vivo* bioluminescence imaging of individual animals, analogous to the system we have developed for the study of lyssavirus *in vivo* infection kinetics[8, 9]. In addition to the wild-type rCedV reporter virus (rCedV-Luc)[28], they have also generated two types of rCedV chimeras; one bearing NiV-Bangladesh[29] F and G (rCedV-NiV-luc) and the other bearing HeV F and G (rCedV-HeV-luc). For these reporters, the NiV and HeV F and G replace the Cedar F and G (**Fig. 1**). Notably, using cell-based infection tropism and growth kinetics assays, the luciferase-expressing chimeras behave identically to the rCedVs that do not encode a reporter gene (data not shown and [28]), indicating that there is no *in vitro* growth inhibitory effect of the added luciferase reporter gene.

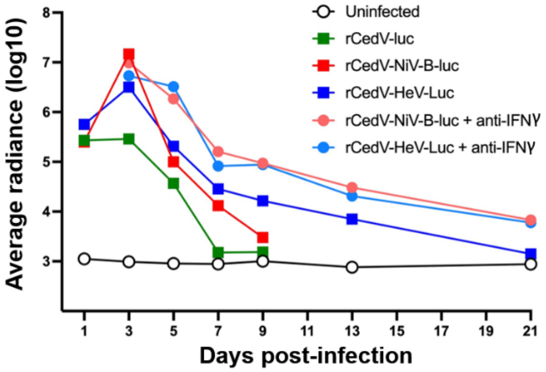

Figure 4. In vivo neutralization of IFNγ inhibits host control of replication of rCedV-luc chimeras. Ifnar1-/- mice were infected with rCedV-luc, rCedV-NiV-luc or rCedV-HeV-luc and untreated or treated every 3-4 days with an IFNγ neutralizing antibody. Whole body bio-luminescence is shown over a 21-day time course.

Pathogenesis by NiV and HeV can largely be attributed to specific viral gene products, C, V and W. Each of these gene products are encoded within the P gene. C is encoded as an alternative reading frame within P, whereas V and W are produced via an RNA editing process, in which non-templated G residues are added at a specific editing site within the nascent P transcript, resulting in a reading frame shift. V and W thus share N-terminal sequence with P, but the C-termini differ from P and from each other[30]. Variants of NiV engineered to lack C, V or W are less pathogenic in a variety of animal models, with V being essential for lethality in ferrets[23, 24, 31, 32]. Although data suggest that these proteins inhibit host immunity via multiple independent mechanisms[33], a very well documented inhibitory effect involves the targeting of the host type-I IFN system. Specifically, data show that the NiV P, V and W protein family can bind to multiple STAT transcription factors[34]. Moreover, these NiV proteins strongly inhibit the STAT1-induced host interferon response via these binding interactions[35, 36]. Although one ferret study has shown that the STAT1 binding site can be eliminated without impacting lethality, NiV (and HeV) have multiple mechanisms of interfering with induction of the interferon response, including antagonism of STAT2 and RIG-I signailing[37, 38]. Collectively, evidence thus indicates that targeting of the host interferon response is a major immune evasion mechanism of HeV and NiV.

CedV does not have the RNA editing site that gives rise to the V and W proteins, and it lacks HeV and NiV mechanisms of antagonizing the host interferon response[21]. Previous studies have shown that wild-type mice are inherently resistant to HeV and NiV infection; however, both HeV and NiV can replicate and cause lethal infection in mice in which the type I interferon receptor is not expressed (Ifnar1-/- mice)[39], further implicating the host interferon response as a major mechanism of limiting HeV and NiV replication and pathogenesis. We thus postulated that rCedV would replicate in Ifnar1-/- mice, but not in WT C57BL/6 mice. As expected, upon intraperitoneal (IP) infection of WT mice with rCedV-luc, no replication could be detected *in vivo*, whereas several days of replication was detected via bioluminescence imaging and qPCR in Ifnar1-/- mice (data not shown, and see **Fig. 2**). Consistent with the non-pathogenic nature of CedV infection in other species[7, 21], there was no morbidity or mortality and no detectable pathogenesis in mice infected with rCedV-luc.

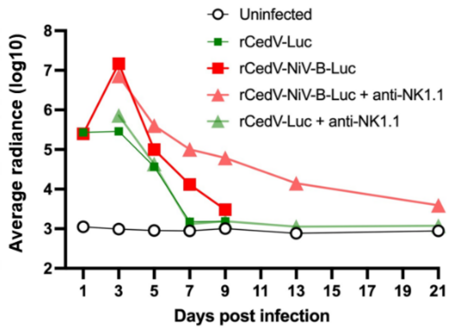

Figure 5. In vivo depletion of NK cells inhibits host control of replication of rCedV-luc chimeras. Ifnar1-/- mice were infected with rCedV-luc or rCedV-NiV-luc and untreated or treated every 3-4 days with an anti NK1.1 antibody to deplete NK cells. Whole body bioluminescence (viral replication) is shown over a 21-day time course.

Because the bioluminescence signal produced within an experimental animal is substantially attenuated by melanin in the skin and fur[40], we crossed Ifnar1-/- mice with B6-albino mice to produce a B6-albino-Ifnar1-/- strain (We maintain this strain in our Charles River Laboratories (CRL) breeding colony). These mice were then infected with rCedV-luc, rCedV-HeV-luc and rCedV-NiV-luc to assess how the chimeric virus replicated in comparison to wild-type over a 9-day infection time course. Interestingly, the chimeric viruses exhibited distinct *in vivo* properties, replicating to a level approximately a log higher than the wild-type rCedV-luc at days 3 and 7 post-infection, and with replication still detectable at day 9. By contrast, rCedV-luc replication was at undetectable levels by day 7 **(Fig. 2**). Viral infection was further assessed on a per-organ basis by qPCR quantification of *N*-gene transcription, demonstrating sustained viral transcription in an array of organs on days 1, 3 and 7. Although viral transcription was generally similar across rCedVs, the notable exception was the brain, where weak *N*-gene transcription was detected for rCedV-luc on day 1 only, whereas both chimeras exhibited *N*-transcription in the brain on days 3 and 7 post-infection (**Fig. 3**). Disease signs were not apparent in any infected animal (data not shown). Thus, rCedVs replicate in B6-albino-Ifnar1-/- mice with an infection kinetic that suggests host immune control of viral replication beginning near day 3 post-infection, with substantially reduced levels of viral replication by day 7 or 9 post-infection (**Fig. 2**). In the brain, rCedV-luc is present only transiently, whereas rCedV chimeras replicate at that site for at least 5 days.

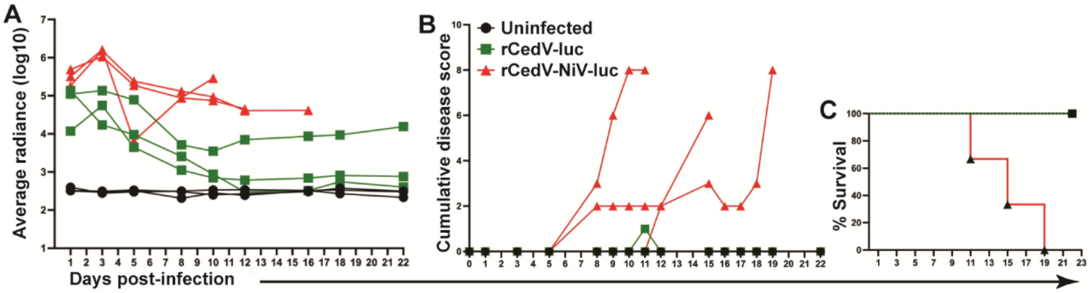

Figure 6. Infections of STAT1-/- mice with rCedV-NiV-luc leads to disease manifestations and death. STAT1-/- mice were uninfected or infected with rCedV-luc or rCedV-NiV-luc and monitored for (**A**) viral replication by bioluminescence; (**B**) disease signs; and (**C**) mortality. Animals infected with rCedV-NiV-luc experienced disease signs and death, whereas animals infected with rCedV-luc survived with no disease signs through this 22-day experiment.

Based on the above data, we hypothesized that more robust *in vivo* replication of rCedVs might be achieved by further impairing the interferon response in the B6-albino-Ifnar1-/- strain. We thus injected rCedV-infected Ifnar1-/- albino mice every 3 - 4 days with the neutralizing anti-IFNγ mAb XMG1.2 (200 µg/injection, starting on day 0). As shown in **Fig. 4**, inhibition of IFNγ activity resulted in increased in vivo levels of rCedV-NiV-luc and rCedV-HeV-luc bioluminescence after day 3 post-infection, as well as a substantially extended *in vivo* replication kinetic, such that both viruses were still replicating at detectable levels at day 21 post-infection. In a similar experiment, we used repeated administration of anti-NK1.1 to deplete NK cells, which are a major source of IFN-γ during viral infection[41]. Depletion of NK cells resulted in an extended kinetic of rCedV-NiV-luc replication, very similar to IFNγ depletion. Interestingly, there was little to no effect on replication of rCedV-luc (**Fig. 5**). Notably, despite the lengthy kinetic of viral replication for chimeric rCedVs, animals treated with either anti-IFNγ or anti-NK1.1 exhibited no disease signs throughout the 21-day course of these infections.

Overall, the above data suggest that type I and II interferons work together to suppress replication of rCedV chimeras. We thus reasoned that type III interferons may also play a role in viral suppression, particularly given that in vitro data have shown that there is a type III interferon response *in vitro* in response to CedV infection, but not HeV infection (presumably due to the suppressive activity of HeV C, V and W genes)[42]. To achieve complete blockade of signaling by types I, II and III interferons, including in the brain (where access of IP-administered neutralizing mAbs is limited by the blood-brain barrier (BBB)), we performed infections of STAT1-/- mice, in which signals from all interferon receptors are highly attenuated. In this initial experiment, we observed that mice infected with rCedV-luc survived for the entire experiment (22 days), with no disease signs and with 2/3 of animals exhibiting virus levels reduced to near the limit of detection by day 12 post-infection. By contrast, animals infected with rCedV-NiV-luc experienced disease signs consistent with neurological dysfunction, with all animals reaching euthanasia criteria between days 11-19 post-infection (**Fig. 6**). As the major differences between these viruses is the ability to sustain infection in the brain (**Fig. 3**), these data suggest that interferon responses play a particularly important role in protecting animals from CNS/encephalitic disease. Thus, our overall interpretation of our preliminary data is: (i) the host interferon response blocks features of viral infection shared across henipaviruses (including CedV) that result in CNS pathogenesis; and (ii) once henipaviruses enter the CNS, pathogenesis will result, if the host interferon response is blocked (e.g., by C, V, W) or not present (e.g., in STAT1-/- mice).

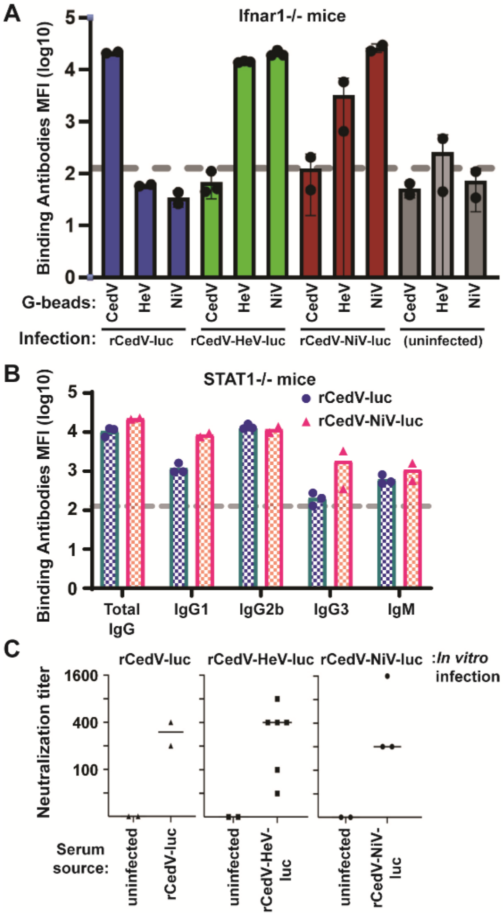

Figure 7. Infections with rCedVs lead to production of G-specific neutralizing antibodies in Ifnar1-/- and STAT1-/- mice. (**A**) Ifnar1-/- mice were uninfected or infected with the indicated rCedVs. G-specific total IgG was detected in sera harvested at the indicated time points using Luminex beads coupled to G ectodomains from CedV, HeV or NiV, as indicated. These specificity controls show the predicted cross-reactivity between anti-HeV and anti-NiV. (**B**) G-specific total IgG, IgG isotypes and IgM were detected in sera of STAT1-/- mice infected as indicated, using methodology of (A). Dashed line is average background. (**C**) *In vitro* neutralization of the indicated viruses with sera from mice infected with the indicated rCedVs. Beads prepared in the **Broder lab (RP2)**; serology run in the **Gunn (Core D, RP1,2) and Laing (RP2) labs**.

In this Aim, we will further optimize the chimeric rCedV-STAT1-/- infection model, to fully define the in vivo kinetics of viral replication, the characteristics of viral pathogenesis and the antiviral humoral response.

Experimental Design

Generation of an albino STAT1-/- strain: Because STAT1-/- mice are not carried in large numbers by the vendor (Jackson Labs) and because the pigmentation (including hyper-melanated birthmarks) of this strain impedes bioluminescence imaging, we will cross STAT1-/- mice to the B6-albino strain. Sequential intercrossings will be performed to produce enough STAT1-/- albino breeding animals to generate age-matched animals in sufficient quantities for our proposed experiments (notably, the F_1 breeding generation has been initiated in our contracted breeding colony at Charles River Labs).

Quantifying in vivo replication kinetics of rCedVs in mouse models. As our findings with the STAT1-/- strain are very recent and limited to the data in **Fig. 6**, further experiments will be conducted using larger groups and *albino*-STAT1-/- animals. We will first perform in vivo titration experiments to determine the lowest amount of virus that leads to 100% mortality. Next, whole animal bioluminescence data will be used to define the kinetics of infection, providing some indication regarding on which days individual organs or groups of organs reach peak infection titers. These studies will be followed up by further bioluminescence tracing studies, in which some individual animals are euthanized at key time points for more detailed analysis of individual organs (liver, lungs, spleen, kidneys, heart, lymph nodes, brain, etc), to quantify transcript levels of rCedVs, comparing rCedV-luc, rCedV-NiV-luc and rCedV-HeV-luc, and providing more granular data regarding the per-organ kinetics of viral replication and transcription. These data will also be compared with infection data from infections of the Ifnar1-/- albino strain (with and without inhibition of IFNγ), to determine the degree to which types II and III interferons contribute to suppression of viral replication across organ systems.

Histological identification of cell types infected and pathological features of infection by rCedVs. We will perform histological analyses, to determine if there is evidence of organ-specific pathology during the course of infection. While brain-specific pathology is of particular interest and will be explored in depth in **Aim 2**, we will perform a thorough analysis of other possible organ-specific pathology in this Aim. To add power to these histological analyses, we are currently developing an anti-Cedar N mAb (via a contract with GenScript), with the goal of producing a highly-sensitive reagent for histological identification of cells infected with rCedVs (note that Cedar N is expressed by all viruses to be used in this proposal). If successfully generated, this reagent will be employed in our protocols using paraformaldehyde-fixed frozen tissues for multiparameter immunofluorescence microscopy, which we perform routinely. The goal of these experiments will be to determine the types of cells infected by rCedVs and how cellular tropism varies between distinct rCedVs (e.g., rCedV-luc vs rCedV-NiV-luc), potentially as a result their incompletely overlapping usage of ephrin entry receptors (xxxRef). A distinct goal of these experiments is to identify subtypes of immune cells that may expand in or infiltrate tissues in areas of viral replication. We will also formalin-fix and paraffin-embed (FFPE) organs for standard H&E staining and histological analysis, using this complementary histological approach to identify features of pathology. Analyses of H&E-stained FFPE sections will either be performed by in-house veterinary pathologists or contracted to Histoserv, Inc. Additionally, we will conduct analogous experiments in albino Ifnar1-/- animals, with and without antibody-mediated inhibition of IFNγ (Figs. xxx), to evaluate whether specific pathological features differ as interferon signaling is combinatorially inhibited (i.e, inhibition of only Type I IFN signaling in the Ifnar1-/- strain; inhibition of Types I+II IFN signaling in Ifnar1-/- mice with anti-IFNγ injection, and inhibition of Types I+II+III IFN signaling in STAT1-/- mice). Our goal is to use the resulting data to form new mechanistic hypotheses regarding the roles of specific interferon types in the virus-host interaction, particularly with regard to *in vivo* control of infection and pathogenesis.

Analyses of humoral responses to rCedVs. To assess the humoral response to rCedV infections, sera will be recovered from animals at various time points post-infection. We will analyze sera for G- and F-specific isotypes, and we will determine neutralization efficiency (**Fig. 7**). In collaboration with the **Gunn group (Core D, RP1,2)**, we will use a systems serology approach to define antibody-dependent mechanisms of host defense against rCedV infection, analogous to what they have published for Ab-dependent host defenses in human and NHP studies (e.g., [43, 44]). Specifically, aliquots of sera will be shipped to the Gunn group for analysis via phagocytosis, antibody-mediated complement deposition (AMCD) and antibody dependent NK cell degranulation (NK-ADCC) assays, in order to determine the degree to which the anti-rCedV Ab response exhibits these Fc-dependent activities. Additionally, sera will be analyzed via Luminex-based approaches for cytokine and chemokine levels, with a particular goal of defining the kinetics of inflammatory cytokine presence (if any). We will also perform Luminex-based analysis of cytokine production in homogenates of any organs that show evidence of virus-induced pathogenesis.

Expected Results

Overall, we expect these data to define infection of STAT1-/- mice with chimeric rCedVs as a highly relevant BSL-2 model for lethal henipavirus disease, in which encephalitis is the major mortality-driving pathological feature, analogous to human disease (xxxRefs). We expect to rigorously demonstrate that as we progressively inhibit the interferon system (type I, then I + II, then I + II + III), replication of rCedVs will increase across organ systems, both in magnitude and duration of infection. Via histological analyses of distinct organs, we expect to identify cell types that are predominant targets for rCedV-luc infection and replication, via combinatorial staining for Cedar N and markers of distinct cell types. We furthermore expect that these cellular targets will only partially overlap the targets of the chimeric rCedVs, due to their incompletely overlapping patterns of ephrin binding (xxxRef). Also, due to its ability to invade the brain, we expect rCedV-HeV-luc to induce mortality with kinetics and frequency indistinguishable from rCedV-NiV-luc.

We expect histological analyses to identify hallmarks of pathogenesis in a subset of organs, particularly in the STAT1-/- model. Our preliminary data (not shown) suggest an enlargement of the liver on days 1 and 3 post-infection, suggestive of a transient hepatitis. Notably, liver involvement in the form of vasculitis has been noted in HeV infections of hamsters[45]. Thus, we expect to observe vasculitis in the liver, and/or leukocyte infiltration. The lungs are also a major henipavirus target, and our qPCR data demonstrate replication of all rCedVs in the lungs of infected animals (**Fig. 3**). As vasculitis/vascular lesions of the lungs have been observed in multiple distinct henipavirus animal models[46], we anticipate similar findings in the STAT1-/- model upon infection with rCedVs. Indeed, given the presence of viral transcripts in many organs (**Fig. 3**), evidence of lymphocyte and macrophage infiltrates is likely across organ systems, particularly in perivascular regions[46].

Preliminary data performed collaboratively between our group and the **Broder, Laing and Gunn groups (RP2)** show robust G-specific IgM and IgG responses are induced in rCedV-infected animals, across all animal genotypes and interferon blockade conditions (**Fig. 7A-B**). Interestingly, our preliminary studies indicate that neutralization titers from sera of infected animals are rather low (**Fig. 7C**). We thus expect that the systems serology assays of the **Gunn group (Core D, RP1,2)** will substantially clarify the potency of various Ab-mediated effector mechanisms against rCedVs in this model system. For example, we may find that although neutralization titers are low, the ability of anti-G (or anti-F) Abs to facilitate NK-ADCC is high.

Pitfalls and Alternative Approaches

Although our pilot study of rCedV-NiV-luc infection of STAT1-/- mice yielded promising results, we may encounter technical hurdles in further development of this model. For example, the frequency of fatality may be less than the 100% rate observed in our pilot study. Alternatively, although disease signs strongly indicate a neurological basis for progression to euthanasia criteria, which is highly consistent with human disease, our histological studies may indicate other effects on major organ systems that are inconsistent with human disease. While many such scenarios can be envisioned that would complicate this model, we believe that the initial data are compelling enough for us to be confident that the STAT1-/- model of henipavirus disease will be of high value for these studies and the overall scientific community. One technical pitfall is that our in-process development of the CedV N monoclonal may fail to yield a reagent of high enough specificity/sensitivity for use in histology. In such a circumstance, we can use the equivalent GFP-expressing variant of each rCedV (the Broder (RP2) group routinely generates both luciferase- and GFP-expressing variants of each new rCedV).

Aim 2: To determine the mechanism of rCedV-NiV neurovirulence in the Stat1-/- mouse model.

Hypothesis: *CNS infection by rCedV chimeras requires functional interaction between G and host ephrin B3; neurovirulence is a property shared by henipaviruses in the absence of host IFN-dependent defenses*.

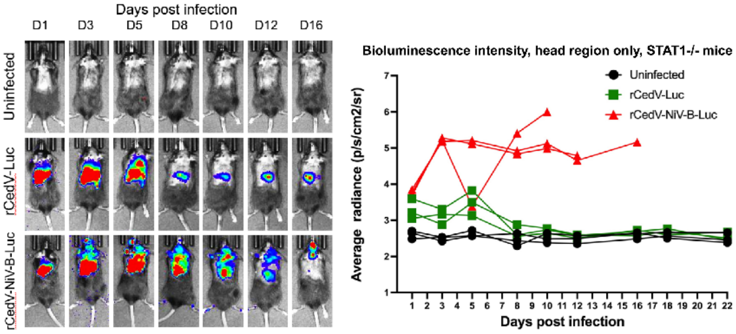

Figure 8. Persistent replication of rCedV-NiV-luc in the brains of STAT1-/- mice precedes death. STAT1-/- mice were uninfected or infected with rCedV-luc or rCedV-NiV-luc. Fur was shaved from the head and back to enable bioluminescence imaging. An ROI was drawn around the head and radiance was quantified (log10 scale). Data show strong replication in the head region of rCedV-NiV-luc, but not rCedV-luc (weak head signal on days 1-5 may reflect bleed of bright signal from chest cavity). See **Fig. 6** for related whole-body luminescence, disease score, and mortality data for these animals.

Rationale

Data in **Figs. 3 and 6** demonstrate that unlike rCedV-luc, both rCedV-NiV-luc and rCedV-HeV-luc are able to establish days-long infections in the brains of Ifnar1-/- and STAT1-/- mice. Because these viruses differ only at their F and G loci, the ability of these viruses to access the CNS must map to either F, G or both cooperatively. Importantly, although CedV G binds to more ephrins than NiV/HeV G, CedV G does **not** bind to ephrin B3, whereas both NiV and HeV G do interact with ephrin B3[26]. Moreover, data suggest that the ability of NiV and HeV (and the inability of CedV) to enter the CNS is due to the fact that brain cells express ephrin B3, but little to no ephrin B2[47]. Thus, our *in vivo* observations with rCedVs lend additional support to the hypothesis that efficient henipavirus entry into the CNS requires interaction between G and ephrin B3.

Notably, for the rCedV chimeras, both viral persistence and pathogenesis appear to be highly influenced by interferon-dependent mechanisms. Specifically, in the case of Ifnar1-/- animals, regardless of IFN-γ blockade or NK cell depletion (**Figs. 2-5**), infection with rCedV-NiV-luc and rCedV-HeV-luc causes neither disease signs nor mortality. However, Ifnar1-/- mice given an mAb that blocks IFNγ or that depletes NK cells exhibited a longer kinetics of viral replication over the 21-day experimental time frame (**Figs. 3-5**), in contrast to the lack of impact of NK cell depletion on the transient rCedV-luc infection of Ifnar1-/- mice (**Fig. 3, 5**). In STAT1-/- animals, which fail to transduce signals from interferon receptors, rCedV-NiV-luc replicated to high levels (**Fig. 6**), including a persistent infection in the head/brain region of these animals (**Fig. 8**), with animals experiencing rapid escalation of disease signs, culminating in death (**Fig. 6**). However, as observed in viral transcription analysis in Ifnar1-/- mouse experiments (**Fig. 3**), rCedV-luc replication in the head/brain region was transient and at a much lower level than rCedV-NiV-luc (**Fig. 8**). Collectively, these data strongly suggest that interferon-dependent signals are required to control henipavirus infection in the brain and to prevent consequent neuropathogenesis and death.

Experimental Design

Defining viral determinants of CNS entry and pathogenesis. To further validate the postulate that CNS entry leads to morbidity and mortality, we will conduct several distinct experiments. Firstly, we will repeat the experiment shown in **Fig. 8** with the addition of rCedV-HeV-luc, a chimera that also stably infects the brain

(**Fig. 3**). Secondly, we will perform experiments in which we infect STAT1-/- albino mice with rCedV-NiV-luc and the rCedV-NiV($B3_{mut}$)-luc virus (expressing a NiV G mutant that binds to ephrin B2 but ***not*** ephrin B3, which is being generated under **RP2)**, to test the requirement for ephrin B3 binding for brain entry and subsequent mortality. Also, the **Broder (RP2)** group has generated data showing that the combination of CedV G and HeV F can mediate viral fusion. Thus, we will test if rCedV-(CedV G/HeV F)-luc is capable of brain infection, to provide a further test regarding whether G or F is the crucial henipavirus determinant of CNS entry. Additionally, we will directly inject rCedV-luc and rCedV-NiV-luc into the brains of Ifnar1-/- and STAT1-/- albino mice, in order to evaluate development of disease signs and mortality under conditions in which CNS entry is independent of the ability to cross the BBB.

Each of the above experiments will be conducted with the necessary number of iterations to robustly define elements of CNS pathology in these animals. In some iterations, animals will be euthanized at intermediate time points prior to the expected earliest mortality date. Brains will be harvested, with one hemisphere being used for RNA collection and the other being used for histology (details below). RNA will be analyzed in qPCR experiments, to determine absolute numbers of both N gene transcripts (**Fig. 3**) and rCedV genomes (we have validated genome-specific primer sets for this purpose), to achieve a thorough understanding of the relationship between viral transcriptional activity and viral load over time and across animal genotypes.

Transcriptomics analysis of gene expression in the brain. To define gene expression changes that correlate with henipavirus pathogenesis in the CNS, we will use a complementary set of unbiased transcriptomics approaches. Our central approach will be 10x Genomics Visium transcriptomics, to map gene expression changes to specific regions and cell types within the brains of infected animals. For these experiments, we will compare rCedV-NiV-infected Ifnar1-/- animals treated with anti-IFNγ (which exhibit an extended kinetic of viral replication in the brain, without morbidity or mortality) with rCedV-NiV-infected STAT1-/- mice (which exhibit viral replication in the head/brain region, leading to disease signs and mortality). We will also include a custom-designed RNA probe for rCedV *N*, to enable correlation of host gene expression changes with viral infection. Based on our initial data (**Fig. 6**), we anticipate choosing a time point in the day 7-10 range, during which virus is present in the brains of both genotypes, and STAT1-/- mice exhibit early disease signs, but have not yet reached euthanasia criteria, and do not have severe brain pathology (**Aim 1** experiments will enable more refined determination of this time point). To further validate and reinforce spatial transcriptomics experiments, we will also perform transcriptomics analysis on total RNA isolated from brain sections adjacent to the sections used for spatial transcriptomics, and from equivalent sections from additional mice in the same group. We will also use a third complementary transcriptomics approach to provide confirmation and additional granularity regarding resident and infiltrating leukocyte transcriptional programs. Specifically, we will perform single-cell transcriptomics on leukocytes recovered from brains of additional animals (i.e., of the same groups and time points as assessed by spatial transcriptomics), to provide further granularity and confirmation regarding leukocyte-centric transcriptional changes that correlate with neurovirulence and mortality. Key differences identified by transcriptomics approaches will be further confirmed by qPCR, using total RNA from sections.

Histological and flow cytometry analysis. To complement and reinforce data collected through the above transcriptomics approaches, we will use multiparameter fluorescence labeling a Zeiss Axioscan Z1 slide scanner to define regions of the brain and cell types that are infected by each rCedV, using a CedV anti-N mAb (see Aim 1) and markers of brain-resident cells and peripheral immune cells that may be recruited to the brains of animals with rCedV infections. These studies will be informed both by transcriptomics data, and analysis of H&E-stained sections, described in **Aim 1**. Additionally, we will also perform dedicated experiments for flow cytometry analysis, in which brains are collected and processed to purify resident and infiltrating lymphocytes, with populations and activation states defined by antibody staining for specific cell surface and intracellular markers (e.g., transcription factors). In some experiments, cells will be stimulated and stained for intracellular cytokines to aid in identification of cellular subpopulations (e.g., types of effector T cells). We are already performing analyses of leukocytes in the mouse brain in similar studies of lyssavirus pathogenesis (xxxRef). We will also extend these flow cytometry studies to the peripheral tissues listed above, in order to determine the degree to which phenotypes of resident or infiltrating leukocytes reflect cellular phenotypes in the brain.

Expected Results

In our experiments testing the requirements for brain entry and mortality, we expect that rCedV-HeV-luc will behave analogously to rCedV-NiV-luc, replicating to high levels in the brain and causing mortality of all STAT1-

/- albino animals, as we have already shown that rCedV-HeV-luc efficiently enters and replicates in the brains of Ifnar1-/- mice. As existing data are consistent with the model that G interaction with ephrin B3 is the key determinant for productive replication of rCedVs within the CNS (**Fig. 3** and [26, 47]), we expect that neither rCedV-NiV($B3_{mut}$)-luc nor rCedV-(CedV G/HeV F)-luc will exhibit stable CNS replication and trigger morbidity and mortality in the STAT1-/- strain. Whether stable CNS infection and mortality can be driven by direct injection of rCedV-luc into the brains of STAT1-/- animals is more difficult to predict. Notably, a wide array of anatomical subregions of the brain express high levels of ephrin B3 and little to no ephrin B2[47], perhaps meaning that viruses expressing CedV G may be unable to efficiently infect brain cells, regardless of BBB penetrance. Thus, our expectation is that we will observe an increased level of brain infection upon direct injection of rCedV-luc as compared to IP delivery, but likely at lower levels and perhaps less persistently; and morbidity and mortality may not occur within the 21-day experiment. Across the above experiments, we expect qPCR experiments to be consistent with longitudinal bioluminescence imaging, with viral transcription levels correlating well with bioluminescence intensity, as we have shown in our lyssavirus studies[9].

We expect that the three complementary transcriptomics approaches will yield data that provide a highly granular picture of rCedV-NiV-luc-induced transcriptional changes that correlate with morbidity and mortality in the STAT1-/- model. Given that we will have rCedV-NiV-luc-infected IFNγ-treated IFNAR1-/- mice as controls in these experiments, analysis of the resulting data should identify gene expression changes *that specifically correlate with pathology* and not simply with CNS viral infection. Notably, the mechanism by which HeV and NiV trigger encephalitis and death remains unknown, with neither a direct cytopathic effect or an immune cell-mediated inflammatory response clearly implicated as primary drivers of morbidity and mortality. We anticipate that both mechanisms are important, and that our transcriptomics data will implicate leukocyte-specific inflammatory gene expression programs as more robustly induced in the STAT1-/- model as compared to Ifnar1-/- mice. We also anticipate that our data will provide gene expression data consistent with induction of stress and apoptosis programs in STAT1-/- animals, with spatial transcriptomics data demonstrating that infected neurons are the focal points of these indicators of cytopathic effects.

In addition, we expect histological and flow cytometry approaches to confirm key pathogenesis-associated changes in cellular phenotypes identified through our combined transcriptomics approaches. Moreover, we expect histological results to provide data that can help to discriminate between potential mechanisms of viral entry into the brain, particularly transcytosis of infected leukocytes, vs. infection of microvascular endothelia cells during viremia. Staining with anti-N plus markers of specific cell types at early post-infection time points should enable identification of initial cell types in the brain that are infected with rCedVs. Later time point data should suggesting which point(s) of early entry ultimately seed infection of the brain parenchyma. We also expect that brain pathology will be observed only with those viruses that cause morbidity and that such pathology will share many similarities with what has been observed in human post-mortem tissues and in animal models of HeV and NiV infection[46, 48].

Pitfalls and Alternative Approaches

While it is possible that our predictions regarding the Ephrin B3-centric role for viral entry are incorrect, experiments have been designed in such a way that data should indicate which viral features are crucial (e.g., F rather than G, or a determinant of G outside of the B3-interaction region). The basis of henipavirus neurovirulence has remained poorly understood for many reasons, including the expense of BSL-4 research and the relatively small number of *in vivo* experiments that have been performed. While it is unclear whether our rCedV-mouse model will recapitulate all crucial aspects of henipavirus neuropathogenesis in humans, there should be commonalities. The use of three separate unbiased transcriptomics approaches will provide multiple independent measures of gene expression changes, leading to new mechanism-based hypotheses regarding henipavirus neuropathogenesis. These data and hypotheses will be of high value to investigators across the henipavirus field, who can perform experiments in diverse models to further test these models.

Aim 3: To define the efficacy and mechanisms of mAb-based therapeutics for CNS-resident henipavirus infections. Hypothesis: *G- and F-directed mAb-based therapeutics will demonstrate Fc-dependent efficacy against CNS-resident henipavirus.*

Rationale

Monoclonal antibodies have been utilized effectively against several disease-causing viruses in humans (e.g., RSV, SARS-CoV-2[49]). Indeed, m102.4, an anti-HeV/NiV G mAb, developed by the **Broder group**, has been employed in humans under circumstances of compassionate use for those exposed to HeV and NiV[2, 50], with all of those treated experiencing no symptoms of henipavirus disease. While virus neutralization has historically been viewed at the key mechanism of action of such mAbs, accumulating data are suggesting varying degrees of contribution of the antibody Fc domain in mediating therapeutic benefits[51, 52].

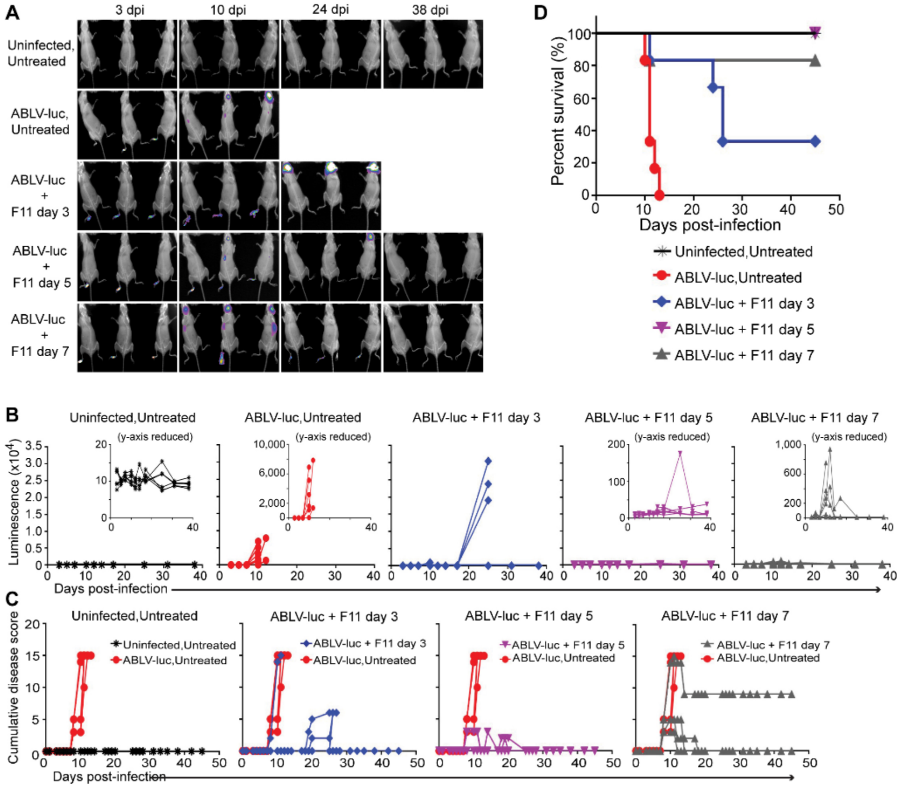

Figure xxx. Single-dose F11 mAb therapy reverses disease signs and prevents mortality in animals with CNS-resident lyssavirus infection. A. ABLV-luc bioluminescence (pseudocolor intensity) overlaid on X-ray images of mice at the indicated days post-infection. Treatments are indicated in the left column. mAb F11 was administered as a single dose of 10 mg/kg on the indicated day. **B.** Mean luminescence intensity (MLI) values from the head/brain region of the indicated infection and treatment groups. Inset y-axis scales are reduced (and **not** × 10^4), to enable clear visualization of lower luminescence values. **C.** Pairwise comparison of cumulative disease scores of different infection and treatment groups. **D.** Kaplan-Meier survival analysis of same groups of mice analyzed in panels A-C..

Importantly, in a distinct Schaefer lab-Broder lab collaborative project focused on development of novel lyssavirus-directed therapeutics, we have made the surprising finding that a single dose of a neutralizing human anti-lyssavirus G mAb, F11[53], can protect mice from a lethal lyssavirus infection, even when administered (via the IP route) after virus is already replicating robustly in the CNS (xxxRef or Fig?). Specifically, day 3, 5 and 7 treatments with mAb F11 had a dramatic effect on reducing virus burden in both the spine and brain during the acute phase of infection (through ~day 14), versus infected untreated controls (**Fig. xxxA-B** and data not shown). Additionally, although most infected, F11-treated animals experienced weight loss and other disease manifestations, F11 therapy completely reversed disease signs in the majority of these animals (some of the day 7 animals had permanent partial paralysis in the inoculated limb, but all animals recovered their lost weight) (**Fig. xxxC** and data not shown). Most remarkably, *100% of the day 5 and >80% of the day 7-treated animals survived* (**Fig. xxxD**). *Indeed, we have monitored day 5 and day 7 F11-treated animals for more than 4 months, and there has been no re-emergence of disease signs in any animal*. Recovery occurred despite the fact that the virus progressed to and replicated within the brain, as evidenced by bioluminescence imaging (**Fig. xxxA-B**). Thus, our data strongly suggest that single-dose human anti-ABLV mAb therapy provides long-term control of viral infection, even when therapy is administered after CNS entry. We also found that F11 therapy was effective against the lethal mouse-adapted rabies strain, CVS-11 (data not shown). Importantly, we have shown that the mechanism of efficacy requires participation of the adaptive immune response, particularly CD4 T cells, with F11 therapy leading to a CD4-dominant T cell infiltration in the brain (in contrast to the balanced CD4/CD8 ratio in the brains of untreated animals) (xxxRef). Moreover, mutation of the Fc region to impede FcR binding leads to dramatically-reduced F11 therapeutic efficacy (xxxRef). Collectively, these data demonstrate that an IP-administered mAb can have therapeutic efficacy against a *brain-resident* virus in a manner that requires CD4 T cells and a functional Fc region.

In this aim, we will investigate whether similar therapeutic efficacy can be achieved via IP administration of henipavirus-directed mAbs, following CNS invasion by chimeric rCedVs. We will also test therapeutic efficacy of nanobodies, including chimeric nanobodies engineered for transport across the BBB.

Experimental Design

IP-administration of mAbs and nanobody reagents as a therapy for CNS infections with rCedVs. Our preliminary data (**Fig. 8**) show that rCedV-NiV-luc reaches high expression in the brain of infected STAT1-/- animals by day 3, with initial disease signs apparent by day 8 and animals beginning to succumb to disease on day 11 (**Fig. 6**). For modeling of human henipavirus disease, we consider it most important to identify therapeutics that demonstrate efficacy in neutralizing virus that is already replicating in the nervous system, with the most broadly useful therapeutics being those that can protect from death after disease signs are apparent. We will thus investigate the day 3-10 post-infection period for administration of therapeutic antibodies, with initial studies investigating therapeutic efficacy on (a) day 3 (early post-CNS entry) and (b) the first day animals show disease signs. Time points for later experiments will be determined based on the results from these initial time points (e.g., if therapy is effective on the first day post-appearance of disease signs, later post-disease sign time points will be tested). As we already have stocks of neutralizing mAbs m102.4 (highly potent human anti-HeV G which cross-neutralizes NiV G[54]) and 1F5 (mouse anti-HeV/NiV F[55]), we will use these candidate therapeutics for our initial investigations.

STAT1-/- albino mice will be infected with rCedV-NiV-luc or rCedV-HeV-luc and treated with m102.4 or 1F5 (with a control group given a non-henipavirus specific mAb of the same isotype). Initial experiments will employ a single 10 mg/kg dose at d3 or d8 post-infection. Viral replication will be monitored by bioluminescence imaging, and cumulative disease scores and mortality will be recorded for each animal over the 21-day experimental time frame. Successful therapeutics will be those that both limit viral replication in the brain and reduce disease manifestations and mortality. In follow-on experiments, the antibody administration protocol may be adjusted, depending on strength of the therapeutic effect, e.g., the mAb could be delivered in a larger dose or in multiple doses over several days. In collaboration with **RP5**, we will also perform therapeutic efficacy experiments as described above with newly developed nanobody reagents that perform well during *in vitro* testing. Of particular interest are chimeric nanobodies that have been engineered to cross the BBB. Such reagents have the potential to both enhance the adaptive immune response and directly neutralize virus in the CNS, following transport across the BBB.

Mechanistic studies of therapeutic antibody efficacy. For any mAb or nanobody found to be therapeutically effective, we will perform additional experiments to investigate the mechanism. To define the importance of Fc function, we will generate a LALA-PG mutant (xxxRef) of the therapeutic mAb, to impair FcR binding and complement activation. Infected mice will be given a control mAb, the WT therapeutic mAb or the LALA-PG mutant. Analysis of outcomes will be as described above. To define gene expression and cellular changes that correlate with therapeutic efficacy, we will use the transcriptomics, histological and flow cytometry approaches of **Aim 2** as independent avenues to analyze the impact of therapies on animal brains. In this way, we can identify the experimental paradigms that lead to the highest therapeutic efficacy. Such data will also contribute to the **Aim 2** goal of defining cellar and transcriptional responses that correlate with pathogenesis.

Expected Results

Given our results with mAb F11 in the lyssavirus system (Fig xxx and xxxRef), we expect to demonstrate significant therapeutic efficacy via IP administration of m102.4 and 1F5 in the d3 – d10 window during which virus is replicating in the brain. Indeed, we have demonstrated >80% efficacy with administration of mAb F11 on d7 (we have not yet attempted later time points). Animals typically first exhibit disease signs on d8 – d10 and generally reach euthanasia criteria 3 – 4 days later. Although mice administered F11 on d7 still exhibit disease signs (Fig xxx and xxxRef), these signs reverse and most animals survive. Thus, the mAb-induced therapeutic effect on CNS disease is relatively rapid, resulting in survival of animals that would otherwise succumb to infection within 4 – 7 days. In our initial experiment with STAT1-/- mice (**Fig. 6**), animals infected with rCedV-NiV-luc reached euthanasia criteria 3 – 7 days after first showing disease signs. Thus, if there is a similar therapeutic effect of mAbs during rCedV-chimera infection of STAT1-/- mice, it is reasonable to expect that mortality rates will drop in response to therapeutic mAbs, possibly even after disease signs are apparent.

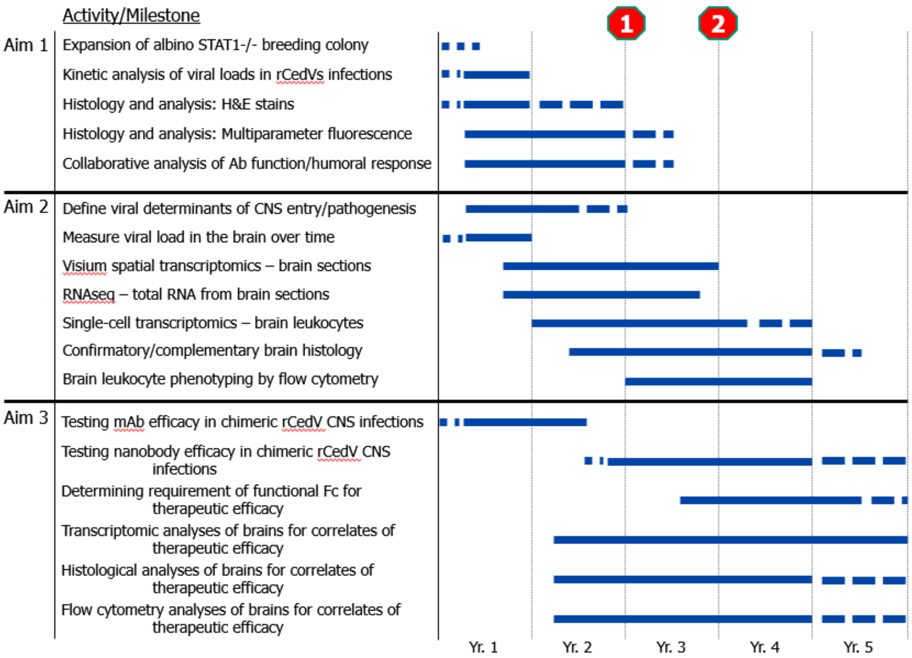
Because the nanobodies produced in **RP5** will include the IgG1 Fc domain, we also anticipate that these reagents will exhibit therapeutic efficacy. Although it is difficult to predict which therapeutics will perform best, we expect chimeric nanobodies engineered for transport across the BBB may demonstrate enhanced efficacy. These therapeutics could potentially both directly neutralize virus in the brain, and facilitate an effective CD4 T cell antiviral response in the brains of infected animals, as we have observed in our lyssavirus work (xxxRef). If BBB-crossing nanobodies prove effective, we predict that multiple doses would increase efficacy, as this approach should lead to higher concentrations of neutralizing nanobodies in the brains of infected animals. For all effective therapeutic antibody reagents, we predict that the LALA-PG mutation will impair functionality, as an intact Fc region appears critical for promoting an effective CD4 T cell response in the brain (xxxRef).

By applying transcriptomics, histological and flow cytometry approaches to the analysis of brains of animals that experience therapeutic benefit from antibody therapy, we expect to identify therapy-driven changes in gene transcription, cellularity and/or cellular phenotype in the brains of treated animals. Such data could suggest mechanisms by which mAb therapy prevents virus-induced death, as well as providing correlates of therapeutic efficacy for development of other types of therapeutics (e.g., small molecule drugs). As discussed in **Aim 2**, the mechanism by which NiV and HeV induce encephalitic death is still undetermined (xxxRef). Thus, the mechanistic studies in this Aim could synergize with **Aim 2** findings to yield novel insights into mechanisms of henipavirus neuropathogenesis, thereby suggesting key target pathways for development of future small molecule therapeutics.

Pitfalls and Alternative Approaches

Based on our surprising findings regarding the potency of IP-administered therapeutics in the lyssavirus system (Fig xxx and xxxRef), we anticipate a similar mechanism and efficacy against chimeric rCedVs with IP-administered neutralizing antibodies. However, it is possible that the mechanism of mAb enhancement of the CNS-directed CD4 T cells response is specific to the lyssavirus model, and will not be generalized to the henipavirus model. If our early data suggest such an outcome, we will focus our efforts on the nanobodies of **RP5**, engineered to cross the BBB and directly neutralize virus in the brain. Another possibility is that IP administered mAbs are effective at early times post-CNS entry of rCedVs, but ineffective once disease signs appear. With such an outcome, we focus our efforts on (i) identification of the most effective mAb/nanobody reagent, and (ii) optimization of the dosing amount and schedule to achieve efficacy as late as possible post-CNS invasion.

Project Milestones and Timelines



Gannt chart outlining project milestones (left). Solid lines represent periods of likely activity to achieve milestone; dashed lines indicate periods of possible early initiation or extended completion of activities. Go/no-go decision points are indicated by *red octagons*.

Go/no-go#1: **Cessation of pathogenesis-associated goals** if neuropathogenesis of rCedV-chimera infections of albino-STAT1-/- mice clearly has no overlapping features with known pathology in currently accepted animal models or human post-mortem cases. Note that therapeutics can still be evaluated on the basis of reduction of viral loads in the brain.

Go/no-go#2: **Cessation of Aim 3 studies** if there is no sign of CNS therapeutic efficacy from any tested mAb or nanobody (*note:* decision will be delayed if not all major planned nanobody designs have been generated by **RP5** AND tested by **RP3**, by the end of year 3).

Resource Sharing Plan

No model organisms will be generated from this research. Strains of mice to be used in this proposal are directly available from Jackson labs, or will be derived via breeding of these commercial strains. As these strains are readily available to the scientific community, no further action on our part is required.

All genomic data resulting from this project will be deposited in NCBI GEO (Gene Expression Omnibus) prior to or concurrent with publication.

In general, we will adhere to NIH policies regarding sharing of resources and data (https://sharing.nih.gov/). Our lab has demonstrated its commitment to sharing by providing published reagents upon request for the last 20+ years. Regarding any novel materials and resources that may be generated in this proposal, the general Resource Sharing Plan developed by the Henry M. Jackson Foundation and USUHS is as follows: Unique research resources, research tools, novel materials, including model organisms or modified strains, and related protocols, genetic and phenotypic data (including data from Genome-Wide Association Studies) that may arise out of the funded studies will be made available to others in the private and public sector as soon as appropriate agreements covering such transfer can be executed. In the case of project data, findings shall be published as soon as possible or otherwise shared with other researchers pursuant to NIH policies regarding data sharing. The USUHS-HJF Joint Office of Technology Transfer (JOTT) will manage all technology transfer activities for data and resources generated by researcher of either USUHS or HJF. The JOTT will adhere to all applicable policies, principles, guidelines and procurement rules in making unique research resources readily available for research purposes to qualified individuals and entities, and in ensuring that there is no more than a short–term restriction on publication or public dissemination of data in order for the JOTT to evaluate and file for patent protection on any subject invention that may arise from the funded study. Dissemination of unpublished data that is considered to be proprietary or confidential shall occur pursuant to a suitable confidential disclosure agreement prepared by the JOTT. Patient data shall be de-identified and shared in accordance with USU and HJF policies and applicable laws and regulations. Data associated with Genome-Wide Association Studies (GWAS) will be submitted to the NIH-designated GWAS data repository. Material transfer agreements, license agreements, and Cooperative Research and Development Agreements (CRADAs), as appropriate, will be used to transfer material property. Material transfer agreements will be established to share resources among the research community for noncommercial research use.

USUHS

Site Principal Investigator: Brian Schaefer, Ph.D.

Select Agents

No select agents are used in this research.

We will perform animal studies with recombinant forms of Cedar virus. These viruses are categorized as BSL-2. Dr. Schaefer has an approved BSL-2 biosafety protocol for research with Cedar virus, including in vivo ABSL-2 studies. All members of the Schaefer research group have received specific training in laboratory safety and the proper use and disposal of BSL-2 organisms (and two current laboratory members have certifications for BSL-3). Dr. Schaefer has BSL-2 certified laboratories where work with these agents will be conducted. Animal experiments are conducted in approved ABSL-2 rooms within the USU animal facility, conducted under USU IACUC-approved protocols.

Specific Aims

Henipaviruses are single-stranded, negative-sense enveloped RNA viruses of the paramyxovirus family[1]. Two henipaviruses, Nipah virus (NiV) and Hendra virus (HeV), cause a systemic and often fatal respiratory and/or encephalitic disease in humans and ten other mammalian species[2-4]. Importantly, NiV and HeV are significant biothreats to humans and economically important livestock in Australia and Southeast Asia[5]. There are currently no vaccines or therapeutics approved for human use. Notably, development of countermeasures for NiV and HeV is hampered by the fact that these viruses require BSL-4 containment, meaning that very few research groups worldwide have access to the required biocontainment facilities to perform preclinical studies with these important human viral pathogens[6].

To address this problem, we are developing a BSL-2 animal model that is based on Cedar virus (CedV), which is a non-pathogenic henipavirus[7]. Specifically, we have engineered recombinant Cedar viruses (rCedVs) in which the NiV and HeV fusion (F) and receptor-binding glycoprotein (G) are expressed in the rCedV genome, replacing CedV F and G. Additionally, we have also incorporated our recently developed *in vivo* bioluminescence methodology[8, 9] to longitudinally trace the dynamics and anatomical progression of rCedV-luciferase (rCedV-luc) infections in individual animals. Using various approaches to inhibit the host interferon response in mice, we have demonstrated sustained replication of rCedV-luc and the rCedV-NiV-luc and rCedV-HeV-luc chimeras. Importantly, whereas rCedV-luc does not establish stable expression in the brain, both of the chimeric viruses do. Moreover, preliminary findings show that rCedV-NiV-luc causes neurological dysfunction and death in STAT1-/- mice. The rCedV-luc platform is thus an authentic henipavirus system that can be used to study henipavirus *in vivo* biology safely and expediently under BSL-2 containment. Our **overall hypothesis** is that rCedV-luc infection of mice lacking interferon responses represents a BSL-2 platform for the study of henipavirus biology and pathogenesis, as well as for development and testing of anti-viral countermeasures. We will address this hypothesis through three Specific Aims:

Aim 1: To optimize the use of Stat1-/- mice and rCedV-NiV-luc/rCedV-HeV-luc chimeras as a robust BSL2 model of pathogenic henipavirus disease. Hypothesis: *Infection of Stat1-/- mice with recombinant rCedVs will recapitulate major hallmarks of pathogenic NiV and HeV infections in humans*. We will establish a breeding colony of Stat1-/- mice on a B6-albino background. We will infect Stat1-/- mice with rCedV-luc chimeras. We will use flow cytometry, spatial transcriptomics approaches and histological methods to define cell types infected, gene expression changes and immune phenotypes that characterize pathological (Stat1-/- model; rCedV-luc chimeras) vs. non-pathological (Ifnar1-/- model; rCedV-luc) infections.

Commented [BS1]: -Collaboration with Core D (systems serology - Gunn)
-Collab with RP2 (other rCedV chimeras)
-Possible exploration of hamster infection (rCedV-NiV-luc), using much larger dose than what was used for UTMB studies to determine if (1) efficient CNS infection can be achieved and (2) if CNS infection is highly correlated with lethality. Hamsters may represent a rCedV lethal model employing a host that is not immunocompromised. Limitations: few specific analysis tools (mAbs in particular) for the hamster model.

Aim 2: To determine the mechanism of rCedV-NiV neurovirulence in the Stat1-/- mouse model. Hypothesis: *CNS infection by rCedV chimeras requires functional interaction between G and host ephrin B3; neurovirulence is a property shared by henipaviruses in the absence of host IFN-dependent defenses*. We will evaluate whether interaction between NiV/HeV G and host ephrin B3 is required for neurotropism. We will employ direct injection of rCedV into the brains of Stat1-/- mice to determine whether neurological disease is a property shared by brain-resident henipaviruses in the absence of a host interferon response.

Commented [BS2]: -Collab with RP2 (rCedV-NiV ephrin B3 binding mutant)

Aim 3: To define the efficacy and mechanisms of mAb-based therapeutics for CNS-resident henipavirus infections. Hypothesis: *G- and F-directed mAb-based therapeutics will demonstrate Fc-dependent efficacy against CNS-resident henipavirus*. Stat1-/- mice infected with rCedV chimeras will be treated with anti-G and anti-F mAbs and nanobodies. We will employ the approaches of Aim 1 to determine the immunological basis of any observed mAb therapeutic effects. We will also specifically investigate the role of mAb-FcR interactions for therapeutic efficacy.

Commented [BS3]: -Collaboration with RP5, nanobodies
- Collaboration with Core D (systems serology - Gunn)

HeV and NiV are emerging human and livestock pathogens with a high fatality rate, demonstrated human-to-human transmission, and a worrisome recent history of outbreaks in proximity to densely populated areas, including Kerala, India[10-12]. There is thus an urgent need to develop novel therapeutics directed against these viruses. However, work with HeV and NiV requires BSL-4 containment, severely limiting translational research efforts. Through the development and investigation of this longitudinal BSL-2 animal model of authentic and pathological henipavirus infection, we will greatly facilitate future development and preclinical validation of therapeutics directed against these deadly human pathogens.

Vertebrate Animals

1. The following mouse strains will be used in this proposal:
   - **i)** **B6-albino-Ifnar1-/- mice**. We maintain a breeding colony of B6-albino Ifnar1-/- mice at Charles River Labs (CRL). We generated these mice by crossing the B6-albino strain (Jackson Laboratory B6(Cg)-Tyrc-2J/J, Strain #:000058) with the Ifnar1-/- strain (Jackson Laboratory B6(Cg)-Ifnar1<tm1.2Ees>/J, Strain # 028288), followed by crossing F1 mice back to B6-albino and then intercrossing white progeny that carried the Infar1- allele. This colony is now producing only albino mice that are homozygous Ifnar1-/-.
   - **ii)** **B6-albino-STAT1-/- mice.** We are currently establishing a breeding colony of B6-albino STAT1-/- mice at CRL. We are currently crossing the B6-albino strain (Jackson Laboratory B6(Cg)-Tyrc-2J/J, Strain #:000058) with the STAT1-/- strain (Jackson Laboratory B6.129S(Cg)-Stat1tm1Dlv/J, Strain # 012606), followed by crossing F1 mice back to B6-albino and then intercrossing white progeny that carry the STAT1- allele. We anticipate establishing a colony of the desired genotype by early 2024..

   We will use mice for in vivo infection with rCedVs, with many experiments including bioluminescent imaging. Animals are housed in an approved ABSL-2 room and all laboratory and animal care staff follow BSL-2 safety precautions. The total number of required mice (including all mice produced during breeding) is 5440. Experiments will be performed with male and female mice. The PI has an IACUC-approved experimental protocol and an IBC-approved biosafety protocol that details the use of the above strains of mice for the described experiments.

2. The goal of this project is to validate the mouse as a BSL-2 model for henipavirus pathogenesis, and as a platform for development and testing of countermeasures. For this work, we must use an experimental animal model to allow the course of in vivo infection and the host immune response to be studied. There is no in vitro model which can model the complex in vivo dynamics of viral infection, moving between distinct cell types and anatomical locations, or the host immune response to infection. We have chosen to utilize mice due to their ease of care, the existence of well-characterized inbred strains and knockout models, and our preliminary data with rCedVs showing robust and reproducible infection of mice which is highly amenable to statistical analysis. The number of animals to be used is based on power analyses, as detailed in our approved IACUC protocols.
3. Experiments will involve the euthanasia of infected animals experiencing pain or distress. Our IACUC protocols also define a weight loss threshold or a combined disease score criterion as end points for virus-infected animals requiring euthanasia. Animals not euthanized for the above reasons will be euthanized for tissue collection, at time points described in our IACUC protocol. Euthanasia will be performed as described in part 4, below.
4. Mice reaching criteria/endpoints described in 3, above, will be euthanized by ketamine or ketamine-xylazine overdose. This method is consistent with AMVA guidelines.

Statement of Intent to Establish a Consortium Agreement with NIH Funds

Dates: 03/01/2024–02/28/2029
Grant: RFA-AI-23-020 Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP) Centers for Bunyavirales, Paramyxoviridae and Picornaviridae
Application Title: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center (PABVAX)
Total Proposed Amount: $2,938,494
Sponsor (grantee Institution): The University of Texas Medical Branch at Galveston

The appropriate programmatic and administrative personnel of each institution involved in this grant application are aware of the NIH consortium grant policy and are prepared to establish the necessary inter-institutional agreement(s) consistent with that policy.

Subcontractor further certifies that it will comply with NIH public access policy, Division G, Title II, Section 218 of PL 110-161 (Consolidated Appropriations Act, 2008) requiring that any final manuscript resulting from research sponsored by NIH be submitted to the NIH upon acceptance for publication, including all modifications from the peer review process, thereby being made available to the public in PubMed Central as soon as possible but no later than 12 months after publication.

In accordance with the provisions of 42 CFR Part 50 Subpart F, 42 CFR Part 94 and the University of Texas System policy, UTS 175, the University of Texas Medical Branch at Galveston (UTMB Health) has revised its conflicts of interest policy (IHOP 11.1.2) in response to the newly enacted NIH rule. UTMB Health's revised conflicts of interest policy was effective January 1, 2012. As an awardee institution, UTMB Health must ensure that its sub-recipients are complying with all applicable policies, regulations and laws concerning Conflicts of Interest. Please complete and sign the attached Conflicts of Interest Disclosure Form for Sub-recipient Institutions.

Conflict of Interest Disclosure Form for Sub-recipient Institutions

Conflict of Interest Disclosure applies to any member of the research team responsible for the design, conduct or reporting of data (each a "Covered Individual")

Grant Award No. RFA-AI-23-020 PI at Institution: Christopher Broder, PhD

Institution Name: The Henry M. Jackson Fdn for the Adv'mt of Mil

Project Title: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center (PABVAX)

UTMB PI: Dr. Thomas W. Geisbert

Sub-recipient organization/institution hereby certifies that it has an active and enforced conflict of interest policy that is consistent with the provisions of 42 CFR Part 50 Subpart F or 42 CFR Part 94.

☒ YES **(If yes, please answer either a or b below.)**

☐ NO, Sub-recipient organization/institution does not have an active and/or enforced conflicts of interest policy and hereby agrees to comply with The University of Texas Medical Branch at Galveston (UTMB Health) policies and procedures relating to financial conflicts of interest. In accordance with this commitment, each Covered Individual as defined in UTMB Health's policy (IHOP 11.2.1) has completed UTMB Health conflict of interest training and disclosure attached hereto.

☒ **(a)** Sub-recipient organization/institution certifies that all personnel involved in the design, conduct and reporting of research data on the above-named project have completed and filed with sub-recipient organization/institution a current Conflict of Interest Disclosure form and none of the personnel involved has an identified Financial Conflict of Interest.

☐ **(b)** Sub-recipient organization/institution certifies that all personnel involved in the design, conduct and reporting of research data on the above-named project have completed and filed with sub-recipient organization/institution a current Conflict of Interest Disclosure form. The personnel listed below have an identified Financial Conflict of Interest which is being managed, reduced or eliminated by the sub-recipient organization/institution.

*In accordance with 42 CFR 50.604, sub-recipient organization/institution certifies that all personnel involved in the design, conduct or reporting of research data on the above-named project will complete training in regard to all applicable policies, regulations and laws before engaging in the research on the above named project.

Sub-recipient organization/institution certifies that the information provided above (if applicable, including any attached Disclosures) is(are) true and accurate to the best of its knowledge and further certifies that site and principal investigator shall comply with 42 CFR 50, Subpart F, Sections 50.601 to 50.607, responsibilities regarding conflicting interests of investigators. Sub-recipient organization/institution will notify UTMB within 30 days of any changes to a covered individual's status as it pertains to Financial Conflict of Interest.

LETTER OF INTENT TO COLLABORATE

June 2, 2023

Thomas W. Geisbert, PhD
Center for Biodefense and Emerging Infectious Diseases
The University of Texas Medical Branch
Keiller Bldg., Rm. 1.104D
301 University Blvd.
Galveston, TX 77555-0609

Dear Dr. Geisbert:

This letter confirms The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc.'s (HJF) intent to collaborate with The University of Texas Medical Branch (UTMB) in response to the RFA-AI-23-020 and is offered on the condition that the UTMB agrees that if it receives an award for the subject project, it will issue a subaward to HJF for the work hereby proposed.

Confidentiality Notice: *This letter of Intent, including all proposal documents attached hereto, contains HJF confidential and proprietary information and is provided for use solely in connection with HJF's and the (Prime Institution) joint pursuit of the project listed below. Any unauthorized use, disclosure or distribution is prohibited.*

Prime Institution:	The University of Texas Medical Branch	
Prime Principal Investigator:	Thomas W. Geisbert, PhD	
Project Title:	Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center (PABVAX)	
Proposed Principal Investigator:	Christopher Broder, PhD (USU-Principal Investigator)	
Proposed Project Period:	03/01/2024-02/28/2029	
Proposed Budget Amount:	$1,841,442 $1,097,052 $2,938,494	Direct Costs Indirect Costs Total Cost

HJF confirms that it has in place a written and enforced financial conflict of interest policy that applies to all HJF investigators and any other HJF employees responsible for the design, conduct or reporting of the budgeted activities. U.S. Government Principal Investigator(s) (if any) are subject to federal regulations governing conflicts of interest.

Your submission of a prime proposal that includes the subaward activities hereby proposed by HJF will constitute your acknowledgment of, and agreement to, the terms set forth in this letter.

Sincerely, (b) (6)

Lisa Straker-Deputy Director, Investigator Initiatives-Business Development

Statement of Intent to Establish a Consortium Agreement with NIH Funds

Dates: 03/01/2024-02/28/2029
Grant: RFA-AI-23-020 Research and Development of Vaccines and Monoclonal Antibodies for Pandemic Preparedness (ReVAMPP) Centers for Bunyavirales, Paramyxoviridae and Picornaviridae
Application Title: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center (PABVAX)
Total Proposed Amount: $3,945,580
Sponsor (grantee Institution): The University of Texas Medical Branch at Galveston

The appropriate programmatic and administrative personnel of each institution involved in this grant application are aware of the NIH consortium grant policy and are prepared to establish the necessary inter-institutional agreement(s) consistent with that policy.

Subcontractor further certifies that it will comply with NIH public access policy, Division G, Title II, Section 218 of PL 110-161 (Consolidated Appropriations Act, 2008) requiring that any final manuscript resulting from research sponsored by NIH be submitted to the NIH upon acceptance for publication, including all modifications from the peer review process, thereby being made available to the public in PubMed Central as soon as possible but no later than 12 months after publication.

In accordance with the provisions of 42 CFR Part 50 Subpart F, 42 CFR Part 94 and the University of Texas System policy, UTS 175, the University of Texas Medical Branch at Galveston (UTMB Health) has revised its conflicts of interest policy (IHOP 11.1.2) in response to the newly enacted NIH rule. UTMB Health's revised conflicts of interest policy was effective January 1, 2012. As an awardee institution, UTMB Health must ensure that its sub-recipients are complying with all applicable policies, regulations and laws concerning Conflicts of Interest. Please complete and sign the attached Conflicts of Interest Disclosure Form for Sub-recipient Institutions.

Conflict of Interest Disclosure Form for Sub-recipient Institutions

Conflict of Interest Disclosure applies to any member of the research team responsible for the design, conduct or reporting of data (each a "Covered Individual")

Grant Award No. RFA-AI-23-020 PI at Institution: Brian Schaefer, PhD

Institution Name: The Henry M. Jackson Fdn for the Adv'mt of Mil

Project Title: Paramyxoviridae and Bunyavirales Vaccines and Antibodies Center (PABVAX)

UTMB PI: Dr. Thomas W. Geisbert

Sub-recipient organization/institution hereby certifies that it has an active and enforced conflict of interest policy that is consistent with the provisions of 42 CFR Part 50 Subpart F or 42 CFR Part 94.

☒ YES **(If yes, please answer either a or b below.)**

☐ NO, Sub-recipient organization/institution does not have an active and/or enforced conflicts of interest policy and hereby agrees to comply with The University of Texas Medical Branch at Galveston (UTMB Health) policies and procedures relating to financial conflicts of interest. In accordance with this commitment, each Covered Individual as defined in UTMB Health's policy (IHOP 11.2.1) has completed UTMB Health conflict of interest training and disclosure attached hereto.

☒ **(a)** Sub-recipient organization/institution certifies that all personnel involved in the design, conduct and reporting of research data on the above-named project have completed and filed with sub-recipient organization/institution a current Conflict of Interest Disclosure form and none of the personnel involved has an identified Financial Conflict of Interest.

☐ **(b)** Sub-recipient organization/institution certifies that all personnel involved in the design, conduct and reporting of research data on the above-named project have completed and filed with sub-recipient organization/institution a current Conflict of Interest Disclosure form. The personnel listed below have an identified Financial Conflict of Interest which is being managed, reduced or eliminated by the sub-recipient organization/institution.

*In accordance with 42 CFR 50.604, sub-recipient organization/institution certifies that all personnel involved in the design, conduct or reporting of research data on the above-named project will complete training in regard to all applicable policies, regulations and laws before engaging in the research on the above named project.

Sub-recipient organization/institution certifies that the information provided above (if applicable, including any attached Disclosures) is(are) true and accurate to the best of its knowledge and further certifies that site and principal investigator shall comply with 42 CFR 50, Subpart F, Sections 50.601 to 50.607, responsibilities regarding conflicting interests of investigators. Sub-recipient organization/institution will notify UTMB within 30 days of any changes to a covered individual's status as it pertains to Financial Conflict of Interest.
